Clinical Importance of *Vamana Karma* in *Tamakshwasa*: A Review

Sahebrao Kadam[1], Shweta Parwe[2], Milind Nisargandha[3]

[1]Associate Professor and HOD, Department of Panchkarma, D. M. M. Ayurved College, Yavatmal, [2]Professor and Head, Department of Panchakarma, Mahatma Gandhi Ayurved College Hospital & Research Centre, Salod (H.) Wardha, Datta Meghe Institute of Medical Sciences, Wardha, [3]Associate Professor, Department of Physiology, Ashwini Rural Medical College, Hospital and Research Centre, Kumbhari, Solapur

Abstract

Vamana Karma (medicated emesis) is the act of eliminating the vitiated *Kapha* through the mouth. *Vamana Karma* is the internal purificatory practice described in Ayurveda which helps to clean the body of excess amount of the vitiated *Kapha, Pitta Doshas* consecutively. *Tamak Shwas* means a state in which a sense of darkness prevails due to movement of *Prana Vayu* in wrong direction. It is a disease in which the patient experience severe symptoms of respiratory distress resemble like Bronchial asthma. Bronchial asthma is a syndrome of variable airflow obstruction. *Vamana* is the first line of treatment for *Utkleshitavastha* of *Tamakshwasa.* In Ayurveda, *Shaman* and *Shodhana* treatment is mentioned. We can't deny the importance of *Vamana Karma* in *Tamakshwasa*, because *Kapha* is the foremost *Dosha* that needs to be taken care of than others. In this article an attempt has been made to search the research works conducted on *Vamana Karma* related to *Tamakshwasa* and to establish its role in *Tamakshwasa*

Data Source: The related data were collected from various research article from the years 2011 – 2019 and from the classical texts Charak samhita, Sushrut samhita and Astang hrudaya Observations: Total 16 various reaserches found and overall outcome is *vamanakarma* is effective in *tamakshwasa. Vamanakarma* is very effective in *tamakshwasa* in *utkleshavastha* because *kaphadosha* can easily eliminate from body

Keywords: *Ayurveda, Tamakshwasa, Sadyovamana, Bronchial Asthama, Vamana, kapha dosha, therapeutic emesis.*

Introduction

The aim of Ayurveda is to maintain and promote the health of healthy as well as to treat the disease of the diseased person.[1] The five procedures of biopurification *Vamanna* (medicated emesis), *Virechana* (induced purgation), *Basti* (medicated enema), *Nasya* nasal insufflation, *Raktamokshana* (bloodletting) purify the body system by removing vitiated *Dosha* from the body.[2] As far as the *Ritucharyaadhyaya* is concerned in Ayurved *Samhitas,* all the sages have advised *Vamana* as *Samshodhana Karma* in *Vasantritu* for healthy and diseased person.[3] *Vamana Karma* (emesis) is the act of eliminating the vitiated *Kapha* through the mouth.[4] It is indicated in many diseases viz. *Kasa, Putinasa, Shwasa, Kushtha, Amlapitta, Sleepada, Apasmar*a, *Agnimandya, Unmada, Visha, Granthi, Garavisha, Arbud*a, *Stanyadosha, Medo-roga, Atisara, Prameha, Pandu*etc.[5] *Tamakashwasa* constitutes of two words i.e. *Tamaka*and *Shwasa*. The word *'Tamaka'* is a specified source of Dhatu "*Tamglanou*" which means Sadness.[6] The name of *Tamakashwasa* is due to the fact that, the symptoms or attack of this disease hapeen

suddenly at night and also during the time of attack, the breathing difficulty is so severe that patient feels entering into the darkness (*Tama Pravesh*). Bronchial asthma is a highly prevalent disease and in most of the etiopathogenesis and symptomatologyit is the one of distressing disease and quite common in all age groups. It is a chronic, inflammatory and episodic in nature. It can be severe, sometimes fatal. As per the W.H.O. by the year of 2020, asthma along with COPD will become the third leading cause of death.[7] *Tamakashwas Tamakashwas viz*. dyspnoea, hack and chest snugness are like that of bronchial asthma. Additionally a portion of the etiological elements like presentation to smoke, dust are comparable. As indicated by Ayurveda, rehashed and long haul introduction to different etiological variables. Causes vitiation of the elements of *Pranavayu (*breathing*),* which over some undefined time frame starts basic change *(Sthanvaigunya)* in the lungs. Flexibility and perfection *(Mruduta* justas *Masrunatva)* at the site begin changing to hardness and unpleasantness *(Kathinatva, Kharatva)* which hampers the ordinary narrowing and dilatation process *(Sankocha and Vikasaprakriya).* To battle the change, emission of mucous *(Shleshma)* increments, however further dries due to *Rukshaguna* and close the bronchial spaces *(Srotas avarodh)* diminishing the lumen of bronchus. Breathing gets troublesome and worked *(Alpalpa, Kupita, Sashabda, Sashoola).* After serious hacking a modest quantity of thick and clingy mucous *(Avila, Tantula and Styana shleshma)* is expectorated. This clears the aviation route and patient feels better as he can relax. These sorts of rehashed assaults for a time of over one yearrealize a lasting or irreversible change in the structure of lungs *(Sthanvaigunya).* Subsequently the sickness becomes *'Yapya'* which implies quiet can't be relieved off by prescription.[8] In Ayurveda *Shaman* and *Shodhana* treatment is mentioned. We can't deny the importance of *Vamana Karma* in *Tamakshwasa*,because *Kapha* is first than other humors *Vamana Karma* detoxifies the body & enhance the elasticity of lung tissue & develops natural immunity of the body. Hence, it is the need to review the topic. In this article an attempt has been made to search the researchers conducted on *Vamana Karma* related to *Tamakshwasa* to establish its role in *Tamakshwasa.* Hence the presence review of study was undertaken to critically analyze the roll of *Vamana Karma* in *Tamakshwasa*.

Need of Study: According to the WHO disease will become the third leading cause of death. In Ayurveda *Shaman* and *Shodhana* treatment is mentioned. We can't deny the importance of *Vamana Karma* in *Tamakshwasa*,because *Kapha* is first than other humours *Vamana Karma* detoxifies the body & increases the elasticity of lung tissue & develops natural immunity of the body. Hence, it is the need to review the topic. The present review is aimed at analyzing the clinical importance of *Vamana Karma* in *Tamakshwasa*. All the classical reffrences regarding *Vamamana Karma* & *Tamakshwasa* are taken for the present study. The publish articles regarding *Vamana Karma* and *Tamakshwasa* are from pubmed and scopes are taken

Observations: The observations in the study are broadly divided into two parts. First observation deals with understanding the role of *Vamana Karma* in *Tamakshwasa* based upon the description in various classical literatures and the second is the role of *Vamana Karma* in *Tamakshwasaas* per the data of various research work conducted till date.

Charaka Samhita: Both (Hikka and Shwasa) are overseen indistinguishably because of their indistinguishable etiology area. The patient of *Tamakshwasa* ought to be overseen first with unctuous sudation by the cylindrical, bed and bolus strategy after he is dealt with salted oil. With this, the mucus gets condensed, to move into the channels, goes to the *Amashya* because of this the entry or channels get mollified and *Vayu* come back to its typical course. After full sudation patient ought to be given the eating routine comprising of rice with unctuous substance alongside meat, soup of fish or pig or with the supernatant greasy layer of curd. Along these lines when *Kapha* is expanded, he ought to be encouraged to take emesis blended in with *Pippali*, rock salt and nectar.[9]

Sushrut Samhita: In Sushrutchikitsa Sthan 33rd chapter indications for Vamana is mentioned. [10] Butprocedureof*Vaman*ain*Tamakshwasa*isnotmentioned in detailed.

Astang Hrudaya: In Astanghrudaya Samhita *Mrudu Vamana* is mentionedin Shwasa. After full sudation patient should be given the diet consisting of unctuous substance i.e. meat of boarand the supernatant fatty layer of curd.[11]

Discussion

Role of *Vamana Karma* in *Tamakshwasa* is described in various classical literatures. Out of *Bruhatrayee,* in Charak *Samhita Adhyaya* 17th there is adetailed description of *Vamana* procedure in *Tamakshwasa.* But in Sushrut *Samhita* it is not mentioned. In Sushruta *Samhita adhyaya* 33rd of *Purvardha Chikitsa sthan* while describing the indication of *Vamana* there is description of *Shwasavyadhi.* However, the process of *Vamana Karma* not mentioned separately *Tamakshwasa*. In Ashtangh hrudayam *Mrudu Vamana* is mentioned briefly.

16 studies have been conducted on the role of *Vamana Karma*in *Tamak Shwasa*, out of 16 studies 7 are clinical studies, 4 are case studies and 5 are review studies. In this studies, different type of *Vamana Dravyas* are used such as *Madanphala dadhi*, *Madanphalachurna*, *Ikshwaku ksheer Madanaphala yoga,Jeemutaka churna Arkapatri swaras, Lavana jala, Pippalichurna* as an emetic drug. *Vamana Karma* is radical treatment to treat *Kapha* malady just as *Tamakashwasa. Vamana karma* treats the *Tamakshwasa* by dispensing with causative factor *Kapha* from its fundamental site of amassing. *Vamana* scrubs the various sorts of harmful materials from the body. *Vamana Karma,* one of the purging treatments reestablishes the *Agni* (impeded digestion) by acting at cell level.[29]

Vamaana Karma or *Sadyo Vamana* can be the choice treatment or procedure in *Vegakalinavastha*. In *Vegagavastha doshas* are in excited stage means ready to expell out from the body. So *Abhyanga and Swedana* followed by *Vamana Karma* are useful for *Vilayana* of this *Grathitha Kapha*, thereby removing the *Sanga* (Obstruction of airway). Once the *Kapha* is removed from airways, it flows back to its base in *Amashaya* from where it i sexpelled out by *Vamana*.[30] Susruta also explained the *Chikitsa* of *Shwasa* is *Urdhva Shodhana* in *balvan* patient that is *Mrudu Vamana* after *Abhyanga*and *Swedana.* Whereas Vagbhata explains that *Utpattisthan* or the place of origin of this *Vyadhi* is *Amashaya*, srotas involved here are *Prana, Anna* and *Udakavaha* and the *Vyaktasthana* being *Ura*which happens because of obstruction of normal movements of *Vata* by *Kapha*.

Both *Sadhyo Vamana* and *Sneha Poorvaka Vamana* are havingequally good effect in relieving the signsand symptoms of *Tamakashwasa* but *Sadhyo Vamana* can be planned only when *Utkleshkshana* is present in the patient. Though the immediate relief rate was almost equal in both *Sadhyo Vamana* and *Sneha Poorvaka Vamana* it can be clearly noted from the above available data that there lief rate obtained just after *Vamana Karma.*

A central emetic drug induces vomiting by directly stimulation of the vomiting centre. These drugs also

stimulate gastric muscles, diaphragm, G.I.T. and also increase peristalsis. Their action is more prompt. Instead of these factors, some other factors also play role in the process of emesis. During the underlying episodes of emesis, the substance of the upper gastro-intestinal tract up to the pylorus alone comes out. Rehashed emesis makes a negative weight inclination towards the lumen of the upper gastro intestinal tract while hypertonic saline water causes a positive osmotic slope towards the lumen. The two reason a constrained extraction of effectively separable substances from the cells of the lumen and those containing waste metabolites arranged close by incidentally. Along these lines, unreasonable lipid that was devoured during the preliminary days blebs into the lumen with the water-solvent substances, which are separated out because of the osmotic slope. Rehashed emesis likewise causes the age of the negative weight slope up to them.

Limitation of the study: Present work includes data obtained from researches conducted in last 9 years i.e. 2011 to 2019 only

Conclusion

From this review it can be concluded that *Vamana Karma* is having significant clinical importance in *Tamakshwasa*. *Sadyovamana* is also having very much importance without any *Snehana Karma* because of already *Utklisthavastha* of the *Dosha* in the disease.

Future studies can be conducted on large number of patients of *Tamakshwasa* to establish its efficacy and mechanism of action.

The Prime Role of Preventive Approach of Ayurveda in Autoimmune Disorder with Special Reference to Vitiligo

Smita S Kamde[1], Gaurav Sawarkar[2]

[1]Intern, Department of Rachana Sharir, Mahatma Gandhi Ayurved College Hospital and Research Centre, Datta Meghe Institute of Medical Sciences (Deemed to be University), Wardha, Maharashtra, India, [2]Associate Professor, Department of Rachana Sharir, Mahatma Gandhi Ayurved College Hospital and Research Centre, Datta Meghe Institute of Medical Sciences (Deemed to be University), Wardha, Maharashtra, India

Abstract

Vitiligo is a skin disease with unknown etiology and has unpredictability on the extent and rate of spread. It is considered an autoimmune disorder that destroys melanocytes in the skin characterized by depigmentation or hypopigmented patches. Vitiligo patients feel distressed and suffer social stigma as it has a significant impact on the quality of life of patients. Treatment available in contemporary medicine has its limitations and side–effects. Hence, maintenance of health and prevention of disease is of utmost importance. *Ayurveda* has incorporated this condition into broad terms of *Shwitra,* which is described under the heading of *Kushta*. *Ayurveda* states the causes of *Shwitra* may be *Chhardivegadharan*, *Atisewan* of *Amla–Katu-Ushna–Lavan Aaharsewana, Virrudha Ahar* and *Atimatra Bhojan* along with *Navanna Sewana* and *Dadhi Sewana*. Hence, a multidisciplinary approach is needed to treat such conditions with lifestyle medications and dietary interventions. *Ayurveda* has a holistic and scientific method in health management. It emphasizes much more on diet and regimen, along with medicines. *Ayurveda* deals with *Pathya –Vyavastha* in a very scientific way. Here an attempt has been made to compile the knowledge of ancient holistic science to throw light upon the concept of *Ayurveda* regarding the modification of lifestyle and the preventive measures effective concerning Vitiligo which will be a subject of benefit to humankind along with the awareness of the fact that the judicious use of food and healthy lifestyle interventions are the real medicines for health, so early responses are necessary for better results.

Keywords: *Shwitra, Autoimmune Disorder, Vitiligo.*

Introduction

Vitiligo is a dermatological disorder with unknown etiology in which skin loses its color in blotches and develops white patches causing cosmetic imbalance, mainly leading to asocial stigma. It is considered an autoimmune disorder that destroys the melanocytes of the skin. The factors responsible for the healthy skin color are hemoglobin, carotenoids and melanin pigments. It is an autoimmune disease in which due to the insufficiency or complete absence of melanin in the skin, hypopigmentation occurs along with the autoimmune destruction of melanocytes in the epidermis resulting in the progression of the disease with hypo-pigmented areas. Though the exact cause is unknown,factors like stress trigger the illness, including the increased levels of catecholamines and neuropeptides[1].

Need of the current era: The numbers of patients suffering from Vitiligo are not only affected physically but also suffer from social stigma and are psychologically

under stress. However, it affects approximately about 0.5% to 2% of the worldwide population, with an overall prevalence of about 1%. It appears to be equally in men and women. The extent and rate of spread is unpredictable[2].

The present-day lifestyle has a high impact on the disease condition. It affects the quality of life of an individual as it leaves behind cosmetic disfigurement. The treatment modalities for Vitiligo in conventional medicine involve topical and systemic steroids, topical and systemic PUVA, which brings forth side effects such as phototoxicity, hyperpigmentation and solar elastosis. Other safer alternatives are highly expensive and thus have limitations to use.

Aim and Objective: Considering this scenario & considering its increasing incidence & prevalence rate due to the current stressful lifestyle, it is necessary to focus on a healthy, stress-free lifestyle. Therefore, the prime of this paper is to throw light upon the concept of *Ayurveda* regarding lifestyle modification and preventive measures practical concerning Vitiligo, which will be a subject of benefit for humanity.

Material and Method

Textual references are compiled from the *Ayurvedic* texts and *Samhitas*, moderntexts, journals and websites.

Observations and Results

- **Concept of Vitiligo with Ayurveda perspective:** In *Ayurveda*, Vitiligo can be correlated with a group of a skin disorder i.e., *Shwitra. Acharya Kashyapa* defines *Shwitra* as *Shweta Bhava* Micchanti[3]. As per *Acharya Sushruta*, it means a reflection of white color. and mentioned it as *Kilas* instead of *Shwitra*[4].
- **Role of *Nidana Parivarjana* in prevention & management of Vitiligo:** The ancient classical texts have mentioned the etiological factors of *Shwitra* as that of *Kushta*. The treatment of *Shwitra* needs a holistic approach which involves *Nidan Parivarjan,* which means avoidance of the etiological factors. It has been given prime importance behind the success of many treatments in *Ayurveda.* The basic principle-‘ prevention is better than cure’ is the first step in the management of *Shwitra*. Therefore, the first step is to avoid the *Nidana*. Various *Hetu* related to *Ahara* & *Vihara* depicted in *Ayurvedic* literature in *Shwitra Nidana* are mentioned in table no. 1[5,6,7].

Acharya Charaka has mentioned some specific causes which might cover the idiopathic aspects such as-*Vachamsi Asatyani* (telling lies)*, Krutaghnabhava* (un-grateful), *Suranam Ninda* (abusing gods), *Guru-Gharshanam* (abusing and disrespecting the teachers and elders), *Papakriya* (being involved in sinful acts), *Purvakruta Karma* (sins done in a previous birth) and *Virodhi Anna* (incompatible foods). The current faulty lifestyle compromises all of these *Hetu,* which are highlyessential to avoid the occurrence of *Shwitra.*[8].

- **Role of lifestyle in the prevention & management of Vitiligo:** *Ayurveda* ensures the lifestyle that depicts the bundle of behavioral and mental aspects of well–being. If anyone follows a healthy diet and lifestyle, no medicine is required to tackle the disease. The controlled diet itself works as a medicine. On the contrary, if someone is not following such diet & lifestyle, no medication will work because improper diet and lifestyle are the prime cause of diseases. In the present era, man has less time to cook and eat food and has replaced it with fast food, which is considered *Mithya Ahar* in *Ayurveda*, a significant cause of disease formation.

The prevention & treatment of Vitiligo needs a holistic and scientific approach that emphasizes diet and regimens and medicines. *Ayurveda* deals with *Pathya Vyavastha* (planning of food) in a very scientific way. Even healthy lifestyle interventions have gained scientific evidence in the treatment of diseases that seem to be as effective as medications and are considered safe without side effects.

- **Importance of *Pathya Apathya:*** The chief foundation upon which an individual is raised depends on *Ahara* and *Vihara. Ayurveda* focuses on diet and regimen as leading causes for diseases. In our *Ayurveda Samhitas,* the phenomenon is implied to *Pathya-Apathya*in terms of *Ahar*and *Vihara*. Once the treatment is adopted, it becomes essential to utilize the dietary rules for efficient results. *Ayurveda* mentions about *Pathya- Apathya* regarding *Ahar* and *Vihar*, which are suitable to the mind and body when followed appropriately. These measures help in correcting the morbid conditions of the *Dhatus* and bringing them to a hemostatic state. Hence *Dhatu Samyata*is established and the disease can be cured, avoiding further complications. *Pathya–Apathya Ahhara* & *Viharas* applicable for *Shwitra*[9] have compiled in table no. 1 & 2.

Table No. 1: *Samanya & Vishishta Nidana* of *Shwitra*

Discussion

The healthy lifestyle and dietetics are to be followed to create a balance by restoring a uniformity in the skin tone, texture & color.

- **Avoidance of *Ahara Nidana***

- ***Viruddhaahara*:** Certain diet and wrong combination, which interrupts the tissues' metabolism and has different properties, is referred to as *Viruddha Anna* or an incompatible diet. The food in the false conjunction with wrong processing and being consumed in the incorrect quantity at the wrong time is *Virrudha*[10].
- ***Guru, Snigdha, Drava Ahara*:** It includes *Santarpanjanya, Krimikara Ahara.* Theguna of *guru Ahara Dravya*are opposite to that of *Agni*. Hence it is *Agnihrasakara* according to *Hrasahetu Vishesh Siddhanta*[11].
- ***Kshira*:** Acts as *Viruddha Ahara* with various combinations like fish[12].
- ***Kulattha:*** *Ushna, Amlapaki,* causes *Kapha–Pitta* aggravation[13].
- ***Matsya*:** *Bahudoshkara*, vitiates *Rakta*[14].
- ***Mulak*:** Riped *Mulak* is *KatuVipaki, Ushna Virya*. *Tridoshkara,Guru*, and *Abhishyandi*[15].

- **Avoidance of *Vihara Nidana***

***Papakarma*[16]:** Behavioural misconduct,anti-social activities,sinful activities bring about psychogenic stress, which is important in pathogenesis as the stress triggered Vitiligo include the increased levels of catecholamines and neuropeptides.

- **Yogic practices (therapy):** Vitiligo is a condition in which the body status reaches a stage called autoimmunity where the melanocytes get in the arena of dormancy or become dead. Yoga detoxifies body and mind and copes up with the condition of autoimmunity, thereby maintaining healthy melanocytes.

Ayurveda has a different approach to the understanding and treatment of *Shwitra*, which requires further researches. However, lifestyle modification and healthy dietetics can contribute significant benefits to the patients of Vitiligo. Thus, the holistic approach of *Ayurveda* for treatment, including its lifestyle prescriptions, is pooled to the mainstream of world medicine today. It can bring a transformation in the quality of health care for the suffering of humanity all over the world.

Conclusion

In today's lifestyle of hurry and worry,stress is increasing day by day. Modern medicines are suitable for short term treatment but have their limitations. It is the need of an hour to have researched and advance the physical and psychosocial aspects of Vitiligo.

Ayurveda is practiced in daily life; it fulfills both the preventive as well as curative aspects. In *Ayurveda*, the treatment is highly emphasized to achieve *Dhatu Samyata*. It can be concluded that by avoiding the use of incompatible diet,faulty lifestyle,and *Pathya Ahar Vihar* and *Shodhan Chikitsa*, mainly *Vaman* & *Mridu Virechan*, it can be managed along with this *AchaaraRasayan* and *Sadvritta Palan* which have high relevance in modern society.

Professor, Department of Conservative Dentistry and Endodontics, Sharad Pawar Dental College and Hospital, [3]Professor, Department of Conservative Dentistry and Endodontics, Dean Academics, Faculty of Dentistry, Sharad Pawar Dental College and Hospital, [4]Department of Conservative Dentistry and Endodontics, Sharad Pawar Dental College and Hospital, [5]Department of Oral Medicine and Radiology, Sharad Pawar Dental College and Hospital, Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (M), Wardha, Maharashtra 442001

Abstract

Background: The root canals of mandibular molar teeth show a wide variation in its system ranging from single to multiple canals. Thorough understanding of the variations present in internal anatomy of teeth is imperative for favorable outcome of the endodontic treatment. The insight of the tooth morphology, variations present related to its root structure, shape and information regarding root canal, with number of orifices and canal configuration, all this should be assessed prior to commence the endodontic treatment

Case Presentation: The present case report describes the variation in second mandibular molar, which is infrequently mentioned in literature. Variation present may not always be in the form of extra canal, it can be in the form of fewer or lesser canal than what is usually seen. On inspection of the pulpal floor with endodontic explorer, a single round orifice was seen at the centre of the floor of pulp chamber. Numerous angulated radiographs were obtained to assure the presence of independent single canal. Individual canal preparation was carried out using ProtaperNiTi instruments (Maillefer, Dentsply) till F5. Using lateral condensation technique along with sealapex sealer, obturation was carried out.

Conclusion: Knowledge of the number of root canals present within the tooth is imperative for successful root canal treatment. Some teeth may show extra canals, while other may show fewer than normal number of canals present. Mandibular second molar may present with single canal and this should be promptly recognized. Single canal identification helps to conserve the tooth structure by eliminating the need for removal of excessive tooth structure in search of extra canal.

Keywords: *Mandibular second molar, Root canal variations, Single canal, Single Root, One canal.*

Introduction

The root canal system presents one of the most complex anatomies in the human body. The thorough understanding of tooth anatomy is prerequisite for favorable long term prognosis of the root canal therapy. The insight of the tooth morphology, variations present related to its root structure, shape and information regarding root canal, with number of orifices and canal configuration, all this should be assessed prior

to commence the endodontic treatment.[1] The routine intraoral periapical radiographs, radiovisiography and recently three dimensional imaging modality such as Computed beam tomography helps us to visualize the otherwise hidden root canal system.[2] The Endodontic literature has constantly discussed the variations in the form, configuration and number of canals present. The variations present in multirooted teeth are most commonly noticed in the number of canals present. The mandibular molars are one of the most common teeth to present with this variation. According to Vertucci FJ, the second mandibular molar is nearly same as the first mandibular molar with only difference observed in root length (shorter) and canal curvatures (more curved).[3] Mandibular second molars generally present with two clearly distinct roots, mesial and distal root. Mesial root mostly presents with two canals and a distal root with one or two canals. Any variation from this should be promptly recognized as it may affect the outcome of the endodontic treatment.[4]

Maggiore C et al. (1998) reported that lower second molar could range from one to three roots.[5] Manning SA (1990) studied the morphology of second molar and reported incidence of single root in 22%, two roots in 76% and three roots in 2 % of the teeth examined.[6,7] Weine F.S et al (1988) studied extensively the mandibular second molar for canal variation and he stated that amongst the entire molar, this tooth is most common to show the anatomical variation. He reported single canal in only 1.3% of the cases. Single Root and Single canal, though present, is an unusual and rare occurrence in the mandibular second molar.[8]

The purpose of this case report is to report occurrence of single canal in single rooted mandibular second molars that required endodontic therapy.

Case Report 1: A 27-year-old female reported to the dental OPD with complaint of pain in the lower right back region of jaw from past 10 days. Pain was localized, sharp and constant type. It got aggravated on intake of cold and associated with posture and relieved on intake of medication. There was no history of swelling, pus discharge and fever. Medical history was not significant. On examination of the area of complaint, occlusal caries was seen with 47. Tooth was tender on percussion and non-mobile. Radiographic and neural sensibility investigations were carried out. On radiographic examination of tooth 47, caries was found to be involving enamel dentin and pulp chamber and fused root with single canal was appreciated. (Fig -1)

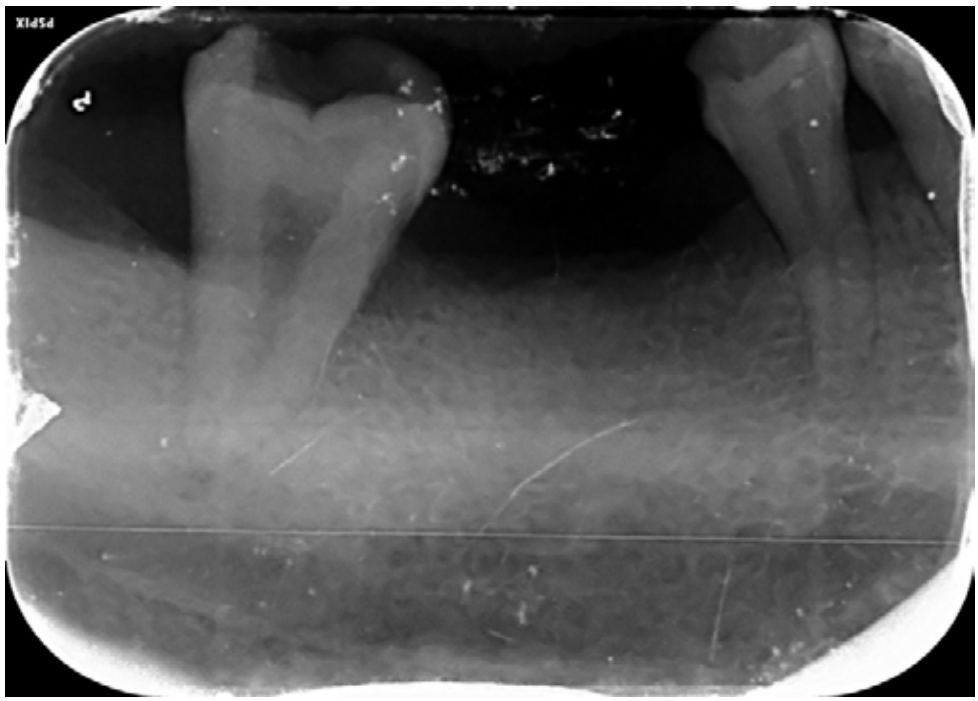

Figure 1- Pre-operative Radiograph

Periodontal ligament space around the roots was found intact with widening of the ligament. On neural sensibility test, the affected tooth showed an exaggerated lingering response to pulp testing. The clinico-radiographic diagnosis was symptomatic Irreversible Pulpitis with Apical Periodontitis with 47, indicating the need of endodontic therapy. The treatment was then initiated; right IANB anesthesia was injected with 2% lignocaine with 1:100,000 adrenaline. Rubber dam was used to isolate single tooth. Caries excavation was done with 47. Access cavity preparation was done with BR-45 (Mani Inc, Japan) round bur and modified using EX-24 (Mani Inc, Japan). Pulp tissue in the floor was removed and canal was copiously irrigated with 5.25% NaOCl(Chloraxid 5.25%, Cerkamed, Poland) for hemostasis. On inspection of the pulpal floor with endodontic explorer, a single round orifice was seen at the centre of the floor of pulp chamber. (Fig 2).

Figure 2: Access opening showing single canal

Cavity walls were extended slightly to check for any other canal, but only single canal was present. The canal patency was obtained using a no. 10 K- file. Numerous angulated radiographs were obtained to assure the presence of independent single canal. Working length was determined using apex locator and confirmed with the help of radiograph.(fig 3)

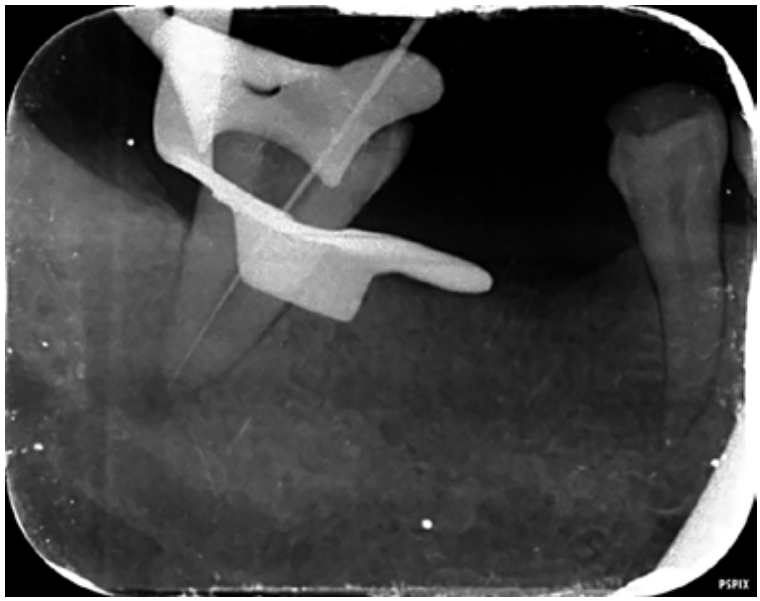

Figure 3: Working length determination

Individual canal preparation was carried out using ProtaperNiTi instruments (Maillefer, Dentsply) till F5. Profuse irrigation was done with 5.25% NaOCl and EDTA alternatively with normal saline. Calcium Hydroxide as an intracanal medicament was placed for 5 days. Intracanal medicament was removed using ultrasonic tip. Canal was again irrigated with 5.25% NaoCl and EDTA alternatively with normal saline. Final flushing with chlorhexidine was done followed by drying of canals using absorbent points. Master cones were selected. (Fig 4).

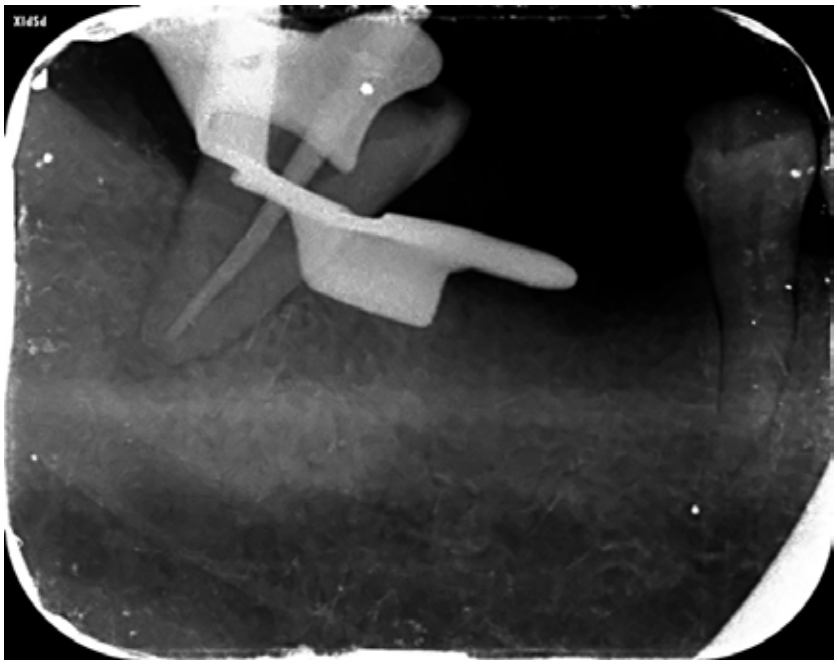

Figure 4: Master cone selection

Using lateral condensation technique along with sealapex sealer, obturation was carried out. (Fig 5 and 6). The post-endodontic restoration was done using composite resin restoration.

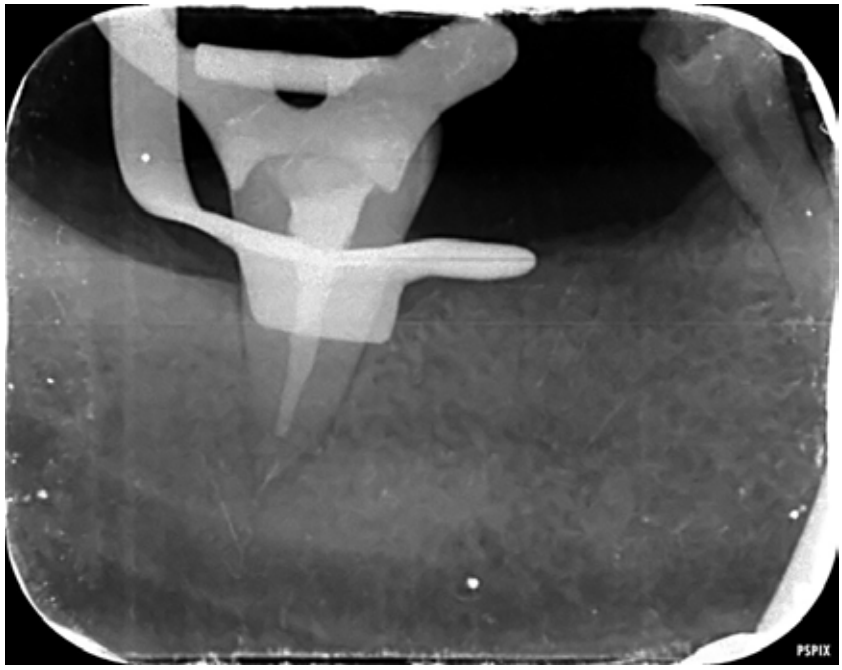

Figure 5: Obturation

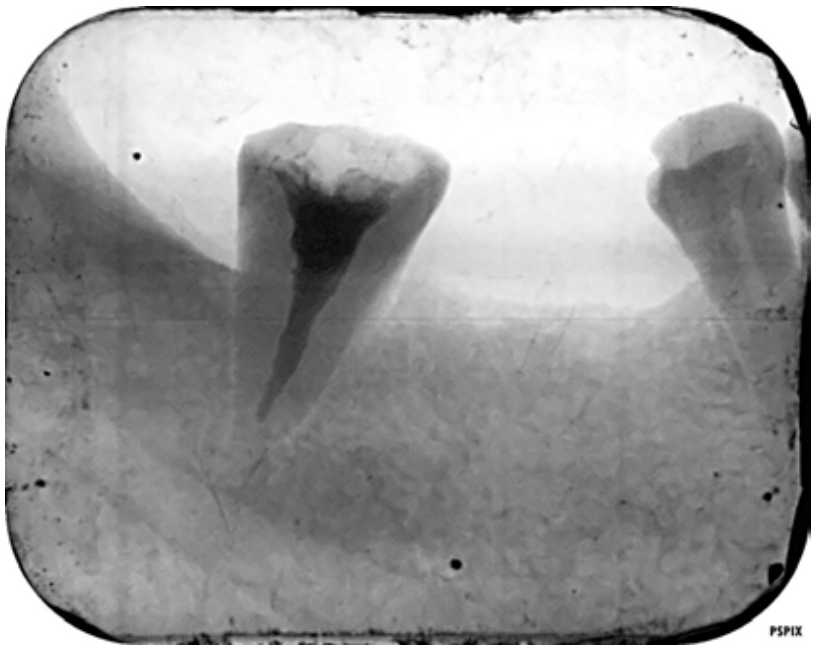

Figure 6: Inverted image showing complete filling of canal

Case report 2: A 30-year-old male reported to the dental OPD with complaint of pain in the lower right back region of jaw since 5 days. On examination of the area of complaint, mesio-proximal caries was seen with 47. Tooth was tender on percussion and non-mobile. Radiographic and neural sensibility investigations with 47 were carried out and root canal therapy was suggested for same. On radiograph, fused root with single canal was appreciated. (Fig 7). After access cavity preparation similar single canal configuration was seen. The further technique performed was similar as discussed above. (Fig 8).

Figure 7: Pre-operative radiograph

Figure 8: Obturation

Discussion

The endodontic therapies of multi-rooted teeth are often challenging, mainly due to existence of countless variations of root canal system. The knowledge of this complex root canal morphology is essential for success of endodontic therapy since missing of even one canal can lead to failure.[9] The diversities in multi-rooted teeth are seen in terms of number of roots, root canals, ramifications, apical deltas.[10] The pattern of such complexity is determined by age, sex and ethnicity of individual.

In case of mandibular molars, mandibular 2nd molar shows more variation than mandibular 1st molar. One of the deviations includes fusion of roots. The external morphology of mandibular 2nd molars seems to be conical or square shaped. The buccal or lingual aspect of fused roots shows presence of radicular grooves. The extensions and depth of grooves decides the internal canal anatomy. If groove is shallow, single wide canal is expected whereas if groove is deep, C-shaped anatomy is expected.[11]

In single rooted mandibular 2nd molar, the root canal may have following presentation: single wide canal, two canals that may or may not join and c- shaped canal. Pansiera & Milano found 6 out of 102 (5.88%) mandibular 2nd molar having single root and single root canal.[12] The present two case also showed single root and single canal configuration. Sabala et al. stated that "the more rare the aberration, the more probable that it is bilateral."[13] Hence suspecting similar morphology on contralateral side, periapical radiograph was evaluated. But no such configuration was found on contralateral side. Fava et al reported rare existence of a single canal in all four 2nd molars.[14]

For diagnosis of such cases periapical radiograph is commonly used. However, limitation of such 2D vision is well documented. The 3D radiography such as CBCT allows studying external and internal morphology. With aid of CBCT, the differentiation of shallow groove with single wide canal and deeper groove with c-shaped canal is possible. In search of canal in fused molar, possibility of perforation is higher. This can be eliminated with proper illumination and magnification and minimally invasive technique.[15,16,17] Since the canal is wider and tapering, the chemo-mechanical preparation should be such that it should be able to eliminate all the debris. The obturation technique used can be cold lateral condensation, warm lateral, thermo-plasticized technique. The thermo-plasticized gutta percha offers better adaption to canal irregularity however, in present case conventional gold standard lateral condensation has been used for obturation.

Conclusion

Knowledge of the number of root canals present within the tooth is imperative for successful root canal treatment. Some teeth may show extra canals, while other may show fewer than normal number of canals present. Mandibular second molar may present with single canal and this should be promptly recognized. Single canal identification helps to conserve the tooth structure by eliminating the need for removal of excessive tooth structure in search of extra canal.

Abstract

Background: Calcification of root (calcific metamorphosis) is usually seen as defensive reaction of pulp to trauma. Intensity of trauma/hit, time span since trauma, pulp response to trauma are multiple factor deciding degree of calcification. Calcification may be seen partially or entirely in root canal. Usually calcified tooth remain asymptomatic, but when tooth becomes symptomatic endodontic treatment need to be done. Treatment of calcified canal is challenge to dentist.

Case report: A female patient reported to the department of conservative dentistry and endodontics at sharad pawar dental college with chief complain of pain in upper front region of jaw. On radiographic examination calcified root canal was associated with upper anterior teeth. Root canal treatment was planned for calcified tooth. Access opening was carried out using BR45. To achieve patency within canal file#8, 10 were used, but initally patency could not be achieved due to calcified canal. With help of chelating agents 17% EDTA liquid and gel and small size K file #8,10 canal negotiation was carried out to achieve patency. Working lengh was then determined and canal was instrumented. Naocl, EDTA was used as intermittent irrigant. Final rinse was done using 2%CHX. Canal was obturated using cold lateral condensation technique followed by permanent restoration. Entire procedure was carried out under magnification.

Conclusion: Calcified canal treatment is bit tedious then routine endodontic procedure. But it can be managed if procedure is carried out under proper illumination, magnification, CBCT, understanding root canal anatomy, use of dye, modified access bur, files, chelating agent, irrigants and irrigation activation system.

Introduction

Goal of endodontic treatment is to completely eradicate micro-organisms and disinfect root canal. This is obtained by biomechanical preparation, use of irrigants, intracanal medicament.It is difficult to access complex root anatomy, calcified canal for complete disinfection. Calcification of root (calcific metamorphosis) is usually seen as defensive reaction of body to trauma. Intensity of trauma/hit, time span since

trauma occurred, body's response are multiple factor deciding degree of calcification.[1] Calcification may be seen partially or entirely in root canal. Locating root canal in such teeth is a tedious job. As there are chances of perforation, excessive dentin removal. Present case report enlighten about endodontic management of calcified canal in upper central incisor.

Management: Local anesthesia was administered "2% lignocaine with 1:80,000 epinephrine".[2]Access preparation was done with high speed round bur (BR 45) and modified using EX24 bur. No canal orifice was visible upon access opening initially. On probing catch was present more towards lingually. File. No. 6 K file was inserted to confirm the opening of canal. File was in canal but not upto working length. File was 5 mm short of working length due to calcification of canal. No. 6 K file got bind at middle third of root. so to negotiate the canal till apex, filling with file # 6 along with use of chelator 17% EDTA gel and EDTA liquid was done. Same procedure was done in canal to create glidepath with No. 8 & 10 K Files & Path Files. working length was recorded using apex locator and confirmed on PSPIx, WL- !7mm .Complete Chemico-Mechanical Preparation was done using Step - back technique by hand K-files upto 80 No. K file, Master apical file was 55 No. k file. 3.5% sodium hypochlorite (Prime dental) and saline was used for irrigation during RCT. Final rinse by 17% EDTA (Prime Dental) followed by 2% CHX (Neelkanth). Master cone fit was taken. Sealapex sealer was coated in canal using lentulospiral and obturated using cold lateral condensation technique.[3,4,5,6] Post endodontic restoration using GIC (Fuji II) was done.[7,8]

Discussion

Mechanism behind canal calcification is not clear. It is believed when trauma occurs it leads to disruption of blood vessel. Clot formation occurs which acts as source for calcification in root canal. 4 - 24% teeth show varying degree of calcification due to trauma. Radiographically loss of pulpal space, discoloration of teeth is suggestive of calcification in teeth. [9] If such teeth is symptomatic treatment of following tooth come into high difficulty class according to " American Association of Endodontists Case Assessment criteria".[10] Pulp chamber and root canal is usually shifted more towards lingually in calcification of upper anterior teeth. Access cavity preparation should be made such that excessive loss of dentin is avoided.[11] Law of color change, i.e pulp chamber will be more darker compared to root dentin. This will help to identify entry in pulp chamber. [12]Use of CBCT, dental operating microscope for treatment of calcified canal is boon. ultrasonic tips to negotiate calcified root canal, use of bur with long shank are used for troughing and to locate calcified canal. Detection of orifice by use of methylene blue dye or champagne bubble test under microscope are useful to locate canal orifice. [13]Multiple angulated radiograph should be taken in deep access preparation to ensure central alignment and no loss of excessive dentin or perforation. ([14] Negotiation of calcified canal, narrow constricted canal is a challenge toward dentist. Usually negotiation is done with use of file #6,8,10 which has small diameter therefore used as pathfinder files. Due to small diameter these files lack rigidity and may fracture if excessive watch winding force is applied. So to prevent fracture of this file and further complication alternate use of file # 6,8,10 should be done.[15,16] Gentle watch winding motion to file with slight push pull motion should be used. Files should be checked before insertion and discarded when sign of distortion appears. Many different file system for negotiation of calcified canal have been introduced. Such file has quadrangular cross section to increase rigidity of file to prevent its breakage.[17] Decalcifying, chelating agents and irrigants should be used during biomechanical preparation to soften canal dentin and facilitate passage of filelike 17 % EDTA gel, 17% EDTA irrigant .[18] Calcification usually occurs from corona to apical direction. Therefore if file is negotiated well at coronal and middle third, instrumentation in apical third becomes easier.[19] Schindler & Gullickson stated if negotiation of canal is not achieved and tooth is symptomatic. root end resection under microscope should be treatment of choice.[20,21,22]

Conclusion

Prognosis, success of root canal treatment rely on complete disinfection till apex. In case of calcified canal to achieve negotiation use of various file system, irrigants, chelating agents, modified bur and procedure under dental operating microscope renders successful treatment of calcified tooth.

Abstract

Background: Preservation of pulp vitality is of utmost importance during management of deep caries cases. There remains a possibility of pulp tissue to repair upon excavation of caries with no pulpal exposure. However, in case of exposure of pulp, such type of minimally invasive management becomes doubtful & impulsive. Indirect pulp capping(IPC) treatment plays an essential role in these cases to prevent pulpal exposure.

Case Presentation: This case report describes the single visit indirect pulp therapy in mandibular molar. Patient reported with a chief complaint of food lodgement and mild intermittent pain. There was no history of night pain and/or spontaneous pain. The clinical and radiological evaluation revealed no peri-radicular pathosis and no pulpal involvement. The tooth was examined for vitality using electric pulp test and revealed vital pulp. The treatment was done with the protocol of Single Visit Indirect Pulp therapy using light cure calcium hydroxide and cavity was disinfected with 2% chlorhexidine. Cavity was lined with Glass Ionomer Cement and final restoration was done using Composite resin restoration. The patient was followed up till 6 months and showed satisfactory outcome eliminating the need for more invasive approach as root canal therapy.

Conclusion: Indirect pulp therapy is a safe, economical and proven treatment option in the teeth that have not involved pulp and with sound peri-radicular tissues. The success of Indirect Pulp Capping relies on proper case selection and diagnosis, complete isolation, caries removal and disinfection with selection of suitable pulp capping material.

Introduction

Deep carious lesion has always been the major topic of attraction.[1] The diagnosis of actual condition of pulp is complicated by the overlying caries, hence it is difficult to precisely diagnose the tooth vitality.[2] Preservation of pulp vitality is of utmost importance during management of deep caries cases. There remains a possibility of pulp tissue to repair upon excavation

of caries with no pulpal exposure. However, in case of exposure of pulp, such type of minimally invasive management becomes doubtful & impulsive. Also there will be a significant decrease in favorable outcome in situations of pulp becoming infected & pulp exposure during excavation.[3]

Indirect pulp capping (IPC) treatment plays an essential role in these cases to prevent pulpal exposure. This type of management could be single step or 2 step procedure or stepwise caries excavation.[4,5] Indirect pulp capping, in cases where removal of entire caries would result in pulp exposure, it requires infected dentin removal & leaves behind affected dentin layer. Both IPC & final restoration of teeth can be carried out in a single appointment.[6] This was recommended from the data from some earlier studies which checked the tooth which undergone indirect pulp capping & was again reopened. The studies came to a conclusion that there was hard demineralized dentin showing no signs of progression of caries.[7] A superfluous risk for pulp exposure might be present during re-entering the cavity for entire removal of caries in 2nd appointment.[8] Therefore single visit indirect pulp capping is indicated wherein the entire procedure in carried out within single appointment and tooth is not revisited again. For pulp protection, remineralization can be induced by placing calcium hydroxide(bactericidal or bacteriostatic liner) on carious dentin, which is considered as a traditional procedure for indirect way of pulp treatment.

Calcium hydroxide is white, odorless powder, less soluble in water & has increased ph.[9] If remaining thickness of dentin is minimum of 0.5mm without any pulpal exposure, the relevance of acidic conditioner on either enamel or dentin would not lead to irreversible pulpitis. [10,11]

Case Report: A 30 year old male patient came to dental OPD with complaint of food lodgment in lower left back region of jaw since 1 month which was associated with intermittent pain. The pulpal status & periradicular tissues were suspiciously examined. When clinically examined, adjacent gingival tissue was normal in appearance & occlusal caries involving enamel as well as dentin was noticed. No peri-apical radiolucency was observed and no periodontal ligament widening was seen. (fig 1) Pulp sensitvity was found well-matched with reversible pulpitis which was confirmed by using thermal test. On application of cold stimulus pain disappeared quickly.

Figure 1 Pre-operative Radiograph

The steps followed during treatment was: The procedure began with the scaling of teeth, subsequently IAN block was given (2% lignocaine 1:2,00,000). Rubber dam isolation was done in the operative field. #6 Round diamond bur along with water coolant was used to remove the infected carious dentin.(fig 2).

Figure-2 Caries removal

Spoon excavator was used to remove the peripheral carious dentin which was followed by using a low-speed round carbide bur which was well-matched in accordance to the size of cavity. Careful caries removal was performed such that only the wet infected dentin was removed with the dry affected dentin left. Careful inspection of the cavity was done so as to remove the complete carious tissue and check for pulpal exposure, if any. Further cavity was disinfected by using 2% chlorhexidine (Consepsis, Ultradent) for 60 seconds. Then the placement of a layer of light cured $Ca(OH)_2$ over the affected dentin was done & cured for 40 sec. (fig 3).

Fig-3 Placement of calcium hydroxide

After that mixing and placement of a layer of GIC, GC Fuji II was over light cured calcium hydroxide was performed. Excess material was removed from the walls & margin.(fig-4).

Figure- 4 Placement of GIC

Sterile dry cotton pellet was placed in the cavity & patient was asked to wait for 15 min for GIC to set. After removing the cotton pellet, tooth was etched with 35% phosphoric acid gel (Scotchbond™ Etchant, 3M/ ESPE) for 30 seconds followed by rinsing and drying. The application of bonding agent (Single Bond™, 3M/ ESPE) was done as per manufacturer's instructions. Incremental technique was used for placing composite increments (Filtek Z250™, 3M ESPE) and each increment light cured for 40 second. (fig5)Occlusion was checked followed by removal of rubber dam.

Figure 5 Composite restoration

Follow-up: After 1 month follow up, on clinical examination & evaluation on radiograph,the results were constant with regular vital pulp. 6 months and 1 year followed up also showed satisfactory result.

Discussion

Indirect pulp capping treatment is opted after the thorough clinical examination and radiographic assessment. The clinical examination should reveal no frank pulp exposure, sensibility test showed positive response and radiograph excluded the peri-radicular pathosis. In the present case, the radiographic images & clinical assessment pointed towards the indirect pulp capping treatment.

Material which could be placed on the dentin still remains a topic of discussion. Materials having bacteriostatic or bactericidal action are applied over affected dentin, for example: zinc oxide eugenol, calcium hydroxide & glass ionomer cements. The use of calcium hydroxide has demonstrated to arrest caries lesion by its action on bacterial activity and growth.[12] Kiranmayi G et al conducted a systematic review and meta-analysis and concluded that calcium hydroxide proved similar results as MTA when used for Indirect Pulp treatment. MTA and calcium hydroxide both demonstrated favorable outcome for this indirect pulp modality.[13] In deep cariesthe success rates of indirect pulp capping using $Ca(OH)_2$ liner ranges from 92%-97%.[14] It was found that the IPC with $Ca(OH)_2$ liner and a consequent high-quality sealing of margins decreased the substrate for micro-organism, reduced progression of lesion and allowed a physiological response in the pulp-dentin complex.[15]

Glass Ionomer cement was placed over calcium hydroxide. It has been suggested that ionomer cement helps to arrest caries and provide antimicrobial effect. Glass Ionomer release fluoride ions and it has thermal expansion variable very close to that of tooth structure and is biocompatible.[16] The permanent restoration can be done with composite resin restoration so as to provide adequate strength at the time of mastication and esthetic results. The restoration with resin composite should be placed so as negligible or minimum amount of microleakage will be anticipated.[17]

Conclusion

Indirect pulp therapy is a safe, economical and proven treatment option in the teeth that have not involved pulp and with sound peri-radicular tissues. The key determinants for successful indirect pulp capping are accurate case selection, adequate isolation, disinfection of the cavity, caries restriction and selection of suitable pulp capping material.

Case Report-Primary Renal Lymphoma: A Rare Entity

K.M. Hiwale[1], Preeti Sahu[2], Sunita Vagha[3]

[1]Professor, [2]Resident, [3]Professor and Head, Department of Pathology,
Jawaharlal Nehru Medical College Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha

Abstract

Background: Kidney involvement is an under-recognized complication of both Hodgkin and non-Hodgkin lymphoma (NHL).[1,2] Many patient presents with acute kidney injury in newly diagnosed NHL, but patient being diagnosed with primary renal NHL is very rare. As it rarely occurs, it may not be considered initially during patient presentation. In patient presenting with idiopathic kidney failure along with non-specific pain in abdomen, primary NHL must be kept in mind. Below we present a patient who presented with pain in abdomen and was later diagnosed as a rare case of primary renal NHL.

Case History: A 65 year old male presented with the chief complaints of pain in abdomen since 2 months and history of nocturia 3-4 times at night and dribbling of urine since 1 month. There were no significant findings on general and systemic examination. CT scan revealed a solitary renal mass of 90 × 85 × 61 mm in upper pole of left kidney. Patient underwent Radical Nephrectomy and on histopathology specimen was diagnosed as - Infiltration of Non-Hodgkins lymphoma in kidney. Primary renal NHL.

Conclusion: Primary involvement of kidney in NHL is extremely rare entity which should be always kept as differential diagnosis in case of radiological suspicion of primary renal mass. NHL is diagnosed on histopathological grounds and can be first proven by performing renal biopsies in order to start chemotherapy which is the main modality in treatment of PRL. Recent immunohistochemical tests allow correct diagnosis and also helps in classifying renal lymphomas.

Keywords: *Non-Hodgkin lymphoma, NHL, Primary renal lymphoma, renal lymphoma, B cell lymphoma.*

Introduction

Kidney involvement is an under-recognized complication of both Hodgkin and non-Hodgkin lymphoma (NHL).[2] Various lymphoma-related renal manifestations makes diagnosis difficult: while abrupt worsening of kidney function may be the first sign of malignant disease, renal effects can be subtle or even silent. The etiologies of renal involvement are similarly varied. Primary renal lymphoma (PRL) is rare and is B cell NHL.[3]

There are many patients who presents with acute kidney injury in newly diagnosed NHL, but patient being diagnosed with primary renal NHL is very rare. As it rarely occurs, it may not be considered initially during patient presentation. In patient presenting with idiopathic kidney failure along with non-specific pain in abdomen primary NHL must be kept in mind. Below we present a patient who presented with pain in abdomen and was later diagnosed as a rare case of primary renal NHL.

Case History: A 65 year old male presented with the chief complaints of pain in abdomen since 2 months

and history of nocturia 3-4 times at night and dribbling of urine since 1 month.

He stated that the pain was present in the umbilical region, continuous dull aching type which aggravated after heavy meals and was non-radiating.

During general examination, the patient was afebrile, moderate GC with all normal vital signs.

There were no palpable cervical, axillary and inguinal lymph nodes. No was no pallor, icterus, clubbing, cyanosis or pedal edema.

On systemic examination, cardiovascular, respiratory, central nervous system were within normal limits.

On per abdomen examination- the abdomen was soft, non-tender, no palpable lump was felt with normal bowel sounds.

Per rectal digital examination was done which revealed enlarged prostate of grade II with normal anal tone. Different laboratory tests and ultrasound examination were carried out in view of above history and examination. Serum urea, creatinine, electrolytes and hemogram were within normal limits. Urine microscopy was normal with no albuminuria and glycosuria.

On ultrasound of abdomen and pelvis well-defined hypoechoic lesion measuring 81 x 68 x 66 mm was seen in left hypochondriac region medial to upper and mid pole of left kidney with good internal vascularity. Suggestive of Renal cell carcinoma arising from upper pole of left kidney or Retroperitoneal mass lesion (Lymphoma). Mild Prostatomegaly (32 cc with median projection noted)In view of the sonographic findings, contrast-enhanced computed tomographic (CECT) scan of the abdomen and pelvis was done.

Routine CECT abdomen and pelvis along with CT Urogram for the evaluation of lymphoma was performed which revealed a solitary renal mass of 90 × 85 × 61 mm was seen in upper pole of left kidney also involving the suprarenal region with distortion of the normal renal architecture lesion demonstrated moderate contrast enhancement and the left adrenal mass was not seen separately. Left renal artery is seen traversing through the mass without any infiltration. Renal vein was normal. No thrombus was seen in IVC. No hydronephosis or mass effect was noted. Enlarged left para-arotic lymph nodes were also seen. Suggestive of retroperitoneal lymphoma/renal cell carcinoma.

Diagnostic laproscopy was done where, enlarged left renal mass with para- aortic lymphadenopathy was seen intraoperatively.

Radical Nephrectomy was planned and specimen was submitted for histopathological examination.

On gross examination left kidney containing diffuse greyish white mass of size 92 x 91 x 65 mm sparing the peripheral portion (0.5 cm) of kidney.

On cut section, diffuse infiltrative greyish white mass seen involving the major portion of kidney.

On microscopy it shows small round cells with condensed chromatin with round to slightly irregular nucleoli of size 6- 12 micron and scanty cytoplasm admixed with mature lymphocytes, arranged in diffuse fashion infiltrating interstitium around the renal tubules.

Diagnosis- Infiltration of Non-Hodgkins lymphoma in kidney. Primary renal NHL.

Discussion –

Our patient presented with abdominal pain and symptoms of benign Prostatomegaly. His histopathological reports of radical nephrectomy concluded to be Primary NHL of kidney or Primary renal lymphoma (PRL).

Primary renal lymphoma accounts for <1% of cases of extranodal lymphoma. [4]

The tumour is mostly a B cell NHL of intermediate or high grade.[5]

PRL is an infiltrating tumour defined as NHL which is originating from parenchyma of kidney and not invading from an adjacent lymphomatous mass. It does not causes disruption of architecture or function. [6]

Its origin is uncertain and debatable as kidneys normally lack lymphatic tissue. In the development of PRL different pathological mechanism have been proposed which suggests the origin from renal capsule having rich in lymphatics or parenchymal invasion from perinephric fat, or the origin can be from lymphocytes existing in chronic inflammation which may be responsible for causing lymphomas.[1,5,7–9]

It is important to differentiate a primary renal lymphoma with a secondary renal involvement from a

primary retroperitoneal lymph node lymphoma. Primary renal lymphoma on histopathological findings show diffuse lymphomatous infiltration of monomorphous population of lymphocytes in the renal interstitium. While secondary involvement of kidney is frequent in NHL, generally presenting with features of renal failure owing to different histopathological renal pathologies such as membranoproliferative glomerulonephritis, crescent glomerulonephritis, minimal-change disease, intraglomerular large B-cell lymphoma e.t.c.[5]

It affects patients of middle age or older age group. The diagnosis of PRL is confirmed on histopathological examination. Mostly the disseminated cases of lymphoma are seen to have a renal involvement as secondaries. However, the frequent findings seen in PRL is acute renal failure, abdominal pain and mass in renal area. [6]

Renal metastasis can resemble renal lymphoma. Renal cell carcinomas have hypervascular enhancement pattern which helps in differentiating it from renal lymphoma. Transitional cell carcinoma and severe pyelonephritis can be confused with diffuse renal infiltration by lymphoma.[10]

Therefore, lymphoma must be kept as a differential diagnosis whenever there is a tumour seen around renal pelvis or ureter, even if there is no abnormality in the renal parenchyma or abdominal lymphadenopathy.

Nephrectomy is considered as the mainstay of treatment modality in patients of renal mass. In contrast, chemotherapy is considered as a standard therapy in cases of primary renal lymphoma. Thus, despite of its rare occurrences, it is very essential to differentiate PRL from carcinoma.

Conclusion

We conclude that the diagnosis of PRL is generally done by radiological assessment, however it is important to have a histological confirmation in order to start chemotherapy which is the main modality in treatment of PRL. Primary involvement of kidney in NHL is extremely rare entity. NHL is diagnosed on histopathological grounds and can be first proven by performing renal biopsies. Recent immunohistochemical tests allow correct diagnosis and also helps in classifying renal lymphomas.

Gastrointestinal Stromal Tumourmetastasis in Lymph Node: A Case Report

K.M. Hiwale[1], Harshala Lokhande[2], Sunita Vagha[3]

[1]Professor, [2]Resident, [3]Head of Department, Pathology Department, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra

Abstract

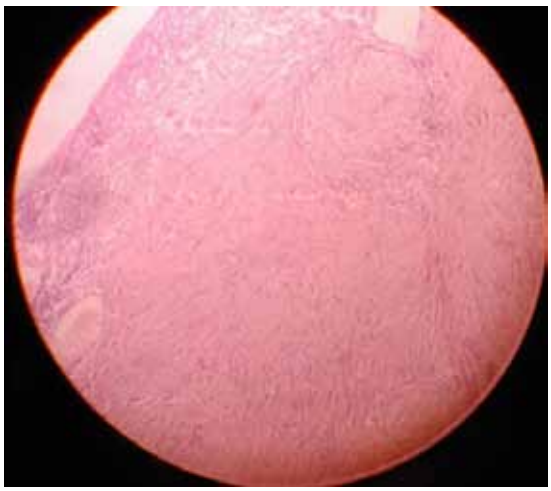
Background: GIST are the tumours originating in the gastrointestinal tract with a high malignant potential and the chance to metastasize and recur. They are widely studied due to their distinctive biologic behavior, clinicopathological manifestations, molecular mechanisms and treatment modalities. They can affect any part of gastrointestinal tract or extraintestinal sites. Most GISTs stain positive for KIT, CD117 andanoctamin-1(DOG-1). Tumorresection along with Imatinib therapy is said to be mainstay of the treatment.

Case Presentation: Here by presenting a case of a male aged 60 years operated for cholecystectomy and intraoperatively found to have a solitary nodule over the stomach, which was later found out to be GIST metastasis to a lymph node on histopathology.

Conclusion: GIST has a low incidence and rare tendency to metastasize to lymph node; therefore it is important to study clinical importance to lymph node in this malignancy. Lymph node dissection should therefore be kept in mind during resection of GIST.

Keywords: *Gastrointestinal Stromal Tumour, Interstitial cells of Cajal, Metastasis*

Introduction



The Gastrointestinal Stromal Tumor (GIST) is a rare mesenchymal tumor of gastrointestinal (GI) tract. The tumour has a peak inclination towards metastasis to liver along with recurrence in the peritoneum. Primary lymph node involvement or metastasis is rare.[1] It can affect any part of the gastrointestinal tract and may also be seen to involve the extraintestinal sites.[2] The origin of this tumour is the Interstitial Cells of Cajal. The incidence of GIST is about 10-20 patients per million and occurs mostly in patients aged more than 5th decade of life.[1] Mainstay of the treatment being tumor resection; lymph node dissection being rarely done due to the rarity of its involvement.[1]

Case Presentation: A 60 year old male presented to surgery OPD with the chief complaints of pain in abdomen since 15 days, progressive in nature. Clinical findings revealed pain in right hypogastric and epigastric region. CECT Abdomen was suggestive of calculus cholecystitis with empyema for which pig tail catherization was done. Elective Cholecystectomy was planned considering the possibility of Chronic Cholecystitis. A solitary nodule on the greater curvature of stomach was accidently discovered intraoperatively while Cholecystectomy procedure, for which wide local excision was done. Gall bladder and nodule specimens were submitted for histopathological examination. The nodule was well delineated, globular, brown, tissue piece measuring 2 X 2 cm. On cut section, white, homogenous areas were seen.

On microscopy, lymph node architecture is

completely effaced by neoplastic element with smooth muscle differentiation arranged into whorl like pattern showing moderate nuclear atypia, pleomorphism and hyperchromasia and also mitosis with condensation of lymphoid follicle towards the periphery.

Discussion

GIST are rare tumours of the gastrointestinal tract. These tumours are mostly seen in 6th and 7th decades of life; mainly in the stomach.[1] Majority of the patients stay 'silent' until the tumor attains a larger size.[2] Common manifestations being pain in abdomen, anorexia, weight loss, vomiting manifesting depending upon the size of tumor.[2]

80% GISTs are located in the gastrointestinal; remaining seen in omentum, mesentry, gall bladder and urinary bladder.[2] Out of these, 60% are found in the stomach.

The diagnosis of GIST are made up by histology and immunohistochemistry findings. The histological variants of GISTs include spindle (70%), epitheloid (20%) and mixed (10%).[6]

Most GISTs stain positive for KIT, CD117 and anoctamin-1 (DOG-1). The major oncogenic pilot for GISTs are mutations in KIT and PDGFRA.[5]

The main factors determining the malignant ability of the tumor are the size of the tumor, site, rate of mitotic activity, C-Kit and PDGFRA genotype; also predicting the prognosis.[4] Tumor resection has been said to be the mainstay of the treatment along with Imatinib therapy.[4]

Even after resection, metastasis and reccurence are not uncommon in these patients. Most common sites being liver and peritoneum.[1]

Kubo N et al; reported a case of 68 year old male with weight loss and anorexia and gastroscopy disclosed a tumor mass with ulceration over the upper body of the stomach. On histopathology, GIST was confirmed. Computed Tomography (CT) findings revealed primary gastric tumor, right mediastinal tumor and a left axillary mass. On dissected and histopathological examination, it showed spindle cells and also positive immunohistochemical stains for C-Kit, said to be a metastasis of GIST.[4,5,6]

In our study, we have seen a 60 year old male being operated for Cholecystectomy and accidently diagnosed to havesolitary nodule over the curvature of stomach. The histopathological findings revealed GIST metastasis to lymph node. The patient was later given Imatinib therapy and follow-up was done for recurrence.

Conclusion

GIST has a low incidence and rare tendency to metastasize to lymph node; therefore it is important to study clinical importance to lymph node in this malignancy. Lymph node dissection should therefore be kept in mind during resection of GIST.

Rhinoscleroma: A Case Report

K.M. Hiwale[1], Harshala Lokhande[2], Sunita Vagha[3]

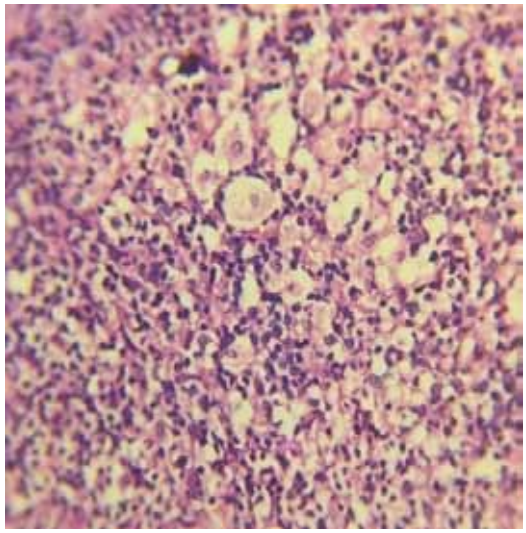
[1]Professor, [2]Resident, [3]Head of Department, Pathology Department, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (M), Wardha, Maharashtra.

Abstract

Background: Rhinoscleroma is a chronic granulomatous disease caused by gram negative bacteria; Klebsiellarhinoscleromatis. Respiratory mucosa is predominantly affected involving mainly the nasal cavity and nasopharynx and further extending to the respiratory tract. Systemic involvement is rare. The bacilli can be stained for histopathological examination by Hand E, Gram's stain and Giemsa stain. Treatment being antibiotics and anti-inflammatory drugs.

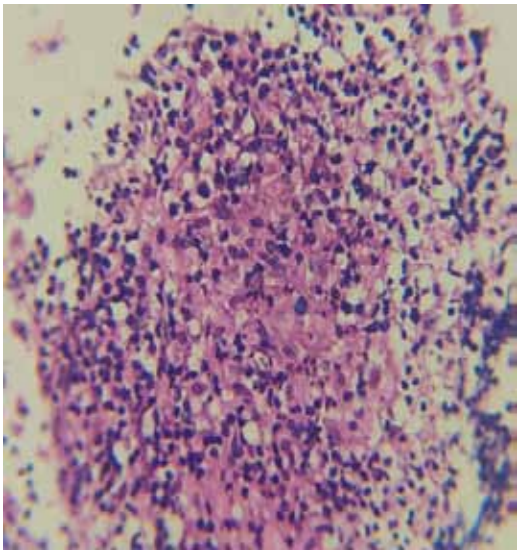
Case Presentation: Hereby presenting a case of 52 year old male with nasal blockage; clinically found to have a mass encasing the bilateral chonchae and nasopharyngeal wall being investigated for malignancy, but proved to be diagnosed with rhinoscleroma on histopathology.

Conclusion: Rhinoscleroma, usually difficult to diagnose, may be confused with granulomatous disease, carcinoma, tuberculosis and leprosy. Seen majorly affecting the respiratory tract, adequate biopsy material sent for histopathology may prove to be useful in the diagnosis; along with a proper clinical history. The presence of inflammatory background containing Mikulicz cells are highly suspicious of rhinoscleroma. The disease often presents with nasal mass therefore clinically mimics with neoplastic mass. Due to its chronic course, it often proves challenging to treat. Early diagnosis thus ensures timely treatment further avoiding relapses and complications.



Keywords: *Rhinoscleroma, Mikulicz cells, Klebsiellarhinoscleromatis, Microscopy.*

Introduction



Rhinoscleroma is a slowly progressive infectious disorder caused by gram negative rod shaped bacilli; Klebsiellarhinoscleromatis.(1) The bacilli mainly involves the upper respiratory passage, with further extension into the lower respiratory passage. Rarely the involvement of other systems have been identified.(2) The disease has been divided into three clinicopathologial stages: Catarrhal-atrophic, granulomatous and sclerotic.(3) Usually the patients present with nasal blockages, foul smelling purulent discharges, crust formations and repeated epistaxis with progression to permanent defects of nasal deformities, anosmia, dysphonia and stridor.(4)

Clinical Case Presentation: A 52 year old married male came to Otorhinolaryngology OPD with the complaints of bilateral nasal blockage since 6 months. On clinical examination, it was found that the patient had bilateral inferior turbinate hypertrophy and congested mucosa; along with a mass encasing the bilateral chonchae and nasopharyngeal wall on both sides. The probable clinical diagnosis were nasopharyngeal carcinoma or hemangiopericytoma of nasopharynx. Radiological investigations were carried out. Computed Tomography (CT) of Paranasal Sinuses findings were suggestive of Nasopharyngeal carcinoma. A biopsy specimen with multiple, whitish brown tissue pieces aggregating 1 x 1 cm were sent for histopathological examination.

40X microphotograph showing foamy macrophages (Mikulicz cells) in the background of inflammatory infiltrate.

40X microphotograph showing epitheloid granuloma in the background of inflammatory infiltrate.

Discussion

Rhinoscleroma is a chronic granulomatous disease; commonly affecting the respiratory tract. [1] Most common site being the nose (95-100%), followed by nasopharynx, larynx, trachea and bronchi. [1,3] The disease is caused by a immotile, short and encapsulated gram negative organism known as Klebsiellarhinoscleromatis.[1] The only host for this organism are the humans.[1] Inhalation of nasal droplets of the infected person is the mode of transmission.(1) Opportunistic disease in immunocompromised people and must be differentiated from other granulomatous diseases.[2] It is seen to affect majorly the people with low socio-economic status and with poor hygiene. [2]

It is categorized as non-neoplastic mass of the respiratory tract. (5) The progression of the disease is seen in three stages: (A) Catarrhal stage- starting with rhinitis and progressing to rhinorrhoea, crust formation and nasal obstruction; can last uptoweeks or months. (B) Hypertrophic stage- It involves granulation tissue formation with nasal pyramid widening and destruction of nasal septum. Symptoms involve epistaxis, anosmia, reduced sensations of the soft palatefollowed by others. (C) Sclerotic phase- Involves extensive scarring and stenosis of the nasal vestibule.[2]

Histopathology plays a key role in the diagnosis of rhinoscleroma. The bacilli can be demonstrated by H and E, Gram's stain, Geimsa stain, PAS. (1) Diagnostic features seen in rhinoscleroma are the dense inflammatory infiltrate, Mikulicz cells and the granulomas.[6] K. rhinoscleromatis is positive in routine cultures on blood or MacConkey agar in 50%-60% of patients in the granulomatous stage.[7] Detection of Klebsiella antigen, CD68 and altered CD4:CD8 ratio are useful in the diagnosis.[1]

Malkud S, et.al; (2017) documented a case of 34 year old female with complains of swelling of lips and gums since 9 months. On clinical examination, a swelling of the peri-oral area, hypertrophy of gingival and crust formation with fissures was observed over the lips. The nose and throat were found to be uninvolved. The biopsy specimens were sent to histopathology for further examination. The slides stained by H and E, Gram and PAS stains were observed under microscope. Presence of inflammatory infiltrates of plasma cells with Russel bodies and Mikulicz cells were the diagnostic findings that were seen. The patient showed significant improvement with Ciprofloxacin and Doxycyclin and advise of follow-up.[1]

Ahmed A, et.al; (2015) conducted a retrospective study to spot the potential diagnostic features of nasal rhinoscleroma when mikulics cells are absent. Predominance of plasma cells with Russell bodies and neutrophils with squamous metaplasia along with nasal crust formations was found to be diagnostic. This also helped in early diagnosis and treatment of the cases.[4]

In our case, male aged 50 years presented with blockage in the nasal cavity and a nasal mass was found on examination. The biopsy specimens sent for

histopathology examination were stained with H and E, Giemsa and Gram's stains. On H and E stain, Mikulicz cells along with epitheloid granuloma was observed which confirmed the diagnosis of rhinoscleroma. The patient was treated indoor with antibiotics and advised for follow-up.

Conclusion

Rhinoscleroma, usually difficult to diagnose, may be confused with granulomatous disease, carcinoma, tuberculosis and leprosy. Seen majorly affecting the respiratory tract, adequate biopsy material sent for histopathology may prove to be useful in the diagnosis; along with a proper clinical history. The presence of inflammatory background containing Mikulicz cells are highly suspicious of rhinoscleroma. The disease often presents with nasal mass therefore clinically mimics with neoplastic mass. Due to its chronic course, it often proves challenging to treat. Early diagnosis thus ensures timely treatment further avoiding relapses and complications.

Signet Ring Cell Carcinoma

K.M. Hiwale[1], Avadh Kishor Tyagi[2]

[1]Professor, [2]Resident,Department of Pathology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (M)

Abstract

Signet ring cell carcinoma is very rare carcinoma of colon and aggressive subtype of colorectal carcinoma that is mostly diagnose inadvance stage. 5-year survival rate is very poor as compared to other adenocarcinoma of the colon. First case reported in 1951 but clinical literature on this subtype of adenocarcinoma is very limited. In this report a 32-year old male presented with SRCC of colon. Our literature review describes the many factors that contribute to the poor outcome and high recurrence in SRCC of the colon. This study prove that survival rate is increased by earlydiagnosis and surgical resection. However, the rarity of this cancer and its propensity for insidious onset and aggressive course prove a challenge to the development of such guidelines.

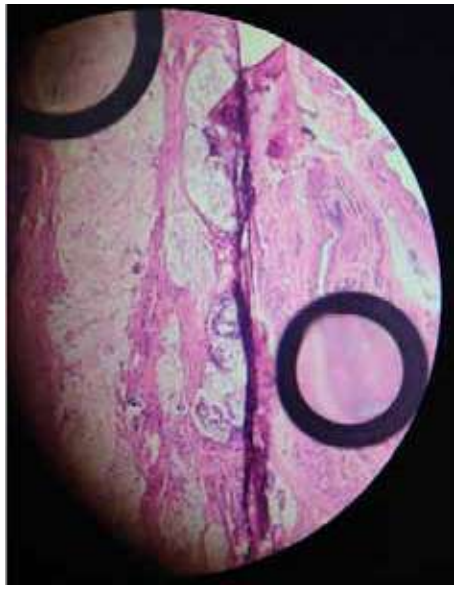
Keywords: *Colorectal carcinoma, Signet ring cell carcinoma, Proctoscopy, Poor prognosis.*

Intoduction

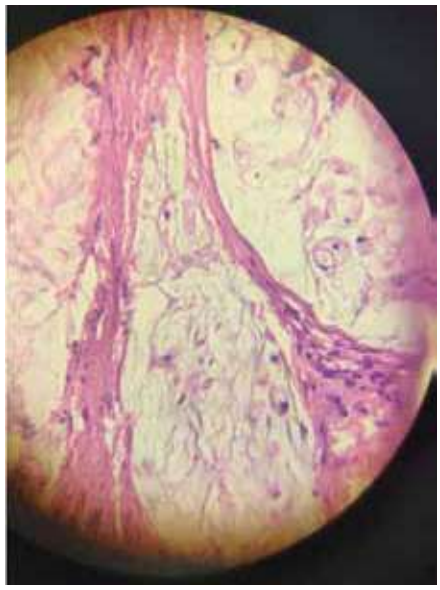
Colorectal cancer (CRC) is third largest cause of cancer in men and second most common cause of cancer in women [1]. In young adults CRC mostly found in the left side[2]. Some studyprove that CRC inyoung age have more dangerous histological features, like perineural and vascular invasion and positive margins after resection[3], inflammatory bowel disease association and positive family history[4]. SRCC is very uncommon type of CRC and occur less than 1% of CRC cases[5]. It is poorly differentiated adenocarcinoma and show more aggressiveness than other adenocarcinoma of colon because of diagnosed in advance stage.[6]

SRCC is a type of mucinous carcinoma, which is histologically characterized by cancer cells with increase intracytoplasmic mucin, which pushed nuclei to peripherally and giving them their "signet ring" appearance. SRCCs mainly arise in stomach, with rest occurring in other organs like breasts, gallbladder, urinary bladder, pancreas and colorectum[7]. Colorectal SRCC, is different from other colorectal adenocarcinomas in terms of early onset, higher rate of peritoneal seeding, higher distant metastasis, lower rate of liver metastasis and the poor prognosis[8]. SRCC has higher tendency of spreading inintrmucosal with sparing of mucosa. That why SRCC is rarely detected in some cases in regular biopsies[9,10]. Here, we describe a case of SRCC of rectum in which definite diagnosis done byproctoscopic biopsies.

Case History: 32 year old male come with chief complaint of bleeding per rectum while passing stool, since 02 months with history of loss of appetite. He has no positive family history of GIT cancer or any disease. No history of vomiting and weight loss and no association with pain.



On clinical examination, abdomen was soft and nontender. No clinical finding of external skin tag, fissure, fistula but ulcerative growth present 1 cm from anal verge on per rectal examination.



CECT finding were enhancing soft tissue density, polypoidal mass lesion arising from the posterior right lateral wall of the anorectal region suggestive of rectal carcinoma with lymphadenopathy.

Proctoscopy was performed and biopsy was submitted for histological examination.

Gross Examination: Multiple, irregular, whitish brown fibrofatty tissue piece aggregating 1 x 1 cm.

Microscopic Examination: Low power view showing mucin lake containing signet cells of adenocarcinoma. High power view showing signet cell in mucin background.

Discussion

According to various study more than 96% cases are found in stomach.SRCC is very uncommon type of colorectal carcinoma, which is 0.1%–2.6% of all colorectal cancer carcinoma[8] and have poor outcome, compared to other adenocarcinomas because it have high tendency of diffusion in intramural, lymph node, peritoneal and distant metastasis[11]. some study shows that survival rate of SRCC is significantly lower than other adenocarcinomas due to advance stage at time of diagnosis and distant metastasis[6]. In this case patient come with bleeding per rectum while passing stool and loss of appetite. CECT and proctoscopy finding were suggestive of diffuse infiltrative carcinoma of rectum[10,11]. With the help of Proctoscopy, sufficient specimens was taken from deeper tissue and confirmed diagnosis was found.

Rectum is most commonly involve, with a incidence of 32.4% to 46.8% bone metastasis from colorectal cancers[13,14,15]. Considering that patient had no lung or liver metastasis. In summary, SRCC diagnosed by proctoscopy biopsies and SRCC is a malignancy of glandular lining of gastrointestinal tract with signet rings like appeared cells under microscopy. The signet ring-like appearance of cells due to the abundant mucin within cells, pushing the nuclei to the peripheries. These cells are mostly associated with pools of extracellular mucin.

Conclusion

SRCC, auncommon histopathologic type of CRC that is more commonly found in younger and has a distinct clinical presentation.SRCC in our study of a patient come with prolonged gastrointestinal symptoms, as SRCC is an aggressive type with poor prognosis when detected in an advanced state. Rule out a primary GI malignancy that has metastasized to other location in the colon is very important.

Homocysteinemia: Cause of a Rare Case Coexisting DVT and Recurrent Foetal Loss in Pregnancy

Nidhi Singh[1], Neema Acharya[2], Sourya Acharya[3], Jaya Kore[4]

[1]Junior Resident, Department of Obstetrics and Gynaecology, [2]Professor and Head of Department, Department of Obstetrics and Gynaecology, [3]Professor of Department of Medicine, [4]Assistant Professor of Department of Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences Sawangi Meghe, Wardha

Abstract

Deep vein thrombosis and venous thromboembolism is a major health problem and one of the leading causes of maternal morbidity and mortality Recurrent pregnancy loss either early or late is a serious problem and has both psychological and physical impact. Thrombophilia are one of the most important causes of DVT as well as Recurrent pregnancy loss as it worsens the physiological hypercoagulable case which exists in pregnancy. Homocysteinemia is rare but an important cause of deep vein thrombosis and recurrent pregnancy loss. Serum homocysteine levels in pregnancy have been linked to preeclampsia,recurrent abortions and low birth weight. Diagnosis of this condition is missed on routine basis due to extremely less frequency of the evaluation of serum homocysteine levels on a routine basis. Here we report a case of hyperhomocysteinemia as underlying cause of bad obstetric history and DVT which are few of the classic presentations of the entity seen in the single patient. the condition was diagnosed by multidisciplinary approach.

Keywords: *Homocysteinemia, Recurrent pregnancy loss, Deep vein thrombosis, Preeclampsia.*

Introduction

Deep vein thrombosis during pregnancy is associated with high mortality and morbidity.(1) The incidence of venous thrombosis in pregnancy is approximately 1 in 1000-2000 pregnancies. Pregnancy being a hypercoagulable state is one of the important factors contributing to venous thrombosis during pregnancy a history of hereditary or acquired thrombophilia or a history of previous DVT has been determined to be most important risk factors. homocysteinemia remains a risk factor for DVT after wellestablished risk factors are excluded. Due to rare association of the condition with deep vein thrombosis serum homocysteine levels are not included in the routine investigations carried out for diagnosis of deep vein thrombosis or recurrent pregnancy loss hence leading to early and specific management of DVT.

Case Report: A 22 years old patient with a h/o spontaneous abortion in second month of her pregnancy presented to casualty at 28 weeks of gestational age with c/o acute abdominal pain and bleeding PV since 6 hrs. patient was drowsy and afebrile on touch. On general examination patient was pale and bilateral pedal oedema was present. on admission Patient had a weak and thready pulse with PR 112/min, bp was recorded to be 150/100 mm hg and albuminuria +2. On abdominal examination patient uterus was tense and tender and was disproportionately larger than the average gestational age. foetal heart rate was absent following which an emergency obstetric ultrasound was done. Obstetric ultrasound showed single foetus in transverse lie with no foetal cardiac activity and hypoechogenic retroplacental clot with intraplacental anechoic areas suggestive of intrauterine foetal demise owing to abruptio placenta. Patient's haemogram and biochemical laboratory tests

Professor and Head of Department of Department of Obstetrics and Gynaecology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences Sawangi Meghe, Wardha

had the following values: hb-7 gm%, TLC-13200/ cumm, platelets-1.23 lakhs/cumm,S. LDH-1017/ cumm,S .uric acid 0.66/cumm. After evaluating the patient's condition,lab investigations and assessing the risk of complications of preclampsia leading to placental abruption and foetal demise of duration more than 6 hrs, an emergency caesarean section was done intraoperatively a hematoma covering 60% of the placenta was observed. a male baby who did not cry was delivered placenta was extracted and sent for histopathological examination [image 1]. 2 units of whole blood were transfused to the patient postoperatively. Patient was started on tab Labetolol 50 mg bd following which her raised BP was well controlled. Owing to history of two unexplained pregnancy losses, patient was evaluated for structural and endocrinal abnormalities, chromosomal anomalies, antiphospholipid antibody panel test which came out to be normal. The lab investigations were not suggestive of any acute or chronic infection in the patient her postoperative period in the hospital was uneventful and the patient was discharged on 5th postoperative day patient had c/o pain,swelling and redness in right lower limb on 9th day of puerperium [image 2]for which she visited medicine OPD and was advised a colour doppler of bilateral lower limbs in view of symptoms suggestive of DVT .thrombosis of femoral, superficial femoral, popliteal, posterior tibial veins was noted in colour doppler of right lower limb. The patient was admitted in medicine ICU following which all the risk factors contributing to DVT were assessed and a battery of investigations was done to rule out the specific cause of DVT in this case. the investigations also included serum homocysteine levels which are not a part of the routine investigations and are rarely considered as a causative factor. However in this case patient's lab investigations came out to be normal except plasma homocysteine level which was elevated[26.58 micromole/l]. patient was started on low molecular weight heparin (enoxaparin) for the management of DVTalong with oral vitamin B6 and B12 tablets once and folic acid 500 mcg twice daily for the treatment of hyperhomocysteinemia. patient had a hospital stay of 7 days and was discharged after relief of symptoms. she conceived spontaneously and visited the obstetric OPD for her regular visits. She was advised to continue low molecular weight heparin as a prophylactic measure for DVT and folic acid tablets supplementation once daily in order to maintain plasma homocysteine levels well within a normal range. A multidisciplinary approach involving physicians and obstetricians helped her in having an antenatal period without any undue complications. Patient presented to casualty at 35 weeks of gestation with c/o appreciation of decreased foetal movements persistently. USG OBS findings were normal and colour doppler showed normal colour flow and spectral waveform. keeping in mind a bad obstetric history of patient an elective caesarean section was performed and the patient delivered a healthy female child of birth weight 2.5 kg. Her intraoperative and postoperative period was uneventful. This case is unique as a simple investigation and treatment of the cause in this case could help the patient in having a favourable pregnancy outcome.

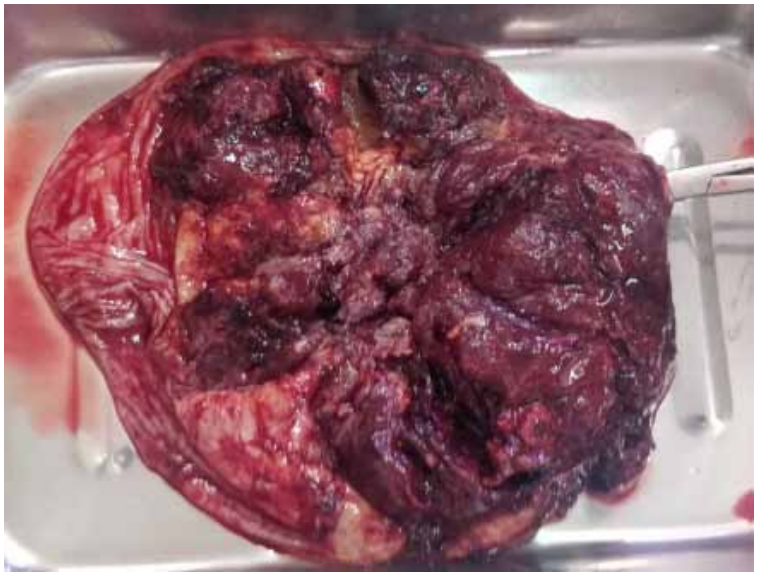

Figure 1: Gross appearance of placenta extracted post LSCS at 35 weeks of pregnancy

Image 2: Unilateral pedal edema in rightcalf seen in patient on 9th day of puerperium

Discussion

Pregnancy and the puerperium are well-established risk factors for venous thromboembolism (VTE). The likelihood of women developing DVT is 5 times more as compared to nonpregnant state. The risk of DVT is accentuated when pregnancy is associated with some specific comorbidities like inherited or acquired thrombophilias, a previous history of thrombosis, antiphospholipid syndrome, lupus, heart disease and sickle cell disease.(2)

Homocysteinemia has been reported as one of the risk factors contributing to recurrent pregnancy loss.Insufficient supplementation of vitamin B12 and folic acid and inherited disorders within the methionine homocysteine metabolic pathway such as MTHFR C677T gene polymorphism can lead to hyperhomocysteinemia(3).

Homocysteine is a sulphur-containing amino acid which is formed by demethylation of methionine. Transsulphuration is important step in homocysteine metabolism wherecystathione beta-synthase catalyses the conversion of homocysteine to cysteine. CBS is vitamin B6 (pyridoxine) dependant enzyme where B6 is an essential cofactor.(4)

Increased incidence of preeclampsia has been noted in women who have raised plasma homocysteine levels in early pregnancy compared to women who have normal levels of blood pressure throughout pregnancy. The incidence can be three times more than that in normotensive pregnant women. Endothelial dysfunction which is pathophysiology implied in preeclampsia can be brought about by homocysteine.

V Stoĭkova *et al* conducted a study and concluded that the women with a severe preeclampsia had a significantly higher serum homocysteine levels than those with mild form (F = 0.025). The study finds a link between the serum homocysteine as an endothelial dysfunction marker and the development of preeclampsia and a relation between the severity of preeclampsia and the degree of the elevation of the serum homocysteine levels.(5)

Nutritional deficiency and/or inherited disorder of methionine metabolism have been a causative factor of hypercystinemia which in turn might be a risk factor for recurrent foetal loss. Hence in such patients a probable association between raised serum homocysteine levels and vitamin B6 and folic acid should be lookedinto so that a nonteratogenic regimen to restore the normal metabolic is begun and there a successful maternal and perinatal outcome.(6) Gris et al reported an association between increased levels of Hcy and a first early pregnancy loss. Del Bianco et al found 25% of women with recurrent loss to have hyperhomocysteinemia or at least a pathological methionine loading test.(7)

Inadequate vascular supply to placental vascular bed might lead to Placental insufficiency,rupture of placenta, recurrent pregnancy loss and pre-eclampsia. A systematic literature review was carried out by JG et al to evaluate the risk of placental pathologies in the presence of metabolic disorders. It was observed among four studies that folic acid deficiency, though statistically insignificant was a prominent risk factor for placental insufficiency and rupture. There was also an association between placental rupture and infarction in the presence of homozygosity of methylenetetrahydrofolate reductase gene and hyperhomocysteinemia with or without methionine loading test. A wide number of observational studies had a common consensus that folate deficiency, hyperhomocysteinemia and homozygosity for methylenetetrahydrofolate reductase thermolabile variant are probable risk factors for placenta-mediated diseases.(8)

Substantial and vast amount of data obtained from the research has shown significant association between mild to moderate hyperhomocysteinemia and vascular disease. Hyperhomocysteinemia is contributing factor

for both arterial and venous thromboembolic events. Langman *etal* conducted a retrospective case control study and observed that fasting hyperhomocystinemia is a remarkable risk factor for venous thromboembolic disease.(9)

The intricate pathway of homocysteine metabolism is regulated by vitamin B6 and Folic acid. vitamin B12 and folic acid are and effective contributors to neural and global development of foetus and embryo. It is not feasible to assess vitamin B12 levels on a routine basis There is very poor relation between levels of intracellular methylfolates (2)active form of folate]and total plasma and/or folates in the red blood cells. Rise in homocysteine levels beyond the normal range has been seen in case of pyridoxine and intracellular methylfolate deficiency(10)

Extensive planning and implementation regarding the management of vitamin B12 deficiency is required but minimal measures have been taken by clinical practitioners and policy makers in India. A reduction of total plasma homocysteine levels has been noted after vitamin B12 supplementation in women in late pregnancy who previously had normal folic acid reserve but had deficiency of vitamin B12.Hyperhomocystinemia is typically managed with vitamin B6,B9 and B12 supplementation.(11)

Conclusion

Homocysteinemia should be considered as a possible diagnosis in pregnant woman presenting with recurrent pregnancy loss and deep vein thrombosis. Early diagnosis and a simple regimen of vitamins supplementation can prevent pregnancy loss especially recurrent pregnancy loss which is be physically and emotionally taxing for couple.

Plasma Cell Gingivitis: A Rare Perpetuating Entity

Anil Agrawal[1], Ayushi Singh[2], Arvind Bhake[1], Sunita Vagha[3]

[1]Professor, [2]Junior Resident, [3]HOD, Department of Pathology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Background: Plasma cell gingivitis is a rare unexpected condition in an individual inconsiderate to be diagnosed for. Although many research has shown the light on the treatment and diagnosis of the disease again exclusion criteria are most considerate. In the current situation patient presented with typical features of inflammation after the confirmatory histopathological diagnosis only plasma cell gingivitis came into contemplation. Properly applied medications were provided to the patient and improvement was seen in follow up. Being congruent with a number of conditions, its diagnosis is served quite succour for mankind.

Case Presentation: A 35-year-old female presented with swollen and occasional painful gums, with intermittent gum bleeding. Her medical, dental, family history and personal history were non-contributory. There was no history of any allergy or Para functional habits such as mouth breathing. No abnormalities were detected in her general physical and extra oral examination. On examination, there was erythema and inflammation of gums suggestive of gingivitis, with normal CBC and PS report. She has been refracted any of the treatment given earlier. Thereafter, a punch biopsy of gums was done and the tissue was sent for histopathological examination.

Conclusion: PCG is a remarkable condition, most likely allergic in nature. While being a purely benign, the clinical appearance and localization may conceal much more detrimental conditions Therefore, each lesion requires due attention.

Keywords: *Plasma cell, gingivitis, rare, inflammation, histopathological.*

Introduction

It is a rare benign inflammatory condition of gingiva characterized by sharply demarcated erythematous and oedematous, non-ulcerative gingivitis often extending to the mucogingival junction occasionally accompanied by cheilitis and glossitis[1,2]. Various synonyms used in literature are idiopathic gingivostomatitis, plasma cell gingivostomatitis, atypical gingivostomatitis and allergic gingivostomatitis and many more[3]. It is been considered as a hypersensitive and immunological reaction to some antigen often chewing gum, toothpaste, or other foreign objects[4]. The exact etiology is unknown but considered mostly due to immunological reaction because of the presence of plasma cells [5]. The allergens identified are mostly cinnamon aldehyde and cinnamon used as flavoring agents. There is no particular sex or age predilection. The diagnosis needs clinical, histopathological and hematological screening to make differential diagnosis other clinically similar conditions[3].

Case History: A 35-year-old female presented with swollen and occasional painful gums, with intermittent gum bleeding. Her medical, dental, family history and personal history were non-contributory. There was no history of any allergy or parafunctional habits such as mouth breathing. No abnormalities were detected

in her general physical and extraoral examination. On examination, there was erythema and inflammation of gums suggestive of gingivitis, with normal CBC and PS report. She has been refracted any of the treatment given earlier. Thereafter, a punch biopsy of gums was done and the tissue was sent for histopathological examination.

Radiological Findings: On radiographic examination, Orthopantomograph (OPG) revealed interdental bone loss with ill-defined radiolucency of apical teeth [figure 1].

Gross findings [Figure 2]:

Histopathological findings [figure 3, 4]:

The section shows squamous mucosa with oedematous squamous acantholytic separation of squamous cells. Submucosa shows diffuse as well as nodular aggregates chiefly composed of mononuclear cells and abundant plasma cells. No vesico-bullous lesion is identified. The plasma-lymphocytic infiltrate at places shows histiocytes but no granuloma or giant cells seen.

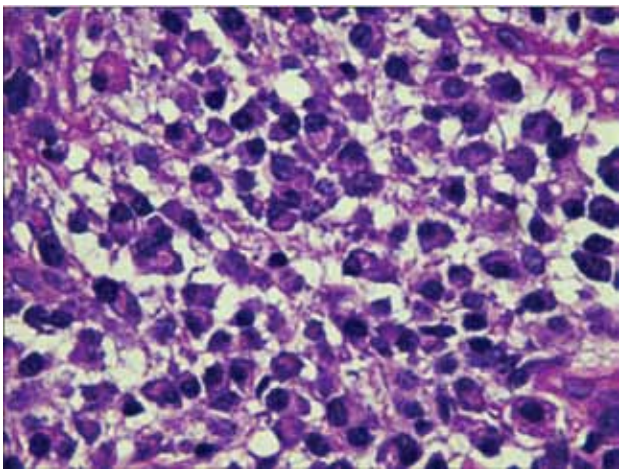

Figure 3

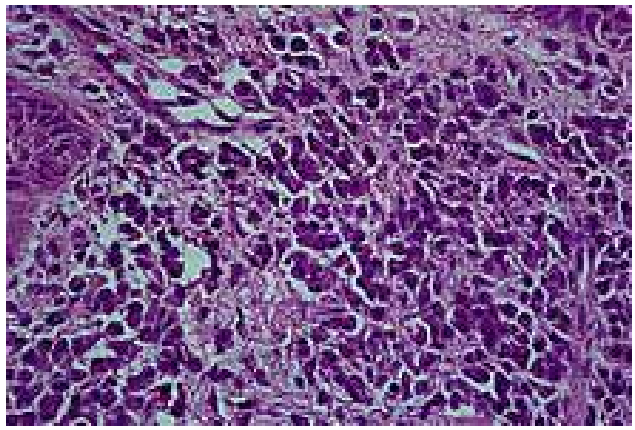

Figure 4

Discussion

The enigma of PCG considered a clinical condition for several years, with many reports appearing in the literature. Clinically, PCG appears as a diffuse erythematous & edematous lesion of gingiva along with a sharp demarcation along the mucogingival junction. It frequently bleeds with little trauma or touch[6]. As seen here the patient also presented with a similar complaint. The exact etiology of PCG is not clear but considered as a hypersensitivity reaction to allergens present in the toothpaste, chewing gums and certain food and oral care products, strong spices and some herbs such as chili, pepper and cardamom. Other than allergic etiology it can also present as a neoplastic lesion or as lesions of unknown cause.[7, 8, 9].

Based on etiology, plasma cell gingivitis is categorized as three types: (1) lesions of unknown cause, (2) lesions owing to some allergen and (3) lesions due to neoplastic origin [10]. Clinically areas of whitening, epithelial sloughing and erosions also have been observed[11,12]. Laboratory investigations usually are within normal limits and sometimes an elevated erythrocyte sedimentation rate can be seen. Patch tests to identify an allergen could be helpful. Also, a biopsy would be of great help in differentiating other gingival conditions [13].In most cases, the first-line therapy should commence with the exclusion of all known potential allergens, as this may result in improvements. Also, oral hygiene improvements and professional periodontal care usually result in the reduction of the marginal gingivitis. excision biopsy of the lesion, wherever applicable, including the case presented here, followed by histological analysis might be not only the best diagnostic approach but also the most beneficial therapeutic option.

Conclusion

PCG is a remarkable condition, most likely allergic in nature. While being a purely benign, the clinical appearance and localization may conceal much more detrimental conditions Therefore, each lesion requires due attention.

Clinical differential diagnosis may include any of the desquamative gingivitis, such as erythematous/ erosive lichen planus, autoimmune vesiculo-bullous diseases, such as mucous membrane pemphigoid and pemphigus Vulgaris, pubertal or pregnancy-induced gingivitis and leukemia-associated gingivitis should be taken into consideration.

Critical Appraisal of e-learning through Mobile Devices in Medical Education

Gaurav Sawarkar[1], Punam Sawarkar[2]

[1]Associate Professor, Dept. of Rachana Sharir, [2]Associate Professor, Dept. of Panchakarma, Mahatma Gandhi Ayurved College, Hospital and Research Centre, Datta Meghe Institute of Medical Sciences (Deemed to be University), Wardha, Maharashtra, India

Abstract

Summary: In COVID-19 pandemic, e-learning is the essential component of education system. All the schools, colleges, universities implemented e-learning program for the purposes of teaching and learning. Syllabus of new session is started for the said academic year through e-learning to minimize the academic loss and to coverup the academic session. Nowadays, medical education is full off with information technology solutions, computer--assisted learning has facilitated teaching of a wide range of topics, including basic science and advanced surgical procedures. The e-learning is totally depending upon the expertise in the handling of technology, electronic devices as well resource material available for the conduction of e-classes and one of the most important factors i.e. internet connectivity. In due course, mental status of students and teachers along with motivation from the teaching institute is also important factor for e-learning program. There were various challenges and disadvantages reported in previous research studies regarding e-learning, suggested for periodic need assessment of educational program, emphasize upon breach in between expected and existing system, resources management system, technical expert team, financial budget, mindset of the teachers and students and training sessions for development of e-learning culture.

Keywords: *COVID-19, E-learning, medical education.*

Introduction

E-learning is the need of the COVID-19 pandemic situation to overcome the educational loss. But students and the teachers are facing problems while conduction of e-learning sessions. Learning is the process which involves variouspsychomotor activities like critical thinking and ability to solve the problems. The precise aim of education system to provide the developers with the best learning tools, so learner can gain thorough understanding, skills and relevant information required for their career(1). In the field of education, technology is not latest revolution but today education system is shifting towards techno based education modalities like app based learning, simulation and in COVID-19 pandemic online teaching(2).

Information technology facilitate medical education and assist teaching-learning with wide range of topics, like basic science and advanced surgical procedures, online learning. Forthe development of field of medical education one should have to consider teaching strategies through advance technology(3).

Nowadays students are more technology friendly, they search and learn most of the required information through various search engines. Up-to-date technologies is required for the upgradation of field of health care and medical education. Consequently, mobile phones are increasingly being used for various purposes as like video conferencing, chatting, entertainment, simulations which enhances the accessibility of information. Thus,

Corresponding Author:
Dr. Gaurav Sawarkar
Mob: 8956977899
e-mail: drsawarkar.gaurav@gmail.com

the upcoming of health care and medical education exceedingly depend upon technological innovations.[4].

Mobile Apps facilitate various learning activities to engage and motivate to the students. Simultaneously, it increases the learner's attainment which eventually reflected into the retention of knowledge[5].Presently various educational programs or applications are available in the cloud that helps the learner in learning process. Newer technologies are the blessing for today's teaching and learning progression.

Medical Education and Information Technology: Introduction of medical students and residents to information technology solutions is the need of the situation which familiarize the students with newer systems presents in clinical environments. The technology solutions can help undergraduate and postgraduate students to study clinical cases, simulation, decision making and management of electronic record[6]. Portable technology for medical education has been evaluated from several perspectives. Personal Digital Assistants became popular, predominantly due to their small size and ease of use for the mobileuser[7]. Recent studies have further explored the use of mobile tablets in medical education. A survey among radiology residents found that 81% of the residents believed that they would spend more time learning if they were provided with mobile tablets for learning difficult cases[8].

Introduction to mobile application: A mobile application is a designed computer program, which can be run on a mobile or tablet. Mobile applications can be run on desktops with windows version and desktop applications that run in mobile with the help of web application through mobile web browsers[9]. The term "app" is the short form of the word "software application". It was listed as "Word of the Year" by the American Dialect Society because of its popularity[10]. These newer smartphones could be named as "app phones" to differentiate them from older version of smartphones[11].Apps are the software designed programs that run on a computer or mobile device to accomplish and facilitate difficult as well as vast task.It is well equipped with faster processors, enhanced memory, advance technology batteries and extremely competent operating systems that easily perform multifaceted functions in least duration [12].

Necessity of Mobile App for E-learning: E-learning is the experience of learning through mobile or wireless computing devices which promoting learning in such a way that knowledge content is always available and accessible anytime, anywhere for the learner. The development of smartphones, tablets and small size laptops with improved capacity and functionality, upgraded memory, bigger screens, the facility to access the highspeed internet and freely downloadable software facilitate e-learning through wide range of uses which enhances communication, diagnostics, self-monitoring with the help of several apps[13]. Users like students and faculty members of various are progressively using mobile devices at the workplace[14,15]; appears to be the part of a technological revolution in medical as well as other sectors [16].Recognizing and keeping up-to-date with developing technology that support workplace as well as distance learning in today's pandemic situation, but it is a key challenge for medical educators[17]. Technology time to time provides help to the learner for enhancement of the knowledge and the skillduly offer a form of dynamic scaffolding[18]. The medical educators need both the factors that gain the knowledge and take part in learning processes, by recognizing and integrating the spirit of learning through participation as well as the distinct attainment of knowledge[13].So, Mobile App is the need of the era to acquire medical education with conventional teaching methodologies.

Mechanisms of e-learning: E-learning that comprises of three key components as follows[19].

1. Technological flexibility- it is the portablefeature of installed hardware and software that enable wireless net connection.
2. Learners' mobility- it means learners can gain knowledge through various sites at a time.
3. Mobile learning processes-it is the process which includes both the technology and the learners in mobile mode.

E-Learning Approach: Mobile learning approach comprises of three important factors-Active instructor or teacher, Active learner and Creative pedagogy for effortlessnesse-learning process[20].

1. Active Instructor: the personfacilitates students, engage them throughout learning process in side or outside the classroom via teaching, assigning work or with continuous assessment.
2. Active learner: the student engage him/herself with self-study, home assignments, self-assessment,

group discussion at digital platform, access course content anytime as he/she want, share as well as exchange knowledge or resulted findings with collogue companion

3. Creative pedagogy: the learning process where instructor and learner mutually agree for teaching content, which create encouragement in the students and keep them active throughout the learning process bycollective learning, discussion on genuine issues, emphasis on challenging themes.

Role of student's in E-learning: Students playsimportant role in four modes- Performance, Satisfaction, Behavior and Motivation.

Performance: E-learning may help the students for learning at anywhere as per ease of learning environment. It facilitates quick learning with new activities, creative thoughts, actions and required skills. Thus, the e-learning allow the learners to improve their study and personal skills through numerous tasks as like communication, critical analysis, problem solving and challenges in learning environment [20].

Satisfaction: The learners satisfaction is the very most important thing depends upon usefulness of the technology, instructors skill as well as quality content learning material, that perceived usefulness directly reflected in to higher satisfaction.

Behaviors: Learners behaviors changes with the content, ease of technology, layout, design of mobile applications. Learners good performance also have the positive effect on their behaviors which boost the moral and increase the positivity. Comfort in using technology also effect on learners' behavior. The appealing interface, layout, colors and overall appearance also influence the learner behaviors.

Motivation: learners performance, satisfaction and positive behaviors motivate the learner for further learning process and also encourage for personal needs, desires and determination.

Advantages of E-learning: Laptops, tabs or mobiles playing an important role in medical education, students and techno savvy faculty using various app as well as software for teaching-learning purpose. Most of the medical students using mobile devices for sharing experiences or notes, access the information, learning new things, clinical case discussions. Nowadays, medical practitioners also using mobiles or various apps for learning or updating themselves with evidence-based information in the competitive era. In the such pandemic situation and distance mode education; mobile devises playing vital role of teaching and learning in medical curriculum.

Considerations for learning Mobile Apps: The learning mobile app should be enough readable and consistence about the contrast colors, type and font of the text. Outlet of the app should be attractive, appealing and noticeable as compared to routine apps. Minimum distractors should be used in Apps for learning purpose except navigators. Make the application in simple format and comfortable as common users can use it easily. Soothing colors should be used to reduce irritation and strain on the eyes for curtailing of visual fatigue.

Challenges of E-learning through mobile app: As per researches regarding e-learning, commonest obstacle of implementing e-learning program is insufficient groundwork of the teachers. So, faculty development program or sufficient training as well as attitude of adoption regarding newer technics of teaching and learning is very important.

Familiarity of power point presentation is the major issue influencing on e-learning interface. In the recent research study, students reported that technical dysfunction in the mobile during online learning is the common scenario found to be triggering factor. Due to small screen of mobile; they were not comfortable to learn science portion which totally depend upon images, analysis. Poor internet connectivity is also the interrupting issue in the e-learning program. There are various problem in e-learning like technology, system quality, data security, self-efficacy of teacher or students and traditional attitude.

Discussion

The technology is the part and parcel of the life in today's scenario, the medical education needs to cope up with the challenges in the education system during COVID-19 pandemic. The researcher suggested that the integration of e-learning into curricular to facilitate learning and learning practice is the need of the education system. The challenges for e-learning are the poor motivation, connectivity, undue expectations, lack of resources, skill and suitability for the content, mere viability of resources is not sufficient but preparedness of the faculty also important. E-learning link the various resources in several variable formats in efficient way due

to its ease and flexibility to use at any time anywhere. On one click learner can connect with the teacher for continuous teaching-learning process. To mitigate the challenges and disadvantages of the online learning, one should have to work on policies of university or institution, design and delivery of the curriculum, learning outcomes in the form of assessments and feedback of the student.For successful implementation of e-learning program in developing countries, it is recommended that effective evaluation and controlling of the e-resources and maintenance of hardware is necessary. Proper training of the teaching staff as well as students to access the advance technology should be incorporated in the university academic calendar as a part of curricula. Partial assignments should be conducted through e-learning mechanism so as to minimize the future discomfort for assessment and evaluation system. Management should motivate the teachers and students through some incentives and competition respectively for the purposes of e-learning. University should allot the separate budget for e-learning mechanism considering a parallel system of teaching-learning and assessment-evaluation.

Conclusion

Periodic need assessment and evaluation of educational system is very important fact. The teaching learning strategies plays important role in the education system. For implementation of newer teaching method like e-learning needs piloting in the same setting to avoid upcoming hitches. So, to sidestep future challenges and expected disadvantages, one should emphasis on need assessment, gap in between present and expected system, resources management system, technical expert team, financial budget, mindset of the teachers and students and adequate training sessions to develop comfort during the teaching and learning.

Professor in Pharmacology, PDMC, Amrawati, Maharashtra, [5]Tutor in Biochemistry, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi Meghe Wardha, Maharashtra

Abstract

Background: Awareness towards tobacco consumption has increased and it is well accepted too but will it help to cease the consumption. With widespread menace of tobacco consumption in developing country like India, not much data of study is available currently about tobacco consumption and osteoporosis around the rural region of Wardha a central part of India.

Aim: Vit D status and osteoporosis in tobacco consumers and non consumers.

Objective: To asses influence of tobacco consumption on Sr. Vit D, Sr. ionized Ca, Sr. Phosphate, Sr. parathyroid hormones the biochemical markers of bone turnover and Bone mineral density in a cohort of 214 healthy men in rural area surrounding Wardha region of Maharashtra.

Design: A cross sectional study

Subjects: 214 healthy men aged around 30-50 years with no disease history were included in the study.

Results: Tobacco consumers had significantly reduced levels of Sr 25 OH Vit D ($P<0.02$), PTH ($P<0.001$). There was no significant difference in Sr ionized Calcium between tobacco consumers and Non tobacco consumers. We got negative effect of tobacco consumption on Sr Osteocalcin ($P<0.01$).

Conclusion: Calcium and Vit D metabolism is significantly deranged by habit of tobacco consumption and cannot be explained by life style factors. Vitamin D- PTH system depression among tobacco consumers represent a other mechanism for the deleterious effects of tobacco consumption on the bones and contribute to reported risk of osteoporosis among tobacco consumers.

Introduction

Tobacco chewing, smoking and other means of consuming tobacco are rampant in rural parts throughout India. Two third of worlds smokers live in only ten countries. 40% live in India and China alone. India counts for 10% of total tobacco consumers[1,2,3].

Vit D is an essential molecule for the development of bone and growth. Tobacco smoking is in most studies found to be associated with a low bone mass and an increased risk of osteoporotic fracture[3]. An increased bone loss has been registered in smokers[4]. The life style habits are more causative factors among smokers compared to non-smokers poor nutrition, less physical activity and more intoxication all of which play a role. Smoking tobacco also has direct toxic effect on bone cells is also a possibility[5]. Hormonal metabolism of pituitary, thyroid and glucocorticoids may also be affected by smoking[6-8]. Metabolites of Vit D and Parathyroid hormone are important in bone and calcium metabolism. Few studies have done investigation on effect of smoking on 25OH Vit D and PTH. [9-15].

This cross sectional study was undertaken to investigate the impact of tobacco smoking and chewing on bone metabolism and compare the circulating levels of Serum calcium and Serum Vit D metabolism of healthy 214 rural men who are in the age group of 30 to 50 years.

Aim: Vit D status and osteoporosis in tobacco consumers.

Objectives:

1. To measure the serum levels of ionic calcium, Phosphate and alkaline phosphatase for screening.
2. To measure the height, weight and BMI
2. To measure the Serum level of total Vit D
3. To measure the Serum level of Para Thyroid Hormone
4. To measure the Serum level of Osteocalcin
5. To measure the Bone mineral Density

Materials and Method

Study Design: A cross sectional study

Study Setting: Department of Biochemistry, JNMC Wardha, under DMIMS DU

Duration of study: 1 Year

Subjects: On the basis of previous pilot study on prevalence of tobacco consumption in rural area around Wardha city 214 subjects were selected by 19 cluster sampling method total 15 different villages around Wardha city.

Materials and Method

Inclusion Criteria: Men in the age group of only 30-50 years were selected. Healthy men who do not having any disease or disorder or on any treatment specially hormones were included in study. Only men around the Wardha from rural area were only included in the study. Females were not included in the study because we wanted to exclude the study of menopause and disorders related to menopause like hormonal and osteoporotic effects.

Exclusion Criteria: Men with no age match are excluded. Men with any disease or disorder excluded.

Biochemical screening was done before inclusion that ensured that all subjects had Sr levels of Ca, PO4 and alkaline phosphatase within normal range.

Sample Size: 214

Sampling Method: By cluster sampling method. It was a cross sectional study, results on pilot study of prevalence of tobacco use in rural region of Wardha was taken into consideration for sample size calculation. 214 men were selected by 10 cluster sampling method from 9 different villages around the Wardha city. The study was carried out during January 2019 to December 2019,

Observation and Results

Of the total tobacco consumers 47 were found to be bidi smokers. They were smoking more than 10 bidis per day, 41 were consuming raw tobacco with calcium carbonate more than 7 times per day, 13 were consuming Gutka/khainy more than 7 occasions per day, none was found using snuff. The age span of the study was kept between 30-50 years and age factor was not counted for any observations. All tobacco consumers those were selected, they have a habit of consuming tobacco at least continuous for 3 years in past. Non tobacco consumers who have left the habit of smoking at least for the past 3 years were also included.

The baseline parameters for inclusion in the study and differences between tobacco consumers and non tobacco consumers are depicted in Table No. 1.

Table No. 1: Base Parameters

Sr.No	Parameters	Non tobacco consumers (n=112) Mean ± SD	Tobacco consumers (n=101) Mean ± SD	P value
1	Age (Yeats)	44±2.9	43±2.1	<0.001
2	BMI (Kg/m^2)	26.63± 4.12	26.76 ±5.72	NS
3	Ionic Calcium (mmol/l)	1.16 ±0.10	1.14± 0.09	NS
4	Sr. Phosphate (mg/dl)	3.54 ± 0.60	3.76 ± 0.61	NS
5	Sr. Alkaline Phosphatase (IU/L)	341.48 ± 106.29	387.26 ± 125.84	<0.006

BMI was just similar for the two groups. No significant difference was observed. No significant differences were found in Sr ionized calcium amongst two groups. Increased Sr phosphate level among tobacco consumers was noted. There was significant difference observed between levels of Alkaline phosphatase amongst two groups.

Table No. 2: Comparison of Non Tobacco consumers versus Tobacco consumers

Sr.No	Parameters	Non tobacco consumers (n=112) Mean ± SD	Tobacco consumers (n=101) Mean ± SD	P value
1	Vit D (ng/ml)	19.51 ± 8.58	16.22 ± 6.23	<0.05
2	PTH (pmol/l)	1.73 ± 1.96	1.281 ± 2.72	<0.039
3	Osteocalcin (ng/l)	15.27 ± 3.7	13.20 ± 3.3	0.1
4	BMD spine (g/cm^2)	1.039 ± 0.13	1.004 ± 0.14	0.05
5	BMD Total hip (g/cm^2)	0.994 ± 0.11	0.816 ± 0.11	0.03

Hypovitaminosis D means Serum levels of 25(OH) D below 20ng/ml was seen in 22.7% of the tobacco consumers and 15.2% in Non tobacco consumers. No linear relationship was observed between number of bouts of tobacco consumption and Total Sr Vit D or PTH.

A non significant decrease of mean serum total Vit D levels was observed when tobacco consumers were classified as Bidi smokers, Raw tobacco chewers and Gutka/Khainy chewers. Low levels of Vit D and PTH in tobacco consumers the mechanism for which could not be explained properly. Many toxic chemicals are present in tobacco and tobacco smoke which must be causing the lower values of Vit D and PTH.

Serum total vit D was not correlated with serum PTH in tobacco consumers. PTH and Serum total vit D were negatively related to each others in Non Tobacco consumers (P<0.04).

Results showed there was positive correlation between BMI and PTH (P<0.001) in both the groups. Body weight was lower in tobacco consumers as compared to non tobacco consumers.

Tobacco consumption was still anindependent predictor of PTH in multiple regression analysis (p<0.005).

Tobacco consumers showed lower levels of Osteocalcin than non tobacco consumers.Osteocalcin and Total Vit D were highly correlated but multiple regression analysis showed smoking was still an independent predictor of Osteocalcin (P<0.01).

To assess the influence of possible confounding factor like alcohol intake on parameters like PTH and total Vit D, we did multiple regression analysis with BMI and smoking. Alcohol consumption was not significant predictor of PTH and Vit D. Smoking was positively correlated with Vit D and with BMI negatively.

Tobacco consumers had decreased age adjusted BMD when compared to non tobacco consumers all the time. Relationship of Total Vit D and Bone density among tobacco consumers and non tobacco consumers was seen. There was inverse relationship between Sr Vit D and bone density. It was of not much significance for the hip bone in non tobacco consumers.

Discussion

As per data of NFHS-III, in India 55.8% male and10.8% female of the age group of 12-60 years were tobacco consumers in different forms. of the males 32.7% were reported to be smokers and 36.5% were tobacco chewers, while in females it was 1.4% and 8.4% respectively[2]. In India tobacco consumption is widespread; it is also prevalent in the central part of India Maharashtra. Our study region and population was not unusual and was suitable for our present study to see the effects of tobacco consumption. In our study population of cohort of normal men, there was significant negative association between tobacco consumption, total Vit D and PTH. William B. Ogunkolade et al also found that there is negative correlation of Vit D and PTH with betel nut and also tobacco consumption in the form of chewing tobacco in their cross sectional study of British Bangladeshi subjects [17].A similar study got the results of 10% lower values of 25(OH)Vit D and PTH in smokers in the control group mean difference was 2.8ng/ml. results correlate well with our study [11]. In one of the Swedish study also it was reported lower values of PTH in young women smokers [12]. In another Swedish study also reported lower levels of PTH in a population based study of men and women aged 25 ± 64 years [13]. Another studdy carried out by Scragg et al 1995 observed no association between smoking and serum 25 (OH) D over elder English women. However these studies of negative findings were consisting of small number of subjects. Lower levels of PTH found in tobacco consumers can't be explained on the differences in ionized calcium or Serum phosphate. We think that the lower levels of PTH are due to corresponding decrease of total vit D levels. In rural set up there was no such noticeable difference among tobacco consumers and non tobacco consumers but confounding factor like alcohol intake. Tobacco consumers can have difference with non tobacco consumers that means tobacco consumption and tobacco non consumption in intake of caffeine, intake of calcium and vitamin D, Exercise and alcohol intake, which also acts as confounding factors and shows association between smoking and vit D and PTH levels[18]. Our study could establish that alcohol consumption by tobacco consumers aggravates the condition and shown lowered levels of VitD. Further more it was observed that tobacco consumption was still associated significantly with serum levels of total vit D and PTH.

Establishment of mechanism by which tobacco consumption lowers the PTH and VitD could not be explained properly. Tobacco itself and its smoke contains various toxic compounds like tars and nicotine. Also contains various heavy metals like nitrosamines, hydroxyquinones, cadmium, thiocynates and others[20,21,22]. Intracellular calcium is increased by hydroxyquinone and it also affects theliver [23]. There may be altered metabolism of Vit D as tobacco consumers have more hepatic degradation of estrogen [24]. The lower values of PTH in tobacco consumers may be due to lower secretion or more degradation of estrogen. We didn't get correlation between lower PTH who has half life of few minutes and,25(OH)2 D who has half life of few hours. Other studies also failed to detect such correlation[25]. There might be an impaired 1-alpha hydroxylation of the tobacco consumers. Accumulation of cadmium in kidney may also cause the lower levels of 25(OH)2 [26,27]. Low levels of serum calcium may be due to the reduced serum 1,25(OH)2 D[28]. Calcium levels in serum are unchanged may be due to the hormones acting for maintaining serum calcium in normal values. Though levels of PTH and 1,25(OH)2 D are low the plasma level of calcium remains unchanged this could be due to decreased uptake of calcium in bone. In our study we observed low levels of Sr. Osteocalcin in tobacco consumers. Low Osteocalcin levels in tobacco consumers shows decreased osteoblastic activity[29,30].In our study there was no significant difference for the Sr. Alkaline phosphatase activity/. There was no difference in serum alkaline phospatase activity in tobacco consumers and non tobacco consumers. A recent study demonstrated the male smokers have lowered parameters such as PTH, Vit Dstatistically significant over non smokers. Our study suggests that tobacco consumption compared to normal males has an inhibitory effect on bone formation. Sensitive bone markers and studies on RNAs also suggest the toxic content of tobacco effect on bone formation. In our study we got decrease in Bone Mineral Density in tobacco consumers compared to non tobacco consumers. Association between Bone Mineral Density and circulating concentrations of 25(OH) D has been demonstrated in number of studies. Non tobacco

consumers may compensate for such as low calcium intake leading to decreased bone mineralization but this compensation is not as much effective in tobacco consumers.

Conclusion

Our study concludes that tobacco consumption decreases total vitamin D and PTH. Tobacco consumers have decrease in serum levels of vit D and decrease in PTH levels. These differences were not explained only by other confounding factors like low socio economic status and intake of alcohol. Lower levels found couldn't be explained with proper mechanism involved. But it is explained only on the basis of observations obtained. The important finding in study was suboptimal levels of Vit D i.e. serum levels of Vit D below 15 ng/ml was 50% higher in tobacco consumers. The trend was higher in age group of 40-50 years. Though the difference found is small and though the size of sample is not large enough the findings are clinically important to correlate among tobacco consumers for the decreased bone mass and for treatment of fractures and osteoporosis.

Role of Frozen Section in Neck Dissection of Oral Cancer Patients

K.M. Hiwale [1], Arzoo Alagh[2], Sunita Vagha[3]

[1]Professor, [2]Resident, [3]Professor and Head of Dept, Department of Pathology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (M)

Abstract

Introduction: Oral carcinoma is emerging as growing problem in many areas of the World and 4th most common cancer among women in India. Globally, over 3,00,000 people are diagnosed with oral cavity cancer each year. Radical or modified radical neck dissection is usually a choice of surgeon in node positive patients. Frozen section when performed along with supra-omohyoid neck dissection provides solution to this dilemma of surgeon by detecting the metastasis in cervical lymph nodes intra-operatively during neck dissection. This study was planned to establish usefulness of frozen section examination in decision of correct plan of management of patients of oral cancer with clinically nonodal metastasis in neck (N0).

Objectives: To study appropriate plan of management for clinically neck examination with lymph node status N0 in patients of oral cancer and to determine efficacy of frozen section examination in detection of occult nodal metastasis in neck in patients of oral cancer.

Method and Materials: In 102 cases, excision of lesion, followed by supra-omohyoid neck dissection was primary mode of treatment and lymph nodes at various levels were sent to frozen section for assessment of metastasis by cancer cells. Intraoperatively during frozen section,if any of the lymphnode between levels I to levels III is found positive for the metastatic disease then the plan of surgery was changed to a more comprehensive Modified radical neck dissection.

Results: Maximum cases were carcinoma tongue followed by cases of carcinoma of gingiva-buccalsulcus. Carcinomas of stage 1,stage 2,stage 3 are 43.8%, 52.2% and 3.9%. Histopathological grading of oral squamous cell carcinoma was done by Broader's grading system as Well differentiated SCC (52 cases), Moderately differentiated SCC (42 cases), poorly differentiated SCC (08 cases). Supra-omohyoid neck dissection was initial plan of management in cases but it changed to modified radical neck dissection in 42 cases as lymph nodes between level 1 to 3 were positive for metastasis of SCC.

Conclusion: Oral cancer should be surgically managed intra-operatively by frozen section examination of alllymph nodes to avoid short term recurrences and institution of post-surgicalchemo/radiotherapy. Frozen section examination of yielded lymph nodes in these surgeries canmodify the extent of dissection of neck.

Introduction

Oral cancer is an emerging as an growing problem in India, with prevalence of 60%[(1,2)]. Men are 2 – 3 times more commonly affected than women. 98% of cases occur in patients aged more than 40 years and are linked to tobacco chewing or smoking[(3-7)]. The spread of oral cancer from primary site to cervical lymph nodes has

been well addressed [8]. The presence of occult metastasis ranges between 10 – 52%. Lymph node metastasis has been found to be one of the most important factors in prognosis of oral squamous cell carcinoma and successful treatment depends on the management of neck. When compared to Node negative disease, the presence of even a single micro-metastasis in a lymph node is associated with a significance difference in recurrence and survival. Supra omohyoid neck dissection (SOND) has been described as a quality staging procedures for OSCC in clinically N0 nodes by some authors[9-11]. Radical neck dissection/MRND is usually a choice of surgeon in Node positive patients.Frozen section when performed along with SOND provides solution to the surgeon by detecting the metastasis in cervical lymph nodes intra-operatively during neck dissection. Incase frozen section detects occult nodal metastasis then SOND get modified to RND/MRND[12-14].

Aim and Objective:

The aim of our study was:

1. To study appropriate plan of management for clinically N0 neck examination in patient of oral cancer
2. To determine efficacy of frozen section examination in detection of occult nodal metastasis in neck in patients of oral cancer

Materials and Method

It was a Prospective study of 2 years conducted in 102 patients of oral malignancy with clinically N0 neck in Pathology department, Jawaharlal Nehru Medical College, Sawangi, (M) Wardha.

Inclusion Criteria:

- Biopsies of patients in OPD of oral and maxillofacial surgeries with ulcer or growth over tongue, lip or buccal or gingivobuccal sulcus were collected with no palpable nodes in neck.

Exclusion Criteria:

- Patients with carcinoma of thyroid and oropharynx
- Patients with diagnosis other than SCC
- Patient with recurrent malignancies
- Patients with lymph node status other than N0

Materials required for frozen section:

- Cryostat (Leica)
- Materials for rapid H and E staining
- Lymph-node specimen
- Tissue freezing medium
- Compound light microscope
- Glass slides and slide marker
- Scalpel and blade
- Normal saline
- Filter paper, forceps and gloves

Method:

Procedure[15]: During the neck dissection lymph nodes at various levels of neck were sent to frozen section for assessment of metastasis. All the resected lymph-node submitted for intra-operative frozen section were grosslyexamined and the respective areas were sectioned and embedded in optimal cutting temperature compound and were freezedat -20 °C to -30 °C in cryostat. The sections were cut approximately 4- 5 µm thick and picked on glass slides whichwere stained with rapid Hematoxylin and Eosin .

Observation: The total of 102 cases in IPD of oral and maxillofacial surgery meeting the inclusion criteria were included and studied for defined objectives. The observation of the study is described in the following tables.

Table 1: Sitewise distribution

Site	No. of Cases and Percentage
Tongue	41(40.19)
Gingivo-buccal sulcus	28 (27.45)
Buccal mucosa	22 (21.57)
Alveolus	07(6.87)
Lip	04 (3.92)

The present study has observed maximum number of cases belonging to carcinoma tongue followed by GB sulcus, by buccal mucosa, alveolus and lip.

Table 2 :Stage wise distribution (n=102)[16]

Stage	No. of Cases and Percentage
T1N0M0 (Stage I)	44 (43.84)
T2N0M0 (Stage II)	54 (52.24)
T3N0M0 (Stage III)	04 (3.92)

TNM staging (AJCC) was adopted for staging of oral squamous cell carcinoma. Stage of oral squamous cell carcinoma defines aggressiveness and prognosis of the tumour .In the study 54 cases belong to stage II followed by 44 cases belonging to stage I category. Only 4 cases of high grade tumour were observed.

Histopathological grading of oral squamous cell carcinoma was done by broader's grading system.[17]

Table 3: Distribution of cases diagnosed on biopsy prior surgery (n=102)

Diagnosis on Biopsy	No. of Cases and Percentage
Well differentiated SCC(WDSCC)	52 (50.99)
Moderately differentiated SCC (MDSCC)	42 (41.16)
Poorly differentiated SCC (PDSCC)	08 (7.85)

In the present study, maximum cases were observed of Well differentiated grade i.e. 52 cases followed by Moderately differentiated grade i.e. 42 cases and only 8 cases belong to poorly differentiated category.

Table 4. Distribution of Lymph node status on frozen section [18]

Initial Surgery Planned	Diagnosis of Lymphnode on FS	No. of Cases and Percentage	Final Surgery Performed
SOND	Negative for metastasis	60(58.82)	SOND
	Positive for metastasis	42(41.18)	MRND

The initial plan of management of all cases was SOND . The level of lymph nodes resected in SOND were level I, IIand III. These lymph nodes were sent for frozen section study. Incase the frozen section detected nodal metastasis, the neck was further dissected upto the level V, which meant that neck dissection was converted from Supra Omohyoid Neck DIssection (SOND) to Modified Radical Neck Dissection (MRND).

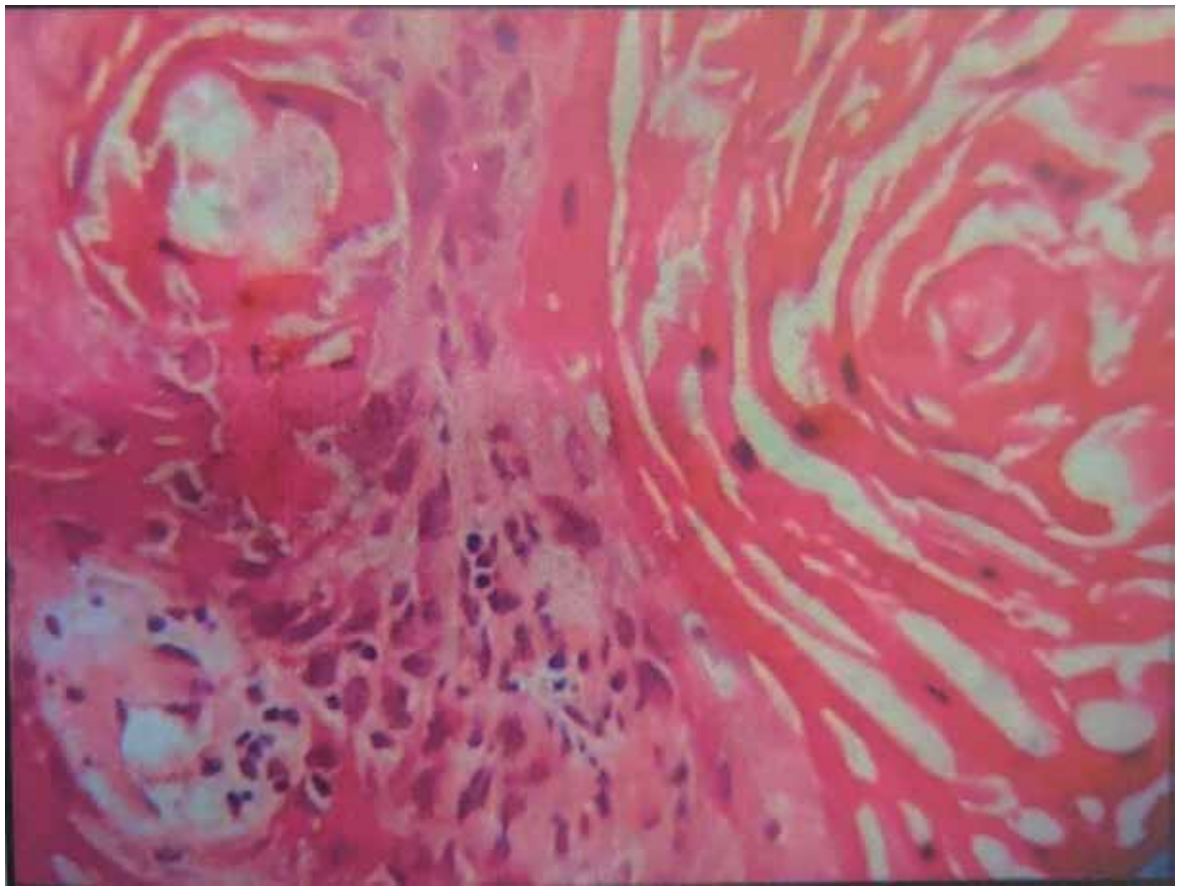

Fig. 2: 40x view of metastasis of WDSCC in lymphnode on FS

Discussion[19-22]

The word "Cancer" derived from a greek word "KARKINOS". According to WHO, cancer is a generic term for large group of diseases characterized by growth of abnormal cells beyond their usual boundaries which can invade other parts or spread to other organs. World is moving towards various non-communicable diseases (modern epidemics) of which cancer is most common cause of mortality in developed countries. Environment and lifestyle play an important role in causing cancers. These days addiction among young population is rising resulting to advance stage disease at an early age. This study intends to access the usefulness of frozen section for the decision of neck dissection management in oral cancer patient with nodal status as N0of neck.

Manni et al.[19] conducted a study in 57 patients with oral squamous cell carcinoma out of which 10 cases were detected as metastasis disease. The initial plan was SOND. After the study they concluded that frozen section biopsy of lymph node suspected to be metastatic during SOND proves a valid staging procedure.

Hoogen et al.[20] also performed a retrospective analysis in 57 patients with an average age of 59 years, performed SOND as an initial treatment in all cases. Amongst them 10 cases showed positive metastasis in lymph node.

Manni and Hoogen et al have suggested SOND as an appropriate staging procedure to manage cases of oral SCC with N0 neck. In the present study, out of 102 cases frozen section examination detected lymph node metastasis in 42 cases. This finding is in concordance with the study done by ***Rassekh et al.***[21]

Chaturvedi et al.[22] in their study on 877 patients used frozen sections to detect intraoperatively and were able to detect 188 cases for metastasis. In studies done by Manniet, Hoogan et al and Chaturvedi et al, the plan of management changed from SOND to MRND in 10, 10 and 188 cases respectively.

In the present study, also the cases which were found in level I, II and III were dissected upto level V i.e. MRND. Out of 102, 42 cases underwent such conversion of dissection of SOND to MRND in the present study which is similar to above mentioned studies.

Conclusion

In clinically N0 nodes of a oral squamous cell carcinoma patients the initial surgical plan preferred is Supra omohyoid neck dissection, however if neck nodes (level I to level III) are found positive for metastasis on FS during surgery then the SOND could get modified as a RND/MRND .

Thus, Frozen section play a major role in the decision on surgery of oral cancer patients, is a easy,possible and life saving technique.

A Study on Designing, Development and Testing of an Innovative External Jig for the Percutaneous Screw Fixation of the Acetabular Column Fractures

Aditya Kekatpure[1], Sandeep Shrivastava[2], Aashay Kekatpure[3], Sunil Nikose[4], Kiran Saoji[5], Ashish Bhagat[6], Ulhas Dudhekar[7]

[1]Assistant Professor, [2]Prof and CEO, Department of Orthopaedics, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DMIMS), Sawangi (M), Wardha, [3]Associate Professor, Department of Orthopaedics, NKP Salve Institute of Medical Sciences, Nagpur, [4]Professor, [5]Professor and Head, Department of Orthopaedics, [6]CAD Consultant, Research and Development, [7]Associate Professor, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DMIMS), Sawangi (M), Wardha

Abstract

Background: Operative treatment of acetabulum fractures often requires open surgical fixation. Minimally invasive surgery (MIS) with percutaneous screw fixation can be done is some acetabular column fractures which are amenable to closed reduction. This can be done free hand using intraoperative fluoroscopy or with the help of advanced 3D navigation system. Free hand technique exposes the operative staff to considerable intraoperative fluoroscopy,has a steep learning curve and there is a risk of screw malpositioning. Even though 3D navigation is highly accurate, the affordability of the navigation system in a rural set up is not feasible. Use of an external universal modular jig which has been routinely used for the fixation of long bone fracture, can give similar results in the fixation of undisplaced/minimally displaced acetabular column fractures amenable to close reduction. Currently such jigs are not available for the management of acetabular fractures.

Objectives: With this study we aim to design a modular jig for the percutaneous fixation of the acetabular column fracture fixation. Also we will validate in vitro efficacy and safety on cadaveric models. To test the clinical efficacy on minimally displaced acetabular column fractures.

Methodology: It will be an observational study conducted at the Department of Orthopaedics, JNMC, Sawangi and Wardha, India. A 3 D model of the pelvis will be made based on the CT scan data of 40 patients using Mimics 10.01 software (Materialize, Leuven, Belgium) software. After the desired jig is made,its accuracy will be checked on the saw bone and cadaveric model. Once the accuracy of the jig has been established, it will be used on the suitable patient population and the results will be compared with the matched patient population who have been operated using the traditional free hand technique under fluoroscopy control.

Results: The results will be compared based on the operating time,radiation exposure,hospital stay and postoperative outcome. During follow up,patients in both the groups will be evaluated clinically with Harris hip score (HHS) and radiologically with Matta outcome grading. To evaluate functional outcome patients the patients will be categorized into excellent (HHS, 90-100), good (HHS, 80-90), fair (HHS, 70-80) and poor (HHS, <70).

Conclusion: This study will help in designing and development of an universal external modular jig for the MIS and percutaneous fixation of acetabular column fracture.

Keywords: *Acetabulum column Fracture, Minimally invasive surgery (MIS) Universal external modular Jig, Percutaneous screw Fixation.*

Introduction

Minimally invasive surgery (MIS) for fixation of acetabular fractures is possible with the advances in intraoperative fluoroscopic imaging.[1] Percutaneously inserted screws in medullary pubic ramus, iliac wing and iliosacral bone can stabilize pelvic or acetabular disruptions directly mean while can diminish operative blood loss, shorten operative time and allow patient's early activity.[1–3] Complications associated with open surgical procedures are similarly avoided by using percutaneous techniques. Several biomechanical studies have shown that screw fixation gives good stability as obtained with plate fixation for certain varieties of acetabular fractures with the added advantage of being minimally invasive thereby reducing blood loss,operative time and patient morbidity.

Stable and safe percutaneous fixation techniques depend on accurate closed reduction, excellent intraoperative fluoroscopic imaging and detailed preoperative planning.[4–6] A thorough knowledge of pelvic osseous anatomy, injury patterns, deformities and the related intraoperative imagery techniques are essential for the surgeon to fulfil the operation of percutaneous acetabular fixation.[7,8]

Although percutaneous screw fixation has several advantages over open surgical procedure in minimally displaced acetabular fractures, there is always a risk of injury to the surrounding neurovascular pelvic structures.[9,10] The learning curve for free hand percutaneous fixation is steep, requires expertise and the intraoperative fluoroscopic exposure to the surgeon is more as compared to open procedure. Image guided Orthopaedic surgery has the potential to be a widely used, minimally invasive and intelligent option.[9] But cost is a major issue for their use on a larger scale in Indian scenarios.

Background: Management of the acetabular fractures is a challenging situation for the orthopaedic surgeon worldwide. Percutaneous fixation is a preferred modality of treatment for certain varieties of minimally displaced acetabular fractures which are amenable to closed reduction. Traditionally percutaneous fixation is done using free hand technique,which requires considerable expertise,is time consuming and requires significant radiation exposure.Navigation guided percutaneous fixation is emerging as a promising treatment option but cost is a major issue for its use in Indian setup.Use of a modular universal jig can significantly overcome the current difficulties,will be cost effective and can improve the postoperative outcome in this patient population. Currently there is no commercial jig available for the percutaneous fixation of acetabular column fractures.

Background/Rationale: Surgical jigs are being traditionally used in the management of long bone diaphyseal fracture of femur, tibia and humerus. They reduce the operative time, intraoperative fluoroscopic exposure and also the surgeon-based errors thereby improving the surgical safety and assuring more predictable outcomes. Use of a modular external jig in the percutaneous fixation of the acetabular column fracture can give similar results. Such jigs are currently not available for the surgical fixation of acetabular column fracture.

Objectives:

1. To design an external jig with modularity for the percutaneous fixation of anterior and posterior acetabular fracture fixation, facilitating accurate insertion of antegrade and retrograde lag screws in the fixation of minimally displaced acetabular column fractures on pelvic specimens.
2. To develop the designed jig into a model through 3D printing (CAD).
3. To validate in vitro efficacy and safety on cadaveric models.
4. To test the clinical efficacy on minimally displaced acetabular fractures.

Method

Study Design: Observational Case Control Study

Setting: The study will be conducted at the Department of Orthopaedics, JNMC, Sawangi, between June 2020 to June 2022. The complete helical CT data will be collected from 40 adult patients (20 males and 20 females) aged between 18 to 75 years without any bone lesions or anatomic abnormalities,who have been advised CT abdomen pelvis for other any medical reason apart from Orthopaedic trauma at JNMC Hospital. The data collected will be used for the reconstruction of 3 D Pelvic model. The entry site for screw insertion will be determined using Mimics software.

Participants: Informed consent will be obtained from all participants. After the jig has been devised and it's validity and accuracy has been checked on cadaveric models,it will be checked on the appropriate patient population.

Eligibility Criteria: All the patients with fresh (less than 05 days old) minimally displaced acetabular column fracture amenable to closed reduction will be included in the study.

Exclusion Criteria:

1. Both column fracture with intra articular component requiring open reduction
2. Old fractures(more than 02 weeks old) not amenable to closed reduction

Variables: We will be checking the accuracy of the jig on the Pelvic Saw bone models and cadavers. Accuracy will be checked based upon the deviation between planned and executed screw at respective screw entry and tip.

Once accuracy has been identified then it will be checked on suitable patient population and the results will be compared with matched patient population in terms of radiation exposure to Operation theatre personnel, operative time and hospital Stay.

Data Sources/Measurement: During follow up,patients in both the groups (MIS using Jig vs MIS using free hand technique and conventional fluoroscopy) will be evaluated clinically with Harris hip score (HHS) and radiologically with Matta outcome grading. To evaluate functional outcome the patients will be categorized into excellent (HHS, 90-100), good (HHS, 80-90), fair (HHS, 70-80) and poor (HHS, <70).

Bias: None

Study Size: Because of the novelty of the current research and as there are no prior previous published similar studies, the sample size cannot be calculated methodically. So purposive or convenient sampling method will be used and the efficacy of the jig will be first checked on 05 cadavers (10 Hips) first. If found to be suitable and accurate then the jig will be used on all the suitable cases as per the inclusion criteria of the current study.

Quantitative Variables: The Student's t-test will be used in evaluating the statistical significance of differences in means. The unpaired t-test will be used in the comparison of mean surgery time between the two groups.

Statistical Method: Data will be imported to Microsoft excel sheet. The level of significance of the Universal modular jig as compared to conventional fluoroscopy for percutaneous fixation, will be measured using Chi square test.

Discussion

Acetabular fracture accounts for 10–22% of all fractures. They are traditionally managed surgically using open reduction internal fixation (ORIF) using plate osteosynthesis.[13,15]

ORIF is a preferred but requires extensive surgical exposure,have higher incidence of soft tissue complications, prolongs hospital stay and increases risk of heterotopic ossification and avascular necrosis of femoral head due to exposure per se. Minimally invasive surgery (MIS) and percutaneous screw fixation is an equally effective alternative in the management of certain variety of acetabular fractures which are amenable to close reduction.[13,16,17]

In the pelvi acetabular surgery,there is a very narrow pelvic corridor with the neurovascular structure in close proximity of the fracture surface and also the overlapping bowel shadow makes the intraoperative fluoroscopic visualization difficult.[14] MIS and percutaneous screw fixation can be done with the traditional free hand method using intraoperative 2D fluoroscopy or with the help of 3D navigation system in the management of certain varieties of minimally displaced pelvi acetabular fractures. Free hand technique is technically

demanding, has a steep learning curve, has a high risk of screw malplacement and exposes the operative staff to prolonged radiation.[17] 3D navigation based MIS is an excellent upcoming option with encouraging results, high safety margin but is very expensive and not a cost effective option in a rural setup.[17]

External jig aided intramedullary interlocking nailing has been used in the management of long bone fractures in Orthopaedic trauma routinely. The advantage of the use of an external jig is that it makes the surgery reproducible, is relatively cheap and decreases the operative time and complications.

We have hypothesized that the use of an universal modular jig would give similar benefits in the management of indicated acetabular column fractures which are amenable to closed reduction and percutaneous screw fixation. Also the use of this new jig would help in decreasing the operative time, surgical exposure, blood loss and would improve the patient outcome and reduce the hospital stay. Such jigs are not available for the fixation of acetabular columns fractures. So through this study we aim to design and develop an innovative external jig for the percutaneous screw fixation of the acetabular column fractures and then check its accuracy first on saw bone and cadaveric specimen. Once its accuracy and safety is established we will use the jig on selected patient population which are suitable for percutaneous acetabular fracture fixation and will compare the outcomes on the matched patient population treated with the current free hand technique using intraoperative fluoroscopy in terms of operative time, functional outcome and radiation exposure.

Key Results: This study will help in the designing, development and testing of an innovative external jig for the percutaneous screw fixation of the acetabular column fractures.

Limitations: It will be a single centre study so reproducibility of the current device would not be possible to check during the current study. A multicentric study comparing the efficacy of the jig will be required subsequently.

Interpretation: This will be the first study to design, develop and test the efficacy of a universal modular jig for the fixation of the acetabulum column fracture. We hypothesize that the development of this jig will help in successful management of the acetabular column fractures in terms of decreased operative time, reduced radiation exposure and improved patient functional outcome.

General is Ability: Once developed and validated a multicentric study will be done to determine the reproducibility and accuracy of the jig.

Ethical Clearance: Taken from institutional ethics committee.

Exploring the Etiological Evidences at Avascular Necrosis of Femoral Head by Investigative Approaches of Histopathology, Clinical Assessment and Radiology

Kiran Saoji[1], Sandeep Shrivastava[2], Arvind Bhake[3], Aditya Kekatpure[4], Sunil Nikose[5], Aashay Kekatpure[6]

[1]Professor and Head, [2]Director and Professor, Department of Orthopedics, [3]Professor Department of Pathology, [4]Assistant Professor,Department of Orthopedics, [5]Professor, Department of Orthopedics, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi Wardha, [6]Associate Professor Department of Orthopedics NKP Salve Institute of Medical Science, Nagpur

Abstract

Background- The avascular necrosis of the femoral head includes interference of the blood flow to the femoral head. This ischemia leads to death of the bone cells and bone marrow followed by the collapse of the bone femoral head, which finally leads to the destruction of the bone tissue and arthritis,

Objectives:

1. Histopathological analysis of the tissue obtained after core biopsy or sections of head after head excision while doing Arthroplasty.

2. Correlation between histopathological evidence with clinical and radiological findings.

Methodology: The tissue will be sampled from site of AVN during surgical procedure that is Core decompression or hip arthroplasty. Tissue material obtained will be transfered to regular histological fixative of 10 % formalin. It will be fixed for a day, later to be reprocessed for decalcification. Formalin fixed tissue will be subjected for treatment of running water to remove excess of formalin. Later the tissue will be examined for its gross appearance of any changes of autolysis The process of decalcification adopted for present work is chemical one. The decalcification tissue will be subjected for histokinette cycle. The tissue is now ready for paraffin block. These paraffin blocks will be subjected to microtomy for obtaining 5 micro milimeter sections. These paraffin sections will be stained for H/E and Van. Giesson stain. Histopathological assessment of the tissue will be carried out for the evidence and grading of avascular necrosis.

Expected Results: Correlation between histopathological evidence with clinical and radiological findings.

Conclusion: This study will be helpful in developing Histopathological staging in correlation with clinical, radiological findings.

Introduction

The avascular necrosis of the femoral head includes loss of blood supply to the femoral head. This leads to death of the bone cells and bone marrow followed by the collapse of the femoral head. Which finally leads to the destruction of the bone tissue, arthritis and loss of function[1]. Avascular necrosis of the femoral head is a disease, which affects young adults, in their 3rd, 4th and

5th decade. This disease affects men more frequently as compared to women. ONFH in North Indian patients[2] is a disease of young individuals, male more than females. This disease affects specially young adults, who are socially and professionally active[3]. These patients are initially without symptoms but eventually need hip arthroplasty surgery until their 5th decade [4].

Nowadays, there are more than 16 different classification systems used to classify and describe avascular necrosis of the femoral head[5]. Classification system introduced by Ficat and Arlet is the most commonly used. The Ficat and Arlet classification system consists of five stages (0 to IV): The first three describe the events that occur before the collapse of the femoral head and the last two stages describe the post-collapse changes.

Stage – 0: Only suggestive on symptoms

Stage – 1: Radiograph is normal except minimal osteoporosis, blurring of bony trabecule

Stage – 2: Femoral head contour is maintained but there is sign of bone remodelling such as cystic subchondral lucency beneath articular surface (crescent sign)

Stage – 3: There is subchondral sequential collapse or flattening of femoral head (crescent sign and eventual cortical collapse).

Stage – 4: Joint space is narrowed and secondary degenerative changes seen in acetabulam along with marginal osteophytes formation.

Other classification is international ARCO staging system[6].

Even after collapse occurs, subsequent cessation of collapse can be expected in certain percentage of hips [7].Collapse of femoral head does not necessarily indicate a poor prognosis In such patients use of bisphosphonates[8][9][10] in the treatment of AVN is encouraging. This is relatively new option.[11][12].

Similarly use of Enoxaparincan prevent progression of stage I and II osteonecrosis of the hip [11].

Avascular necrosis of the femoral head is either primary (idiopathic) or secondary may be due to post trauma, alcohol consumption, smoking, steroid induced and following sickle cells disease.

Background/rationale

There is a paucity of histopathological evidence with specific etiopathogenesis in AVN of femoral head. The proposed study is first of its kinds to explore potential of histopathological analysis and attempting to establish it's clinical and radiological correlation.

Objectives:

1. To analyse clinical, radiological and histopathological correlation in avascular necrosis of femoral head"
2. Histopathological analysis of the tissue obtained after core biopsy from different sectors of femoral head while doing core decompression or sections of head after head excision while doing Arthroplasty.
3. Radiological analysis of X-ray and MRI findings
4. Correlation between histopathological evidence with clinical and radiological findings.
5. Secondary objective of the correlation between haematological investigations and histopathological evidence.

Materials and Method

Study plan:

Study design: This will be a Prospective Observational Studyat DMIMS (DU) Jawaharlal Nehru Medical College,Department of Orthopedics, Sawangi Meghe Wardha, during the period from July 2020 to JULY 2022.We will include all patients suffering from non traumatic Avascular necrosis of femoral head. Age group will be from 20 to 60 yrs.

Data Collection: The tissue will be sampled from site of AVN during surgical procedure that is Core decompression or hip arthroplasty. Tissue material obtained will be transferred to regular histological fixative of 10 % formalin. It will be fixed for a day, later to be reprocessed for decalcification. Formalin fixed tissue will be subjected for treatment of running water to remove excess of formalin. Later the tissue will be examined for its gross appearance of any changes of autolysis The process of decalcification adopted for present work is chemical one. The decalcification tissue will be subjected for histokinette cycle. The tissue is now ready for paraffin block. These paraffin blocks will be subjected to microtomy for obtaining 5 micro millimetres sections. These paraffin sections will be stained for H/E

and Van. Giesson stain. Histopathological assessment of the tissue will be carried out for the evidence and grading of avascular necrosis.

Participants: Patients suffering from non traumatic Avascular necrosis of femoral head. Age group will be from 20 to 60 yrs,of both sex

Inclusion Criteria:

1. Patients suffering from non traumatic Avascular necrosis of femoral head attending orthopaedic OPD.
2. Those who are ready to undergo this study with written consent

Exclusion Criteria:

1. **Patients with metabolic disorders:** Variables: Participants who are included in the study having avascular necrosis of femoral head will have a differentetiology like Sickle cell disease,Alcohol induced,Steroid Induced and Idiopathic.

Data sources/measurement: The Histopathological data obtained from this study will be critically analysed according to etiological factors and compared accordingly for each variable of interest.

Data will be collected from the pathologist and tabulated according to findings across various etiological factors. Source of data and details of method of assessment (measurement) will be described Comparability of assessment method will be judged in different groups.

Bias: Measures will be taken to control the selection bias.

Statistics: Raw data processing will be done by using convenient sampling. we will include 10 patients in each group during the study period.

Discussion

Avascular Necrosis of the femoral headis a disease characterized by loss of blood supply to the affected part of the head of the femur which ultimately leads to it's death. Hence it is also called as coronary disease of the hip. Head of femur receives blood supply from 3 main sources-reticular branches from the lateral circumflex femoral artery (supplying majority of the head) which anatomises which branches from medial circumflex femoral artery (supplying area around greater a trochanter) and third source is obturator artery which gives rise to artery of ligamentumteres (supplying small portion of the head.[1] The condition usually involves patients in their early adult hood and middle ages i.e. 30 to 40 years.[2]Every year 10to 20 thousand cases of avascular necrosis of femoral head[3] are diagnosed in the united states, out of which approximately 10%undergo replacement surgeries.[4] The condition is usually unilateral but it gradually progresses to become bilateral. Studies have shown that the etiopathogenesis of avascular necrosis of femoral head is varied and very confusing. Usually the term avascular necrosis refers to the non traumatic, non infective or idiopathic . Broadly the term can be divided into two main groups that is one group with directly identifiable causative factors and other group without any directly identifiable causative [3]factors. Excessive steroid usage for longer duration and chronic alcoholism accounts for approximately more than 80% cases of avascular necrosis of femoral head .exact pathogenesis of this varied aetiologies is not yet established. Various studies are being under taken to establish the exact stapes in the pathogenesis.

Generally following Factors are thought to be associated with the pathogenesis of avascular necrosis of femoral head. End effect all the aetiologies lead to hindrance of blood supply to the femoral head, which in term may be due to occlusion of vessels supplying to the femoral head, stenosis of the blood vessels supplying the femoral head, atherosclerosis involving the arteries supplying femoral head, hyercoagulation, increases intra-osseouspressure, mechanical forces disturbing vascular supply to femoral head (hip dislocations and displaced fracture neck of femur) or various metabolic diseases which hampers blood supply to femoral head.

Due to variability of etiopathogenesis, the clinical, histopathological and radiological pictures also vary. Various staging system[5] have been developed to categorize various patients in groups and then to develops suitable management protocols for the groups. But there has not been single ideal staging system for avascular necrosis of femoral head till date. The diagnosis of avascular necrosis of femoral head is routinely done with the help of detailed history, clinical examination, assessment of the gait, bony palpation of hip and surrounding structures, presence or absence of deformities, limb length discrepancy. Clinical findings start to appear in the patients in late stages of avascular necrosis that is after the collapse[6] of femoral head. After the collapse of the femoral head, the modalities meant

for salvage of femoral head do not work and patient will required total hip arthroplasty.

Radiological staging is based on various radiological modalities like plain radiographs (plain anterioposterior radiograph of pelvis with both hip joints and frog leg or lateral view), CT scan and MRI scans. There are more than 16 various classification[5] and staging system base on radiological modalities out of which two most commonly used are Ficate and Arlet classification and University of Pennsylvania classification. Most of these imaging modalities based staging systems take into account exact site of the lesion, exact size and the extent of the lesion and presence of subchondral fracture or collapse. The exact site of the lesion is best visualised using plain radiograph (cost effective, simple and easily available but not useful in early stages) exact size and extent of the lesion is best visualized with help of MRI scan (high sensitivity and specificity, modality of choice for screening) and subchondral fractures are best studied with the help of CT scan (most sensitive for subchondral fractures). There are various staging systems which consider all these radiological modalities.

There is no staging system which takes into account all the three aspect that is clinical, histopathological and radiological pictures of the patients. Although various studies have shown that histological staging done by taking biopsy from the affected lesion helps in differentiating early stage disease from late and it thus helpful in delaying the replacement surgeries. Histological changes start to developed after few weeks of the starting of the disease. Usually biopsy is done once the disease has been diagnosed. By that time irreversible changes might have occurred in the femoral head. So early biopsy should be promoted. In our study we have tried to correlate histological staging of the patient with clinical and radiological findings. This will help in developing a new staging system which incorporates all the three modalitiesthat is histopathology, clinical and radiology. Thus it will help in developing ideal staging system for the patients suffering from avascular necrosis of the femoral head. It will in terms help in better understanding of the disease, proper categorisation of the patients in various groups and then in determining the ideal treatment modality for those groups.

Various treatment modalities available for treatment of avascular necrosis of femoral head ranges from non surgical modalities like observation and non weight bearing mobilization, various pharmacological agents like bisphosphonates[7][8][9][10] Enoxaparin are shown to be useful in some studies, hyper baric oxygen therapy (all these non surgical modalities are useful in early stages of avascular necrosis of femoral head). Surgical modalities like core decompression with or without additional procedures that is bone grafting, biologicadjutants– Platelet Rich Plasma, stem cells etc. In advance stage of AVN rotational osteotomies or replacement surgeries are indicated. For such a complex disease with varied aetiopathological factors and varied treatment modalities a proper staging system is must. Our study will help in proper staging and thus selecting the appropriate treatment modality for a particular patient especially in cases of early stage of the disease. This will also help in prediction of Prognosis.

Conclusion

This study will be helpful in developing Histopathological staging in correlation with clinical, radiological findings.

Ethical Clearance: Taken from institutional ethics committee.

Role of Anion Gap as a Prognostic Indicator in Acute Coronary Syndrome (ACS)

Nandita Sharma[1], Anuj Varma[2], Sourya Acharya[3], Samarth Shukla[4]

[1]MBBS Student, [2]Associate Professor, Dept. of Medicine, [3]Professor, Dept. of Medicine, [4]Professor, Dept. of Pathology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (Deemed to be University), Sawangi (Meghe), Wardha-442001, Maharashtra, India

Abstract

Background: Cardiovascular diseases are the leading cause of mortality in India and acute coronary syndrome (ACS) is one of its anomalies, affecting mainly the coronary arterial blood supply and further the functioning of heart muscle. Its subtypes are Non-ST elevation myocardial infarction (NSTEMI), unstable angina, and ST-elevation myocardial infarction (STEMI). There are various diagnostic tools available to detect ACS like; electrocardiography (ECG), Cardiac stress test, Coronary CT angiography, Coronary angiogram and cardiac biomarkers. Yet, tools for assessment of prognosis are scanty and new prognostic tools are always welcomed, one such is anion gap, which can be detected by assessment of certain ions present in the serum, urine or plasma, etc. In this study we will assess the role of anion gap, in the assessment of prognosis in ACS.

Objective:

1. To estimate anion gap (AG) in cases of acute coronary syndrome (ACS) at the time of diagnosis;
2. To evaluate association of anion gap (AG) with the prognosis of acute coronary syndrome (ACS)

Methodology: The study will be conducted in the Department of Medicine of a Rural Tertiary Care Hospital. Estimation of anion gap (AG) in cases of acute coronary syndrome (ACS) will be evaluated at the time of admission and after five days of treatment. Anion gap will be calculated or measured as difference between measured cations (Na+ + K+) and the measured anions (Cl- + HCO3-) in serum. Any complications during the management will be noted (Heart failure arrhythmias, Hypotension, Reinfarction, Death) will be correlated with anion gap (AG). Chi square test will be applied to evaluate statistical difference between among anion group quartile groups.

Results: The study will play a key role in identifying and assessing various other prognostic tools like anion gap, in assessing the severity of disease to some extent in patients with acute coronary syndrome.

Conclusion: High value of serum anion gap levels is associated with poorer prognosis of the disease outcome in patients with acute coronary syndrome.

Introduction

India is the second most populated country of the world with a high mortality rate caused due to various medical conditions and diseases, especially cardiovascular diseases (CVDs) becoming the leading cause of mortality in India.[1] In 2017, CVD caused an estimated 17.8 million deaths worldwide.[2] Coronary

artery disease(CAD) is the most common type of heart disease caused due to reduction in oxygen and blood supply to the heart muscle due to build up of plaque in the arteries of the heart i.e. the coronary arteries. Epidemiologic studies have shown that there are at present over 30 million cases of CAD in the country.[3] Furthermore, acute coronary syndrome(ACS) is a subtype of CAD. Itis a group of diseases in which blood supply to any of the coronary arteries is decreased partially/completely which causes the heart muscle either to function improperly or its death. The following are the subtypes of ACS are:- Non-ST elevation myocardial infarction (NSTEMI), unstable angina, and ST-elevation myocardial infarction (STEMI) .There are various tools for diagnosing these conditions like- ECG, Cardiac stress test, Coronary CT angiography, Coronary angiogram, Blood Tests, etc.

Presently used prognostic tools for acute coronary syndrome are various biochemical markers like estimation of cardiac troponin, natriuretic peptides, growth-differentiation factor-15, etc. These are some of the mose efficient prognostic biochemical markers.

New prognostic tools in CAD patients are always welcomed. The serum anion gap (AG) is a mathematically derived parameter that has been used for more than 50 years.[4] Till now AG has been used as a prognostic indicator in studies related to advanced kidney disease,[4] hypertension,[5] insulin resistance[6] & cardiac deaths.[7] It is yet unknown whether AG can alter the course of prognosis of ACS. Therefore dearth of medical evidence relating to association of AG & ACS. So, this study will evaluate AG & its prognostic implication in case of ACS.

Aim: To assess the anion gap as a prognostic indicator or tool in patients with acute coronary disease.

Objective:

1. To estimate anion gap (AG) in cases of acute coronary syndrome (ACS) at the time of diagnosis
2. To evaluate association of anion gap (AG) with the prognosis of acute coronary syndrome (ACS)

Methodology

Study Design: Cross sectional study

Study Population: Will be carried out in 50 consecutive patients

Study period: Two-Months

Study setting: This cross-sectional study will be conducted in the Department of Medicine of a Rural Tertiary Care Hospital. Consecutive patients or subjects with diagnosis of acute coronary syndrome (Ischemic chest pain, ECG changes, and Cardiac biomarkers) admitted in the intensive care unit (ICU) of a tertiary care hospital. The study will begin after clearance from institutional ethical committee. Detailed history of Rural or Urban backgrounds, Physical activity levels, Addiction (smoking, alcohol intake), Family history of Blood Pressure and Diabetes will be recorded and Clinical Examination will be done.

Estimation of anion gap (AG) in cases of acute coronary syndrome (ACS) at the site of diagnosis:- Anion gap will be evaluated at the time of admission and after five days of treatment. Assessment of severity of coronary artery disease (CAD) will be done on the basis of severity of coronary artery stenosis (in coronary angiography), Killip's classification and cardiac function grades based on left ventricular ejection fraction (LVEF). Grades of cardiac function compromised normal (defined ≥50%), preserved (40%-49%), and reduced (<40%) LVEF.[8] Significant coronary artery stenosis was defined as ≥ 75% narrowing of the diameter of at least one major epicardial vessel.[9]

Evaluation of association of anion gap (AG) with the prognosis of acute coronary syndrome: Any complications during the management will be noted (Heart failure arrhythmias, Hypotension, Reinfarction, Death) will be correlated with anion gap (AG).

Calculation of Anion gap (AG)**:** Anion gap is calculated or measured as difference b/w measured cations (Na+ + K+) and the measured anions (Cl- + HCO3-) in serum.

Formula: The formula used will be

ANION GAP= (Na+ + K+) – (Cl- + HCO3-)

The concentrations will be expressed in the following units i.e. of milliequivalents/litre (mEq/L) or in millimoles/litre (mmol/L).

Selection Criteria:

Inclusion Criteria: Adults ≥ 18 years admitted to intensive care unit (ICU) with diagnosis of acute coronary syndrome

Exclusion Criteria:

1. Heart failure due to other causes
2. Acute coronary syndrome with cardiogenic shock
3. Any infection at the time of presentation
4. Subjects not giving consent
5. Other causes of high anion gap levels like advanced kidney disease, metabolic acidosis, etc

Implications: It is a rural tertiary hospital-based study carried out through assessment of anion gap levels in patients of acute coronary syndrome. High anion gap levels will be observed in patients with worsening cardiac functions. We can interpret prognosis of individual patients based on their anion gap levels along with its severity to some extent; allowing to give better treatment & management based on individual prognostic values; allowing better life value.

Methodology in PICOT format:

P (Population): 50 consecutive patients attending Medicine OPD and ICU of Rural Tertiary Care Hospital in the backdrop of Central India.

I (Intervention): Assessment and understanding of anion gap as a useful prognostic indicator in a group of cardiovascular diseases i.e. acute coronary syndrome.

C (Comparison): Not applicable.

O (Outcome): Knowledge of a prognostic indicator i.e. anion gap to assess and predict severity level of the disease in individual patients

T (Time): Study will be conducted over a duration of 2 months

Measurements: Anion gap is calculated or measured as difference b/w measured cations (Na+ + K+) and the measured anions (Cl- + HCO3-) in serum.

The formula used will be: ANION GAP = (Na+ + K+) – (Cl- + HCO3-)

Quantitative Variables: Serum albumin land phosphate levels and unmeasured ions

Statistical Method: Chi square test will be applied to evaluate statistical difference between among anion group quartile groups. Ordinal logistic regressions will be used to evaluate between anion gap and severity of acute coronary syndrome. P values of <0.05 will be considered statistical insignificant. Software used in analysis will be SPSS 25.0 version.

Results

The study will play a key role in studying the association of serum anion gap in prognosis of acute coronary diseases along with determining its severity to some extent.. It will be observed that in patients who are severely affected, high values of serum anion gap will be obtained. This is similar to high values of anion gap observed in patients with metabolic acidosis and kidney failure. This will enable us to understand a unique yet somewhat efficient prognostic tool for study i.e. anion gap.

Discussion

Cardiovascular diseases are one of the leading causes of death in our country. Acute coronary syndrome is one of the heart anomalies. Though there are many diagnostic tools for detection of the disease but prognostic tools are being developed every day. One such tool is anion gap which can be assessed to determine and give prognosis based on individual patients, thus providing somewhat efficacy in treatment and management options.

In a study done by Yang, Shi-Wei, et al. in the year 2017, it concluded that higher levels on anion gaps were associated with worsening cardiac functions and cardiovascular diseases [10], similar to the results expected results in this study.

A study by Taylor, Eric N., John P. Forman, and Wildon R. Farwell in 2007 and another study by Abramowitz, Matthew K., Thomas H. Hostetter, and Michal L. Melamed in 2012 on determinants like hypertension[11] and cardiorespiratory fitness[12] respectively;these determinants were associated with cardiovascular diseases which lead to increase values of anion gap levels.

Another study by Ahn, Shin Young, et al. in 2014 showed that higher levels of serum anion gap were associated with an increased risk of cardiac deaths or mortality.[7] This indicates a poorer prognosis if the serum anion gap levels are found to be high.

Similarly, higher value of serum anion gaps are obtained in diseases like metabolic acidosis and kidney disease. A study done by Cheng, Bihuan, et al. in 2020 showed that high levels of anion gap were associated with poor prognosis in patients with acute kidney

injury[13]. Few studies on related aspects of this issue are available[14-18].

The results will be concluded and determined from this study, and will help to indicate the role of anion gap as a prognostic indicator in acute coronary syndrome.

Ethical Clearance: Taken from institutional ethics committee.

Comparative Evaluation of Effective Route of Administration of MASAM Oil in *Vishwachi* (Cervical Radiculopathy): A Study Protocol

Shweta Parwe[1], Vaishali Kuchewar[2], Milind Nisargandha[3], Manoj Patil[4]

[1]Professor, Department of Panchakarma, Mahatma Gandhi Ayurved College Hospital & Research Centre, Salod (H.), Datta Meghe Institute of Medical Sciences, Wardha, [2]Dean, Professor, Department of Kayachikitsa, Mahatma Gandhi Ayurved College Hospital & Research Centre, Salod (H.), Datta Meghe Institute of Medical Sciences, Wardha, [3]Associate Professor, Department of Physiology, Ashwini Rural Medical College, Hospital and Research Centre, Kumbhari, Solapur, [4]Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

Background: Ayurveda proposed a lot of *Vatavyadhi* treatments. The cervical problems mimic the disorders in the *vata*. Thus in the present study, the *vata* management of medicated oils by rectal is better management for the identified clinical condition *Vishwachi* (Cervical Radiculopathy). Among such disorders Ayurvedic classics in the name of *Vishwachi* have described a disease. In Harrisons Principles of Internal Medicine and Davidsons Principles of Internal Medicine and Golwalla Medicine for Students, the symptoms of Cervical Spondylosis with Radiculopathy, such as a neck pain that radiates to the upper limbs, restricted movements of the neck have been explained. Due to today's modern lifestyles, food, behaviors, stress and anxiety, more people face these problems and the incidence of the *Viswachi* disease increases dramatically everywhere.

Aim and Objectives: To evaluate and compare the effect of MASAM oil for improving the Nerve Conduction Velocity in patients of *Vishwachi*(Cervical Radiculopathy) and to compare the MASAM oil through different routes of administration (*Pana*, *Abhyanga*, *Basti*) for improving Nerve Conduction Velocity in patients of *Vishwachi* (Cervical Radiculopathy).

Methodology: The proposed study, 120 subjects will be randomly divided into three groups in every group 40 patients will be including. In Group A (*Pana*) –with MASAM OIL dose of 24 ml will be administered orally a day in empty stomach for 21 days and Group B (*Abhyanga*) – local massage on affected side with MASAM OIL dose of 24 ml a day at morning after breakfast for 21 days and Group C (*Basti*) MASAM OIL 24 ml a day will be administered through rectal route after meal for 21 days. The record of assessment will be taken at zero day 21st day and after 21st for followup.

Results: On the basis of objectives outcome changes will be observed. Changes will be observed in objective outcomes.

Conclusion: It may conclude that the parameters included in this study will be reducing pain, tingling sensation and improvement in Nerve conduction parameters.

Keywords: *Vishwachi, Matrabasti, Abhyanga, Pana, Nerve Conduction Study, Cervical radiculopathy.*

Introduction

Cervical Radiculopathy disease occurs if an irritated nerve in the neck enters the spinal canal. Cervical radiculopathy, commonly known as "pinched nerve," is typically a herniated disk or spurt of the bone that

pushes the inflamed nervous root into one. These are usually a consequence of degenerative neck changes. The significant cause of neck pain and disability may be cervical radiculopathy (CR). 83.2/100.000 people report an annual CR incidence[1]while the reported prevalence is 3.5/1000 persons[2]. In today's world, cervical radiculopathy is more common with more cervical problems. We are used to electronic and/or work-related instruments. Therefore it is not possible to avoid it and to find a better healing area. The characteristic of *Vishwachi* may be correlated with cervical radiculopathy. Under *vatavyadhi* (disorders of *vata*), *Vishwachi* is identified because *Vishwachi* can be explained as disease starting from posterior part of hand and prakoshtha, hands, and fingers, manifest due to flexion and extension of the nerves which gives strength for the movements[3]. Ayurveda proposed a lot of *Vatavyadhi* treatments. The *vata* conditions are imitated by cervical problems. Therefore, the *vata* management of orally, rectal and surface (external) medicated oils is better controls in the current study of the clinical condition of *Vishwachi* (Cervical Radiculopathy).

Rationale of the study: *Vata* diseases are commonly expressed in musculoskeletal and neurological disorders. The selected disease condition *Vishwachi* is a neuro-musculoskeletal disorder. The nerve conduction test or demylination and degeneration are not attributed to *vatavyadhi* with any measurable parameters. As there were no studies in relation are found to determine the nerve conduction in terms of *vata* here an attempt is made to evaluate and compare the effect of MASAM oil through *Basti*, *Pana* and *Abhyanga* for the improvement of nerve conduction. The main *Chikitsasutra* (principle) of *Vatvyadhi* is *Pana*, *Abhyanga* and *Basti*[4]. Yet, this tool of Nerve Conduction Velocity study didn't use in Ayurvedic research. There are no such evidences in*Vishwachi* (Cervical Radiculopathy) regarding Nerve Conduction Velocity (NCV)

Hence, we selected NCV studies to find out the better route of administration and effectiveness of MASAM oil in *Vishwachi* (Cervical Radiculopathy).

Aim and Objectives

Aim: To evaluate and compare the effect of MASAM oil for improving the Nerve Conduction Velocity in patients of *Vishwachi* (Cervical Radiculopathy).

Objectives:

1. To evaluate the effect of MASAM oil for improving Nerve Conduction Velocity in patients of *Vishwachi* (Cervical Radiculopathy).
2. To compare the MASAM oil through different routes of administration (*Pana*, *Abhyanga*, *Basti*) for improving Nerve Conduction Velocity in patients of *Vishwachi* (Cervical Radiculopathy).

Case Definition: A diagnosed *Vishawachi* subject with *Bahuprusthatha* symptoms (the back aspect of the upper limb) and with tingling sensation to the left or right, along with positive spurling test and a cervical distraction test along with range of motion.

Research Question: Whether MASAM Oil through different routs of administration (*Pana*, *Abhyanga*, *Basti*) is effective in improving Nerve Conduction Velocity in patients of *Vishwachi* (Cervical Radiculopathy)?

Research Hypothesis: MASAM oil is effective in *Vishwachi* (cervical radiculopathy) because of its composition qualities.

Null Hypothesis: There is no effect on MASAM oil in *Vishwachi* (cervical radiculopathy).

Study Type: Interventional

Trial Design: A Randomized Comparative clinical trial.

Methodology

Place of Study: This study will be plan in M.G. Ayurved College Hospital & RC Wardha.

Registration Number: CTRI/2020/01/023022.

Composition of the trail drug: MASAM (Manjishta, Ashwgandha, Sahachar, Atmagupta, Masha) oil

Table no. 1 Contents of MASAM oil

Sno	Sanskrit name	Botanical name	Parts used	Quantity
1	Manjishta	Rubia cordifolia Linn	Root	1 part
1.	Masha	Vingna Mungo	Seed	1 part
2.	*Atamagupta*,	Mucuna pruriens Hook	Seed, root, pod hair.	1 part
3.	Sahachar	Barleria prionitis	Panchanga,leaf	1 part
4.	Ashwagandha	Withania somnifera	Root	1 part
6	Til	Sesamum indicum.Linn	Seed,oil,leaf,root	4 part

Eligibility Criteria: A 20 yrs to 60 years of both sexes, A diagnosed *Vishawachi* subject with Cervical compression.

Diabetic neuropathy, Post operated cervical radiculopathy and Indicated for Surgery and Severe giddiness and loss of function are excluded.

Table no. 2. Interventions table

Group	A	B	C
Sample size	40	40	40
Intervention	Abhyanga	Pana	Basti
Dose	24 ml	24 ml	24 ml
Duration	21 days	21 days	21 days
Follow up period	21 day	21 days	21 days
Total duration	42 days	42 days	42 days

Criteria for discontinuing or modifying allocated interventions: Subject will be pulled back from the investigation if any untoward rate, highlights of medication affectability or some other malady or issue emerges, Free treatment will be offered to the patients till the issues dissolves.

Follow up: After 21 days

Primary Outcomes: We will observe the efficacy of MASAM oil through *Pana*, *Basti* and *Abhyanga*on pain and tingling sensation before and after management. Data will be expressed as mean and standard deviation at 5% significance level. It may assumed that MASAM oil will be more effective through *Pana*, *Basti* or *Abhyanga* and we will compare the effect between the *Pana*, *Basti* and *Abhyanga* in pain, tingling sensation with no any adverse effects.

Secondary Outcomes- We will see the effect of MASAM oil through *Pana*, *Basti* and *Abhyanga* on Nerve Conduction Parameters like Latency, Amplitude and Velocity.

Discussion

Numerous studies established for *vatavyadhi* like *Panchakarma* procedure and shaman *chikitsa* too. The essential driver of cervical radiculopathy is age-related degeneration. In any case, there are a few special cases where spinal wounds to the plate can enlarge the degenerative procedure in the more youthful patient. An optional appearance of spondylosis is identified with the pressure of the vascular and neural structures brought about by a misfortune in the plate tallness and impinging osteophytes that add to the deadness, stun like sensations, pain, and interminable motor and tangible effects, which if not revised may prompt lasting incapacities[5]. Local application of MASAM oil may help to correct the *vata* vitiation. Moreover according to Ayurveda pain was caused by because of *vata* vitiation. All drugs have property of *vatahara* (anti inflammatory) and all drugs have property of nerve protector or working as a nervine tonic. So selected for this study.

Manjishta-is Anti-inflammatory, antioxidant[6]. ***Aatmagupta***–is Neuro-protective and Neuro-restorative[7]. L-DOPA characterized by a deficiency in the synthesis of the neurotransmitter dopamine in nerve cell[8]. ***Sahachar*** –is commonly used in Neurological disorders and *vatakaphahara*[9]. ***Masha***-is Anti-inflammatory and Nervine tonic[10]. The response involved in inflammatory as complex array of enzyme activation, mediator release, cell migration, fluid extravasations, tissue breakdown and repair. ***Ashwagandha***–is Neuroprotective, Immunomodulatory and Anti – inflammatory.

Statistical analysis: Data will be analysed on the basis of appropriate statistics paired unpaired test and ANOVA by using SPSS software.

Time duration till follow-up: The treatment duration for the patients is 21days and after that follow-up for 21 days.

Followup period: 0 day, 21 day and followup 21 day

Time schedule of enrolment, intervention: *Matrabasti*, *Pana* and *Abhyanga*

Recruitment: 40 (every group) sample recruited by single randomizing sampling.

Method: Literature review search, plane of work, Blue print in the form of flow chart, preparation of medicine, Data collection, treatment and its effect, will be observe which route of administration is best and statistical analysis.

Data collection Method: Randomized sampling

Objective Criteria: Assessment of numerical pain scale, neck disability index, cervical distraction, range of motion, Nerve conduction velocity, all the variables will be assessed before and after intervention of different route of administration.

Data management: The data coding will be done by principle investigator.

Statistical Method: Paired and unpaired for objective criteria, non parametric for subjective criteria, ANNOVA for comparing between three groups.

Ethics and dissemination: Research ethical approval: After critical evaluation and presentation the ethical committee has approve the research topic reference No – DMIMS (DU)/IEC/2018 -2019/7352.

Consent assent: Patient will be given detail information regarding intervention in his own language. Then written consent will be taken from patients before starting the study.

During study the confidentiality will be maintain.

Dissemination policy: The data will be spreading in the form of paper publication and Monograph. Authorship eligibility guidelines and any intended use of professional writers

Informed consent materials: Patient will be given all consent material in the form of hard copy, and related documents will be given to the participants.

Strengths: MASAM oil will be work for the nerving tonic and to find out best route of administration. If projected work results in the positive outcome then it will be established new mode of management for the cervical radiculopathy.

Limitation: Specific geographical area, convincing the patients for Nerve conduction study.

Conclusion

Conclusion will be mentioned after the deliberate and analyzing data.

Ethical Clearance: Taken from institutional ethics committee.

Source of Funding: Self.

Conflict of Interest: Nil.

A Concise Review of Gingival Depigmentation Techniques and Re-Pigmentation

Chitrika Subhadarsanee[1], Prasad V. Dhadse[2]

[1]Postgraduate Student, [2]Professor and HOD, Department of Periodontics and Implantology, Sharad Pawar Dental College and Hospital, Sawangi (Meghe), Datta Meghe Institute of Medical Sciences (DU), Wardha (Maharashtra), India

Abstract

Gingiva pigmentation has an impact on patient's esthetics and formulates pscyhological negativity. Gingival pigmentation is most predominant and endogenous pigmentation among oral mucosa. The gingival pigmentation can be physiologic and pathologic. It can be a genetic trait in some population. The physiologic melanin pigmentation does not possess a medical problem, it is mainly associated with individuals with high smile line and excessive gingival display. Pigmentation of gingiva is due to deposition of melanin in basal and suprabasal layer of epithelium. The gingival depigmentation is a esthetical correction technique where hyperpigmentation is removed. The treatment depends on patient need and skin complexion. Proper treatment method is required for treating the unesthetic gingival pigmentation. Perio-esthectic is focused on proper equilibrium of both pink and white(teeth) tissue. To overcome this problem wide array of method are put forth which include scalpel method, cryosurgery, gingival ablation method, electrocautery, chemical method, lasers and grafts. Each technique has its own advantages and disadvantages.

Keywords: *Gingival pigmentation, depigmentation, repigmentation, various techniques of gingival depigmentation.*

Introduction

"The science of beauty is nothing but aesthetic" as rightly quoted in the literature, which makes any living or non living object attractive to the eyes.(1) Aristotle correctly said as "Beauty is a greater recommendation than any letter of introduction."(2) A harmonious smile is described by various factors which include shape of the teeth along with the proper positioning. Other factors which should be considered are the color of the tooth as well as how well it goes with the gingiva. The major component of an aesthetic smile is definitely gingiva which is in its healthiest form. Other gingival factors which are responsible for a healthy smile are removal of gingiva which shows pigmentation which is required for a smile which boosts confidence and oozes aesthetics.(3) One of the most commonly tissues which are seen with pigmentation is gingiva which is dependent on several factors like epithelial thickness, amount of keratinization, amount of vascularisation and existence of pigments within the gingival tissues like melanin(4) ''Melas,'' is a Greek word which means black from which the word melanin was derived.(5) One of the most common pigment secreated endogenously, Melanin, is present in the basal and suprabasal layers of the epithelium.(6) Melanin is secreted by Melanocytes which were first isolated by Dr Becker et al in the year 1927 in the oral epithelium(7) After a few years, Melanocytes isolation was carried out from samples tissues of gingiva by Dr Laidlaw et al. ***Dummett***in his study stated that presence of pigmentation oral cavity observed in black race is:

Corresponding Author:

e-mail: chitrikasubhadarsanee403@gmail.com

"gingiva 60%; hard palate, 61%; mucous membrane, 22%; and tongue, 15%".[8] Evidence of first melanin pigmentation occur 3 hours after birth. Pigmentation are mainly caused by five primary pigments:- "Melanin, Oxyhemoglobin, Melanoid, Carotene, Reduced haemoglobin".[9,10]

1. **Pigmentation seen in gingiva due to physiologic factors(ethnicity/race):** Colour variation may be seen on one side, or both the sides, it can beuniform, or have a macular distribution, Mottling or blotching can also be seen. It can be seen on gingival papillae. or the whole in general and into other oral structures. Pigmentation due to normal physiology can be clinically manifested as being multifocal or diffused general. More pigmentation occur in attached gingiva.
2. **Various pathologic causes of gingival pigmentation[12]:**

Endocrine disease	Addison's disease Acromegaly Nelson's disease Albright's disease
Drug-induced	Quinine Zidovudine Chloroquine Minocycline Cyclophosphamide
Heavy metals	Lead Bismuth Arsenic
Mucosal conditions	Lichen planus Blue nevus HIV oral melanosis Hemangiomas Oral melanoacanthoma Inflammatory mucosal lesions
Malignant neoplasms	Melanoma Kaposi's sarcoma
Idiopathic melanin pigmentation	Peutz-Jegher's syndrome Leopard syndrome Carney syndrome
Tobacco associated	Smoker's melanosis
Others	Amalgam tattoo Gingival tattoo

Depigmentation of Gingiva: The definition of gingival depigmentation can be given as "a periodontal plastic surgical procedure whereby the gingival hyperpigmentation is removed or reduced by various techniques."When the patient desires better aesthetics the procedure of depigmentation can be carried out and is not a clinical indication.

Bur abrasion method: The first case of depigmentation with bur was documented by Ginwalla *et al. in 1966.*

Technique: A medium grit football shaped diamond bur is used at high speeds to denude the epithelium. It takes around 45 min to 1 hour to complete.[10]

Advantages:

1. Easy to perform
2. Simple, non-aggressive and safe
3. Less discomfort to patient
4. Good esthetic outcome

Disadvantages:

1. Difficult in controlling the depth of de-epithelialisation
2. Technique sensitive
3. Post operative pain
4. Longer treatment time
5. High recurrence rate
6. Periodontal dressing required

Complications:

1. Harm to underlying periosteum and bone
2. Gingival recession
3. Wound healing is delayed
4. Enamel loss can occur

Scalpel surgical technique:

Synonyms: Surgical stripping and split thickness epithelial excision

Technique- Pigmented gingival epithelium is removed along with a layer of underlying connective tissue with the help of a surgical blade and allow it to heal by secondary intention.[10]

Advantages:

1. Economically feasible
2. Does not require any extensive armamentarium

3. Rapid wound healing

Disadvantages:

1. More bleeding during and after surgery
2. Periodontal dressing required
3. Re-pigmentation can occur by migration of active melanocytes from adjacent untreated area {Dummett and Bolden (1963)}

Contraindication:

1. Thin gingival biotype
2. Narrow papillary areas

Electro-surgery:

Technique: After administration of local anesthesia, the needle electrode is used in a sweeping motion in the operated area. Feather-light brushing strokes with high frequency electrical current in the range of 1.5-7.5 Megahert are used for de-epithelization. The procedure is performed in a cervico-apical direction and operated area is cleaned with the help of sterile gauze soaked in 1% normal saline solution.[13]

Advantages:

1. It controls hemorrhage
2. Permits adequate contouring of tissue
3. Lesser operating time
4. Less scar formation after surgery
5. Less discomfort to patient

Disadvantages:

1. More expertise required
2. More post operative pain
3. Causes undesired tissue destruction
4. Periodontal pack required

Complications:

1. Intense inflammation occured
2. Loss of crestal bone height seen

Cryosurgery: Technique- freezing of gingiva is carried out with variousagents which include liquid nitrogen. Cryoprobe which is cooled to a minimum of -81 °C is the basic necessity used for application in the areas which show pigmentation for a oeriod of about 10 seconds. A little degree of erythema occurrs within a time span of 1 minute. The following method uses the idea of rapidly freezing the water & followed by slowly melting slow .This leads to the deterioted tissue formation . The Dehydration of Cell, denaturation of protein, enzyme inhibition,including the death of cell which occurs due to the shock due to thermal activity are few of the many effects which occur due to the process of cryotherapy. Cryotherapy leads to changes in the vascular supply and also affects the immunity of the individual leading to cell death.[14]

Advantages:

1. Easy and rapid to apply
2. Done in less time
3. No anesthesia required
4. No suturing needed
5. No bleeding encountered
6. No scar formation seen

Disadvantages:

1. Post operative swelling
2. Increased soft tissue destruction
3. Difficult to control depth of penetration

The Procedure of Cryosurgery: Tissue type, size and depth of the lesion are used to decide the dose and delivery method. Additionaly underlying structures, thickness of the epidermis, local blood flow and the water content of the skin can be considered.[10]

1. Dipstick method
2. Spray technique
3. Cryoprobe technique

Spray technique using spray tip: This is also known as Open-spray technique. The hand held or table top cryosurgical unit filled with liquid nitrogen is used, Select a spray tip that sprays within the border of the lesion. For single short freeze, no local anesthesia is required . But if the lesion is large and requires more freeze time, then 1% lignocaine is given . The spray should be done 1 cm away from the area and is administered at the centre of the lesion. The lesion is allowed to thaw slowly i.e. come back to room temperature. Thaw time is usually double of freeze time .

Cryoprobe technique: In this method, liquid nitrogen is circulated to cool the tip of cryoprobe. Hence,

freezing occurs by conduction. This technique is slower than spray technique.[10]

Disadvantages:

1. Excessive tissue damage
2. Depth of penetration difficult to control
3. Burning sensation or pain
4. Stinging sensation

Lasers: Lasers are introduced by Maiman in 1960, since than it is used widely in medical field. This method has been conceded as one of the pleasant, reliable and effective method.

Types	Wavelength
Carbon dioxide (CO2)	(10,600 nm)
Neodymium-doped: Yttrium, Aluminum, and Garnet (Nd:YAG)	(1064 nm)
Diode	(820 nm)
Erbium (Er)-doped:YAG	(2940 nm)
Erbium- and chromium-doped: yttrium, scandium, gallium, garnet (Er,Cr: YSGG)	(2780 nm)

Advantages:

1. No periodontal dressing required
2. Minimalpost operative pain and swelling
3. Less discomfort (protein coagulum formation)
4. Blood less field (sealing nerve endings)

Disadvantages-

1. Thermal damage
2. Delayed wound healing
3. Expensive treatment
4. Bone exposure and gingival fenestration can occur[15]

Diode laser: This laser is a solid-state semiconductor that utilizes light energy from electric energy. Flexible quartz fiber optic hand piece can be used. Wavelength spectrum of 800 to 980 nm is used to absorbed by water, soft tissue and chromophores, such as oxyhemoglobin and melanin.

Advantages:

1. Good visibility
2. Excellent hemostatic agent
3. Better patient comfort
4. Less damage to periosteum and underlying bone
5. Shorter operating time

Disadvanatges:

1. Slight discomfort
2. Dry and itchy feeling during procedure

Er: YAG laser: It is manufactured with a wavelength of 2940 nm, which is ideal for absorptionby water and hydroxyapatite.

Advantages:

1. Less thermal damange
2. Less pain
3. Rapid wound healing

Disadvantages:

1. Wavelength of this laser cannot absorb melanin

Nd: YAG laser: This laser is set at 60 mJ per pulse, 6 W and 100 pulses per second. A 320 micron diameter fiber optic is used in the pigmented area with a contact mode.[10]

Advantages:

1. No complications
2. No bleeding
3. No pain

Radiosurgery: It is the most advanced form of electrosurgery. It is used for removal of soft tissue with the aid of radio frequency energy.“Frequencies of 3.0 MHz (MHz) to 4.0 MHz is being used where 4.0 MHz being the optimal frequency”.(10)

Advantages:

1. Produce coagulation in the treated site
2. Less thermal damage
3. Faster healing (4MHz wave technology)
4. Self sterilising method
5. Little or no scar formation seen
6. Better visibility due to bloodless field

Disadvantages:

1. Atleast two appointment required

2. Cannot be used in pacemaker patients
3. Uncomfortable to patients due to foul smell

Chemical method: Chemical agents like 90% phenol along with 95% alcohol is used.

Disadvantages:

1. Tissue necrosis
2. Pain
3. Burn the gingiva

Free gingival graft: Free Gingival Grafts are used extensively in root coverage procedure and to increase the width of attached gingiva. According to *Tamizi, Taheri (1996), Kumar et al., 2012 and Fowler et al.(2000),* a free gingival graft is required after depigmentation procedure for better esthetic outcome. It showed no evidence of repigmentation even after 4.5 years. ***Vikas V Pakhare etal (2017)*** in their case report, used free gingival autograft for treating gingival melanin hyperpigmentation and no repigmentation was seen even after 6 months.[16]

Advantages:

1. No reoccurrence
2. Esthetically appreciated

Disadvantages:

1. Second surgical site needed
2. More discomfort to patients
3. Extensive procedure
4. Poor colour matching of tissue
5. Healing is slow and painful
6. Limited donor area available

Acellular dermal matrix allograft: Surgical blade no. 15 is used for two vertical incisionon the non-pigmented tissue both mesial and distal to the pigmented area. In the pigmented area, partial thickness flap is reflected and excised by a horizontal sulcular incision. The graft is then trimmed according to the treated area and secured with sutures. This technique yields better result compared to gingival abrasion method.[14]

Advantages:

1. Less time compared to free gingival graft
2. Less post operative discomfort
3. Less post operative complications

Disadvantages:

1. Clinical expertise required
2. Expensive procedure
3. Contraction of graft can happen

Reasons for repigmentation: "Reappearance of melanin pigmentation after a certain period of depigmentation is called repigmentation".[14]

- ✓ Migration of melanin pigments from untreated area to treated area causes repigmentation.
- ✓ Repigmentation can occur by the left over melanocytes during surgery
- ✓ Hormonal changes, Excessive sunlight exposure genetic and ethnic factors(17)

Prevention of repigmentation: Complete removal of melanin pigment including free gingiva, interdental gingiva and marginal gingiva.[14]

Repigmentation based on evidence[15-23]:

Kaur et al 2010	Higher reoccurance of pigmentation in the dark-complexioned patients seen as compared to wheatish- or brown-complexioned patients in a 9 month followup.
Hegde et al 2013	Er:YAG-laser-treatedsites resulted more repigmentation than the surgically or CO2-laser-treated sites.
Kumar et al 2013	3 out of 10 cases showed mild areas of repigmentation on the 30th day where other 7 cases didnot show any repigmentation till 2 years.
Ribeiro et al 2014	Slight reapperance of pigmentation was found in five of the patients using Nd;YAG laser and scalpel technique.
Grover et al 2014	In 11 cases, four laser and seven scalpel, a patchy repigmentation was observed at the end of 3 months
Giannelli et al 2014	Er:YAG and diode lasers gave satisfactory clinical results, with no recurrence of gingival pigmentation in a six month study.

Gupta et al 2014	7 sites in the scalpel excision group showed recurrence, whereas only 4 site showed recurrence in the electrosurgically treated group.
Basha et al 2015	Repigmentation appeared in the interdental and marginal tissues in both surgical stripping method and laser technique.
Suragimath et al 2016	At the end of one year, slight melanin repigmentation was observed in three subjects treated with scalpel depigmentation procedure.
Bakutra et al 2017	At 12 months followup study repigmentation is significantly lesser in surgical stripping compared to laser ablation method.
Narayankar et al 2017	Recurrence of pigmentation was observed in five cases in scalpel group and two cases in TFE group in 6 month followup.
Gholami et al 2018	After 12 months, surgical stripping and Er, Cr:YSGG laser treatment techniques showed similar trends in re-pigmentation where as one laser treated site, a short melanin strip recurrence seen.
Kamboj et al 2020	Repigmentation was observedin four cases out of 16 sites treatedwith electrocautery technique.
Chandra et al 2020	At 6 month, nearly 62.5% of cases showed postsurgical repigmentation of gingiva in both scalpel and laser techniques

Conclusion

The patients which show excessive gingiva should be advised for the procedure of Depigmentation thickness of gingiva, the level of experience the clinician holds, the preference of the patient, and rate with which pigmentation recurs,are the major factors which influence treatment selection the available studies in the field of depigmentation are mainly case reports, so Randomised control trials with longer follow up period are required to establish better treatment needs for gingival depigmentation.

Abstract

Electronic globalization with such a gigantic technological advancement during last few decades have made a huge impact on our everyday life. Artificial intelligence has been a breakthrough in hi-tech progression and has entranced the brains of scholars worldwide. It is field of technological science dealing with computer science and ability of computers to mimic the function of human brain to perform the tasks readily. Ever since its commencement in the field, dental science has witnessed modernization. From patient data records preservation, diagnosis and treatment planning to robots performing surgeries in supervision of clinician has now become possible because of artificial intelligence. In current scenario, it has become necessary for dental professionals to get oriented with clinical as well as technological advancement to provide easy, quick, relatively cost effective and excellent patient care. Though artificial can't replace all the traits of human mind, it has made a huge contribution in reducing a dentists efforts and assisting him in decision making. It is of prime importance for a practioner to be alert of the potentials of artificial intelligence to assimilate this technology for a enhancing his practice in forthcoming years.

Keywords: *Artificial intelligence, technological advancement, computer science, diagnosis, treatment planning, dental professionals.*

Introduction

In the era of hi-tech world, with such a speedy advancements in the field of technology, machines have become a big part of human life. In an attempt to reciprocate the functions of a human brain containing some traits of its mind,technological advancement have been witnessed over time. Advanced technology provide specific tools to unravel problems encountered when decision making and investigation is done. Hence, the involvement of computers in health industry has lately became a much of significance. The main object of this paper is to enlighten the readers about present-day accomplishments of artificial intelligence in clinical science.

Artificial intelligence is defined as "the study of intelligent agents, any device that perceives its environment and takes action that maximize its chance of successfully achieving its goals (Russell and Norvig 2003)"[(1)]. Artificial intelligence signifies nothing but machines that performs human tasks and so often

referred as machine intelligence. The AI research have been significantly based on reasoning, natural knowledge processing, planning, learning, interpretation, logistics, ability to move and ease of knowledge representation.

Artificial intelligence has been classified into two subdomains; machine learning and deep learning. Machine learning (ML) was first referred by Arthur Samuel[2] which is based on set of rules to learn the arithmetic frameworks and edifices in data which permits prediction of concealed data. ML model are neural networks (NNs) which can outdo conventional ML systems specifically on dynamic figures.

Deep learning is precisely useful for complicated data because of their skill of image representation and its organizedtopographies. It is a machine learning method where the models are trained using artificial neural networks (ANN).ANN is a group of numerous organized processing elements whiche valuatedata by their computerized potent response to external inputs. It has established substantial results in many non-health and wellness programby means of computer imaging and natural language processing. Deep neural networks are considered universal approximation machines (Hornik 1991)[3].

History: AI was founded in the year 1956 at a conference but it gained much recognition from 1980s with the arrival of neural networks[4]. The beginning of AI can be traced back to more distant past and typically linked with the discovery of first functioning computers after the Second World War, or in the year 1956 when John McCarthy used the term in its full meaning for the first time[1]. Hence, known as father of Artificial intelligence[5]. Philosophers and mathematicians have offered explanations of the development of anthropological intellectual and decision making, determined to describe overall forms and guidelines underlying the process since prehistoric times. The first real successes to create 'intelligent machine' have arisen with the encounter of digital electronic computers and scientific papers of a British mathematician, Alan Turing who laid the foundation of artificial intelligence and created the Turing test which is "a test to measure a machine's aptitude to reproduce human intelligence" in 1950[6,7]. Electronic diagnostics & decision making codes extemporize the course of evidence based guidelines, apt clinical medical assessment and be a foundation for education and investigation.[8,9]

Application of Artificial Intelligence in dentistry[10-23]:

General dentistry: AI has been significantly used toper form different tasks in routine dental practice. Because of this the need of man power has been reduced and fewer errors with increase in precision in comparison to human has been achieved. From the date of admission of patient, case history recording, arriving at clinical diagnosis of a disease, interpreting X-rays and then making a detailed treatment plan for patient has now become easier with the help of these computer systems[24].

Endodontics: Endodontics has always been the most rapidly developing branch in dentistry. With the use of AI, devices has been made to measure the pain level of patient and thus providing proper medication. Studies have been done in an attempt to make accurate diagnosis of caries. AI has contributed to test the vitality of tooth which has always been a crucial factor of treatment planning by introducing various method such as electric pulp testing, pulse oximetry, laser dopplemetry etc. The operating microscope and ultrasonics has heightened the quality of treatment and represent a modern aide in treatment of tough cases[25].

Prosthodontics: Fabrication of prosthesis has been most technical process. It requires accuracy, time and effort from the dentist and even the patient. With the increasing need of prosthesis various technology has been used to make the task easier. AI in combination with the designing software's can help the clinician to make the finestpossible and aesthetic prostheses bearing in mindnumerous factors like facial form, colour, patient desire, etc[26].Since 1980, 'digitizing the impression procedure'and 'computer aided design and computer aided manufacturing (CAD/CAM) technology' was made known todentistry[27]. To minimize the error in impression making, digitalized impression recording was introduced. CAD/CAM is the most enormously emerging part in dentistry. In the current scenario there are two possible method for using the CAD/CAM system in fabrication of dental crowns, laminates, veneers electronically: the direct and the indirect method[28]. Laboratories are using CAD/CAM to mechanically produce unconventional dental restoration, planned to seamless fit and supreme function beyond aesthetic outlooks [29].

Forensic odontology: It is the appropriate handling andinspectionwith thoroughevaluation of dental evidence which can be presented as a evidence in the interest of justice. Age estimation is the main area of practice for dentist in forensic odontology. Recent studies has shown that along with the tooth eruption pattern and tooth wear the deposition of cementum has shown the annual pattern of deposition. Age estimation using facial pattern has been under research since a long time.With arrival of AI, there are numerous software design by using ANN whichcommands the computers to inevitably estimate the age.[26]

Oral medicine and radiology: Computer-based diagnosis has become much popular and reliable because of its capability to spot and diagnose lesions which are difficult to diagnose and difficult to catch by the human eye[30]. Breakthroughs in image interpretationwith the addition of artificial intelligence Systems has been transformed from a myth to reality in the radiology practice within a short span of time. In the context of head and neck and imaging, AI offers additional power with its inimitable skill to learn.Ultrasonography helped in differentiating benign and malignant tumors, cystic and non-cystic lesions and also helped in on screen nodal measurement[31]. 3D imaging systems such as 'Cone Beam Computed Tomography (CBCT)'along with 'Magnetic Resonance Imaging(MRI)' has provided advantage in determining the extend and progression of lesion that may have gone unnoticed to human eye. The introduction of digitialized radiographs have eliminated the use of the manual processing of radiographs thereby reducing the chances of errors in processing of radiographs. This has also helped to keep the dental records digitalized making it accessiblefor future reference. Additional 3D system has been used in dental radiology such as intraoral scanners. These intraoral scans are then examined by dental inspection software. In order to locate minor apical foramen, artificial neural networks has been found to improve the working length determination for root canal treatment by radiographs[32], cephalometric analysis and diagnosis of caries[21].It also given adequate sensitivity, specificity, and accuracy with digital radiographs in detection of vertical root fracture [33].Study has shown use of artificial neural network (ANN) help to establish a diagnostic tool to diagnose subtypes of temporomandibular joint (TMJ) disorders[14]. Artificial intelligence has helped to establish relation of oral cancer to genetic factor significantly in large population and to differentiate between premalignant and malignant lesion helping us to categorize the disease and providing treatment appropriately.

Orthodontics: Movement of the teeth in the position where maximum function and esthetic can be achieved

has always been difficult to achieve. How much force to be applied for tooth movement keeping in mind the anatomic landmarks and the outcome of treatment is now done using AI [34]. Orthodontic diagnosis, treatment planning and long term monitoring of treatment is being done by analysing digital radiographs and facial photographs records (35).A model was trained to evaluate the craniofacial skeletal and dental anomalies in cephalometry and the same was compared with the expert opinion. The analysis results of both were found to be equal. Furthermore, the model also showed inconsistencies offered in the datawhich were missed by the clinicians, thus stressing on the importance of AI in orthodontic analysis [36].

Oral Surgery: Introduction of Robotic surgery in oral and maxillofacial surgery has been the greatest contribution of AI where human body motion and intelligence is imitated by robots while performing surgery in the guidance of expert [37]. AI s has abetted the surgeon in planning surgeries by preserving the vital structures around the lesion with higher intra operative precision with reduced operation time there [38]. The oral soft and hard tissue structures when lost due to some pathology or accidental reasons can be reformedthroughan advanced AI technique known as "bio-printing" through which organs and living tissues are formed in consecutive thin layers of cells in the future [39].

Periodontics: Deep learning AI is used in early detection, diagnosing and treatment planning of periodontal diseases using intraoral radiographs by aiding the initial finding of periodontal changes[40], furcation involvement, bone loss, and scoring bone density. Peri-implantitis recognition also help in primary intervention during placement of implant.[41]With help of electronic toothbrush now it has become easy for patient to asses the level of plaque in their oral cavity on their mobile screen.

Conclusion

Artificial intelligence has made a huge contribution in the health care sector. It has certainly helped us in improving the patient health care system. Technologies have helped clinicians and research workers to assimilate different arenas of knowledge. That day is not far, when dentistry will totally be revolutionized with the advancement of artificial intelligence based technology and we will be familiarized to errorless clinical procedures with greater accuracy and increase in patient care. Though it can never replace a dentists judgment, but it will surely aid the dentist in decision making. Therefore, to understand the countless notions and the system involved in artificial intelligence will have a strong benefit in the future. AI may assist in addressing the weaknesses harshly criticized in conventional dental care (Watt et al. 2019).

Abstract

Summary: Coronavirus (COVID-19) is diversely found in human beings and wild animals. It is an enveloped RNA virus. There are a total six species which cause disease in humans. They commonly infect respiratory, neurological, enteric, and hepatic systems. There is history of endemic outbreaks in past in the form of Middle East respiratory syndrome coronavirus (MERSCoV) and severe acute respiratory syndrome related coronavirus (SARS-CoV).We have seen another outbreak due to a new strain called the SARS-CoV-2 virus which presented as a pneumonia of unknown etiology in patients in Wuhan, China. The epicenter of infection was linked to seafood and exotic animal wholesale markets in the city. It is highly contagious and has resulted in a rapid pandemic of COVID-19. As the number of cases continue to rise, it is clear that these viruses pose a threat to public health. This review will describe clinical features and treatment of COVID-19 patients and raise awareness among healthcare workers and general population during the current pandemic. This review article aims at giving up-to-date information about the disease and counselling of patients.

Keywords: *RNA virus, COVID-19, SARS-CoV-2, MERSCoV, Coronavirus, Pneumonia.*

Introduction

Coronavirus (CoV) is a single-stranded RNA virus that belongs to the Nidovirales order. The order includes Roniviridae, Arteriviridae, and Coronaviridae families which are subdivided into Torovirinae and Coronavirinae subfamilies.[1] Coronavirinae is further subclassified into alpha-, beta-, gamma-, and delta- COVs.[1] Viral RNA genome ranges from 26 to 32 kilobases in length and can be isolated from different animal species such as birds, livestock, and mammals such as camels, bats, masked palm civets, mice, dogs, and cats.[2] Human pathogenic subtypes of CoV are associated with mild clinical symptoms. In 2012, Middle East respiratory syndrome coronavirus (MERS-CoV) was first detected in Saudi Arabia and was responsible for 2,494 confirmed cases, which led to 858 deaths.[2] In 2002, a severe acute respiratory syndrome related coronavirus (SARS-CoV) rapidly spread across Guangdong, China which resulted in 8,000 infections and 774 deaths in 37 countries.[2] The outbreak in 2020 has presented in the form of pneumonia of unknown etiology in Wuhan, China. Deep sequencing studies and lab investigations have identified the culprit as a new strain of COV.[3] Initially, this virus was designated as 2019-nCoV. However, the International Committee on Taxonomy of Viruses designated it as the SARS-CoV-2 virus.[4] On February 11, 2020, the World Health Organization (WHO) announced the disease caused by this novel virus as coronavirus disease-2019 (COVID-19). The repeated emergence and outbreaks of CoVs indicate a public health threat. This suggests the possibility of animal-to-human and human to-human transmission of newly emerging CoVs. The ongoing changes in ecology and climate make future emergence of such infections more likely.[3]

History of Coronavirus: In 1960 corona virus was first identified as a causative agent for common cold. One study was carried out in Canada in 2001, flu-like symptoms were present in more than 500 patient. Virological analysis by polymerase chain reaction (PCR)

Corresponding Author:

e-mail: dr.pankajwagh@gmail.com

of these patients showed that 3.6% of these cases were positive for the HCoV-NL63 strain. By 2002 Corona virus was considered as a relatively simple, nonfatal virus.

After the outbreak in 2002-2003 in Guangdong province in China, which resulted in spread to many other countries, including Vietnam, Hong Kong Singapore, Thailand, Taiwan and the United States of America, caused severe acute respiratory syndrome (SARS) and high mortality, microbiologists and infectious disease experts focused on the understanding the pathogenesis of the disease and discovered that this infection was caused by a new form of corona virus. Corona virus is not a stable virus demonstrated by the evolution of this virus and can adapt to become more virulent, even lethal to human. In 2012 in Saudi Arabia, it resulted in many deaths and spread first to other countries within the Middle East and then worldwide.[5]

Types: Corona viruses are the members of subfamily Coronavirinae in the family Coronaviridae. Uptill now seven types of coronaviruses are recognised that can infect humans.

Common types:

1. 229E (alpha coronavirus)
2. NL63 (alpha coronavirus)
3. OC43 (beta coronavirus)
4. HKU1 (beta coronavirus)

MERS-CoV strain causes more severe complications like Middle East respiratory syndrome (MERS), and SARS-CoV, leads to severe acute respiratory syndrome (SARS). In 2019, a new dangerous strain was discovered called SARS-CoV-2, causing COVID-19 disease.

Corona virus life cycle:

Steps:

1. Attachment and entry
2. Replicase protein expression
3. Replication and transcription
4. Assembly and release.

Epidemiology: As of April 27, 2020, the WHO has confirmed 28,78,196 cases globally and of these confirmed cases,1,98,668 (6.9%) patients have succumbed to the virus.[6] In the Europian region out of 13,59,380 confirmed cases,1,24,525 (9.2%) patients,in the region of America out of 11,40,520 confirmed cases,58,492 (5.1%) patients, in Eastern Mediterranean Region out of 1,65, 933 confirmed cases 6991(4.2%) patients, in Western Pacific Region out of 1,44, 121 confirmed cases 5958 (4.1%) patients, in South-East Asia Region out of 46,060 confirmed cases,1824 (3.9%) patients, in African Region out of 21,470 confirmed cases 865 (4.1%) patients have succumbed to the virus. [6] The majority of cases and deaths have been reported in USA. of the total number of cases, 9,31,698 (32.4%) patients have been identified in USA.[6] Likewise, the majority of fatalities (47,980 [24.2%]) have also been reported in USA.[6] It is important to note that confirmed cases are clinically diagnosed and laboratory-confirmed. Due to the ongoing nature of the pandemic, the number of cases and involved countries are expected to vary.

Table 1 Provides a comparison of the epidemiological characteristics of SARSCoV, MERS-CoV, and SARS-CoV-2.

Features	SARS-CoV-2	SARS-CoV	MERS-CoV
Estimated R0	2.68	2.5	>1
Host of virus	Bats are natural hosts,pangolins are Intermediate hosts, and humans are terminal hosts	Chinese horseshoe bats are natural hosts, masked palm civets are intermediate hosts, and humans are terminal hosts	Bats are natural hosts,dromedary camels are intermediate hosts, and humans are terminal hosts
Transmission Mode	Human-to-human through fomites, physical contact, aerosol droplets, nosocomial transmission, zoonotic transmission	Human-to-human through aerosol droplets,opportunistic airborne transmission, nosocomial transmission, fecal-oral transmission,zoonotic transmission	Respiratory transmission, zoonotic transmission, nosocomial transmission, limited human-to-human transmission,aerosol transmission
Incubation Period	6.4 days (range:0-24 days)	4.6 days	5.2 days

SARS-CoV-2, severe acute respiratory syndrome coronavirus 2; SARS-CoV, severe acute respiratory syndrome coronavirus; MERSCoV, Middle East respiratory syndrome coronavirus; R0, reproduction number

Etiology: CoVs are a large family of RNA viruses that are found diversely in animal species and known to cause diseases of the respiratory, hepatic, nervous system, and gastrointestinal systems in humans.[3] They have crown-like appearance under the electron microscope, due to the presence of envelope spike glycoproteins.[4] CoVs belong to the Roniviridae, Arteriviridae, and Coronaviridae families.[3] The Coronaviridae family can be classified into four genera of alpha-COV, beta-COV, delta-COV, and gamma-COV.[4] Furthermore, beta-COV can be sub-divided into 5 lineages.[7] Bats and rodents are the gene source of alpha-COV and beta-COV, while avian species are the gene source of delta-COV and gamma-COV.[4] CoVs causes about 5-10% of acute

respiratory infections.[3] Some common human CoVs include HCoV-OC43, HCoV-HKU1, HCoV-229E, and HCoV-NL63.[4] CoVs clinically present with self limitimg respiratory infections and common cold in immunocompetent individuals.[4] In the old age and immunocompromised idividuals, they can involve the lower respiratory tracts.[4] Other human CoVs such as MERS-CoV, SARS-CoV, and SARS-CoV-2 present with pulmonary and extra-pulmonary features.[4]

SARS-CoV-2, which is responsible for the COVID-19 pandemic, is a type of beta-COV. Genomic characterization studies of the new strain have indicated an 89% nucleotide match with bat SARS-like CoVZXC21.[3,8] and 82% nucleotide match with the human SARS virus. [8] Therefore it is to be called SARS-CoV-2. SARS-CoV-2 is sensitive to ultraviolet light and heat.[4] The Virus binds to their target cells through angiotensin-converting enzyme 2 (ACE2), which is expressed in the lungs. These viruses can be destroyed with the use of ethanol (60%), ether (75%), and chlorine-containing disinfectants.

Transmission: The initial cases of Covid 19 were associated with direct exposure to infected animals (animal-to-human transmission) at a seafood market in Wuhan, China. But human-to-human transmission of the virus is also possible and human-to-human transmission is now considered the main form of transmission. Asymptomatic individuals could also transmit the virus.[4] However, the symptomatic people are the most common source of infection .Most commonly transmission occurs from the spread of respiratory droplets through coughing or sneezing.[4] But close contact between individuals can also result in transmission.[9] There are more chances of transmission in closed spaces due to elevated aerosol concentrations.[4]

SARS-CoV-2 has a basic reproduction number of 2.2.[4] This suggests that a patient can transmit the infection to two other individuals. Current data suggest that the virus has an incubation period of three to seven days.[10] These findings are based on initial cases. Therefore, further studies are needed to address transmission dynamics and incubation times.

Clinical features: COVID-19 manifests as a spectrum ranging from asymptomatic patients to septic shock and multiorgan failure.[4] COVID-19 is classified on the basis of severity of presentation as mild, moderate, severe, and critical.[4,11] The most common symptoms of patients include fever (98.6%), fatigue (69.6%), dry cough, and diarrhea.[11]

Mild Disease: These patients may present with symptoms of an upper respiratory tract viral infection which includes dry cough, mild fever, nasal congestion, sore throat, headache, muscle pain, and malaise.[4] Dyspnea is not present in such cases. The majority (81%) of COVID-19 cases are mild in severity.[4] Radiological changes are also absent in such cases.[11] But these cases can quickly deteriorate into severe or critical cases.

Moderate Disease: These patients present with respiratory symptoms of cough, shortness of breath, and tachypnea.[4] However, signs and symptoms of severe disease are absent.

Severe Disease: These cases present with severe pneumonia, acute respiratory distress syndrome (ARDS), sepsis, or septic shock[4]. These cases are diagnosed on the basis of clinical findings and radiographic studies. Clinically these cases are presented with severe dyspnea, tachypnea (respiratory rate > 30/minute), respiratory distress, $SpO2 \leq 93\%$, $PaO2/FiO2 < 300$, and/or greater than 50% lung infiltrates within 24 to 48 hours.[4] Fever can be absent or moderate even in these cases.[4]

About 5% of patients can develop respiratory failure, RNAaemia, cardiac injury, septic shock, or multiple organ dysfunction.[4,11] Chineese Centres data for Disease Control and Prevention (CDC) suggest that the case fatality rate for critical patients is 49%. [4] Patients with pre-existing co-morbidities like diabetes (7.3%), respiratory disease (6.5%), cardiovascular disease (10.5%), hypertension (6%), and oncological complications (5.6%) have a higher case fatality rate and those without co-morbidities (0.9%).[11]

Acute Respiratory Distress Syndrome: It occurs within one week as a complication of known infection which indicates worsening respiratory failure. PaO2/FiO2 values are used to distinguish ARDS based on varying degrees of hypoxia. $PaO2/FiO2 \leq 100$ mm Hg is indicative of severe ARDS, between 100-200 mm Hg are diagnostic for moderate ARDS and between 200-300 mmHg indicative of of mild ARDS.[4] Higher levels of AST (aspartate transaminase) and ALT (alanine transaminase) at the time of admission result in rapid clinical deterioration to ARDS.

In addition to this chest imaging modalities such as chest X-ray, computed tomography (CT) scan, and

lung ultrasound can be used to support the diagnosis. The most frequent finding on CT scan includes ground-glass opacity (86%), consolidation (29%), crazy paving (19%), bilateral disease distribution (76%), and peripheral disease distribution (33%).[12] It is important to note that a chest X-ray has a lower sensitivity (59%) to detect subtle opacities. A CT scan can further detect mediastinal lymphadenopathy, nodules, cystic changes, and pleural effusion.

Sepsis and Septic Shock: Sepsis and septic shock are considered to be the most critical of them all. The accompanying multi-organ dysfunction results as a consequence of dysregulated host response to infection. Signs of multi-organ dysfunction include severe dyspnea, low oxygen saturation, reduced urine output, tachycardia, hypotension, cold extremities, skin mottling, and altered sensorium.[4] Laboratory evidence of other homeostatic dysregulation includes acidosis, high lactate levels, hyperbilirubinemia, thrombocytopenia, and evidence of coagulopathy[4].Patients with septic shock are persistently hypotensive despite volume resuscitation. They may also have an accompanying serum lactate level of >2 mmol/L.

Laboratory Features: Laboratory findings include elevated prothrombin time, LDH (lactate dehydrogenase), D-dimer, ALT, C-reactive protein (CRP), creatine kinase and the early stages of the disease shows marked reduction in CD4 and CD8 lymphocytes.[11] Patients in the intensive care unit have shown higher levels of interleukin (IL) 2, IL-7, IL-10,GCSF (granulocyte colony-stimulating factor), IP10 (interferon gamma-induced protein 10),MCP1 (monocyte chemotactic protein 1), MIP1A (macrophage inflammatory protein alpha),and TNF-α (tumor necrosis factor-α).[13] They also displayed other abnormal findings indicative of coagulation activation, cellular immune deficiency, myocardial injury, renal injury, and hepatic injury.[11] In critical patients, amylase and D-dimer levels are significantly elevated and blood lymphocyte counts progressively decreased.[4,13] Common to non-survivors are the elevations in serum ferritin, neutrophil count, D-dimer, blood urea, and creatinine levels.[14] Elevations in procalcitonin levels are not a feature of COVID-19. Therefore, an elevated level of procalcitonin may suggest an alternative diagnosis such as bacterial pneumonia. Levels of CRP correlate directly with disease severity and progression.

Diagnosis: The U.S. CDC has developed criteria for persons under investigation (PUI).[4] If a person is considered a PUI, immediate prevention and infection control measures are undertaken. Epidemiological factors which are used to assess the requirement of testing include close contact with a laboratory-confirmed patient within 14 days of symptoms or travel history to an infected area within 14 days of symptom onset.[4]

According to WHO recommendations the samples should be collected from both the upper and lower respiratory tracts which includes expectorated sputum, bronchoalveolar lavage, or endotracheal aspirate.[4] By using polymerase chain reaction (PCR) these samples are then assessed for viral RNA. If the test is positive then it is recommended to repeat the test for re verification purpose and if the test is negative with a strong clinical suspicion, CDC recommends repeat testing.

Management: Isolation and social distancing remains the most effective measure for containment of COVID-19. Neither specific antiviral medication nor vaccine is currently available for treatment.[4] Hence, the treatment consists of symptomatic care and oxygen therapy. Patients with mild infections require early supportive management which includes use of acetaminophen, external cooling, oxygen therapy, nutritional supplements, and anti-bacterial therapy.[11] Critical patients require high flow oxygen, extracorporeal membrane oxygenation (ECMO), glucocorticoid therapy, and convalescent plasma.[11] The use of systemic corticosteroid is not recommended to treat ARDS.[4] Unnecessary administration of antibiotics should also be avoided. ECMO should be considered in patients with refractory

hypoxemia despite undergoing protective ventilation.[4] Intubation, mechanical ventilation, high-flow nasal oxygen, or non-invasive ventilation is recommended in patients with respiratory failure. Hemodynamic support with the administration of vasopressors is requires in patient of septic shock. Patients with multiple organ dysfunction require Organ function support. [4]

Therapeutically, suggested drugs are aerosol administration of alpha-interferon (5 million units twice daily), chloroquine phosphate, and lopinavir/ ritonavir. [4] Other suggested anti-virals include ribavirin and abidor.[11] The use of three or more anti-viral drugs simultaneously is not recommended. Ongoing clinical studies suggest that remdesivir (GS5734) can be used

for prophylaxis and therapy.[4] The antiviral drug, called favipiravir or Avigan, has been used in Japan to treat influenza, and the drug was approved as an experimental treatment for COVID-19 infection. So far, reports suggest that the drug has a high degree of safety and is clearly effective in treatment. Furthermore, a fusion inhibitor targeting the HR1 domain of spike protein is reported to have the potential to treat COVID-19.

Prevention: Preventive measures must focus on optimizing infection control protocols, self-isolation, and patient isolation during the provision of clinical care. The WHO has advised against close contact with patients, farm animals, and wild animals.[4] Patients and the general public must cover their mouth while coughing and sneezing to help prevent aerosol transmission. Frequent hand washing with soap and water is also required and hand sanitizers can also be used. It is very important to avoid public gatherings by immunocompromised individuals. Strict hygiene measures for the control of infections must be applied by emergency medicine department. Healthcare personnel must use personal protective equipment (PPE) such as N95 masks, FFP3 masks, gowns, eye protection, gloves, and gowns.

Conclusions

The COVID-19 pandemic is spreading across the globe at very fast rate. It is considered as more infectious than SARS or MERS and responsible for more infections and deaths as compared with SARS or MERS. Old age and immunocompromised patients are at the greatest risk of infection. Due to rapid spread of disease there is need for intense surveillance and isolation protocols to prevent further transmission. Neither confirmed medication nor vaccine has been developed. Currently treatment strategies include symptomatic care and oxygen therapy. For the future prevention of COV-related epidemic or pandemic prophylactic vaccination is required.

Role of Ayurveda with Multi Modal Therapy in Prevention and Management of Autism Spectrum Disorders (ASD): The Whole System Approach

Renu Rathi[1], Bharat Rathi[2]

[1]Professor, Department of Kaumarbhritya, [2]Professor, Department of Rasashastra & Bhaishajya Kalpana, Mahatma Gandhi Ayurved College and Hospital and Research Centre, Salod (H), Wardha, (Maharashtra), Datta Meghe Institute of Medical Sciences (Deemed to be University), Sawangi (M) Wardha

Abstract

Introduction: Autism is a neuro-developmental ailment seen in the preschool age. It is a lifelong condition and requires long term and multiple treatment interventions.

Aim and Objective: To review and present a possible prevention and treatment protocol on Autism Spectrum Disorder (ASD).

Material and Method: The present study is based on the literature search from Ayurveda compendia, recent pediatric textbooks, articles published in research journals from 1983 to 2019.

Observations and Result: ASDs are the complex diseases with imbalance *of Tridosha* and *Dwimanasdoshas* (fundamental principles of body and mind), based on typical clinical features which match with DSM-V (Diagnostic and Statistical Manual) that can be correlated with *Unmada* (Psychosis/insanity). ASDs can be classified into Autism, Asperger's and Rett's syndrome. The probable etiopathogenesis may be defective organogenesis, brain damage, metabolic or genetic changes.

Discussion: *Acharya* emphasized on *Yuktivyapashray* (rational therapy), *Daiva vyapashray* (non-pharmacological spiritual therapy) and *Satvavajay chikitsa* (Ayurveda psychotherapy) altogether in *Unmad* treatment due to its complex nature. Recently developed therapies such as play therapy and cognitive behavioral therapy-CBT can be a good adjuvant with Ayurvedic management of ASDs for better quality of life.

Conclusion: As no satisfactory treatment is available in modern medicine till now, multi-modal treatment such as Ayurveda, behavioral therapy, physiotherapy, occupational therapy and early educational interventions might be beneficial to treat ASDs effectively. This review paper will be a torchbearer in the prevention and management of ASDs with the whole system approach and proposed management algorithm.

Keywords: *Autism Spectrum Disorder, Autism, Ayurveda, Multi-modal Therapy, Unmada, whole system approach, management algorithm.*

Introduction

ASDs are the third most common developmental disability which are inadequately understood. They are easily diagnosed by the main differentiating features like lack of interpersonal and communication skills, poor eye contact, delayed speech with pervasive abnormal body movements or posture.[1]Till 1980, they were uncommon disorders but recently then umbers are increasing drastically, maybe due to adoption of western lifestyle, prenatal stress, maternal complications, faulty diet and daily regimen. The definite etiology is not known but many environmental predisposing factors may be responsible for the occurrence of these disorders.[2] ASDs are neuro-behavioral and neuro-developmental

ailment[3] which can be correlated with *Unmad* described in Ayurveda. *Unmada* is characterized by perversion of mind,memory, desire,behavior and conduct with five varieties.[4] Management of *unmad* and ASD has need of utilizing multiple interventions including various behavioral and educational strategies[2,4] repeatedly for long duration. Present review is an effort to interpret and analyze the concept of Autism through Ayurveda perspective along with other multiple interventions which play a synergistic role in its prevention and management.

Material and Method

A retrospective clinical review to evaluate the effect of Ayurveda modalities, modern medicines, association of biochemical parameters, other interventions in ASDs. Method of data Source: Google scholar, MEDLINE (Pub med), Cochrane and Ayurveda were searched from 2010 to 2019. Manual search was also done to access the articles or thesis wherever possible. Electronicsearch included the following key words search to find the clinical studies with use of MeSHterms-Double blind study, "Ayurved*" AND|OR autism, Autism Spectrum Disorder, clinical trials, RCT, meta-analysis, systematic review, the diagnostic tests and interventional studywhich were reviewed thoroughly. Inclusion Criteria a) randomized clinical trial. b) Published in English accessible in full text. c) Evaluated on the effect of autism prevention and management or treatment.

Observations and Result

Many complex signs and symptoms are present in clinical features of ASD such as behavioral problems, screaming, developmental delay in all milestones i.e. gross motor, fine motor, personal-social and language. Such patients have strong interests in irrelevant things (like rope), mood-anxiety disorder, obsessive-compulsive disorder, gastro-intestinal upset, mental retardness, phobia, sleeplessness, etc. Imaginative play, communication and social interaction severely lack in ASDs.ASDs are classified into Autism, Asperger syndrome, Rettsyndrome, Pervasive developmental disorder (PDD) and Childhood disintegrative disorder (CDD) mentioned in table no 1. [2]

Some investigations such as Karyotyping, DNA, IQ test etc. help to rule out differential diagnosis and hidden associated features. In particular, diagnosis of ASDs are based on DSM -V criteria, typical clinical features, examination and history with so many other assessment scales such as ADI-RAutism diagnostic interview-Revised; ADOS-G-autism diagnostic observation schedule generic; CARS- childhood autism rating scale; DISCO-10: diagnostic interview for social and communication disorders-tenth revesion; GARS-2: Gilliam autism rating scale; 3 Di: Developmental, dimensional and diagnostic interview. [17]

Samprapti: The probable etiopathogenesis is based on faulty organogenesis, brain damage, trauma, obstructed labour, metabolic changes in intra-uterine life. ASDs may be caused due to genetic predisposition or defects, radiation, pollution, *Dushivishasevan* (food with toxic elements),improper use of food and medicines. Environmental triggers like stress during ANC, perinataland postnatal insults, *Vega Dharna* (suppression of natural urges)and other known or unknown reasons may provoke the disorder. It is a *Tridoshajvyadhi* with variation in their single or mix dominance, also vitiates *Mansik Doshas.* They together affect *Buddhi*-intellect *(Dhee*-short time memory *Dhruti*-act with dedication,*Smruti*-memory*)*and create various clinical features especially abnormal pervasive movements, screaming suggesting ASD[4,18] An attempt has been made to correlate treatment of unmad with features of autism in table no. 2

Table no 1: *Doshaj* variance matching with ASD features with Ayurveda management [2,4,19]

SN	Type	Characteristic features	Resemblance to Autism	*Shaman* therapy/ Pharmacotherapy	*Shodhan* (bio-purification Therapy)
1	Vataj Unmada	Sudden abnormal laughing, crying, talking, body movements	Repeated movements of eye brow, lips, chin, hands-feet and other organs, Frothing of saliva, Excessive screaming, dancing, singing, Frequent utterance of uncontrolled sound and voice	*Deepan-pachan-Anuloman, Snehpan, Medhyakalp, Sandnyaprabodhan, Ashwasan*/assurance *Saraswatarishta, Unmdgajakesariras* with milk, *Ghrit*	Mrudurechan, Basti, Nasya

SN	Type	Characteristic features	Resemblance to Autism	*Shaman* therapy/ Pharmacotherapy	*Shodhan* (bio-purification Therapy)
2	Pittaj Unmada	Impatient, irritable, aggressive, demanding food and water	Aggressive behavior, Irritable, recurrent fever, Harsh high pitch screaming	*Trasanchikitsa* & above all	*Mrudu-rechan, Basti*,
3	Kaphaj Unmada	Limited talk & movements, sleepy, drooling of saliva	Stay in one place or spot, less -talkative, clumsiness, less mobility. Drooling of saliva, running nose, dislike for bathing and toileting	Same asabove	Snehan-Swedan, Vaman, Virechan
4	Sannipataj Unmada	Mixed features	Mixed features	Same asabove*Doshaj* treatment	As per dominance
5	Agantuj Unmada	Extraordinary behavior in knowledge & strength	Sudden grief, loss/separation of close relative, brain trauma etc. Features seen of *Vataj* and *PittajUnmada* mainly	*Ghritkalpa, Nasya, Ashwasanchikitsa,* counselling sessions	--

Prevention:*Acharya Charak* has suggested implementation of pre-conceptional *Shodhan* and *Rasayan* (rejuvenation therapy) for newly wedded couple. He also advised genetic counselling, consanguinity check, pursue dailyregimen, seasonal regimen and *Yoga.* While during pregnancy, adoption of *Garbhiniparicharya* (antenatal checkup), fulfillment of *Dauhrida* (desires during pregnancy), avoidance of *Garbhopaghatakara Bhavas,* stress (detrimental factors affecting fetus) are some measures that play the pivotal role in prevention of ASDs.[20,21] *Pathya* (dietary restrictions) and *Nidanparivarjan* (restricting causative factors) are dynamic in etiology with abidance of *Satvavajaychikitsa* (mind control therapy), *Achar Rasayan*and *Sadvritta* (good conduct)to control *Niyamak Buddhi.* These factors are essential for prevention of *Pradnyaparadha* (intellectual blasphemy), *Asatmendriyarthasanyog* (incompatible contact of sense organs with their objects) and *Parinama* (time factor for chronological error)[22] which are three basic causes of all diseases. Prevention is easy and better dealt with Ayurvedic interventions than management.

Algorithm of ASD Treatment proposal: As both *Sharirika*s well as *Mansik Doshas* are involved in etio-pathogenesishence multi modal treatment approach is necessary for the whole system correction. [23] Initiating with *Yuktivyapashraychikitsa-YC* (rational therapy), medicines having *Deepan* (appetizer), *Pachan* (digestive) and *Anulomak* (mild laxative) properties must be added because *Agneemandya* (poor appetite, digestion & metabolism) is essentially present with *Vatadushti*. Coherent use of *Yuktivyapashraychikitsa* which mainly comprise *Shaman* (pharmacotherapy), *Mrudu Shodhan* (purify and detox therapy) and *Rasayan* (Rejuvenation therapy) along with multimodal treatment approachcanplaya vital role in the management of ASD.[15, 24-25]

Medhyaghritkalp: As the main involved site is brain hence any *Ghritkalp* fortified with *Medhyadravyas* (Ghee with nootropic/intelligence boosting medicines, such as *Bramhighrit, Kalyanak*or *Guduchyadi-Bhringrajadighrit* etc.[26]) is very important in prevention and treatment. *Medhyashamanaushadh/* nootropic medicine's action is synergistic to *ghritkalpa* with *Balya- brihan & Rasayan* (General tonic for rejuvanation) efficacy.[27]

Panchakarma-Poorva Karma: Pre-procedures such as *Rukshan, Deepan, Pachan* and *Snehan-swedan* are important for facilitation of *Pradhankarma* (main procedures).Long term and repeated use of some procedures like *Talapothichhil/Shirolepa, Shirodhara, Udvartan, Udsadan, Annalepan, Patrapottali, Pindasweda, Kwathdhara, Takradhara, Kanjidhara* or

*Tailadhara*etc are beneficial to pacify ASDsfor better efficacy. Multiple sittings of these procedures are required to treat ASDs due to its complex nature.

Pradhan Karma: *Nasya, Basti-Niruh, Matrabasti* are mainly beneficial in all types of Autism.As per *Doshaj* predominance *Vaman* and *Virechan* can be used.

Paschat Karma: S*ansarjankrama* (light diet therapy), followed by *Balya-brihan & Rasayan* therapy (anabolic action) is recommended.[28]

Satvavajayachikitsa: It comprises the act of controlling mind which can be achieved by doing *Buddhiniyaman* to avoid committing basic causes of all diseases[29], *Sadvritta*, *Achar Rasayan* and *Trasan* (act to deviate mind by frightening or eliciting painful stimulus).[19] *Yog*a, meditation and its other modalities are also helpful in achieving positive results in autism.[30]

Daivvyapashraychikitsa: Itincludes non-pharmacotherapy with spiritual belief which provides assurance and due to its psychological impact on mind, such measures can be useful to treat psychiatric illness to some extent.[19]. It synergistically acts with or without main treatment for a particular disease like Mantra chanting, use of amulets, holding therapy etc.

Multi-modal treatment such as, counselling of parents for tackling children affected with ASD, play therapy, Cognitive behavioral therapy, applied behavior analysis, Yoga, Speech therapy, Occupational therapy, Physiotherapy, Music therapy, Hydrotherapy, Reiki etc. can be incorporated as whole system approach[23].

There is no comprehensive management available in any system but synergistic action of these therapies altogether may prove better quality of life. Hence, a hypothesis of treatment guideline is framed to resolve this issue with the whole system approach for ready reference to Ayurveda physicians to treat ASDs effectively.

Discussion

(a) Key of preventing ASDs: It is necessary to prevent ASDs by strictly adapting daily and seasonal regimen, CAM-complementary and Alternative medicine-Yoga-meditation, recreational activities to keep away stress, pre-conceptional *Shodhan* and no consanguineous marriages to prevent mutational genetic changes *Beejdushti*, *Vatadushti,* and *Agneemandya*[15,25] All other etiological factors should be avoided with happy gestational period to boost *Satva*and balance *Raja-Tama.*

(b) Rationale of Shodhana Therapy: *Shodhan* therapy aims at removal of the vitiated *doshas* and correction of *Agni* and metabolic derangement which are the prime causative factors of all diseases. *It also facilitates the link between sense organs and brain efficiently.* [39,24] In Autism, mainly *Nasya* and *Basti* are more important procedures as *nasya* stimulates the function of brain and all *urdhvajatrugat* organs. [28] *Basti* is the main pathway of the gut-brain axis to pacify the vitiated *Vata* and stimulates brain function.[32] Other pre-*Panchkarma* procedures and all previously narrated therapies support motor function by strengthening muscles, joints, ligaments and facilitate in achieving day to day activities on their own.[33] In table no 4, there is a description of pre and main panchakarma procedures with their mode of action and references.

(c) Rationale of *Shamana* therapy (Internal medication): The process by which vitiated *Dosha*s ubside and return to normal without creating an imbalance of other humours is known as *Shamana*. This treatment is achieved by the use of appetizers, digestives, Rasayanas, symptomatic treatment, exercise etc.[19]

(d) Rationale of Diet therapy: It comprises *Pathya* (indications) and *Apathya* (contra indications) with respect to diet and eating habits. This is done to enhance the effects of therapeutic measures and to impede the pathogenic processes.[40]

(e) Role of *Nidan Parivarjan*: It is to avoid the known disease-causing factors with respect to diet, environmental issues and lifestyle of the patient. It also encompasses the idea to refrain from precipitating or aggravating factors of the disease. [19]

(f) Role of *Rasayana* therapy: It deals with the promotion of strength, vitality, immunity against the disease.[38]

(g) Role of *Satvavajaya:* It is an Ayurvedic psychotherapy. *It* concerns mainly with the area of mental disturbances which includes restraining the mind from desires for unwholesome objects and intellectual blasphemy in *collaboration* with *good conduct.[29]*

(h) Role of *Daivavyashray Chikitsa*: It was a proven

therapy since time immemorial but since medieval period it declined drastically due to the influence of modern medicine. Not manystudies have found to prove the scientific role of its various components. Some randomized controlled trials (RCTs) of music interventions for ASD have reported positive effects of music on emotional engagement, social interaction, communication and parent–child relationship.[13,40]

(i) **Role of Multi-modal Treatment and Whole System Approach:** It aims to evaluate the outcome of disease related to multiple variables individually.[23] It is an emerging approach for a complex disease management. It is not possible to fully understand the role of each component individually of whole system approach when implemented together.

Conclusion

Multi-modal treatment facilitates synergistic action for good outcome in ASD.Long duration is required to correct the whole system which gets impaired due to multifaceted nature of the disorder. Each course of these therapies either separate or together as per the symptoms and tolerance, magnify steady results in terms of sensory, motor integration, immunomodulation and ability of verbal communication. *Satvavajaychikitsa* is a broad term which may comprises all other multi-modal treatments those are developed separately nowadays. Thus, the three main *Chikitsa* modalities of Ayurveda-*Yuktivyapashray, Daivavyapashray* and *Satvavajay* are stepping stones in the management of ASDs (which is a life-long condition), giving a ray of hope and indicating the need towards more research in this arena. *Agneemandya* and *Vatadushti* are most important cause of ASD and should be eliminated. By implementing need-based modalities with multi-dimensional and wholistic approach, Ayurveda plays a fundamental role in not only its prevention but also in management, with improvement in quality of life to much extent.

Nanotechnology in Periodontal Regeneration: A Review

Gargi Nimbulkar[1], Priyanka Multani[2], Khushbu Balsara[2], Kumar Gaurav Chhabra[3], Shravani Deolia[4], Amit Reche[1]

[1]Assistant Professor, [2]Intern, [3]Associate Professor and Head, Department of Public Health Dentistry, Sharad Pawar Dental College and Hospital, Datta Meghe Institute of Medical Sciences, Sawangi [Meghe], Wardha, Maharashtra, India, [4]Research In-charge, Vidya Cancer Hospital, Gwalior, Madhya Pradesh, India

Abstract

Periodontitis involves destruction of the periodontal ligament and supporting structures. It ranges from a simple inflammation of gums to major damage resulting in loss of bone. Multiple conditions like trauma, periodontal disease, reconstructive surgery, ageing, osteoporosis and neoplastic pathology, have a common characteristic feature being loss of bone and tissue. The regenerative procedures that are currently practiced aim to regenerate the lost tissue via means of grafting, placement of membranes and many more, but have been accompanied with a set of limitations and major disadvantage being graft rejection. Periodontal regeneration still endures to be a partially unsolved algorithm. In dentistry, a new arena of development is being exploited to set a new approach for regeneration that is Nanotechnology. This branch involves tissue engineering which aims to regenerate the lost tissues via manufacturing scaffolds which transport signaling cells and molecules. These scaffolds possess magnificent physical as well as chemical properties and biomimetic features that act as a substitute of the highest standard offering innumerable benefits for promoting cell growth and tissue regeneration via tissue engineering.Nanomaterials because of their refined physiochemical characteristics and biomimetic attributes serve as a scope worthy substitute that offers several advancements for stimulation of cell growth and tissue regeneration. This review provides an insight to basic information about nanotechnology, the various nano particles having application in periodontal regeneration, the advanced regenerative procedures fabricated on the principles of nanotechnology, their applications, the clinical studies highlighting the achievements so far, supremacy over the conventional method and limitations.

Keywords: *Nanotechnology, periodontal regeneration, nanomaterials, tissue regeneration, bone augmentation*

Introduction

Periodontal tissue regeneration serves to be the pioneer for the lost tooth and the supporting structures. The regenerative and augmentative procedures are multiplex in nature and therefore challenging for the maxillofacial and periodontal surgeons. Variousailments liketrauma, periodontal disease, reconstructive surgery, ageing, osteoporosis and neoplastic pathology, have a common characteristic feature being loss of bone and tissue. Due to increased consumption of tobacco and betelnut, the prevalence rates of periodontitis are quite high in India.[1] Currently, many approaches exist in tissue regeneration and bone augmentation, but they are not efficient enough to deliver consistent results.[3] This is where nanotechnology comes into picture as it has manufactured and processed an entity called nano scaffolds. These scaffolds possess magnificent physical as well as chemical properties and biomimetic features

that act as a substitute of the highest standard offering innumerable benefits for promoting cell growth and tissue regeneration via tissue engineering. Hence, the paramount of this literature-based article is to bring for than outline of diverse nanoscale scaffolds as vital elements in tissue engineering and regenerative medicine prototype used for alveolar bone regeneration and bone augmentation.

Tissue Regeneration and Bone Augmentation: Present view: At present, autografts, allografts, xenografts and synthetic graft materials are currently used for tissue regeneration and bone augmentation.[4,5] But they have their own set of limitations.[6–8]Tissue engineering is a process where the wound healing is manipulated to achieve tissue regeneration.[9] This process broadly covers three key components: the signaling molecules, scaffolds and cells.[10,11] Tissue engineering shows improved results with the use of advanced materials such as "enamel matrix derivatives (EMD)" for treatment of infra-bony defects, "platelet derived growth factor (PDGF)" and "transforming growth factor-β (TGF-β)" are the growth factors that are effective for periodontal regeneration."Guided tissue regeneration (GTR)"and "laser-assisted new attachment procedure (LANAP)" can also be considered for new attachment, but requires further clinical trials.[12,13]

Tissue engineering demands the cells to stay alive inside the human body and continue to perform the function, which becomes difficult due to poor biomechanical and physico-chemical properties of the traditional scaffolds.[14] Hence, nanotechnology set the ball rolling on the evolution of tissue regeneration and bone augmentation.

What is Nanotechnology?: Nanotechnology is an arena of scrutiny and novelty concerned with fabricating things on the extent of atoms and molecules and has reached to all areas of science. A nanometer is one-billionth of a meter that is ten times the diameter of a hydrogen atom. This field offers advanced alternative solutions for scientific and medical problems. It involves manipulation of atoms and molecules to form larger nano structures, this is called the bottom approach. Whereas, larger structures or pieces are broken down to generate nanostructures from them, this is the top-down approach.[15,16] Nanotechnology has been exploited on a large scale over the last twenty to thirty years in various fields. For example, in dentistry use of submicron grained size ceramics for production of all-ceramic restorations improves its appearance, aesthetics and mechanical properties, increase the resistance to wear and increase strength.[17]

Nano biomaterials for tissue engineering and bone augmentation: In oral biology, the main purpose of practicing these procedures is to restore the functionality of the lost tissue and the tissue itself that take place during alveolar and periodontal tissue genesis, with the help of scaffolds carrying signaling molecules and cells.[2,14] This technology has outlooked to integrate scaffold matrix technologies with the regenerative potential of stem cells which are in close proximity, mainly to dental pulp, periodontal ligament (PDL) and alveolar tissue.[18] Therefore, an ideal biomaterial prospective should involve a scaffold that is functionally categorized where the chemical constituents and 3-D construct of each recess should match the detailed framework, biochemical components and mechanical attributes. Additionally, the matrices are supposed to degrade at a suitable rate so as to meet the regeneration pace of the tissues.[19,20]A study stated that there has been development of a scaffold which is a "3-layered construct" for concurrent regeneration of hard and soft tissue structures of the periodontium, like cementum, alveolar bone and PDL.[21]

Nano scaffolds: The current developments in nanotechnology have been cutting edge because of their ability to cause osteogenic enhancement.[22]It has acknowledged remarkable advancement of these scaffolding materials to propose distinctive 3-D matrix conditions for cells and tissues.[23] Nano scaffolds show superior most attributes in every dimension than various conventional approaches that are practiced for the purpose of tissue regeneration and bone augmentation.[24,25] The existing examples of scaffolds like "3-layered construct" suggest the nanomaterials that are used often should be multi-layered for multi tissue regeneration as this helps in exacting reproduction of even the minute characteristics of the structures that are to be regenerated.[26]

Nanoparticles, due to their reduced size, aid in quick reaction to extraneous stimulants such as ultrasounds, magnetic fields, X-ray and pH exposure. Delivery by nanoparticles which is controlled, depends mainly upon their reduced size and subsequent high surface area. The topography of nanoparticles is such that it imparts definitive physicochemical signals to cells such that it becomes easy for the cells to adhere and differentiate.

Besides, various active molecules and biological proteins are usually amalgamated along with the scaffolding materials to employ therapeutic efficiency and structurally control the cellular activity at nanoscale level. This is how nano tissue engineering succeeds in achieving structures that mimic their native tissue and develop structures of equivalency to the dentin, cementum, pulp, PDL and alveolar bone.

Role of extracellular matrix [ECM] in tissue regeneration: Extracellular matrix is an elaborate molecular complex made of three major constituents: protein, glycoconjugate and glycosaminoglycans. These elements along with cell adhesion receptors interact to form a complex in which cells live in tissues and organs. These receptors send cues to the cells from ECM which regulates manifold and paramount procedures like, proliferation, metastasis, growth and differentiation.

The ECM mainly contains collagen fibers which are produced via self-computing of smaller subunits. These self-computed fibers of collagen result in the mineralization of hydroxyapatite nanocrystals in a highly organized way. This bottom-up approach creates a structure of fine architecture that mimics the native tissue with accurate details. This can provide an engineered entity with distinctive mechanical properties. This enables amelogenesis and dentinogenes is induction in the matrix protein.

Hence, manipulation of nano construct of native tissue has been the matter of contention in current research era of tissue engineering scaffolds.

How are nano scaffolds produced?: Nano scaffolds are commonly produced by approaches such as: phase separation, peptide synthesis and electrospinning approach. Nanofibrous scaffolds which are built of poly-l-lactide acid (PLLA) can be incorporated through the "phase-separation" as well as "porogen leaching method." These scaffolds, in human dental pulp cells, manifest the stimulation of odontogenic differentiation in contrast to solid-walled PLLA scaffolds.

In recent times, scientists have invented scaffolds made up of biopolymers in combination with bioactive glass, known as nanocomposite nanofibrous scaffolds. These nanoparticles play a key role in upgrading mineralization and remineralization of mutilated dentin matrices. Furthermore, a study reported incorporation of magnesium phosphate into nanofibrous scaffolds, where they helped in enhancing the rate of differentiation of pulp stem cells.

Nanoparticles: A nanoparticle (NP) is a minuscule particle which usually ranges between 1 to 100 nanometers in diameter. They have peculiar physicochemical properties to their material counterparts of comparatively larger size. They are classified as nanospheres and nanocapsules. Nanospheres are those nanoparticles that have a matrix type of construct where a drug is dispersed. Nanocapsules have a membrane wall construct with an oil core in the center containing the drug. Several applications use nanospheres in delivery of drugs, genetic material and growth factors. These include controlled drug delivery using porogens for reinforcement of a mechanically weak scaffold as bioreactors of microscopic nature helping in the formation of hydroxy apatite crystals, followed by mineralization using microspheres for providing the sites for cell adhesion and preparation of formulations like suspensions, colloidal gels and injectables to be used in minimal invasive surgery.

Inorganic Nanoparticles

i. Synthetic Polymers: The ones customarily used are "poly-α-hydroxyesters [poly-glycolic acid (PGA), poly-lactic acid (PLA), poly-lactic-glycolic acid (PLGA) and poly-caprolactone (PCL)]" for biomedical applications. They are available at reasonable cost, easy to adapt and have a high safety index. Major disadvantage is hydrophobicity and degrade via autocatalysis.Various combinations of TGA/PLA/PLGA/PEG/PCL have been tested for alveolar bone regeneration and have shown positive results.

ii. Ceramic NPs: Ceramic materials are "synthetic crystalline, solid, inorganic non-metallic materials". Bioceramics include "bioactive glass, bioactive glass–ceramic, calcium phosphate groups and alumina." These have been used to refine the morphology and performance of the scaffolds. For example, calcium phosphate, mineral trioxide aggregate (MTA) and bioactive glass.

iii. Silica NPs: These can be integrated as bioparticles, either core or shell silica NPs and mesoporous silica nanoparticles (MSNPs). They have been used in biomedical field and for drug delivery because of their unique structure and increased pore volume and surface area. The limitation of silica NPs is variable toxicity.

iv. Metallic NPs: They are the safest and most commonly used is gold NPs because of their ability to be drawn into variable shapes such as rods, cages or spheres. Thus, can be implemented in drug delivery, bio-imaging, photo-thermal therapy and biosensing. The combination of gold and silver NPs along with chitosan have shown successful outcomes for bone regeneration, mineralization and osteointegration of implants. They are biocompatible NPs with less cytotoxicity.

v. Magnetic NPs: They show paramagnetic properties of long duration and non-invasive tracking. Therefore, in biomedical field, cobalt, nickel, iron and their subsequent oxides have been used for cell tracking, drug delivery, as biosensors, 3-D cell organization and imaging procedures.

Organic nanoparticles:

i. Liposomes: Liposomes are mostly used in imaging and drug delivery. They are bilayer structures made up of phospholipids. Their properties vary because of their size, composition, surface charge and preparation and are used in imaging and drug delivery.

ii. Natural Polymeric NPs: These are classified as proteins and polysaccharides. They are biocompatible and bio-degradable materials that possess bulk physical characteristic features.NPs hold high capability for drug loading,have a flexible synthesis and their structure constitutes of polymer chains which show a broad variety in terms of composition and characteristics. Collagen, gelatin, alginate, chitosan and fibrin are some of the natural polymericNPs.

iii. Carbon:

a. Carbon nanotubes (CNTs)- these are cylindrical structures made of carbon allotropes. They are mechanically and chemically stable with conducive electrical properties.Usually come eitherin the form of a single or multi-walled tubular architecture. CNTs show effective performance on bone and tissue regeneration, also aid in multiplication of cells and bone integration.

b. Graphene and its derivatives: A film which is single layer,1 atom thick and is arranged with carbon atoms in 2-D hexagonal construct which shows similarity to honeycomb.They constitute large variation of graphene derivatives like, graphene oxide(GO) and reduced form of it, called as reduced graphene oxide(rGO).

Composite Scaffolds: Combinations of various organic as well as inorganic particles have been evaluated as composite scaffolds, which in turn improve the properties and decreases the limitations of singular components. Many researchers have experimented with varied composite scaffold designs of different combinations such as, nHA with high molecular-weight polymers, nHA with PLA, PCL[88], PLGA, chitosan, collagen, coralline and polyamide. Most of these combinations have come up with ameliorated mechanical strength and scaffold biocompatibility.

Hazards of Nanotechnology: Although there are many potential advantages of using nanotechnology, it ought to be countervailed against the risks. The physical and chemical properties have enormous ramifications in many ways via which these nanoparticles interrelate with biotic constituents, their uptake, accretion and excretion through the body and interact with environs at large. The interplay between nanoparticles and human tissue can be physical or chemical. The physical interactivity mostly leads to disintegration of membranes and its activities such as "protein folding, aggregation and various transport processes."Whereas, the chemical interactions result in oxidative damage and formation of reactive oxygen species. Besides these, environmental reactions also determine the nanomaterial toxicity.

It is difficult to avoid the exposure to nanoparticles, being airborne in nature. Humans are exposed to these, knowingly through nanotherapy or unknowingly through natural/human-induced particles leading to multiple entry routes due to high reactivity, which aggravates the condition.[98]Interaction of nanoparticles with proteins, enzymes, molecular structures DNA, RNA in a reversible or irreversible manner may lead to devastation in biological systems resulting in emergence of new diseases. This warrants detailed studies to evaluate the toxicity of nanoparticles before using them for therapeutic purpose.

Future prospects: This multidisciplinary domain of science is undergoing colossal development and has grown immensely in the past few years, thus exhibiting a step aheadof existing practice in the healthcare sector. The research and development has paved its way in the field of nanoengineering which will change the practice of dentistry, medicine and day to day life, moulding it into

a better future.Like other technologies, nanotechnology also has the aptitude to be exploited and misused on a large scale.

In the field of dentistry, nanotechnology will give a superiorperception to preventive management, which is the latest trending treatment approach along with advantages like early detection of the disease and treatment of oral cancer.

Conclusion

One of the recent exploitations in periodontology has been the use of nanoparticles in oral biology. Periodontal regeneration still endures to be a partially unsolved algorithm. The purview of periodontal tissue regeneration in nanotechnology is to rejuvenate the lost structure using tissue engineering, in conjunction with materials called "nanoscaffolds" which manipulate the physiological and biological processes for an improved performance of the objective. This will revolutionize the province of periodontal tissue regeneration. In the subsequent wave of research and innovation, the underlying fundamental mechanism of interactions conducted in vivo between nanoparticles and cells at a molecular scale will remarkably facilitate the evolution of this domain.

Abstract

Forensic odontology is a branch of forensic sciences which proof to be very helpful during investigation of criminal cases and during person identification by providing the dental expertise in the court and to the legal system so that proper justice can be done based on evidence. The tongue is a crucial organ very much encased inside the oral cavity and shielded from nature. Tongue print is the subtleties present on uncovered section of tongue when the surface and shape are assembled. The morphology and surface highlights are attributes of each person, and these characteristics can be utilized for criminological distinguishing proof. It has unique shape and surface textures in each individual. The shape, colour and texture of tongue are different in identical twins. And hence it can be used as a new method for personal identification with further elaboration. The unique features make it a valuable tool in forensic odontology. The exposed portion of tongue contains information with visible differences from one individual to another therefore it is helpful in identification of suspect during forensic investigation. Tongue becomes the forensic evidence for establishing the cause of death. It is an evolving science in the field of forensic and there is greater scope for its further development. The use of tongue print as forensic identification is at budding stage but now its use as a biometric authentication system is gaining a lot of popularity. This review is aimed at describing the distinctive features of tongue, application of tongue prints in personal identification and as biometric system and the challenges faced in its use.

Keywords: *Tongue print; Forensics; Biometric; Identification; Forensic odontology.*

Introduction

Forensic science or forensics is a multidisciplinary branch of a science which uses the scientific concepts in issues of law[1]. Forensic odontology can be characterized as a part of dentistry which manages the suitable taking care of and assessment of dental proof and with the correct assessment and introduction of dental discoveries in light of a legitimate concern for equity[2]. Forensic odontology is a branch of forensic sciences which proof to be very helpful during investigation of criminal cases and during person identification by providing the dental expertise in the court and to the legal system[3]so that proper justice can be done based on evidence.Forensic dentistry or forensic odontology includes various zones; the general definition might be the mix of the science and craft of dentistry and lawful

framework, a junction of dental science and law[4]. It is an evolving science in the field of forensic and there is greater scope for its further development. As the dental tissues are often preserved even after death of person, whether the person's body is decomposed, skeletonized, burnt, or dismembered[5]. Therefore, it has established a great popularity in medico-legal matters and in the identification of the dead person.

With advancement in technology, the tools have evolved as well. The various tools currently used in forensic odontology include bite mark analysis[6], Cheiloscopy[7,27], Tongue print[8], Rugoscopy[9], Odontometric[10], Tooth print[11], Radiographs[12], DNA analysis[6], comparison with past dental records[6] etc.

Therefore this review aims to throw light on new tool- tongue prints which has evolved in recent times owing to its uniqueness. It is an effort to summarise the distinctive features of tongue, its usefulness in personal identification, use as a biometric tool, its limitations and future scope so as to understand its implication in forensic odontology.

Tongue Print: Tongue print is the subtleties present on uncovered section of tongue when the surface and shape are assembled[13]. Tongue can be effortlessly exposed for inspection but at the same time it is well protected from any kind of environmental influences and therefore it is quite difficult to manipulate or forge the tongue print[14]. However, the use of tongue print as forensic identification is at budding stage[5] but now its use as a biometric authentication system is gaining a lot of popularity[13].

Overview of Tongue: The tongue is an exceptionally movable set of muscles, which is richly supplied with blood and nerves[15].Tongue is joined to the mandible, hyoid bone, pharynx, sense of taste and styloid process by means of muscles. It comprises two sections; a foremost 66% and a back 33% which is partitioned by V-formed sulcus terminalis[16]. The root of the tongue is securely anchored to the floor of the mouth[15]. The mucous layer of tongue has three kinds of papillae. The dorsum of the tongue show filiform papillae. Fungiform papillae are seen close to the surface of tongue, are marginally redder and increasingly at tip and edges of the tongue. Circumvallate papillae are approximately 8 to 12 in number[17]. They are bigger in size and are positioned at the intersection of oraland pharyngeal tongue[17]. It is pink in colour and moist with neither localized nor diffuse discoloration nor ulceration[17]. The human tongue is known as the mirror of the oral and general health[18].

Unique Features of Tongue: Tongue is the main organ that is available inside which can be ordinarily and easily be uncovered for investigation purposes in forensic odontology[19]. The process of tongue inspection gives a reliable confirmation of life[20]. It has unique shape and surface textures in each individual[19]. The shape, colour and texture of tongue are different in identical twins[21]. And hence it can be used as a new method for personal identification with further elaboration[21]. It performs various functions such as articulation of speech, perception of taste, and formation of bolus[22].

When the morphology of the tongue is examined it displays a "U-shape", with slightly round off tip. The other commonly seen shape of the tongue was trapezoidal, which have the large base at the oral commissures level and a smaller base at anterior side[8]. In the dorsum surface of the tongue there is presence of fissures which is the most common morphological feature[13]. A preliminary study stated that geographic tongue and sharp tips are commonly found in female subjects, whereas a septate tip is a common feature in males[18]. Gender wise differences are observed in width and length of the tongue with Males depicting an increased width and length of tongue as compared to females[23].

Recording Tongue Print: There are different ways that can be used to obtain tongue prints. Some of the basic features of tongue like the colour of the tongue, variations in surface texture, mobility and any other special characteristics if present they can be inspected by simple visualisation.

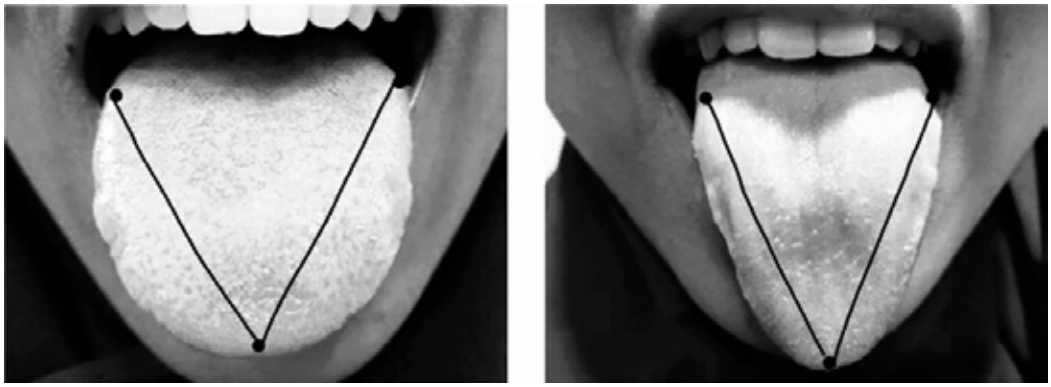

Figure 1: Reference points on tongue for shape determination 24

Determination of the shape of tongue is done by utilizing three reference focuses. The reference focuses incorporate the area of the tongue in contact with the commissure of the lips when distended outside the mouth and the tip of the tongue, as depicted in Figure 1[24]. The most viable option for tongue assessment is a three dimensional analysis.

Alginate impressions followed by cast preparation can be used for analysis. The unique features of tongue can be captured and those can be reproduced on cast for study purpose[18]. Digital images can also be used for analysis. Digital software autocorrects the colour and hue along with positional alterations and later analyses the tongue for it to match with data base for positive identification. However, there are a number of researches going on to prepare an exact algorithm for analysis of tongue images[25].

There are various other method that are been used to capture the video of tongue and to pull out the images from it as this organ is non-rigid. The most common technique used in tongue diagnosis is sublingual valve analysis. An ultrasound transducer is introduced that is positioned in sublingual area for the analysis of the tongue function[26]. Another method that is helpful for the examination of tongue is the Histological examination. Tongue dorsal surface is different in each person. Even between identical twins the characteristic features of tongue are different[21]. The most useful proof in forensic odontology is taking impression of the dorsal surface of tongue including lateral borders when it is used in combination with Cheiloscopyand Rugoscopy[10,27].

Application of Tongue Print in Forensic Odontology: It has unique features like colour, shape, and surface features which are different from person to person. They are different between identical twins also making it a tool for personal identification. Both texture and shape of the tongue is used for identification purpose. The exposed portion of tongue contains information with visible differences from one individual to another therefore it is helpful in identification of suspect during forensic investigation.

Tongue becomes the forensic evidence for establishing the cause of death. Bitten tongue in addition to protruding eyes or anus and swollen abdomen is important evidence in drowning. Protrusion of tongue is evidence in detecting the death by hanging whereas dark tongue becomes the evidence in case of poisoning.

Tongue Print as Biometric System: There are various biometric systems that are used for recognition of person's identity which includes fingerprint, face, palm print, iris, hand shape, gait, voice, and signature. However, this traditional biometric system has some restriction as they can be easily forged[19]. Each biometric system has some advantages and some disadvantages. The disadvantages of these systems make it vulnerable to use in forensic sciences. Fingerprints cannot be trusted because of their biggest disadvantage that they can be eroded, altered by surgery, and are subjected to injuries due to which finger print can be altered. The disadvantage with the voice is that it can get affected by sickness such as cold and cough. The most sensitive being the retinal scan. But cataract and astigmatism can be a down fall in case of retinal scans. Yet another type of biometric system is skin colour, but it is subjected to stability problems due to the differences that are seen with age, burns, diseases, and use of skin creams or medications.

Lately, tongue print is increasing a great deal force as a significant apparatus in biometric verification. A study was done in which Dual tree complex wavelet transform (DT-CWT) was used to draw out some unique features of tongue (size, shape, textures). This revealed that use of the sensors and some other contributed resources in real time environment, with DT-CWT, tongue would be definitely a stepping stone in personal identification and authorization process by means of security[30]. Though the research is in budding stage the results are promising.

Future Scope of Tongue Print: Various technologies are being used to capture and analyse tongue prints including spectral analysis, Gabor filter and wavelet transformers, all these technologies yield different results. The tongue print verification procedure can be done by tongue images, which goes to pre-processing for shape analysis and texture analysis of tongue. After matching the score of shape vector and texture code, fusion and decision is taken placed for verification and matching of the tongue. Therefore, the complexity involved in capturing and analysis for achieving accurate results becomes a limitation as it requires expensive resources and expertise. Rapid advancement in technological field will overcome these limitations and enable easy use of this tongue prints in forensic odontology and therefore the future looks promising.

Conclusion

The uniqueness of tongue prints makes it a good tool for personal identification and biometric system. Dentists can adopt the technique for tongue prints on a regular basis. The lingual photographic image which taken by dentist can serve as a guide for personal identification. Tongue prints hold a promising future in this digitalized word as a tool in forensic odontology.

Impact of Covid 19 Pandemic on Tuerculosis

Deepanshu Chawla[1], Pankaj Wagh[2], SaoodAli[2], Ulhas Jadhav[3], Dr Babaji Ghewade[4]

[1]Junior Resident, [2]Assistant Professor, [3]Professor and HOD, [4]Professor, Dept of Respiratory Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Summary: Covid19 is the most dreaded pandemic of the century causing wide spread and on the other hand Tuberculosis is an age old disease killing billions. Tuberculosis is an air borne infection while Covid spreads via droplet spread and through fomite as well. Tuberculosis and complications related to it may lead to increased mortality due to poor lung compliance. Moreover Tuberculosis control programmed may get affected due to the ongoing pandemic. To decrease the adverse outcome of Covid19 on Tb strict measures like proper social distancing, hand hygiene, compliance to Anti Tubercular drugs, domiciliary Tb care and strengthening immune system may prove important.

Keywords: *Covid19, Tuberculosis, Pandemic, fomite, Social distancing.*

Introduction

The novel coronavirus-19 (nCoV-19) also known as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a new coronavirus recently discovered in 2019. The disease has expanded to more than 150 countries with around 45 lack cases and more than 3 lack deaths around the globe.(1)

According to WHO, "TB is a worldwide pandemic. TB has killed around 1 billion people between 1800 and 2000. It attacks the human body more slowly than viral diseases like flu or COVID-19. It kills around 4000 thousand people every day in under developed and developing countries."

In this article we would like to discuss the possible impact of Tuberculosis during the Covid 19 pandemic and vice a versa and an observation on what Measures are being taken by a Rural Hospital in Central India for Control of Covid19 and Tuberculosis.

Pathogenesis of Covid19: Virus Structure: Coronavirus virus has a simple structure, it is a round and pleiomorphic, 80 to 120 nm in diameter in size.(2) It is club-shape with spike projections emanating from the surface.Nucleocapsid is in the envelope containing positive-strand RNA. There are four main structural proteins in coronavirus particles. These are the spike (S), membrane (M), envelope (E), and nucleocapsid (N) proteins.(3) Spike protein with ACEII receptors helps in adhesion to the target cell.

COVID-19 infection induces IgG antibodies against N protein that can be detected by serum as early as day 4 after the onset of disease and with most patients seroconverting by day 14. Laboratory evidence of clinical patients showed that a specific T-cell response against SARS-CoV-2 is important for the recognition and killing of infected cells, particularly in the lungs of infected individuals.(4) T cell response is also seen in patients of Tuberculosis.(5) BCG vaccine (vaccine given to prevent complication of Tb) is predicted to protect from Covid infection. This could be because of "off target effects" of and increases the ability of immune system to fight infections other than Tb. Though further studies are being done to prove such claims. The virus binds to carbohydrates and hinds behind it (Carbohydrate Camouflage) makes it difficult for body's immune system to detect it. Moreover it has a very high secondary attack rate compared to SARS (SARS Cov 1) and MERS, which makes it more fatal.

Spread of Covid 19: Covid spreads via droplet infection when a person is in in close contact (within 1 meter) with patient having respiratory symptoms (e.g., coughing or sneezing) and the respiratory droplets can infect the exposed mucosae (mouth and nose) or conjunctiva (eyes). Transmission also occur through fomites. The virus can spread by direct contact with infected people and indirect contact with surfaces and objects[1]. Transplacental and feco-oral spread are also reported.

Spread of Tuberculosis: Airborne spread from one person to another. The TB bacteria are suspended in the air when a person with TB coughs. People nearby may breathe in these bacteria and become infected.[6] Unlike Covid19 TB is NOT spread by shaking hand, touching bed linens or toilet seats. Reactivation is common in Tb which has not been reported in Covid19.

Comorbidities, like hypertension, diabetes and coronary heart disease, have shown poor outcomes.[7] It is not clear whether having underlying lung disease like TB, will increase the severity of COVID-19. Both COVID-19 and TB cause respiratory symptoms – cough, fever and shortness of breath. One of the biggest differences is the progression of onset of symptoms. TB symptoms do notoccur immediately, butdevelop over a period of weeks, unlike COVID-19, where symptoms can occur within a few days.

Possible Impact on Tuberculosis in Covid19 Pandemic: The majority of TB hospitals in China have been converted to COVID-19 hospitals because of their roles in communicable disease. Likewise India could face a similar problem of lack of staff for management of Tb as most of the Pulmonary Physicians, technician and other staff are shifted towards Covid19 management and screening. Due to lockdown the patients might not be able to visit hospitals for treatment or follow up. This might lead to delay in diagnosis and initiation of treatment. Lack of availability of Anti Tubercular drugs due to lock down. Active Tb cases might be at increased risk for Covid19 due to poor lung functions, or patient of Tb with HIV the severity and mortality of Covid might be higher. Covid patient might develop Tb due to reactivation due to temporary weakened immune system due to Covid or corticosteroid therapy, few such cases were reported during the SARS outbreak. Patients with post tubercular complications like destroyed lung, bronchiectasis, and extensive fibrosis might also show increased complications and higher mortality due to poor lung compliance. This may lead to poor outcome and increased overall mortality in the ongoing Pandemic. If the situations arises in a country of high Tb prevalence like ours where the Covid cases goes very high, then the Tb patients might not get ventilators or ICU support due to poor outcome of these patients.

These conditions may lead to increased neglect of the tubercular patients moreover the relative/caretaker of Tb patients are at higher risk for Covid19 due to frequent hospital visit.

Due to Covid19 pandemic the Tb eradication program might take a hit back. There can be chances of increase in Tb spread during or after the Covid pandemic. Due to above reasons WHO on 20th March 2020 has stated- "COVID-19: Considerations for tuberculosis (TB) care services-As the world comes together to tackle the COVID-19 pandemic, it is important to ensure that essential services and operations for dealing with long-standing health problems continue to protect the lives of people with TB and other diseases or health conditions. Health services, including national programmes to combat TB, need to be actively engaged in ensuring an effective and rapid response to COVID-19 while ensuring that TB services are maintained".

Measures to be taken by people with TB to reduce their risk for COVID-19: Social distancing with "reverse-quarantine": Remain at home and avoid contact with people as much as possible. Wash hands frequently with soap and water. Avoid touching face, nose, eyes with unwashed hands. Avoid close contact with those who are unwell. Strictly adhere to your TB treatment. Avoid hospital visits as much as possible and keep in touch with your doctor/nurse/health facility by phone. Strengthening of the domiciliary care for Tb should be done. Admissions of Tb patients and management of complications should be done as per protocol. Use masks, and take extra caution to maintain hygiene such as - disinfection of hands, used surfaces, proper disposal of used tissues, etc.

Measures taken in a Hospital in Central Rural India to fight Covid19 and Tuberculosis: Measures taken to control Covid19: A separate section of the Hospital has been assigned where suspected patients are admitted. The block consist of a separate ICU with ventilators, separate ward with designated rooms for dawning and dwarfing of PPE (Personal Protective Equipment) and designated staff. The entry and exit

of the block is kept separate from the Hospital's entry. Personal Protective Equipments including N-95 mask, gowns, helmets etc is being provided to the staff present in the block. Patients who falls under following criteria- 1. All asymptomatic patients with history of foreign travel 2. All contacts of laboratory confirmed cases 3. Health care workers managing respiratory distress/ Severe Acute Respiratory Illness should if they become symptomatic 4. All Hospitalized patients with Severe Acute Respiratory Illness or previously hospitalized patients showing signs of atypical pneumonia and 5. Patients with flu like symptoms arriving from districts where cases of Covid19 are reported. Those patient's are being admitted and oropharyngeal and nasal swabs are been send for testing.

For the screening purpose a separate OPD(Out Patient Department/Unit) has been set up, all the patients as well the at tenders visiting the hospital are being screened before entering the wards and OPDs and their temperature is being measured by infrared (gun) thermometers. All the suspects are advised either home quarantine or hospital admission accordingly. Multiple hand washing units with washbasins and soaps have been set up and hand washing is mandatory for everyone entering the Hospital premises. The use of masks and hand hygiene is being promoted extensively. Assemblage of people is being discouraged. Limited number of people are being allowed to enter the hospital. Barricading has being done to avoid gathering of people. A separate screening unit has been set up in front of the Emergency (casualty) department for proper screening triage and management of the patients.

Measures taken to control Tuberculosis: Tuberculosis treatment and management of complications due to tuberculosis is practiced according to the RNTCP (Revised National Tuberculosis Control Programme) according to Government of India guidelines. Patients of Tuberculosis are being admitted in the TB Isolation ward with designated staff. Gloves and masks has been provided to the staff. Patients of Multi Drug Resistant tuberculosis and tubercular patients with comorbidities like Diabetes Mellitus, Hypertension etc. are given special attention and nutritional care. The visit of attendants and relatives have been restricted or allowed for limited time with due permission. The supply of Anti Tubercular Drugs is being maintained. Hospital's DMC (Designated Microscopy Center) Laboratory is kept functional for diagnosis and management of Tuberculosis patients. Domiciliary Tuberculosis treatment is being encouraged. Those patients which are unable to visit hospital due to lockdown or restricted transportations are being closely monitored and managed telephonically. The use of mask and repeated hand washing with soap or alcohol based sanitizers is advocated to the patients and the relatives.

On the contrary we have seen a sharp fall in Tb cases in our hospital in last 2.5 months. The number of Tb have fallen less than half in month of March and April. The possible reasons could be – As the Covid19 cases spread from China to other parts of the world in later half of February and March, it made big news on media and social media and other platforms as well. This lead to the people becoming more aware regarding the coughing and hand hygiene. Practices like splitting/coughing in the public have reduced significantly. Social Distancing could play a major factor in decreasing the spread of Tb. Pan India lockdown might also have played a major role in breaking the chain of Tb transmission. Lack of transport could also be a reason. But to prove this extensive research needs to be undertaken on this with more data collection. Anything to comment regarding this would be too early.

Conclusion

Both Covid-19 and Tb are global pandemics, while one is a newer disease the other is centuries old. Both disease spread can be halted by proper cough hygiene, hand wash and proper isolation. Breaking the chain of transmission is important to stop the spread of both the diseases. Mortality related to Covid19 in Tuberculosis may be more as compared to normal individual. Domiciliary care in Tb may prove beneficial in management of Tuberculosis. Strengthened immune system and absence of co-morbid conditions like diabetes, hypertension leads to lesser complications and mortality. The factors like social distancing, hand hygiene,cough hygiene etc. which break the chain of transmission for Covid19, those factors might as well reduce Tuberculosis in the country but this needs further research and time.

Case Report on Acute Lymphatic Leukemia

Nilam Raut[1], Archana Mourya[2], Manoj Patil[3]

[1]M.Sc. Nursing Student, [2]Prof. of Child Health Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Datta Meghe Institute of Medical Sciences (Deemed to be University), Wardha, Maharashtra, India, [3]Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M),Wardha India

Abstract

Background: Leukemia are the most common cancer in children, the malignant neoplasms are the cancer of the blood or bone marrow produce blood cells. Leukemia can happens when there is a problem with the production of blood cells. About 30 to 40 percentage of childhood malignancies include leukemia. There is higher proportion of T- cells. Linkage. Acute lymphocytic leukemia ALL.

Case Presentation: The female patient 6yr old who was apparently admitted in AVBRH on date 16/09/2019. Patient has fever since 1 month of continuous fever spike with high grade fever, swelling over neck since one month and pain in the leg. Patient was diagnosed with Acute lymphatic leukemia one year back, was brought here with complaint of one complaint of one month of continuous fever, they checked for the complaint in two hospitals of Yawatmal, they referred to AVBRH for further management.

Investigations: Complete blood count, history and physical examination, complete blood count and differential count, peripheral smear examination and platelets count, bone marrow aspiration and Patient doesn't have surgical history. Patient was treated with tab prednisolone, Induction therapy,chemotherapy Nursing management: patient care was given according to patient complaint, Keep patient safe from falls at risk of weakness or paralysis. Provide pain management, protection from infection, check lab reports,

Conclusion: Patient was admitted to hospital for further treatment of acute lymphatic leukemia and he was admitted in AVBRH and got treatment and now the patient condition is satisfactory.

Keywords: *Acutelymphatic leukemia, ALL.*

Introduction

Leukemia are the most common cancer in children, the malignant neoplasma are the cancer of the blood or bone marrow produce blood cells. Leukemia can happens whenthere is a problem with the production of blood cells. Leukemia is one of the blood cancers which affect WBC of body. WBC are they playing a major role in our body like they acts as fighting mechanism and help the body from harmful foreign bodies.[1]

But in case of leukemia there will be the fighting mechanism are disturbed because the white blood cells it changes their ability to fight with infection and it changes into cancerous cells form in spongy tissues and bones.[2]

Incidence: About 30 to 40 percentage of childhood malignancies include leukemia. There is higher proportion of T- cells. Linkage.[3] Acutelymphatic Leukemia in children aged between 0 to 4 year with 7.55 and 3.32 cases per 100,000 patients in year for male and female child respectively[4,5].

Objective:

- To know general idea regarding disease condition
- To explore knowledge regarding surgical, medical and nursing management.

Present history: The female patient 6yr old who was admitted in AVBRH on date 16/09/2019 and she is known case of Acute lymphatic leukemia. Patient had

fever since 1 month of continuous fever spike with high grade fever, swelling over neck since one month and pain in the leg.

Past history: Patient was diagnosed with Acute lymphatic leukemia one year back, was brought here with complaint of one complaint of one month of continuous fever,they checked for the complaint in two hospitals of Yawatmal, they referred to AVBRH for further management

Birth History

Pre-Natal History

Nature of pregnancy- Normal

Nature of marriage – non consanguineous

History of drug and tobacco- Not present

Exposure to radiation-Not present

Tetanus toxoid vaccines - taken

Natal history

Type of delivery- normal vaginal delivery

Place of delivery- Home delivery

Birth Weight- 3kg

Post Natal History: A newborn baby born immediately and healthy. There was no complication and infection in both the child and the mother

Surgical history: There is no surgical management of acute lymphatic leukemia. In my patient doesn't have surgical history

Clinical findings: Fever, generalized body pain and headache was present

Investigations

Blood tests

- Total WBC Count was increased 11330/cu.mm
- Platelet count 0.25 lac/cm decreased
- Total RBC count 2.18 million decreased

Physical examination

Temperature**-100 0 C**

Pulse – 86beats/min

Respiration Rate **– 22breaths/min**

Bone marrow aspiration: Use to detect leukemia and the responses of treatment, reports not available

Management: Multidisciplinary health care team are involved in care of patient with Acute lymphatic leukemia

Patient complaints like:

- Pain in upper and lower limb
- Swelling
- Fever
- Headache
- Generalized body ache

The Treatment for Acute lymphatic leukemia patients is divided into four stages:

Induction Therapy: The goal of this phase is to eradicate leukemia such that at the end of this phase is L5 percentage leukemia blasts in the bone induction therapy with the regimen marrow induction therapy with the regimen

Chemotherapy: The aim of the chemotherapy to eradicate the malignant cell and restore the normal bonemarrow function

Maintenance Therapy: It is given for 2.5 to 3 yr with mercaptopurine and MTY method of upper recommended dose

Reinforcement therapy: It is provided to vincristine and prednisone every four week

CNS Prophylaxis: In case of CNS involvement triple therapy i.e. Methotrexate, hydrocortisone cytosine are administered once a week during induction and every 8 week for 2 yr

Supportive and symptomatic management

To prevent the complication like

- Infection
- Bleeding
- Anemia
- Pain

Intravenous Antibiotic therapy blood and platelets transfusion,bone marrow transplantation

- Multidisciplinary health care team
- Pediatrician

Prescription of medications

Tab. Prednisolone -40 mg- once in a day orally

Syrup Gelusil – 5ml/TDS

Nurses Responsibility

- Monitored vital signs closely
- Assessed the condition of patient location, onset and severity of pain
- Evaluate the therapy responses
- Monitored the weight of the patient
- Assessed motor strength
- Checked lab reports
- The platelets counts are low child was observed for hemorrhage
- Maintained oral hygiene
- Observed the episodes of convulsions
- Assessed in bone marrow aspiration
- Assessed radiation therapy

Dietician:

- Provide balanced meal
- Low fat dairy products they prescribe the patient
- Protein rich food
- Whole grains and legumes

Discussion

Case of female patient 6yr old who was apparently admitted in AVBRH on date 16/09/2019. Patient has fever since 1 month of continuous fever spike with high grade fever, swelling over neck since one month and pain in the leg . Patient was diagnosed with Acute lymphatic leukemia one year back, was brought here with complaint of one complaint of one month of continuous fever,they checked for the complaint in two hospitals of Yawatmal, they referred to AVBRH for further management there clinical signs of patient is fever, generalized body pain and headache was present undergone the diagnostic evaluation are complete blood count, history and physical examination, complete blood count and differential count, peripheral smear examination and platelets count, bone marrow aspiration . Patient doesn't have no present surgical history. Patient was treated with tab prednisolone, Induction therapy,chemotherapy Nursing management for acute lymphatic leukemia Monitor vital signs closely, Keep patient safe from falls at risk of weakness or paralysis. Provide pain management, protection from infection,check lab reports, observed the side effects of chemotherapy drugs, maintained oral hygiene, observed for convulsions, associated with bone marrow aspiration. Patient was admitted to hospital for further treatment of acute lymphatic leukemia and she was admitted in AVBRH and got treatment and now the patient condition is satisfactory.

The condition of patient was improved after giving the care by various multidisciplinary health care team and supportive management . Pain is slightly reduced as per evidence by patient verbalization, patients nutritional pattern is improved as per evidenced by her health condition.

The patienth as reduced the swelling, pain over leg and fever was reduced as giving all the management the symptoms of the patient reduced as verbalize by the patient and their parents. Now the patient condition is satisfactory.

A study by Deshpande et al reflects on biomarkers of human cancers 6. Khatib et al have focused on therapeutic options for cachexia in cancer patients.

Conclusions

If we provide proper care with the help of various multidisciplinary health team and there supportive management,it helps to improve the condition of the patient .Now the patient is conscious, alert improved his condition

Case Report on Thalassemia in Children

Laltanpuii[1], Archana Mourya[2], Manoj Patil[3]

[1]M.Sc. Nursing, [2]Professor, Department of Child Health Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Wardha, Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, [3]Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

Introduction: Thalassemia which is also called as Cooley's anemia or Mediterranean anemia is a group of hereditary hemolytic anemia characterized by reduction in the synthesis of hemoglobin. The word 'thalassemia' is derived from the Greek word 'Thalassa' which means the great sea.

Clinical Findings: Abdominal pain, fever (Temperature - 101°F), Anemia (Hb – 6.4gm%).

Diagnostic Evaluation: Blood test: Hb – 6.4gm%, Total RBC count – 2.3 millions/cu mm, RDW – 18.2%, HCT – 20.2%, Total WBC count – 3200/cu mm, Monocytes – 02%, Granulocytes – 20%, Lymphocytes – 77%, AST(SGOT) – 112 U/L.

Peripheral Smear: RBC – mild hypochromic with mild cytosis which show few microcytic and mildly hypochromic. Platelets – Reduced on smear, APC – 62,000 cells.

Ultrasonography: Splenomegaly.

Therapeutic Intervention: Blood transfusion, Inj. Cefotaxime 750mg IV x BD, Syr. Azee 4ml x OD, Tab. Folic Acid 5mg x OD, Tab. Udiliv 150mg x BD, Cap. Hydra 500mg x OD, Tab. Prednisolone 10mg x BD.

Outcome: After treatment, the child show improvement. His fever and abdominal pain were relieved and his Hb% increased from 6.4gm% to 11gm% after blood transfusion.

Conclusion: My patient was admitted to Pediatric Ward No – 14, AVBRH with a known case of Thalassemia and he had complaint of fever and abdominal pain. After getting appropriate treatment his condition was improved.

Keywords: *Thalassemia, Cooley's anemia, Mediterranean anemia, hereditary, hepatosplenomegaly.*

Introduction

Thalassemia produces hypochromic microcytic anemia due to defective hemoglobinization of RBCs, hemolysis and ineffective erythropoiesis. It can be considered as hemolytic and hypo - proliferative anemia related to abnormal hemoglobin.

It was first noticed in patients, originating from the littoral countries of the Mediterranean Sea. At present the disease has been found in several countries all over the world. The prevalence of the disease in India is high among Gujaratis, Sindhis and Punjabis. Millions of people are found to be carriers of thalassemia gene and every year thousands of thalassemic children are born in our country.[1]

Progressive pallor, anemia, fatigue or weakness, jaundice, hepatosplenomegaly, recurrent respiratory infection, failure to thrive, facial bone deformities are common symptoms of thalassemia.[2] Blood examination, Bone marrow study, Osmotic fragility test, radiological screening are common investigations done in thalassemia.[1]

Mild thalassemia might not be needed to be

treated but severe thalassemia required regular blood transfusions along with symptomatic treatment.[2]

Thalassemia is classified into three main types, the classification depends on the number of gene mutation and the part of hemoglobin molecules which are affected either alpha or beta.[3] The different types are: *Thalassemia major* – Here thalassemia genes (beta) are inherited from both the parents and it is associated with homozygous state. Synthesis of beta chain is markedly reduced. *Thalassemia intermedia*: It is a chronic hemolytic anemia caused by alpha or beta chain synthesis. It is also a homozygous form. *Thalassemia minor*: It is a mild form of illness and produced by heterozygosity of either alpha or beta chain.[1]

Management of thalassemia is mostly done by Repeated blood transfusion, iron chelation therapy, splenectomy, folic acid supplementation, bone marrow transplantation, gene therapy and gene mutation, supportive management.[1]

Patient Identification: A male child of 8years from Shirajgam admitted to pediatric ward no 14, AVBRH on 23rd January 2020 with a known case of Thalassemia major. He is 25kg and his height is 126cm.

Present medical history: A male child of 8 years old was brought to AVBRH on 23rd January 2020 by his parents with a complaint of abdominal pain (left hypochondriac region) and fever and he was admitted to Pediatric ward no 14. He is a known case of Thalassemia Major and his Hemoglobin level at the time of admission was 6.4gm%. The child is weak and inactive on admission.

Past medical history: My patient was diagnosed to have thalassemia at the age of 8 months when he was admitted to hospital due to fever. Till then, he was admitted to hospital time to time for the purpose of blood transfusion.

Family history: There are four members in the family. My patient was diagnosed to have Thalassemia major and his parents were diagnosed to be carrier of thalassemia. Type of marriage of the parents is non – consanguineous marriage. All other members of the family were not having complaints in their health except for my patient who was being admitted in the hospital.

Past interventions and outcome: My patient was diagnosed with thalassemia when he was 8 months old, from that time onwards he was admitted to hospital time to time for treatment of the disease mostly blood transfusion. It was found effective as the patient does not develop complications till then.

Clinical findings: Abdominal pain, fever (Temperature - 101˚F), Anemia (Hb – 6.4gm%)

Etiology: Thalassemia occurs when there is mutation or any abnormality in anyone of the gene which take part in producing hemoglobin. When there is genetic abnormality, it can be pass – on from parents to children. When only one of the parents is a carrier, there is chance of developing a mild form of thalassemia that is thalassemia minor where symptoms might not be seen but the person will be a carrier. When both the parents are carrier, there is a great chance of developing severe form of thalassemia like thalassemia major or thalassemia intermedia.[4]

Physical examination: There is not much abnormality found in head to toe examination, the child is lean and thin and having dull look. He is weak and not so cooperative. Though it is found that the child is having splenomegaly from ultrasonography, it is not palpable.

Diagnostic assessment: Blood test: Hb – 6.4gm%, Total RBC count – 2.3 millions/cumm, RDW – 18.2%, HCT – 20.2%, Total WBC count – 3200/cumm, Monocytes – 02%, Granulocytes – 20%, Lymphocytes – 77%, AST(SGOT) – 112 U/L. **Peripheral Smear**: RBC – mild hypochromic with mild cystosis which show few microcytic and mildly hypochromic. Platelets – Reduced on smear, APC – 62,000 cells. **Ultrasonography**: Splenomegaly.

Therapeutic Intervention: Blood transfusion, Inj. Cefotaxime 750mg IV x BD, Syr. Azee 4ml x OD, Tab. Folic Acid 5mg x OD, Tab. Udiliv 150mg x BD, Cap. Hydra 500mg x OD, Tab. Prednisolone 10mg x BD.

Discussion

A male child of 8 years old from Shirajgam was admitted to pediatric ward no 14, AVBRH on 23rd January 2020 with a complaint of abdominal pain, fever and Hb% less than normal limit. He is a known case of thalassemia major which was diagnosed when he was 8 months old. As soon as he was admitted to hospital investigations were done and appropriate treatment were started. After getting treatment, he shows great

improvement and the treatment was still going on till my last date of care.

A study was done on, "A clinico - epidemiological study of thalassemia cases in India". It was done to assess the clinical presentation and managements practices in thalassemia. For the study, patients case sheets were collected between 2005 - 2014 which is 10 years. These case sheets were being examined and recorded in a specially made proforma for the study. The result from the study were - a total of 183 cases are recorded and among those, 179 (97.8%) were beta thalassemia major, 3 (1.6%) were beta thalassemia intermedia and 1 (0.6%) was beta thalassemia minor. Most of the case were diagnosed at age of 1 year, and one fourth of the case were diagnosed in first 6 months. Fever present in 34 patients (18.6%), pallor found in 179 patients (97.8%), hepatomegaly seen in 172 patients (94%) and bone deformity found in 13 patients (7.1%). One third of the under five patients were found to be underweight and more than half of the patients were found to be stunted. Mean post - transfusion value of hemoglobin after 1 year of transfusion among cases was 10±1.6g%, 51 patients (27.9%) were given desferrioxamine as iron chelation therapy and the mean age of starting this therapy was 11.1±8.2 years. In 4 cases of beta thalassemia major splenectomy was done at a mean age of 10.7±4.8 years. On treatment of thalassemia with desferrioxamine lenticular opacity was found in greater proportion. The study concluded that among thalassemic patient different kinds of complications were found so it is important to involve different specialization in care of thalassemia patient to control the problems.[5] Baliga et al studied about the Malondialdehyde Levels in Serum and Saliva of Children Affected with Sickle Cell Anemia[6]. Jaiswal et al conducted a comparative study on peripapillary retinal nerve fiber layer thickness in patients with iron-deficiency anemia to normal population[7]. Garg et al studied about Dengue serotype-specific seroprevalence among 5- to 10-year-old children in India[8]. Puri et al [9] and Uddin et al [10] analyzed on infants and young child nutrition. Taksande et al reported on 3 cases of children with rare diseases[11]. Tendolkar et al reported about physical abuse of children whereas Khatib et al reviewed the effect of electronic media on children. All these studies have some aspects related to thalassemia, anemia and other nutritional disorders.

Conclusion

Thalassemia is one of the most common case found among children, its is very important to diagnose in early stage so that the child will not develop complications from the disease. It is also very important to take preventive measures like antenatal screening and giving genetic counseling are very important. My patient show great improvement after getting the treatment and the treatment was still going on till my last date of care.

Abstract

Introduction: Pregnancy specific complication characterised by hypertension, proteinuria, after 20 weeks of the gestation, and along with various signs of damage to organ systems, haemolysis, elevated levels of liver enzymes and low platelet count (HELLP syndrome) is collectively termed as eclampsia.

Method: Cross-sectional study with 3 groups of pregnant women, were taken followed by inclusion and exclusion criteria for characterisation. The study was approved by ethical board of DMIMSU. Minerals and their relationship were estimated using different method. Preeclamptic group with and without supplementation and pregnant women without preeclampsia were included in the study. Significant differences were seen in Na+, K+, Ca, Mg, Se, and Mn when compared with each group.

Result and Observation: The levels of K were increased significantly ($P < 0.001$) in pre-eclamptic group as compared to control group. There was significant change in levels of Mn when pre-eclamptic group was compared to control. Mn was also found to decrease significantly ($P < 0.001$) in cases as compared to control. However, the levels of Se, Mg, Ca and Na between cases and control were not highly significant. In supplementation and without supplementation group, Significant differences were seen in levels of Na, K, Ca and very significant difference was seen in levels of Mn. ($p<0.0001$).

Conclusion: Pre-eclamptic pregnant women have higher levels of serum potassium and our finding on Mn, an essential trace mineral, provides new insight into a potentially modifiable way to prevent preeclampsia. In multi-ethnic, predominantly urban and low-income pregnant women high level of Mn is associated with pre-eclampsia.

Keywords: *Mn, Na, K, Se, Ca and Preeclampsia.*

Introduction

Pregnancy specific complication characterised by hypertension, proteinuria, after 20 weeks of the gestation, and along with various signs of damage to organ systems, haemolysis, elevated levels of liver enzymes and low platelet count (HELLP syndrome) is collectively termed as eclampsia.[1]

Eclampsia is simply convulsions of pregnancy due to rise in blood pressure. Pre-eclampsia maybe seen before a eclampsia, condition where swelling can be seen on feet, face and urine usually consists proteins.[2]

WHO, recognise eclampsia as major cause of fetal and maternal morbidity and mortality.[3]

Prevalence of pre-eclampsia stands around 3 to 10% in world population. Whereas factor such as obesity, diabetes, calcium deficiency advanced maternal age, oxidative stress, placental ischaemia, genetic factors and immune maladaptation have been implicated. [4] In addition, the American heart association recently added preeclampsia as a risk factor for future cardiovascular diseases in women. [5]Also, modified lipid profile has a possible role in the development of endothelial dysfunction and preeclampsia expression. Early detection of such lipid parameters will benefit pregnant patients in preeclampsia by avoiding maternal and fetal complications, which can also enhance preeclampsia management.[6] Only low dose of aspirin maybe effective in preventing the pre-eclampsia here in women at high risk.[7]

Some of the evidences from various line for examples the essential mineral manganese (Mn) and Selenium (Se) toxic heavy metals such as cadmium, lead and mercury. These minerals have opposing roles in the development of the preeclampsia.[8-10] and for early detection of PE and eclampsia serum uric acid, serum creatinine and serum urea are better diagnostic and predictive marker. With the help of these parameters most cases are detected early in the pregnancy before they can progress to eclampsia.[11] Due to limited number of studies result on epidemiologic studies on Mn have varying results. Se in pregnancy, reduce oxidative stress and also improve preeclampsia features in rats. Although need of large-scale studies in human is required.[12-17]

Aims and Objectives: The present study was undertaken in the Department of Biochemistry and Dept. of OBGY at Jawaharlal Nehru Medical College, and AVBRH (Datta Meghe Institute of Medical Sciences) Sawangi, Meghe, Wardha, in collaboration with Datta Meghe Medical College and Shalinitai Meghe Hospital and Research Centre Hingana, Nagpur, Maharashtra India with the following aims and objectives: -

Aim of Study: To estimate role of minerals, in patients with pre-eclampsia.

Objectives of study:

1. To estimate sodium, potassium, magnesium, calcium, manganese and selenium in pregnant women with pre-eclampsia and eclampsia.

2. Find out correlation of sodium, potassium, magnesium, calcium, manganese and selenium in pre-eclampsia and compare with normal pregnant women.

Material and Method

Study Area: The present study was undertaken in the Department of Biochemistry of Jawaharlal Nehru Medical College, and AVBRH (Datta Meghe Institute of Medical Sciences) Sawangi, Meghe, Wardha in collaboration with Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur, Maharashtra India.

Study Population: 250 subjects were included in the study and were grouped as under.

Group 1: 100 pre-eclampsia diagnosed subjects without any mineral supplementation.

Group 2: 50 pre-eclampsia diagnosed subjects with mineral supplementation.

Group 3: 100 Normal pregnant women.

Study Type: Cross sectional interventional study

Data collected was entered into Microsoft Excel Worksheet and statistically analysed by using SPSS (Statistical Package for Social Sciences) version 20. For quantitative data mean, standard mean, standard deviation, t-test and Karl Pearson's Coefficient of Correlation were calculated. P value < 0.05 (0.01) will be considered as statically significant (highly significant) at 95% confidence interval. The proposed study was undertaken subject to approval by Institutional Ethical Committee.

Observations and Results

Table 1. Serum minerals levels in pregnant women with preeclampsia and norm tension.

Serum minerals	Group III	Group I	'P' Value
Potassium	4.38 ± 0.80	4.95±0.99	P<0.001
Sodium	140±1.12	139±1.95	p<0.01
Calcium	7.27±1.46	7.96±0.22	P<0.05
Magnesium	1.37±0.22	1.42±0.19	P<0.05
Manganese	0.13 ±0.077	0.072±0.068	P<0.001
Selenium	62.33±9.42	58.23±8.44	P<0.0014

Table no 1 showed the levels of serum trace elements in control and preeclamptic women are seen in table 1. Analysis of trace elements found that mean values of K, Na, Ca, Mg, Mn and Se were 4.38 ± 0.80, 140±1.12, 7.27±1.46, 1.37±0.22, 0.13 ±0.077 and 62.33±9.42. in control group and 4.95±0.99, 139±1.95, 7.96±0.22, 1.42±0.19, 0.072±0.068, and 58.23±8.44 women with pre-eclampsia respectively. The levels of K were increased significantly ($P < 0.001$) in pre-eclamptic group as compared to control group.

There was significant change in levels of Mn when pre-eclamptic group was compared to control. Mn was also found to decrease significantly ($P < 0.001$) in cases as compared to control. However, the levels of Se, Mg, Ca and Na between cases and control were not highly significant.

Table 2. Serum minerals level in pregnant women with preeclampsia and eclampsia without and with supplementation.

Serum minerals	Group I	Group II	'P' Value
Potassium	4.95±0.99	4.23±0.98	P<0.001
Sodium	139±1.95	141±1.40	P<0.001
Calcium	7.96±0.22	8.53±0.21	P<0.001
Magnesium	1.42±0.19	1.39±0.21	P<0.3803
Manganese	0.072±0.068	0.131±0.058	P<0.0001
Selenium	58.23±8.44	60.48±7.63	P<0.1144

Table no 2 showed the levels of serum minerals in cases with pre- eclampsia with and without any supplementation are depicted in table 2. On the analysis of serum minerals among patients with pre-eclampsia without supplementation the levels for K, Na, Ca, Mg, Mn and Se were 4.95±0.99, 139±1.95, 7.96±0.22, 1.42±0.19, 0.072±0.068 and 58.23±8.44 respectively. And the levels for K, Na, Ca, Mg, Mn and Se in patients with supplementation were 4.23±0.98, 141±1.40, 8.53±0.21, 1.39±0.21, 0.131±0.058 and 60.48±7.63 respectively. Significant differences were seen in levels of Na, K, Ca and very significant difference was seen in levels of Mn. (p<0.0001).

Table no 3 showed the levels of serum minerals in cases of pre- eclampsia with supplementation and normal pregnant women are depicted in table 2. On the analysis of serum minerals among patients of pre-eclampsia with supplementation the concentration of K, Na, Ca, Mg, Mn and Se were 4.23±0.98, 141±1.40, 8.53±0.21, 1.39±0.21, 0.131±0.058 and 60.48±7.63. In normal

pregnant the concentration of K, Na, Ca, Mg, Mn and Se were 4.38 ±0.80, 140±1.12, 7.27±1.46, 1.37±0.22, 0.13 ±0.077 and 62.33±9.42 respectively.

Table 3. Serum minerals level in pregnant women with preeclampsia and eclampsia without and with supplementation.

Serum minerals	Group II	Group III	'P' Value
Potassium	4.23±0.98	4.38 ± 0.80	P < 0.3177
Sodium	141±1.40	140±1.12	P < 0.0001
Calcium	8.53±0.21	7.27±1.46	P < 0.0001
Magnesium	1.39±0.21	1.37±0.22	P < 0.5950
Manganese	0.131±0.058	0.13 ±0.077	P < 0.9355
Selenium	60.48±7.63	62.33±9.42	P < 0.2303

No Significant differences were seen in levels of K, Mg, Mn and Se (P < 0.3177, P < 0.5950, P < 0.9355 and P < 0.2303) respectively, but in levels of Na and Ca significant difference was seen. (p<0.0001).

Discussion

Calcium as well as magnesium are very important for metabolism at the cellular level and are mandatory for muscle contraction, also for neuronal activity making it very essential in pregnancy[18,19]. **Mitchell et. al (1990)**discovered that eclampsia was in arrears to maternal deficiency in calcium through foetal absorption and held that good results were achieved by calcium administration. He stated that the hypocalcaemia of eclamptic patients led to an accumulation of fat in the liver and therefore impairment of its function resulting into sudden attacks[20]. **Knight and Keith (1992)** studied calcium supplementation on normotensive and hypertensive pregnant women. A significant inverse relationship was observed between dietary calcium intake and blood pressure[21]. **Jama (1997)** observed that pre-eclampsia still remains a dangerous entity with an elusive pathogenesis and causes significant morbidity in both, the mother and foetus[22]. It has been found that women on a high calcium diet have a low incidence of pre-eclampsia. It is also known that pre-eclamptic women have reduced urinary excretion of calcium, so there is an inverse relationship between the dietary consumption of calcium and events of eclampsia. **Walker (2000)** stated that calcium supplements lower the risk of pre-eclampsia and eclampsia because calcium is required for maintaining tone of muscles[23].

Present study finding showed no change in serum sodium levels in preeclamptic as compared to normotensive pregnancies. It also showed that serum magnesium level was significantly depleted in mothers with pre-eclampsia as compared to healthy control group. This finding suggests that hypomagnesemia may be one of the aetiologies of preeclampsia.

Serum Potassium levels were highly significantly increased in preeclamptic pregnant women as compared to normal. These findings are in close conformity with the findings of **Agyei Frampong et al**[24] who demonstrated that there was only slight correlation between the plasma sodium levels and diastolic blood pressure with no significant difference between normotensive and pre-eclamptic subjects. Serum potassium levels however, showed a highly significant increase in pre-eclamptic women. These results were consistent with earlier study by **Handwerker et al**[25] where the study group had significantly higher levels of serum potassium than control group. Normal pregnancy has been associated with a decrease in mean serum potassium possibly related to a physiologic increase in Na+/K+ adenosine triphosphatase activity in the cell membranes, causing a shift of K+ into cells with extrusion of Na+.

Seydoux J et al. study concludes that serummagnesium leveldecreases with progress in pregnancy.[26] These results are were consistent with earlier study by **Seydouse et al, Handworker et al and Zhao F**[27-28] where the study group has lower serum magnesium than control group.Our study on preeclamptic women with and without supplementation shows remarkable differences in calcium levels p<0.001.

Thus, our findings of higher extracellular K+ levels in toxaemia may be of interest and our study also concludes that minerals supplementation also decreases K+ levels in preeclamptic women after supplementation.

Furthermore, in a prospective cohort study of 620 pregnant women in Iran, **Goodarzi Khoigani et al**[29] reported that Mn intake in the third trimester, estimated using 48-hour dietary recalls, was significantly lower among women who developed preeclampsia compared with those who did not. In contrast, in a case–control study of 396 participants (31 preeclampsia cases) in Iran, **Vigeh et al**[30] reported that Mn concentration in umbilical cord blood, but not maternal blood, was associated with higher odds of preeclampsia after adjustment.

Conclusion

In the light of the above interpretations it can be determined that pre-eclamptic pregnant women have **higher levels of serum potassium**, **decreased level of serum calcium** and **magnesium** and **no significant difference in sodium** levels as compared to normotensive pregnant women in their pregnancy during third trimester.

Our finding on Mn, an essential trace mineral, provides new insight into a potentially modifiable way to prevent preeclampsia. In multi-ethnic, predominantly urban and low-income pregnant women high level of **Mn is associated with pre-eclampsia**. Our study also concluded thatserum **Se have no contribution in pre-eclampsia** and eclampsia.

Moreover, study of serum lipid profile in pre-eclampsia showed by **Shreya Yadav et. al**.[6]with our study helpful to early detection and used in better management of preeclampsia which is important to improve the maternal and fetal outcome. Further research with information on characteristic features of preeclampsia (such as severity of blood pressure and proteinuria) and clinical subtypes of preeclampsia (e.g. early-onset versus late-onset) is needed to elucidate the potential heterogeneity of mechanisms that are responsible for the effect of trace minerals.

Abstract

Introduction: Preeclampsia is a multifactorial pregnancy-specific disorder which is symbolized by the development of hypertension and proteinuria after 20 weeks of gestation. With the greatest morbidity and mortality, preeclampsia affects 5% to 7% of all pregnant women.

Material And Method: 390 subjects were included in the study and were grouped.

Results: Mean maternal age of cases in years was observed as 26.68±4.2, mean gestational age in weeks was 36.2. Systolic and diastolic BP in mmHg was 159.4 and 104.8 respectively. Mean weight was observed as 72.6 Kg and Height was 158.4 cm. There was statically significant correlation observed between vitamins in Group I and Group II, but Vitamin E and Vit B 12 does not show any significant correlation between them. No Stastical significance were found in the vitamins level in Group III and Group II. Statistically significant difference was observed between group I and Group III, for vitamin B12, vitamin D, vitamin C and vitamin A. No statistical significance difference was observed in vitamin E levels.

Conclusion: The intended intervention of Vitamins has a protective effect against recurrent preeclampsia. Vitamins supplementation therapy in pregnancy could help in reducing the incidence of gestational hypertension/preeclampsia.

Keywords: *Pre-eclampsia, eclampsia, Vit B12, VitA, Vit C, Vit D and Vit E.*

Introduction

Eclampsia is a serious disorder affecting women during pregnancy. Early symptoms are known as pre-eclampsia, which further develop to eclampsia and can land up in complications during pregnancy. Thus, eclampsia requires immediate medical treatment. Most cases are detected early in the pregnancy before developing eclampsia.[1]

Preeclampsia is a multifactorial pregnancy-specific disorder which is symbolized by the development of hypertension and proteinuria after 20 weeks of gestation.[2] Hypertensive disorders is a common complication of pregnancy that put women and their foetuses at disproportionate risk for further complications, as well as life-long sequelae.[3]

PE is a very notable disease which complicates from 2% to 5% of pregnancies in Europe and America and can reach up to 10% of pregnancies in developing countries, mainly due to the lack of incompetence of emergency care. [3] According to the WHO its incidence is seven times higher in developing countries (2.8% of live births) than in developed countries (0.4%).[4] PE is associated with an increased risk of placental abruption, preterm birth, foetal intrauterine growth restriction (IUGR), acute renal failure, cerebrovascular and cardiovascular complications, disseminated intravascular coagulation, and maternal death.[5]

With the greatest morbidity and mortality, preeclampsia affects 5% to 7% of all pregnant women but it is responsible for over 70 000 maternal deaths and 500 000 fetal deaths worldwide every year. [6]

Preeclampsia progresses in 2 stages:

A. Abnormal placentation early in the first trimester followed by

B. Maternal syndrome in the subsequentially second and third trimesters characterized by an excess of antiangiogenic factors.[7]

The end stage of pre-eclampsia is eclampsia which is defined by generalized seizures, with or without raised blood pressure and proteinuria, occurring during or after pregnancy with or without other identifiable cause. The cause is usually multifactorial including cerebral vasoconstriction, ischemia, vasogenicedema, or other pathology. In the first stage, abnormal placentation and deficient spiral artery remodeling leads to placental ischemia. Placental ischemia in turn influence on the clinical manifestations of preeclampsia, including the development of hypertension and proteinuria. Although eclampsia occurs mostly in women with severe pre-eclampsia, there is no convincing test for predicting its onset.[8-11]

Aim: Correlation of Vitamins levels before and after supplementation in pre-eclampsia

Objective: To determine serum vitamin A, C, D, E, B12 levels in pregnant women attending maternity clinic at AVBRH Wardha and SMHRC Nagpur.

Material and Method

The present Study was carried out in the Department of Biochemistry and Dept. of OBGY at Datta Meghe Medical College, Shalinitai Meghe Hospital & Research Centre, Nagpur in collaboration with Jawaharlal Nehru Medical College and AVBRH (Datta Meghe Institute of Medical Sciences), Sawangi (Meghe) Wardha Maharashtra.

Study Population: 390 subjects were included in the study and were grouped as under.

Group 1: 90 pre-eclampsia diagnosed subjects without any supplementation.

Group 2: 90 pre-eclampsia diagnosed subjects with supplementation.

Group 3: 210 Normal pregnant women.

Study Type: Cross sectional interventional study

Statistical Analysis: All estimated results were expressed as mean±SD. Mean values will be assessed for significance by unpaired student –t test. A statistical analysis will be performed using the Statistical Package for the Social Science program (SPSS, 24.0). Frequencies and percentages will be used for the categorical measures. Probability values $p < 0.05$ will be considered statistically significant.

Observation and Results

Table 1: Baseline Characteristics

Variables	Cases (n=90)
Maternal Age (years)	26.68±4.2
Gestational Age (weeks)	36.2
Systolic BP(mmHg)	159.4
Diastolic BP (mmHg)	104.8
Weight(Kg)	72.6
Height (cm)	158.4

Table no. 1 shows that mean maternal age of cases in years was observed as 26.68±4.2, mean gestational age in weeks was 36.2. Systolic and diastolic BP in mmHg was 159.4 and 104.8 respectively. Mean weight was observed as 72.6 Kg and Height was 158.4 cm.

Table 2: Levels of Vitamins before and After Supplementation.

Vitamins	Group I Mean±SD (n=90)	Group II Mean±SD (n=90)	Group III Mean±SD (n=210)
Vitamin B12	149±40.09	195.67±104.34	264.4±269.57
Vitamin D	10.73±3.46	12.43±4.43	14.67±17.82
Vitamin A	0.325±0.143	0.63±1.10	0.92±2.144
Vitamin E	5.44±7.725	5.7±7.80	6.49±9.13
Vitamin C	0.38±0.172	0.53±0.531	0.77±1.63

Table no 2 shows the mean values in Group I, Group II and Group III of Vit B 12, Vit D, Vit A, Vit E and Vit C were (149±40.09, 195.67±104.34, 264.4±269.57), (10.73±3.46, 12.43±4.43, 14.67±17.82), (0.325±0.143, 0.63±1.10, 0.92±2.144), (5.44±7.725, 5.7±7.80, 6.49±9.13), (0.38±0.172, 0.53±0.531, 0.77±1.63) respectively.

Table 3: Correlation of Vitamins levels in pre-eclamptic and after supplementation.

Vitamins	Group I	Group II	t-value	p-value
Vitamin B12	149±40.09	195.67±104.34	-3.93	0.50
Vitamin D	10.73±3.46	12.43±4.43	-2.84	0.0024
Vitamin A	0.325±0.143	0.63±1.10	-2.73	0.0034
Vitamin E	5.44±7.725	5.7±7.80	-0.27	0.390
Vitamin C	0.38±0.172	0.53±0.531	-2.81	0.002

P value <0.05 Significant

Table no 3 shows there was statically significant correlation observed between vitamins in Group I and Group II, but Vitamin E and Vit B 12 does not show any significant correlation between them.

Table 4: Correlation of Vitamins levels in normal with supplementation.

Vitamins	Group III	Group II	t-value	p-value
Vitamin B12	264.4±269.57	195.67±104.34	-2.343	0.0198
Vitamin D	14.67±17.82	12.43±4.43	-1.176	0.2405
Vitamin A	0.92±2.144	0.63±1.10	-1.780	0.0716
Vitamin E	6.49±9.13	5.7±7.80	-0.716	0.4744
Vitamin C	0.77±1.63	0.53±0.531	-1.365	0.1733

P value <0.05 Significant

Table no 4 shows no Stastical significance were found in the vitamins level in Group III and Group II.

Table 5: Correlation of Vitamins levels inpre-eclamptic with normal.

Vitamins	Group I	Group III	t-value	p-value
Vitamin B12	149±40.09	264.4±269.57	-4.038	0.001
Vitamin D	10.73±3.46	14.67±17.82	-2.079	0.0385
Vitamin A	0.325±0.143	0.92±2.144	-2.628	0.0090
Vitamin E	5.44±7.725	6.49±9.13	-0.954	0.3408
Vitamin C	0.38±0.172	0.77±1.63	-2.262	0.0244

P value <0.05 Significant

Above table no 5 shows that statistically significant difference was observed between group I and Group III, for vitamin B12, vitamin D, vitamin C and vitamin A. No statistical significance difference was observed in vitamin E levels.

Discussion

The prevalence of PE has been reported to be 5-7% of all pregnancies, mainly due to the lack of or inadequacy of emergency care. PE is associated with an increased risk of placental abruption, preterm birth, foetal intrauterine growth restriction (IUGR), acute renal failure, cerebrovascular and cardiovascular complications, disseminated intravascular coagulation, and maternal death. PE is a leading cause of maternal mortality it affects both mother's and foetuses health during pregnancy.[12-16] Epidemiological research suggested that preeclampsia has a multifaceted etiology that includes an immunogenetic component [17].Established risk factors include nulliparity, family history of preeclampsia–eclampsia, and preeclampsia in a previous pregnancy, obesity, increased insulin resistance, hyperlipidemia, multiple gestation, molar pregnancy. Protective factors include a prior completed pregnancy and a terminated pregnancy for women conceiving again with the same partner [18-21], therefore, PE prevention is highly crucial. Several factors may increase homocysteine levels in women with preeclampsia. Metabolism in the kidney is the major route by which homocysteine is cleared from plasma and this route of elimination may be affected by pre eclamptic changes in the kidney.[22] Similarly, in a systematic review by Mignini et al., folic acid and vitamin B12 concentrations were lower in pre eclamptic women when compared with those of normotensive women.[23] From early pregnancy placenta assumes a state of oxidative stress arising from increased placental mitochondrial activity and leads to the production of reactive oxygen species (ROS), mainly superoxide anion.[24,25] In preeclampsia, an increased level of oxidative stress is seen. The source had been allocated to the placenta, where free radical synthesis occurs, with maternal leukocytes and the maternal endothelium likely contributors. [26,27] The superoxide–producing enzyme NADPH oxidase, shown to be present in placental trophoblast. Women with early onset of preeclampsia have been found to have increased superoxide production compared with those with late-onset disease.[21] However, clinical trials of antioxidant therapy with vitamins C (1000 mg) and E (400 IU) have been dismayed and were associated with an increased number of low–birth weight babies in the treatment.[28] So in this study we are trying to see the role of Vitamin in PE, as preeclampsia remains a challenge to diagnose. Therefore, the ability to provide an early diagnosis of PE is vital for health of both mother and fetus. A study conducted by **A. P. Mackay, C. J. Berg et. Al**[6] studied that Mortality from preeclampsia and eclampsia increased with increasing maternal age. A study conducted by **Azami M, Azadi T, Farhang S et. al**[7] studied that the incidence of preeclampsia in group A was significantly lower than the control group (p=0.03), while there was no significant difference between group B and controls (p=0.50), as well as groups A and B (p=0.063). The incidence of neonatal complications in the group A was significantly lower than the control group (p=0.01), while there was no significant difference between group B and control (p=0.48). The present study concluded that multimineral and vitamin D during pregnancy can be a low-cost and affordable way to reduce the incidence of preeclampsia in women who are at high risk of preeclampsia. A study done by **Rudra P, Basak S, Patil D, Latoo MY**[8] concluded that out of 8,524 deliveries, 104 cases of pre-eclampsia were documented giving an overall prevalence of 1.2%. The prevalence in 2009, 2010, and 2011 was 0.7%, 1.2%, and 1.5%, respectively. Fifty-nine case notes were available for analysis (56.7% retrieval). The mean age of the patients was 27 ± 4.9 and majority; 25 (42.4%) were in the age group 25-29 years. The mean parity was 1.1 ± 1.4 and 26 (44.1%) were nulliparous. 11 (18.6%) had family history of hypertension, 2 (3.4%) had personal history of hypertension, and 2 (3.4%) had a personal history of pre-eclampsia. The slight increase in the prevalence rate over the years underscores the need for close surveillance. A study done in 2016 by **Hariharan N, Shoemaker A, Wagner S**[9] concluded that preeclampsia remains a complex disease process with multiple components intertwined in its development including angiogenic and endothelial dysfunction. A study done by **Mayrink J, Costa ML, Cecatti JG**[10] figured that preeclampsia is still one of the main causes of death and severe maternal morbidity. A case control study was carried out in the Neonatal Division, JNMCH, in 2018 by **Prasad D, Smita KS, Nisha S**.[19] In the study 208 mothers were divided into two groups with newborns birth weight <2.5 kg (cases) and 2.5 kg or more (controls). Maternal vitamin D levels were estimated. Maternal vitamin D statuses of both groups were compared. Study done by **Raijmakers MT, Dechend R, Poston L**[20] concluded that Preeclampsia remains a frequent

and potentially dangerous complication of pregnancy. A study done by **Bastos Maia S, Rolland Souza AS et. Al**[21] concluded that adequate levels of vitamin A during pregnancy are of critical importance for the health of pregnant women and their fetuses. Study done by **Mujawar SA, Patil VW, Daver RG**[22] evaluated the occurrence of association between homocysteine, folic acid and vitamin B_{12} in patients with preeclampsia. A study conducted by **Mignini L, Latthe P et. al**[23] concluded that Homocysteine concentrations are slightly increased in normotensive pregnancies that later develop preeclampsia and are considerably increased once preeclampsia is established, because of a lack of consistency in data, dose-response relationship, and biologic plausibility, the observed association cannot be considered causal from the current literature.

Conclusion

Our study findings suggest that levels of Vitamins are altered in Pre-eclampsia patients. Maternal vitamins deficiency can lead to serious complications. Supplementation with vitamin C and E may be helpful in reducing the risk of preeclampsia. The intended intervention of Vitamins has a protective effect against recurrent preeclampsia. Vitamins supplementation therapy in pregnancy could help in reducing the incidence of gestational hypertension/preeclampsia.

Prevalence of Depression in College Students During Covid-19 Pandemic

Samiksha Sathe[1], Kirti Thodge[2], Abhishek Joshi[3]

[1]Assistant Professor, Department of Musculoskelatal Physiotherapy Datta Meghe College of Physiotherapy, Nagpur, [2]MPT Cardiovascular and Respiratory Physiotherapist, [3]Associate Professor Dept. of Community Medicine Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe) Wardha

Abstract

The outbreak of Covid-19 has caused major amount of suffering around the globe. Along with the physical symptoms in affected cases, it has severely spoilt the mental health of general public. College students too are facing multiple challenges in the stir of this COVID-19 outbreak. The present research is an attempt to assess the prevalence of depression among students residing in Nagpur region. A total 433 students responded to the online 9-item questionnaire (PHQ 9) based survey. Our survey showed that 96% of college students were affected with varied levels (minimal to severe) of depression resulting from the COVID-19 pandemic. of these, about 9% experienced severe depression, about 13% experienced moderately severe depression, about 21% experienced moderate depression, about 29% experienced mild depression and about 23% experienced minimal depression. It is suggested that a timely concern should be given to students' psychological health as they are flagbearers of country's success and future.

Keywords: *Covid-19, questionnaire, psychological health, Depression, mental burden.*

Introduction

Covid-19 believed to be originated from Wuhan, China has spread worldwide, with high mortality rate.[1] At present, the situation has turned troublesome as medicine or vaccines are yet to be available for Covid-19.[2] In order to restrain the spread of the virus a lockdown has been imposed in many provinces worldwide.[3] Residents have been strictly advised to obey the instructions of maintaining physical distance, using hand sanitizers and mask.[4] As a result along with a risk to life, mental burden has also increased.[5]

India has similar scenario, when it comes to there strains of lockdown.[6] Studies have shown increased mental burden in the form of fear, anxiety, stress and depression in the times of epidemic[8] and COVID 19 being a pandemic may definitely have a larger impact. Thus along with evident physical symptoms, mental health has also been affected. Stress may be put into words as an emotional feeling raising from any occurrence that seems to be hazardous to our daily life or routine.[9] On the other side of the coin, anxiety is the fear of the untold[10] whereas lack of concern in daily activities is considered as Depression. It is inferred that people fronting a pandemic without a vaccination or assured drug would have anxiety and psychological affection. Evidently, during pandemics such as SARS mental health issues (stress, depression, and anxiety) had raised.[11] Moreover, the World Health Organization has also delivered certain guidelines regarding psychological concern that may ascend during this Covid-19 pandemic.[3] In India, the present lockdown has affected people with regards to their gender, profession, physical health, socioeconomic status and their place of residence[3] Various reports of people emptying malls and supermarkets and panic purchases indicates anxiety in times of this crisis.[12]

Methodology

The study was conducted on students in various colleges across the Nagpur region. Students from various courses viz. Engineering, Medical Sciences, Arts and Commerce, were invited to take part in the study. The survey was conducted by creating and circulating a Google form questionnaire link on various online stages. The respondents were sampled by virtual snowball sampling technique. The survey took approximately 5-10 minutes to complete and remained open for 8 days. The questionnaire was kept anonymous, thus ensuring the privacy and reliability of the information.

Total 433 participants completing the online questionnaire were incorporated in the study. By clicking on the link provided, the participants were first informed about the nature, purpose and confidentiality of survey. After approving the consent to participate in the survey, they were directed to the next page of the survey. The first section of the survey comprised of the demographic data (Name, Age, and Gender) and name of college and course.

The second section of the survey consisted of Patient Health Questionnaire 9 (PHQ-9). The Patient Health Questionnaire (PHQ) is a tool widely used to diagnose depression and other mental disorders. PHQ-9 consist of the actual nine items or symptoms which forms the basis for DSM-IV depressive disorders diagnosis.[13] It is a self-administered questionnaire consisting of total 9 items that enquired the frequency of symptoms experienced by the participant during the previous 2 weeks. Respondents reported their symptoms as 0- Not at all, 1-Several days, 2-More than half the days, 3- Nearly every day. The total score ranged from 0 to 27 points. Among adults, PHQ-9 score have been used for grading the severity for depression as: a score 1-4: Minimal depression, 5-9: Mild depression, 10-14: Moderate depression, 15-19: moderately severe depression, 20-27: severe depression. In adult population, PHQ-9 is found to have high sensitivity (73%) and high specificity (98%) in diagnosing major depression. Also, The PHQ-9 is a dual-use instrument that, with its 9 items, can diagnose a depressive disorder and also grade its severity.[14]

Results

A total of 433 responses were received throughout the study duration through the online questionnaire survey.

Table 1: Demographic data of the students

Mean age of students (in years)	Male participants	Female Participants
20 ± 2	121	242

The above table shows the age gender distribution across the study population. The mean age of participants was 18–22 years. Among the 433 students, 121 were male and 242 were female.

Table 2: Distribution of severity grade of depression according to PHQ 9

Depression Severity grade	Total Number of Students
No depression (0)	17
Minimal depression (1-4)	102
Mild depression (5-9)	127
Moderate depression(10-14)	90
Moderately severe depression (15-19)	58
Severe depression (20-27)	39

The above table shows that 17 (4%) students were found to have no depression, 102 (24%) had minimal depression, 127 (29%) were categorised as having mild depression, 90 (21%) students have moderate depression, 58 (13%) had moderately severe depression and 39 (9%) had severe depression.

Table 3: Distribution of students with severe depression among different courses.

Name of course	Number of students with severe depression	Percentage of students with severe depression
Engineering	24	9.4 %
Medical Sciences	11	9.8 %
Arts and Commerce	4	6%

The above table shows that approximately 9% of the engineering students, approximately 10% of the medical sciences students and 6% of arts and sciences students were suffering from severe depression when assessed on PHQ 9.

Table 4: Percentage of severe depression among male and female students.

Gender	Percentage of students with severe depression
Male	9.04 %
Female	9.09 %

The above table shows that 9.04% of male students and 9.09% of female students suffered from severe depression when assessed on PHQ 9

Discussion

The present research intended to inspect the levels of psychological suffering in the form of depression in college students during this pandemic. Depression is one of the most prevalent diseases worldwide and a chief factor in problems of mental health[15] Researchers suggest that global health emergencies can have many psychological effects in the form of mental distress on college students, expressed in the form of anxiety, fear, worry and depression **[16]**An Indian study showed that about 33.2% respondents of the online survey had significant psychological impact regarding COVID-19.[15]

Our survey showed that 96% of college students were suffering from depression because of the corona virus outbreak. of the total students, about 9% experienced severe depression, about 13% experienced moderately severe depression, about 21% experienced moderate depression, about 29% experienced mild depression and about 23% experienced minimal depression. In our study we also found that medical college students were slightly more depressed (psychologically distressed) as compared to engineering college students. Our findings are in line with various other studies showing similar results. A study done to compare psychological strain, depression and anxiety among medical and engineering students showed that overall prevalence of stress, anxiety & depression was higher among medical college students in comparison with engineering college students.**[17]** Also females were found to be more severely depressed as compared to males. A number of studies linking university students, stress, and gender [18-19] noted that female students had higher levels of depression than male students [20-21] A study done by Anbumalar C showing gender differences in perceived stress level revealed females reporting higher feeling of anxiety and depression as compared to males.[22-25]

Also Cornine et al intheir study have stated that depression among college students during this pandemic might be in relation with the effect of corona virus on studies and uncertainty of future jobs or employment.[16,26] Unavailability of educational resources such as online network, cell phones and laptops may also lead to stress and anxiety. In addition, owing to technological issues online learning may be troublesome.**[16]** Getting acquainted with fluent use of them may require some time as well, leading to unconscious fear and stress. A recent study exploring the blow of COVID 19 on undergraduate education and welfare showed that approximately one fourth of their samples reported experiencing psychological distress, certainlycorrelating with raised apprehension about academic interruptions and delays, economic out turn and aftermath of the pandemic. **[16]**

In addition, a rise of psychiatric symptoms and of mental health problems is expected in the general population.[27] Common responses representing eminent risk factors for several mental disorders particularly, frustration, loneliness, and worries about the future are evident.[28] Hawryluck et al. studied 129 quarantined persons during previous epidemic revealing high prevalence of psychological distress. Symptoms of depression were found in 31.2% study population. Longer duration of quarantine was more associated with more symptoms[29]

Also the detrimental impact of quarantine and physical distancing on the mental health has been studied in the current pandemic. Qiu et al. in their study found that slightly more than one third of the study population experienced psychological distress, particularly women and individuals aged between 18 and 30 years. The same could be one of the reasons of students' anxiety & depression. It has been identified that the absence of interpersonal communication may trigger and worsen anxiety disorders.

Loneliness and mental health are evidently associated the strongest association being with depression. Adding to the straight effects of imposed separation and quarantine, loneliness as an unintentional consequence of outbreak has become troublesome for youth. Cutting off from others and feeling debarred may result in affective depression.

Furthermore, some previous studies have shown, not living with parents or living away from parents is linked with emotional and psychological distress. Due

to lockdown many students could not reach their native places and had to live away from their family leading to psychological stress. Friends or relatives being diseased with corona virusis considered as an independent predisposing factor of anxiety in collegiate, which might be in relation to the soaring infectiousness of the new coronavirus pneumonia

Additionally, the financial stability of family may also be a notable factor of psychological affection during this crisis. Some studies have indicated that the financial system of the country and residents will be significantly swayed in addition to the health crisis. Because of the spread of the virus and subsequent lockdown, some families may have lost their job or employment, and students might be worried about paying their coaching charges.[16]

Conclusion

COVID-19 crisis has given rise to a lot of ambiguity in the students' lives and its convoying effects will continue affecting college students' mental health and wellbeing profoundly. Many studies have shown that there are significant adverse effect of epidemics and pandemics on the psychological health of collegiate. The main aim of our survey was to explore levels of depression in the college students of Nagpur region. About 9% college students are suffering from severe depression because of this COVID-19 outbreak. The research outcomes direct that students need superior attention because of the higher psychological distress. As students represent tomorrow's future, it is recommended that the college authorities and parents should team up to solve this problem in order to provide finest psychological services to college students.

Abstract

Background: Induction of labour is a very common in obstetrics, for that both mechanical and pharmacological method used for induction. Mechanical Foley's with misoprostol is an effective method to cut out course of labour in safe timely manner, for safe neonatal and maternal outcome.

Aims and Objective: The aim of this study was to compare combination of transcervical Misoprostol with Foley's catheter balloon to misoprostol alone for induction of labour and cervical ripening in uncomplicated pregnancy, with regards to safety and effectiveness.

Result: A prospective, randomized controlled study was conducted on 220 term singleton women admitted in our hospital for induction of labour were randomly allocated to Group 1 (combination of Foley's and misoprostol) and Group 2 means (misoprostol) each 110. Combination of Foley's and vaginal misoprostol was much more effective in nulliparous female than multiparous women. Induction delivery interval was shorter in combination group;14.4±5.70 hours than misoprostol group; 17.1±5.62 hours; p value is 0.007.

Conclusion: This study showed that the use of misoprostol with a trans cervical Foley's is an effective method to shorten the course of labour compared with misoprostol alone. This study suggest that combination may be useful to achieve safe and timely delivery in unripe cervix.

Keywords: *Transcervical Foley's, Misoprostol, LSCS, Induction.*

Introduction

The incidence of labour induction has continued to rise over the past decades. The World Health Organization Global Survey on Maternal and Perinatal Health, conducted in 24 countries which included nearly 3, 00,000 observations, showed that 9.6% of them were delivered by labour induction.(1) Mostly labour starts spontaneously near term, but in high risk antenatalcases, labour induction is often required. There are many method of IOL such as mechanical, surgical, pharmacological (prostaglandins (PG) E1 and E2, oxytocin, relaxin) and combined method. Previously for induction of labour, mechanical method were used for dilatation of cervix as well as cervical ripening in women with unfavourable cervix. At term, Osmotic dilators are effective, but they are associated with an increase in maternal infection.(2,3)

Induction of labour is a common obstetric procedure;it is defined as the stimulation of uterine contractions during pregnancy before initiation of labour before its spontaneous onset for the purpose of delivery of the foeto-placental, which ultimately aims at achieving vaginal delivery depends on the Bishop's score at the time of induction.(4) The patients with a poor Bishop's score have unacceptably higher rates of failure of induction.(5)

Mechanical cervical dilatation is an old method that was used routinely.(6) Transcervical Foley's catheter balloon found to be effective and a safe method for unripe cervix. Mechanical method leads to separation of membrane from lower uterine segment, leads to release of lytic enzymes which stimulating the production of prostaglandins.(7) Misoprostol is a prostaglandian E1 analogue (methyl- 11a 16 - dihydroxy- 16 methyl- 9-oxoprost- 13 enloate), it has uterotonic and cervical ripening action. It is widely used for termination of pregnancy, management of incomplete abortions, induction and augmentation of labour and treatment of postpartum haemorrhage.(8) It is used by sublingual, oral, buccal, vaginal and rectal route. Oral route of misoprostol has several publications been shown to be effective method for induction of labour comparable to oxytocin.(9,10) The main disadvantage of prostaglandins is uterine hyperstimulation contributing to arisk for foetal hypoxia and may leads to operative intervention. As mechanical Foley'sleads to dilation of the cervix and misoprostol result in soften and efface the cervix.(11)

Aims and Objective: The aim of this study is to assess effectiveness and safety of transcervical Foley's catheter with vaginal misoprostol combination for cervical ripening and induction of labour in term as compare to misoprostol alone.

Material and Method

A prospective, randomized controlled study was conducted on 220 women admitted to labour room for induction of labour with term singleton pregnancy, cephalic presentation, viable gestation, intact membranes, and having poor bishops score were included in this study for cervical ripening and induction of labour over a period of one year. Informed consent was taken from Patients who were admitted to hospital for induction of labour. The women with History of prior uterine surgery (LSCS or myomectomy), multiple gestations, malpresentation, heart disease in mother, contraindication to prostaglandins, vaginal bleeding (placenta previa, active herpes infection), anomalous foetus, foetal demise, patients not giving consent were excluded from the study.

Patients were select randomly in to group 1 (misoprostol alone) and group 2 (cervical ripening using misoprostol with Foley's bulb). Simple Randomization with one to one was achieved through a computer-generated assignment with 110 patients in each group. A detail history was taken of all admitted patients along with detailed general and systemic examination was done. In group 1, women were received with F16 Foley's catheter with balloon filled with 50 ml normal saline inserted intra-cervical. The catheter was taped to the patient's inner thigh under gentle traction. Simultaneously they received 25 micrograms of misoprostol per vaginum in posterior vaginal fornix which was repeated every 4 hours for a maximum of 6 doses. Catheter was removed after 24 hours if women didn't go into labour. In group 2 women who were received, misoprostol (prostaglandin E1) 25 micrograms inserted vaginally into the posterior fornix every 4 hours, up to maximum of six doses under all aseptic precautions as per our standard hospital protocol. If cervix became favourable or patients goes in active labour then oxytocin was started after titrating dose, Partograph was maintained throughout the labour. If the cervix was not favourable for artificial rupture of membranes after the stipulated six doses, the induction was considered to have failed. A further dose was withheld in case of tachysystole, hypertonus or hyperstimulation or if patient was in progressive active labour and spontaneous rupture of membranes. Patients were monitored till patient delivered vaginally or by Caesarean section. The two groups were then compared with respect to indication of induction, induction to delivery interval,mode of delivery, maternal side-effects and foetal outcome.

Statistical Analysis: The data collected was organised in a separate sheet programme (MSExcel) and analysed with the help of Statistical Package for Social Science for testing. At the end of the study, the data was collected and analysed by using Student t-test and Chisquare test. A p value of < 0.05 was considered significant.

Result and Observations:

Total cases of 220 patients were taken for studied 110 were divided to each group and result as follows:

As shown in this study, maximum numbers of patients were in the age group of 26to 30 years in both the groups, in (Foley's plus Misoprostol) group 1 26.4±3.80 and in (Misoprostol) group 2, 25.9±3.81. In this study, maximum primigravida were 81.9% women in Group 1 and 71% in Group2 (Table 1) In our study most common indication for induction of labor were 26.8% postdated pregnancy, 22.7% GDM, 20.9% oligohydramnios and 19.1% preeclampsia. (Table 2)

Table 1: Demographic data:

Variables	Group 1	Group 2	P value	Significance
Age	25.9±3.81	26.4±3.80	0.90	Not significant
Primigravida	81.9%	71%	0.056	Not significant
Bishop score	3.0700±.76877	3.5600±.68638	0.124	Not significant

Table 2: Indications of induction of labor.

Indications of induction	Group 1	Group 2	Total
Postdate	35.5%	18.1%	26.8%
PIH	10%	28.2%	19.1%
Oligohydramnios	14.5%	27.3%	20.9%
GDM	29.1%	16.4%	22.7%
IUGR	10.9%	10%	10.45%

In group 1, 78.1% delivered vaginally, 21.9% underwent caesarean section due to meconium stain liquor and foetal distress, tachysystole. In Group 2, 76.4% delivered vaginally, 23.6% women underwent caesarean section due to foetal distress and meconium stain liquor.

In our study, women were delivered in 6-12 hours in Group 1 55.8%, whereas 33.1% in Group 2. In Group 1 majority of the cases (93%) delivered within 24 hours and only 7% of the women needed > 24 hours to deliver whereas in other group, 16.7% delivered in >24 hours. The mean induction delivery interval (IDI) in Group 1 came out to be 14.4± 5.70 which was shorter than Group 2 duration17.1±5.62.

Table 3: Indications of LSCS.

Indications of LSCS	Group 1	Group 2
Meconium stain liquor	37.5%	38.4%
Fetal distress	21%	19.3%
Tachysystole	21%	26.9%
Failure of Induction	16.6%	11.5%
Abruption	4.1%	3.9%
Totle	100%	100%

Table 4: Duration of induction to delivery interval.

Time in hours	Group 1		Group 2	
6-12 hours	48	55.8%	28	33.4%
>12-24 hours	32	37.2%	42	50%
>24 hours	6	7%	14	16.7%
Total	86		84	
Mean ± S.D.	14.4± 5.70		17.1±5.62	
P value	P-value 0.007			
Significance	Not significant			

Neonatal complications in the form of mild birth asphyxia were seen in 8.1% of the neonates in Group 1 and 12.7% of the neonates in Group 2. Neonatal jaundice occurred in 5.45% of the newborn in Group 1 and 7.27% in Group 2. Around 1% of the newborn in both groups had hypoglycemia. In maternal side-effects, hypertonic uterine action was observed in 5.45% of the cases in Group 1 and 6.36% of the cases in Group 2. The other less common side-effects were postpartum hemorrhage, shivering, nausea and vomiting. No case of chorioamnionitis was seen in our study (Table 5).

Table 5: Maternal and neonatal outcomes

Variables		Group 1	Group 2
Neonatal complications	Birth Asphyxia	8.1%	12.7%
	Neonatal jaundice	5.45%	7.27%
	Hypoglycaemia	1.1%	1%
	Uterine hypertonic action	5.45%	6.36%
Maternal outcome	PPH	1%	2.7%
	Nausea & Vomiting	6.3%	4.54%
	Shivering	2.7%	1.1%
	Rupture uterus	0	0
	Chorioamnionitis	0	0

Discussion

In this study, showed that in misoprostol group 56.3% and in Foley's plus Misoprostol group 54.5% in the age group of 26 to 30 years. The mean age group were25.9±3.81 and 26 ±3.80 and in combination group and misoprostol alone respectively. Others study was similar to our study, in *Agrawal M et al.[12]the mean age group of the participants was 24.72 and 24.12 in group 1 and group 2 respectively.* In Noor et al, in misoprostol mean age were *25.1 ± 2.8 and in Foley's catheter mean age were 25.6 ± 4.1[13].*

In this study, 76.4% women were primigravida and 23.6% were multigravida. Other study which was comparable to our study were Agrawal M et al.[12] In our showed that vaginal delivery was 78.1% and 76.4% while 21.9% and 23.6% delivered by caesarean section in group 1 and group 2 respectively. Others study which was comparable our study were Charaya E at el [14] and Baron B at el [15] whereas Chung JH et al [16] and Carbone JF et al [7] studies have shown higher caesarean rates. The studies by Kehl S at al[17] and Ande AB at al[18] showed lesser LSCS rate in combination group.

In this study showed that rate of success means induction to delivery interval was shorter in (14.4±5.70) Foley'scatheter plus misoprostol than misoprostol alone (17.1±5.62). Others study which were similar to our study that Carbone et al. [7],Hussein et al[14],Ande et al, showed that combination of *Foley's* with vaginal misoprostol for induction takes significantly shorter duration of time in cervical ripening and induction to delivery time. In Charaya E at elInduction to delivery interval was 11.76±5.89 hours in combination group and 14.54±7.32 hours in misoprostol group with difference of 2.78 hours. The study by Levine et al showed that shortening in the induction to delivery time by 4 hours 30 minutes with the combination group as compared with the misoprostol-alone group. In Hill JB et.al, the time from induction to delivery in group Foley's catheter and oral misoprostol (12.9 hours) was significantly shorter than that in group vaginal misoprostol (17.8 hours). Maternal and neonatal outcome were maximum in misoprostol group than combination group.

Conclusion

The results of this prospective, comparative study showed that the combination of Foley's with vaginal misoprostol results in a shorter duration of labour as well as induction to delivery interval compared with vaginal misoprostol alone. These results also suggest that the combination of Foley's with vaginal misoprostol may be useful to achieve timely and safe delivery in the presence of unripe cervix mainly with nulliparous. So, all nulliparous women with poor bishop should be offered induction with combination of Foley's bulb with vaginal misoprostol.

Online Teaching in the Time of Covid 19-Effectiveness and Challenges

Rucha R. Lohi[1], Nikita Dhahikar[2], Ranjit Ambad[3], Dhruba Hari Chandi[4]

[1]Assistant Professor, [2]Student, Datta Meghe Institute of Management Studies Nagpur, [3]Associate Professor, Dept. of Biochemistry Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur, [4]Assistant Professor, Dept. of Microbiology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe) Wardha

Abstract

India is facing COVID 19 Education Crisis many students have been affected by the closure of schools and colleges. This has caused a dramatic change in the education with a distinctive shift to e-learning where the teaching is done on digital platforms. Most of the schools and colleges are conducting online classes to cope up with the situation and to save the students from the loss. However it has its own drawbacks like issues of internet connectivity, availability of required resources, understanding the software application and lack of personal attention, less student attentiveness, etc. This paper studies the effectiveness of online students classes conducted to evaluate the effectiveness of online teaching. It also includes the software applications that can be used to conduct online classes. Online teaching is the future of students.

Keywords: *Online Teaching. Software application, digital platforms, Education Crisis.*

Introduction

The corona pandemic has led to the education crisis; all the schools and college have been closed till further notice of the government. To ensure that the students do not lag behind due to this temporary closure many of the schools and colleges have started online classes[1,2,3.] So that students can continue their education from the comfort zones of their home. The Schools and colleges are using software applications like Zoom, Google Classroom, Webex Meet to conduct online lectures. These applications are having many features to make online teaching more engaging and effective. However it has many drawbacks like availability of resources, internet connectivity & speed, usage of software application. In online lectures it is very difficult for the faculty to monitor all the students and also to ensure students attentiveness[4,5]. If the students are having proper access to right technology learning online can be effective in many ways. Thus the Institutes are making continuous efforts to make online teaching effective. Most commonly used Software Applications used for conduction lectures by schools and colleges is google class room and Zoom. While the shift is difficult for the students to adapt even the faculties are facing difficulties understanding the features of the applications and conducting classes[6,7,8.]

Objectives of the Study:

- To evaluate the effectiveness of online classes conducted
- To analyse the problems faced in conducting online classes
- To study and analyse the areas of concern in online teaching

Significance of the Study: Due to the present scenario of COVID 19 there has been an education crisis

Corresponding Author:
Dr. Ranjit Ambad
Associate Professor Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur
e-mail: ambad.sawan@gmail.com

and a major shift from traditional classroom teaching to online teaching. The instant shift has been a challenge for the education sector and the situation is such that the schools & colleges have no other choice left than to conduct online classes. As the infrastructure is a problem it is not possible to conduct classes maintaining the social distancing norms. Also it is not right to make the children open to the risk of getting infected. The study helps to identify the effectiveness of online teaching it also address the major challenges involved in it.

Research Methodology

For the purpose of research, data was collected from 500 students who attended online class conducted. An online Class was conducted for Undergraduate final year students on digital platform. Primary data was collected from the participants via questionnaire. The data was collected via questionnaire from the participants of the online class after the session.

Hypothesis: There is a lack of effectiveness in online teaching

Data Collection & Analysis:

The data collected using a questionnaire and analysed as below:

Table 1: One-Sample Statistics

	N	Mean	Std. Deviation	Std. Error Mean
Digital platform used	500	1.6905	.46099	.02062
Login issues	500	1.6710	.43547	.01948
Session audible	500	1.7455	.46426	.02076
Power point presentation visibility	500	2.2170	.35272	.01577
Disturbances	500	1.7365	.46972	.02101
Interaction Internet connectivity	500	1.7015	.44432	.01987
Number of participants	500	1.7755	.47241	.02113
Overall Satisfaction	500	2.0360	.43166	.01930
Recommended in future	500	1.6790	.45428	.02032

Table 2: One-Sample Test

	Test Value = 1.5					
	t	**df**	**Sig. (2-tailed)**	**Mean Difference**	**95% Confidence Interval of the Difference**	
					Lower	**Upper**
Digital platform used	9.240	499	.000	.19050	.1500	.2310
Login issues	8.780	499	.000	.17100	.1327	.2093
Session audible	11.824	499	.000	.24550	.2047	.2863
Power point presentation visibility	45.454	499	.000	.71700	.6860	.7480
Disturbances	11.258	499	.000	.23650	.1952	.2778
Interaction Internet connectivity	10.141	499	.000	.20150	.1625	.2405
Number of participants	13.040	499	.000	.27550	.2340	.3170
Overall Satisfaction	27.766	499	.000	.53600	.4981	.5739
Recommended in future	8.811	499	.000	.17900	.1391	.2189

The mean value obtained in all the above cases is more than 1.5 and the significance (2-tailed) value obtained is also less than 0.05 ($p<0.05$) hence it can be concluded that there is lack of satisfaction in online teaching among the students. Thus from the above, it is concluded that the hypothesis "There is a lack of effectiveness in online teaching" is accepted.

Conclusion

The digital platforms are not user friendly to start with for the students. The students need assistance in understanding the software application initially. Most of the audience faced the issue understanding the application it delays the session and cascading effects are on the further schedule of the day[9,10]. The students also need assistance to login into the software application. Though this is only a one time problem faced as once the login id is created further the same is used. Audibility is a big concern as students unmute the audio and the background noises makes it difficult to hear. Also many students don't understand the basic functions so cannot understand & follow the instructions given. The visibility is proper if the laptop is used by the presenter in case of smart phone the visibility is not up to the mark. Audio and video is disturbed in case the internet bandwidth is low. Thus many participants have issue in the audibility & visibility. Interaction during the session is disturbed due to the issue of low bandwidth internet or connectivity. Even the attentiveness of students is an issue in case of online teaching. It is difficult to monitor their presence and attentiveness[11].

Many students have internet connectivity issues due to which they often leave the class and login again. Thus the students miss the important content delivery in class and cannot understand the complete concept.If the number of participants is more then it impacts the effectiveness of the online teaching negatively. If the number of participants is less in class it is possible for the faculty to monitor the students and engage them well. In case of larger audience it becomes difficult and thus negatively impacts the effectiveness. Overall satisfaction is not there as the online classes had issues related to audibility, visibility and interaction. As the students have internet connectivity problem therefore they do not understand the concepts delivered in class. Due to the various issues faced by the participants there is no willingness to attend the classes online and it further makes it ineffective.

The transition from traditional offline teaching to online teaching is not easy and is impacting the effectiveness of teaching. The online classes are not that effective due to the above mentioned reasons but the pandemic has left no other option. As if the schools and colleges open the children will be open to the risk of getting infected. Till the scenario improves education of students is going to be a big question in front of the academicians and government.

Estimation of Stature from Foot Anthropometry in Central Indian Population

Karan Jain[1], Ninad Nagrale[2], Ranjit Ambad[3], Nandkishor Bankar[4], Swapnil Patond[5]

[1]Tutor, Department of Community Medicine, [2]Associate Professor, Department of Forensic Medicine, [3]Associate Professor, Department of Biochemistry, [4]Assistant Professor, Department of Microbiology, Datta Meghe Medical College, Nagpur (MS), [5]Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, DMIMS, Wardha (MS)

Abstract

Out of many parameters for human identification, stature is a principal anatomical variable. Stature estimation, especially in post-mortem cases where only some parts of an individual is available or cases where only footprints are available, foot anthropometry will be extremely useful. The objective of the current study is to find out interrelationship between the stature & foot length & formulating a regression equation for determination of height from foot length among individuals from Central India. This cross sectional study was conducted at the department of Forensic Medicine & Toxicology of Datta Meghe Medical College, Nagpur from June 2020 to August 2020. Collected data was entered in Microsoft Excel sheet & analysed using SPSS software. Mean stature in male was 165.8 cm with SD of 6 cm, while in female, it was 159.9 cm with SD of 6.7 cm. Gender wise difference in mean stature & foot length was statistically significant. This research found remarkable positive correlation between stature & foot-length in both sexes. Regression formula was derived which will be extremely helpful to forecast the height of an individual from known foot-length in cases of medicolegal importance.

Keywords: *Stature, Foot length, Central India, Anthropometry, Regression equation.*

Introduction

Establishment of human identification especially in cases of decomposed bodies, mutilated remains, amputated bodies, charred bodies etc has become of paramount importance in homicidal investigation. Also identification of human remains is extremely important in mass disasters (both natural & man made) like floods, earthquakes, cyclones, aircraft accidents, wars, blast injuries & the list goes on. Persons involved in medicolegal investigation are well aware of the fact that in many such cases at the death scene or crime scene, only some bony remains or human remains are available & they have to utilize their knowledge regarding various anthropometric techniques for human identification. In forensic anthropology, there is a long list of parameters for human identification, out of which height of an individual is of immense importance. Many researchers have done studies regarding estimation of stature from evaluation of both upper limb & lower limb but in extreme mutilated cases, even complete limbs are not available[1]. In such cases, it has been found that the reliability of prediction of stature from foot anthropometry has shown promising results[2,3,4].Epiphyseal union & maturation in foot occurs earlier than long bones and this fact will be of immense help in cases of adolescents requiring medicolegal attention[5].

Aims & objectives: To find out relationship between height & foot length and to develop a regression equation for estimation of stature from foot length among Central Indian population.

Methodology

This is a cross sectional study was conducted at the department of Forensic Medicine & Toxicology, Datta Meghe Medical College,Nagpur during the period of June 2020 to August 2020. 140 domicile individuals from Nagpur, who are born & brought up here were registered for this study. Informed written consent was taken from each individual & their participation was voluntary. Socio-demographic parameters for each individual were noted. The study participants who are having any disease, physical deformity, any history of injury or fracture or any surgical intervention were not included in the study.

The stature of an individual was measured between the vertex & floor in standing & erect position & head in Frankfurt plane. It was measured using stadiometer. As per recommendations of International agreement for paired measurements at Geneva (1912), left foot should be selected for measurements but in our study, both sides were included. Foot length was measured as a direct distance from the most prominent point of the back of the heel to the tip of the hallux or to the tip of the second toe when second toe was longer than hallux using spreading callipers (nail extensions were excluded in the measurements). Measurements were taken during the fixed time duration of the day i.e between 11:00 AM to 2:00 PM to exclude any diurnal variation & single observer took all the measurements to avoid bias. The obtained data was entered in Excel sheet and was analysed using SPSS (statistical package for social sciences).

Results:

Table 1: Gender-wise distribution of study subjects:

Sex	Number
Male	70
Female	70
Total	140

In this study, 140 healthy subjects were included with 70 males and 70 females. All subjects were grown adults with age ranging from 23 years to 50 years.

Table 2: Descriptive statistics for foot length & stature with respect to gender (all readings are in cm):

	Male			Female			Combined		
	Left foot length	Right foot length	Stature	Left foot length	Right foot length	Stature	Left foot length	Right foot length	Stature
Mean	24.5	24.5	165.8	23.4	23.3	159.9	24.2	23.9	162.9
SD	1.5	1.4	6.0	1.7	1.7	6.7	1.8	1.6	7.0
Minimum	22.3	22.3	155.3	20.8	20.9	148.4	20.8	22.3	148.4
Maximum	27.4	27.3	181.4	26.7	26.7	172.4	26.7	27.4	181.4

Left and Right foot length as well as height were noted for males and females. It was observed that the left foot length in males varied from 22.3cm to 27.4 cm with mean (SD) of 24.5 (1.5) cm. The mean (SD) right foot length in males was found to be 24.5 (1.4) cm varying between 22.3 cm to 27.3 cm. In females, left foot length ranged from 20.8 cm to 26.7 cm while the right foot length varied from 20.9 cm and 26.7cm with mean (SD) of 23.4 (1.7) cm and 23.3 (1.7) cm respectively. Mean (SD) combined left foot length was 24.2 (1.8) cm whereas for right foot length it was 23.9 (1.6) cm. The stature in males varied from 155.3 cm to 181.4 cm with mean (SD) stature of 165.8 (6.0)cm and for females the reading was noted to be 159.9 (6.7) cm ranging from 148.4 cm to 172.4 cm.

Table 3: Paired t-test for left & right foot length comparison:

	Left foot length (cm)	Right foot length (cm)	p – value
Male	24.5 ± 1.5	24.5 ± 1.4	>0.05
Female	23.4 ±1.7	23.3 ± 1.7	>0.05

There was no significant difference observed between left and right foot length in males as well as females. Hence, regression equations for estimation of stature were obtained with left foot length only.

Table 4: Regression statistics:

Stature (Dependent variable - DV)	Left Foot length (Independent variable-IV)		
	Male	Female	Combined
Intercept	73.37	77.3	74.43
Regression coefficient	3.71	3.52	3.66
Correlation coefficient	0.91	0.92	0.93
R^2 (coefficient of determination)	0.83	0.85	0.87
Significance	<0.01	<0.01	<0.01

It is observed that there is a strong positive correlation between dependent variable stature and in dependent variable foot length. The correlation coefficient for foot length of male and stature is 0.91, foot length of female and stature is 0.92 and correlation of foot length with stature of any person irrespective of gender is 0.93. The R^2 (coefficient of determination) shows how good fit is the linear regression between the independent and dependent variable. In this study it is noted that the foot length of male explains 83% of variability in male stature while for females it explains 85% of stature variability. R^2 is maximum for foot length irrespective of gender, it explains 87% of variability in stature.

Linear regression equation is expressed as:

DV = Intercept + Regression coefficient*IV

In this study, stature is DV and foot length is IV, thus the estimation of stature can be done by following equations.

1. Estimated stature of males

Est. Stature (M) = 73.37 + 3.71 (Length of left foot print)

2. Estimated stature of females

Est. Stature (F) = 77.3 + 3.52 (Length of left foot print)

3. Estimated stature irrespective of gender

Est. Stature = 74.43 + 3.66 (Length of left foot print)

Discussion

Sr. No.	Author	Region	Year	Mean foot length(cm)		Mean Stature(cm)		Correlation Coefficient		R^2 (coefficient of determination)	
				Male	Female	Male	Female	Male	Female	Male	Female

8	Jat et al[8]	Rajasthan	2016-2017	25.47	24.05	162.1	150.5	0.94	0.93	0.88	0.86
9	Lalwani R et al[9]	Central India	2019	25.99	23.23	169.52	154.75	0.731	0.686	0.534	0.47
10	Karan Jain	Central India	2020	24.5	23.4	165.8	159.9	0.91	0.92	0.83	0.85

Current study was done to find out the correlation between foot length & stature and in turn to formulate a regression equation for the population of Central India. It will be of immense help in medicolegal cases requiring anthropometric assessment. When we compare our study with the other studies done in the past we found out that, our study is in total agreement with study conducted by Jat et al[8] in Ajmer region (Rajasthan). Like our study which is from Central India, Lalwani et al[9] conducted similar study in this region in 2019, where the researchers concluded that, mean foot length (25.99 cm) in males & (23.23 cm) in females along with that, height in males (169.52 cm) & in females (154.75 cm) are similar to our findings. Also in the same study, the correlation is positive (high) but in our study, it is 0.91 (for males) & 0.92 (for females) which indicates strong correlation. Similar study was conducted in Puducherry[4] which is in Southern part of India in 2011. When we compare our study with this study, it is in agreement with correlation between height & stature. Studies conducted by Kanchan et al[3], Atal et al[7] & SanliS et al[1] showed low degree of correlation between height & stature, hence the estimate for stature would be poor.

Conclusion

Our study found significant positive correlation between height & foot length in both genders. Regression equation was formulated for Central Indian population, which will be of tremendous help in determining the height of an individual from foot length especially in medicolegal cases. When we go through all the studies which we have taken into consideration, there is a lot of variation in correlation coefficients between height & foot length which may be due to improper sampling or sampling error. So to study this discrepancy in correlation more & more studies from different regions of India must be conducted to check whether it is sampling fluctuation or the difference is actually variable for the different regions. Also the studies must include larger sample size which will result in reduction of sampling variability & will provide stronger estimates.

Radiological Evaluation of Innominate Bone for Age Estimation: A Cross Sectional Study from Central India

Ninad Nagrale[1], Swapnil Patond[2], Ranjit Ambad[3], Nandkishor Bankar[3], Karan Jain[4]

[1]Associate Professor, Department of Forensic Medicine, Datta Meghe Medical College, Nagpur (MS), [2]Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, DMIMS, Wardha (MS), [3]Associate Professor, Department of Biochemistry, Datta Meghe Medical College, Nagpur (MS), [4]Tutor, Department of Community Medicine, Datta Meghe Medical College, Nagpur (MS)

Abstract

Age is cardinal in both civil & criminal cases as it not only affects the way an individual is treated, both in court and with regards to bail, but it also influences the defence under Indian Penal system. The defence for children is easier to establish than that for an adult. This study focuses on investigating the relationship between the stage of fusion of secondary ossification centres of innominate bone & biological age in Chhattisgarh population. This study was carried out in 140 healthy subjects (70males and 70 females) aging from 17 to 24 years. The obtained results revealed that the complete fusion of both epiphyses of innominate bone is seen at 21-22 years. Comparatively, females were developing epiphysealunion at a younger age than their male counterparts. Results also suggest that the age of epiphyseal fusion at iliac crest & ischial tuberosity is found to vary greatly all over the India, indicating the need for separate standards for separateregions.

Keywords: *Epiphyseal union, iliac crest, ischial tuberosity, innominate bone.*

Introduction

Evaluation of age by radiological study of union of ossification centers is helpful to solve many civil & criminal cases like capital punishments, sexual offences, abductions, kidnappings, matrimonial disputes, contract agreements, consent for medical examination, admission & eligibility for various institutions etc. Also, age determination at the time of death is of supreme importance for identification purpose. It is also true for bio archaeological studies, where the reconstruction of health and disease patterns or demography of past societies is evaluated. The fusion of the various epiphyses occurs at a specified order and period of time in life and their correlation is useful to establish an age in both antemortem & post-mortem cases. By taking into account the radiological analysis of epiphyseal union at iliac crest & ischial tuberosity, this study will be of immense help in further understanding the details of accurate assessment of age in Central Indian population.

Aims and Objectives:

1. To evaluate age specific difference in epiphyseal union at iliac crest & ischial tuberosity.
2. To estimate age from epiphyseal union at iliac crest & ischial tuberosity.
3. To compare bisexual difference in epiphyseal union at iliac crest & ischial tuberosity.
4. To compare the findings of epiphyseal union at iliac crest & ischial tuberosity in Central Indian population with other parts of India.

Material and Method

The present study was carried out in the Department of Forensic Medicinein collaboration with Department of Radiology, SSIMS, Bhilai, Chhattisgarh. A total of 140 individuals participated in this study. The subjects included were individuals of 17-24 years of age from Bhilai & Durgcity. They are born to parents domicile

Corresponding Author:
Dr. Swapnil Patond
Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, DMIMS, Wardha

from Central India & have lived here since birth. The subjects do not have any disease/deformity related to bones or chronic disease affecting the general health. An informed consent was taken from all the subjects prior to each procedure. Skeletal maturity was evaluated according to the Jit & Kulkarni's classification[1] of four stages: Appearance, Non fusion, Partial fusion & Complete fusion. X-Rays showing clear gap between the epiphyseal and diaphysial ends & showing saw tooth like appearance end were designated as "Non-fusion" (NF) X-rays. X-Rays showing a line replacingthe hiatus between the epiphyseal & diaphysial ends & not showing saw tooth like appearance were designated as "Partial Fusion" (PF) X-rays. X-Rays showing the same bony architecture in the diaphysis and epiphysis & showing scar of the previous stage were designated as "Complete Fusion" (CF). It was classified, analysed and compared with known standards. At the end conclusions were drawn, which were compared with available results of various previous studies.

Results

Table 1: Epiphyseal fusion in males:

Age (years)	Iliac crest			Ischial tuberosity		
	NF	PF	CF	NF	PF	CF
17-18	4	6	0	7	3	0
18-19	2	8	0	3	7	0
19-20	0	10	0	0	10	0
20-21	0	2	8	0	7	3

Table 2: Epiphyseal fusion in females:

Age (years)	Iliac crest			Ischial tuberosity		
	NF	PF	CF	NF	PF	CF
17-18	2	8	0	6	4	0
18-19	0	10	0	0	10	0
19-20	0	5	5	0	8	2
20-21	0	2	8	0	6	4
21-22	0	0	10	0	0	10
22-23	0	0	10	0	0	10
23-24	0	0	10	0	0	10
Total	**70 (100%)**			**70 (100%)**		

In males, iliac crest shows: non fusion in 6 (8.57%) cases in age group of 17-19 years, partial fusion in 26(37.14%) cases in age group of 17-21 years & complete fusion in 38 (54.28%) cases in age group of 20-24 years. Complete fusion is seen in all the subjects in age group of 21-24 years. In females, iliac crest shows: non fusion in 2 (52.85%) cases in age group of 17-18 years, partial fusion in 25 (35.71%) cases in age group of 17-21 years & complete fusion in 43 (61.42%) cases in age group of 19-24 years. Complete fusion is seen in all the subjects in age group of 21-24 years.

In males, ischial tuberosity shows: non fusion in 10 (14.28%) cases in age group of 17-19 years, partial fusion in 27 (38.57%) cases in age group of 17-21 years & complete fusion in 33 (47.14%) cases in age group of 20-24 years. Complete fusion is seen in all the subjects in age group of 21-24 years. In females, ischial tuberosity

shows: non fusion in 6 (8.57%) cases in age group of 17-18 years, partial fusion in 28 (40%) cases in age group of 17-21 years & complete fusion in 36 (51.42%) cases in age group of 19-24 years. Complete fusion is seen in all the subjects in age group of 21-24 years.

Discussion

Table 3: Comparison of Age of union (years)

Iliac Crest: The observations of present study for males, matches with work of Parikh[7], SankhynS et al[8], BhiseS et al[10] & Sharma Y et al[13]. For females, the observations match with the findings of SankhynS et al[8], Bhise S et al[10], Devraj N et al[11] & Sharma Y et al[13].

Ischial Tuberosity: The observations of present study for males, matches with work of BhiseS et al[10], Sharma Y et al[13] & Singh P et al[14]. For females, the observations match with the findings of Parikh[7], Bhise S et al[10], Devraj N et al[11], Sangma W et al[12], Sharma Y et al[13] & Singh P et al[14].

Summary and Conclusion:

1. This study was conducted exclusively on the young indigenous population of Central India.
2. The epiphyseal union at iliac crest in both males & females is completed in all instances (100%) at the age of 21-22 years.
3. The epiphyseal union at ischial tuberosity in both males & females is completed in all instances (100%) at the age of 21-22 years.
4. Central Indian inhabitants are of diverse type comprising of various castes, religions & tribes. The opinion about age should always be given in the range.
5. From this study, range of 1-2 years of margin of error can be concluded.
6. For age estimation, pertinent joints should be radiologically examined for different centres and opinion should be arrived considering the status of multiple centres.

Age Estimation among Adolescent Individuals from Fusion of Tri-Radiate Cartilage: A Radiological Study from Central India

Ninad Nagrale[1], Swapnil Patond[2], Ranjit Ambad[3], Nandkishor Bankar[3], Karan Jain[4]

[1]Associate Professor, Department of Forensic Medicine, Datta Meghe Medical College, Nagpur (MS), [2]Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, DMIMS, Wardha (MS), [3]Associate Professor, Department of Biochemistry, Datta Meghe Medical College, Nagpur (MS), [4]Tutor, Department of Community Medicine, Datta Meghe Medical College, Nagpur (MS)

Abstract

Age determination in living individuals, dead persons & in human remains may shed light on issues with notable legal and social consequences for individuals as well as for the community. In the age determination of the deceased individual; the post-mortem circumstances can change the body parts and make age estimation difficult. In such cases, skeletal remains are extremely helpful for age determination. This study focuses on investigating the relationship between the stage of fusion of tri-radiate cartilage of innominate bone & biological age in population of Central India. This study was carried out in 120 healthy subjects (60 males and 60 females) aging from 12 to 18 years. The obtained results revealed that the complete fusion of tri-radiate cartilageis seen at 16-17 years. Comparatively, females were developing union at a younger age than their male counterparts. Results also suggest that the age of fusion of tri-radiate cartilage is found to vary greatly all over the India & world, indicating the need for separate standards for separate regions.

Keywords: *Tri-radiate cartilage, innominate bone, Central India.*

Introduction

Preciseage determination of an individual is foremost in matters with respect to law and medicine. The word 'Adolescent' literally means 'passing from childhood to maturity'. WHO defines 'Adolescents' as individuals in the age group of 10-19 years. However, among this age group, individuals of 14 to 16 years are considered immensely important in routine medico-legal practices as they are more pivotal in matters (civil or criminal)with reference to sexual offences, kidnapping,juvenile delinquency, substance abuse, child marriages, factory employment & so on. All over the world, parameters like secondary sexual characters, skeletal ossification progression, time of eruption of teeth etc are admissible in court as unparalleled scientific evidence in deciding disputes in adolescent age determination. All these parameters at their best can tend to fix the age of the person (either live or dead) only at a near approximate range and not the exact age. It is also true for bio archaeological studies, where the reconstruction of health and disease patterns or demography of past societies is evaluated. The fusion of the various epiphyses occurs at a specified order and period of time in life and their interrelationship is useful to establish an age in both living & dead cases. By taking into account the radiological analysis of fusion of tri-radiate cartilage, this study will be of enormous help in further understanding the details of accurate assessment of age in Juvenile population of Central India.

Aims and Objectives:

1. To evaluate age specific difference in fusion of tri-radiate cartilage.

2. To estimate age from fusion of tri-radiate cartilage.
3. To compare bisexual difference in fusion of tri-radiate cartilage.
4. To compare the findings offusion of tri-radiate cartilagein Central Indian population with other parts of India & the world.

Material and Method

The present study was carried out in the Department of Forensic Medicinein collaboration with Department of Radiology, DMMC, Nagpur. A total of 120 individuals participated in this study. The subjects included were individuals of 12-18 years of age from Nagpurcity. They are born to parents domicilefrom Central India & have been residing here since birth. The subjects do not have any disease/deformity associated with bones or chronic disease affecting the general health. Age was confirmed from history and from documents like drivinglicense, passports, ration card, voter's cardaadhar card etc. An informed consent was taken from all the subjects prior to each procedure. Xrays of Tri-radiate cartilage, AP & lateral views were taken & five differentstages of union were graded. The 5 stages are: F1 (Non union): epiphysealcartilage did not begin to decrease in thickness, F2 (Commence of union): thickness of epiphyseal cartilage was found tobe reduced appreciably (1/4th united), F3 (Incomplete union): epiphysis has begun to fuse with shaft and complete union was well underway (1/2 united), F4(Complete union): epiphyseal cartilage was bony in architectureand its density indistinguishable from the epiphysis & diaphysis in its neighbourhood butan epiphyseal line called epiphyseal scar couldstill be distinguished. (3/4 united) & F5 (Complete union): absence of epiphyseal scar. The appearance and fusion of Triradiate Cartilage was assessed radiologically and the results were compared with the previous known standard studies.

Results

In males, Triradiate cartilage shows: commencement of fusion in12(20%) cases in age group of 12-14 years, Incomplete fusion in 9(15%) cases in age group of 13-15 years, complete fusion with epiphyseal scar in 14 (23.33%) cases in age group of 13-16 years & complete fusion without epiphyseal scar in 25 (41.66%) cases in age group of 15-18 years. Complete fusion is seen in all the subjects in age group of 16-18 years.

Table 1: Extent of fusion of Triradiate cartilage in males:

Age (Years)	F1	F2	F3	F4	F5
12-13	0	10	0	0	0
13-14	0	2	6	2	0
14-15	0	0	3	7	0
15-16	0	0	0	5	5
16-17	0	0	0	0	10
17-18	0	0	0	0	10

Table 2: Extent of fusion of Triradiate cartilage in females:

Age (Years)	F1	F2	F3	F4	F5
12-13	2	8	0	0	0
13-14	1	9	0	0	0
14-15	0	2	6	2	0
15-16	0	0	0	3	7
16-17	0	0	0	0	10
17-18	0	0	0	0	10

In females, Triradiate cartilage shows: non fusion in 3 (5%) cases in age group of 12-14 years, commencement of fusion in 19 (31.66%) cases in age group of 12-15 years, Incomplete fusion in 6 (10%) cases in age group of 14-15 years, complete fusion with epiphyseal scar in 5 (8.33%) cases in age group of 14-16 years & complete fusion without epiphyseal scar in 27 (45%) cases in age group of 15-18 years. Complete fusion is seen in all the subjects in age group of 16-18 years.

Comparison between Immediate Effects of MET and Passive Stretching Techniques on Hamstring Flexibility in Patients with Hamstring Tightness: An Experimental Study

Samiksha Sanjiv Sathe[1], Tejal Rajandekar[2], Kirti Thodge[3], Vasant Gawande[4]

[1]Assistant Professor, Datta Meghe College of Physiotherapy, Nagpur, [2]Lecturer, Narayana Hrudayalaya College of Physiotherapy, Bangalore, [3]MPT Cardiovascular and Respiratory Physiotherapist, [4]Associate Professor Dept. of Orthopedics Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Background: Muscular flexibility is an important part of functioning of human being and hamstring muscle is prominently found to be tight in human body. Hamstring muscle flexibility can be improved by a variety of stretching method and other techniques, yet very little work has been done to compare muscle energy technique (MET) and passive stretching techniques. The objective of our study was to compare the immediate effectiveness of muscle energy technique (MET) and Passive stretching on hamstring flexibility in individuals with hamstring tightness.

Method: 42 participants who met the inclusion criteria were randomly divided into two equal groups, Group A – MET and Group B – Passive stretching. The range of motion (ROM) of knee extension was measured before and after both the techniques by AKET using universal goniometer.

Results: There was a significant improvement in hamstring flexibility in both the groups following the application of MET and Passive stretching.

Conclusion: From the present study we can conclude that both MET and passive stretching techniques have an immediate effect on reducing hamstring muscle tightness. From the mean difference values it is visible that MET (12.81) is slightly more effective than passive stretching (6.38) although statistically significant difference is not seen.

Keywords: *Muscle energy technique, Passive stretching techniques, hamstring tightness.*

Introduction

Flexibility means the ability to elongate skeletal muscle and tendons. In rehabilitation of any muscle, flexibility is a significant component. Static flexibility can be measured through Range of Motion (ROM), which is equivalent to tolerance threshold toward stretches, and dynamic flexibility which implies necessary resistance toward stretch is measured through stiffness. Muscle stiffness means the ratio of torque changes to muscle length changes.[1] There are multiple factors and varied reasons for decrease in joint ROM and one of which is muscular tightness. Muscle "tightness" is defined as an increase in tension from active or passive mechanisms. Passively, muscles can become shortened through postural adaptation or scarring and actively, they can become shorter because of either spasm or contraction. This type of tightness will limit range of motion and may create a muscle imbalance.[2]

Hamstring muscles have a great tendency to shortening,due to their multi-joint function and their tonic postural character. It is very well known that the length of the hamstring muscles is known to play an essential role in both the effectiveness and efficiency of human movements like running, walking etc. It has been proved in the literature that reduced hamstring flexibility is a common clinical finding in the general populationas

well as athletic populations which result in major muscle imbalances, predisposing athletes to muscle injuries,patellar tendinopathy, and patellofemoral painas also it may lead to low back pain.[3]

There are variety of techniques used in physiotherapy for improving joint muscle flexibility in different set ups. Some of them include- Muscle energy techniques, passive and active stretches, positional release technique, active release technique,static stretching etc. Out of which we will be considering two techniques here -MET and passive stretching. Passive stretching includes the stretching through the use of mechanical devices, the assistance of gravity, or use of a partner. In the process of passive stretch, an external force is applied, usually through a person in a rehabilitative setting and that person holds that stretch for a period of time and this is how the muscle gains new length. Passive stretching is also widely used in conjunction with active stretches as a part of warm up and cool down programs, apart from being a main intervention.[4]

Muscle energy technique (MET) is a procedure in which there is voluntary contraction of a patient's muscle in a precisely controlled direction with different levels of intensity. In this particular technique, the client provides the initial effort while the practitioner will facilitate the process. The benefits of MET are restoring normal tone in hypertonic muscles, strengthening weak muscles, preparing the muscle for subsequent stretching, improved joint mobility.[5] It is hypothesized that one of the efficient treatments to increase hamstring flexibility is Muscle Energy Technique (MET), which includes controlled isometric contraction in the targeted muscle. The results of various studies have shown that MET was effective in improving the flexibility as well as reduction of pain and discomfort and caused more immediate and long term changes.[1] There are multiple studies showing the effectiveness of MET and Passive stretching in hamstring tightness.[6-9]Apart from this, both the techniques have proved to be safe and easy for achieving hamstring flexibility. So in order to compare which of these techniques has more immediate effect on hamstring flexibility, this study was carried out on individuals with hamstring tightness.

Materials and Methodology

Study design: An experimental study

Sampling method: Simple random sampling

Sample size: Total 42

- **Group A:** 21 subjects received MET treatment
- **Group B:** 21 subjects received passive stretching treatment

Study setting: DattaMeghe College of Physiotherapy, Nagpur

Study duration: 2 months

Inclusion Criteria:

- Patients with Hamstring tightness of 15 degrees or more on AKET
- Gender – male and female both
- Patients willing to participate in the study

Exclusion Criteria:

- Patients with any low back pathology.
- Patients with history of any recent fracture or surgery of lower limb
- Patients with of knee joint pain or hypermobility
- Patients with any neurological disorder.
- Patients with history of recent hamstring injury

Material used: Plinth, Stabilising belt, Universal goniometer, Stop watch

Outcome measure: For measuring the hamstring flexibility, the active knee extension test was used in both the groups.

Active knee extension test (AKET): The patient lies in supine lying with hip flexed to 90 degrees. The patient is asked to perform active knee extension movement and stop when he/she feels strong resistance to the movement. The range of motion of knee joint is measured with the help of goniometer at this end range.[10]

Procedure: The study was carried out at the DattaMeghe College of Physiotherapy, Wanadongri, Nagpur. Ethical approval was obtained from Institutional Ethical Committee & an informed consent was obtained from the participants. Total 47 patients were assessed for the study. Inclusion and exclusion criteria were applied and 5 patients were excluded from the study. The study was conducted on 42 patients fulfilling the inclusion criteria. The participants were randomly divided into two groups by computer generated randomized table into groups of 21 each. Group A received Muscle energy

technique treatment and Group B received passive stretching treatment. The pre and the immediate post reading of AKET were measured

Group A - MET For Hamstrings tightness

- The contralateral leg may be either flexed or may lie straight on the plinth.
- The affected leg was flexed at both the hip and knee joints, and then slowly straightened by the therapist until the restriction barrier was identified
- The limb was moved a little away from the restriction barrier and the isometric contraction against resistance was introduced.
- The patients were asked to resist the movement with no more than 25% of strength. The contraction was held for 7-10 seconds followed by complete relaxation of the limb.
- On exhalation, the knee joint was straightened (extended) towards its new barrier and through that barrier a stretch was applied and maintained for 30 seconds.
- 3 repetitions of this process were done[11]

Group B - Passive stretching For Hamstrings tightness: The patient were in supine lying with a small pillow below the contralateral knee. The patient were asked to maintain the hip in 90 degrees of flexion, with the help of both hands. The ankle joint was in a relaxed position. The patient's foot was placed on therapist's shoulder and the hamstring muscles were maximally stretched from this position. The stretch was maintained for a period of 30 seconds and the procedure was repeated for a total of three times.[12,13]

Results

The software MYSTAT 12 was used in this study. Active knee extension test (AKET) was used as an outcome measure. Descriptive statistics such as mean and standard deviations were calculated to describe all the variables. The paired t-test and the unpaired t-test were used to verify differences between pre- and post-intervention. The statistical analysis was conducted at 95% confidence level, and $p<0.05$ was considered statistically significant.

The gender ratio was 13:8 (13 females and 8 males) in Group A – MET group and 11:10 (11 females and 10 males) in Group B – Passive stretching group. The difference in the mean age of both the groups was statistically not significant (Table 1)

Comparison of the pre and post intervention values (student's paired t test) of the outcome measure showed that there was statistically significant difference in AKET values in both the groups. (Table 2 and table 3) Inter group comparison (student's unpaired t test) showed that there was no statistically significant difference between the two groups in terms of AKET (Table 4).

Table 1: Baseline demographic data of both the groups

Group	Group A	Group B	t value	p value	Inference
Age (years)	38.19±14.12	38.38±13.81	2.02	0.96	Not significant
Gender ratio (M:F)	13:8	11:10			

Table 2: Mean and SD scores of Group A(Paired t test)

Group A - MET				
			Paired t test	
	Pre intervention	Post intervention	Mean Difference	p value
AKET	144.14 ± 18.33	156.95 ± 15.44	12.81	0.000

Discussion

In our study we found out that there was an immediate positive effect on hamstring tightness in terms of AKET in both the groups. Various studies have shown similar effects of MET on hamstring muscle tightness.[5,14] Desai Sonali et al conducted a study to compare effectiveness of Muscle Energy Technique (MET) & Static Stretching on hamstring tightness in healthy young individuals and found that both MET and static stretching showed significant improvement in reducing Hamstring Tightness in agreement to our study [9]

Bandy et al in their research have stated, the optimal duration for an effective stretch as a duration of 30 seconds.[13] During MET, muscle elongation is maintained for this duration thus leading to increased muscle length with a combined effect of creep and plastic changes occurring in the connective tissue.[15,16] Holuskova et al stated that the variations in the connective tissue show mechanical properties associated with both elastic and viscous constituents. Creep is the temporary lengthening of the connective tissue during the stretch period (viscoelastic property).[17] Fryer et al in their study have explained that the reasons of increased flexibility after MET may be the result of biomechanical or neuro-physiological changes or increased stretch tolerance.[15,18]

Ivan et al affirmed MET as an effective and non-traumatic manipulative technique. MET is said to have an inhibitory effect on motor activity acting through the muscle spindles or the Golgi tendon organs. [19]Post isometric relaxation technique reduces of the tone of the muscles. The afferent nerve impulses entering the dorsal route links up with the inhibitory motor neuron, stopping the efferent motor neurons impulse discharge, thus preventing further contraction and decreasing the muscle tone. This in turn relaxes the agonist muscle. [20] During this period, as a result of reduced tone, lengthening becomes easier. Kuchera et al in their study discussed similar reasons.[9,21] They explained that the inhibitory golgi tendon reflex is said to be activated during isometric contraction of muscles leading to reflex relaxation of the muscle.[22]

June-Su Yua et al, on 51 healthy individuals with tight hamstrings compared the immediate effect of hamstring stretching techniques and found that static stretching and PNF-hold relax showed a significant effect on ROM measured by active knee extension (AKE) test.[23] Phil Page in clinical commentary on current concepts in muscle stretching for exercise and rehabilitation has also stated that Static passive stretching is effective at increasing ROM. A static stretch of 15-30 seconds applied 2 to 4 times showed increase in ROM not because of increased length (decreased tension) of the muscle but simply due to an increased tolerance of the individual to stretching.[24] Patrick G De Deyne in his perspective on Application of Passive Stretch and Its Implications for Muscle Fibers explained that the increase in the range of motion immediately after application of static passive stretch can be because of the viscoelastic behaviour of muscle and short-term changes in muscle extensibility. Passive stretching leading to positive changes in range of motion often may involve biomechanical, neurological, and molecular mechanisms.[25] Static stretching leading to increased range of motion might be due to increase in the number of sarcomeres in series (muscle length) due to prolonged exposure to the stress. In addition, stretching causes increase in viscoelasticity and decrease in stiffness of muscular and connective tissues that results in improved muscular extensibility.[26] Also, during passive stretching it is assumed that the Golgi Tendon Organ, monitoring tension resulting from stretch of a muscle-tendon unit, may result in muscle elongation by intervening any assisting impulses from the primary afferents of the muscle spindle (Ia afferent fibers) and may contribute to muscle relaxation by inhibiting tension in the contractile units of the muscle being stretched. [4]

Maryam Azizi et al in their pilot study concluded that a single session of MET (3 repetitions) resulted in significant immediate improvement in flexibility and reduction in stiffness of hamstring.[1] Yuichi Nishikawa et al in their study on Immediate effect of passive and active stretching on hamstrings flexibility found that both active and passive static stretching had significant effect on

improving hamstring flexibility immediately however, passive stretching elicited greater improvements in hamstring flexibility than active stretching.[27] Shadmehr et al. in their study related to passive stretch and MET on hamstring flexibility concluded that both techniques relatively had the same effect on increasing the flexibility in healthy young females which is similar to our results aswell. Thus the results of our study corroborates the previous findings about a significant immediate effect of single session of MET and passive static stretching (3 repetitions each) on improving flexibility of hamstring.

Ethical Clearance: Taken from institutional ethics committee.

Source of Funding: Self.

Conflict of Interest: Nil.

Conclusion

From the present study we can conclude that both MET and passive stretching techniques have an immediate effect on reducing hamstring muscle tightness. From the mean difference values it is visible that MET (12.81) is slightly more effective than passive stretching (6.38) although statistically significant difference is not seen.

Role of Prolactin and β-hCG in Female Infertility

Mahendra Dhabe[1], Ranjit S. Ambad[2], Archana Dhok[3]

[1]Associate Professor, Dept of Biochemistry, Swami Ramanand Teerth Rural Medical College, Ambajogai, [2]Associate Professor Dept. of Biochemistry Datta Meghe Medical College, Shalinitai Meghe Hospital & Research Centre, Hingana, Nagpur, Maharashtra-441110, [3]Professor & Head Dept. of Biochemistry, Jawaharlal Nehru Medical College, DMIMSU, Sawangi, Wardha.

Abstract

The World Health Organization (WHO) describes infertility as a disability for couples in childbirth to attain pregnancy within 12 months of daily sexual intercourse. Infertility affects 13–20 per cent of couples worldwide, regardless of race or ethnicity. Human chorionic gonadotropin (hCG), also known as the "pregnancy hormone," plays a significant role in human reproduction. The present study was conducted in the departments of biochemistry and dept. of obstetrics and gynaecology. The study was conducted on two groups of 40 infertile Females and 40 healthy controls. Blood sample was collected for the estimation of prolactin and hCG was assessed by dry chemistry analyzer. Serum prolactin levels in infertile females is 33.96±11.46 and hCG levels was86.38±12.45 which was higher in infertile female as compare to healthy control with a p value of<0.05. Present study concludes that hyperprolactinemia is a major contributing hormonal factor in infertility among infertile women and, as such, prolactin and hCG should be measured in infertile women.

Keywords: *Prolactin, female infertility, hCG.*

Introduction

The reproductive years of women begin when she starts her menstrual cycle during puberty (about 13 years of age, and the capacity to have a child typically ends about age (45) years, although it may be possible for a woman to become pregnant before her cycles end with menopause (about 51 years of age)[1]. Already born girl bears around (400000) immature eggs (oocytes) in her body. These are stored in small, fluid-filled sacs, called follicles, in her ovaries. Upon reaching her reproductive years, she begins to have one egg (or, less generally, more than one) monthly, which can join a male mobile sperm cell during fertilization and become pregnant[2].

The production and release of the egg is largely dependent on hormone balance (chemicals that signal the body organs to perform a particular task). Some of these hormones are produced in the ovaries, while others are derived from the two brain glands, the hypothalamus and the pituitary[3]. Primary infertility is a term that describes a pair who has never been able to conceive through unprotected sex after a minimum of one year of attempting to do so. Primary infertility causes include a wide array of both physical and emotional factors[4]. Infertility is described as the failure of a couple to achieve conception after one year of unprotected and adequately timed intercourse (regardless of cause) [5]. It may be primary i.e. if a couple never conceived following cohabitation and exposure to sexual activity over a two-year span or secondary infertility i.e. if a couple had previously achieved pregnancy but frequent unprotected sexual intercourse did not result in a second pregnancy[6]. Human infertility is a complicated issue that has various implications depending on the context of society and culture, gender, lifestyle, the sexual history of the people it affects. Infertility is a major problem for

public health, partially due to its importance in etiology as well as its difficulty in preventing, diagnosing, and treating it[6]. Although some find infertility primarily a woman's problem, men also contribute to it and are also affected[7]. Essentially, infertility is graded into two primary infertility and secondary infertility. Predominant infertility in a couple who have never had a child is infertility. Secondary infertility means the inability to conceive following a previous pregnancy. Infertility can be caused by male or female infection, Infertility is often perceived as a predominantly female disorder, although male-factor infertility is equally prevalent, and half of the infertile couples fail to reproduce due to man fertility problems. Prolactin (PRL) is a 198 polypeptide amino acid hormone secreted from the anterior pituitary and synthesized by lactotroph cells. It weighs 23 kDa and many factors affect its secretion including stress, sleep, pregnancy, food ingestion, and stimulation of the chest wall (trauma, or pain). Prolactin plays an important role in controlling reproductive functions. Although it's level increase beyond normal (hyperprolactinemia) can be either physiological, pathological, or idiopathic, its clinical manifestations can vary from extreme to none [8]. Endometrial cells were found to have prolactin receptors. Endometrial prolactin secretion helps to preserve endometrial receptivity and has been shown to provide an ideal environment for implanting blastocyst transferred during periods of in-vitro fertilization (IVF). A sufficiently high level of prolactin may inhibit the proliferation of luteinizing granulosa cells, and may also interfere with the function of the corpus luteum resulting in luteal phase defects as well as irregular implantation and embryo growth. Specific studies have shown the presence of a state of hyperprolactinemia during cycles of IVF/Intra cytoplasmic Sperm Injection (ICSI)[9,10,11]. In the early stages of pregnancy, hCG is luteotropic, preserving progesterone development and endometrial support. In maternal semen, hCG can be detected eight days after ovulation[12] and in blastocysts as early as seven days after fertilization [13]. HCG levels in the maternal blood steadily rise in early pregnancy until peak levels are reached at seven to nine weeks.[14] They progressively decrease until about 20 weeks when plasma levels remain relatively small and steady until the end. Episodic fluctuation in maternal hCG levels occurs in the first trimester, indicating pulsatile secretion, with a nadir at 1900 hours and peak at 0700 hours. The daily variation in concentrations of maternal serum hCG can be up to 20 percent. Early in pregnancy, there is no link between hCG rates and fetal sex or birthweight. Higher rates of hCG are therefore associated with female fetuses in late pregnancy [15,16].

Aim and Objective:

Aim: To study the levels of prolactin and beta hCG in female infertility.

Objective: To correlate the levels of prolactin and beta hCG in infertile womens and healthy controls (age matched) attending AVBRH Wardha and SMHRC Nagpur.

Material and Method

The present Study was carried out in the Dept. of Obstetrics and Gynecology and Department of Biochemistry at Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe) Wardha Maharashtra in collaboration with Datta Meghe Medical College, Shalinitai Meghe Hospital & Research Centre, Nagpur.

Total 80 subjects were selected for study. Out of which 40 infertile female and 40 age and gender matched healthy control.

Sample Collection: Blood sample was collected, prolactin and beta hCG level was measured in Dry Chemistry Analyzer.

Inclusion Criteria: Women with primary and secondary infertility.

Exclusion Criteria:

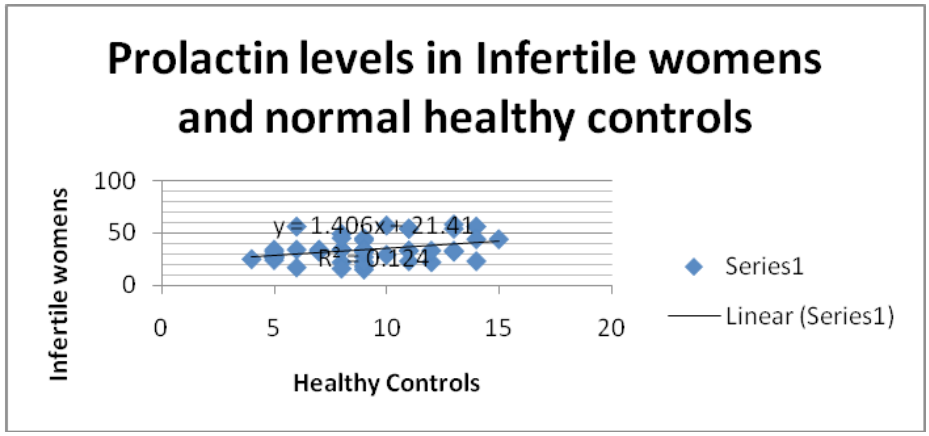
- Urogenital tract anomalies
- History of thyroid disease/thyroid surgery/thyroid medication.
- Women unwilling to participate or sign the informed consent

Statistical Analysis: All estimated results were expressed as mean ±SD. Mean values will be assessed for significance by unpaired student –t test. A statistical analysis will be performed using the Statistical Package for the Social Science program (SPSS, 24.0). Frequencies and percentages will be used for the categorical measures. Probability values $p < 0.05$ will be considered statistically significant.

Observation and Results

Table 1: Age Distribution

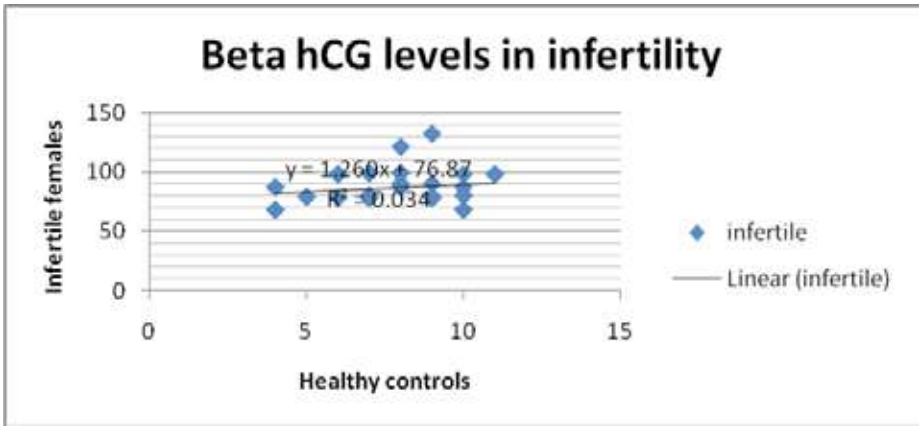
Groups	Number	Age	P value
Cases (Infertile Female)	40	31.67±9.05	0.2531
Control (Fertile Female)	40	29.62±6.70	



The above table depicts the age distribution in cases and controls, the mean age in cases is 31.67 and in control 29.62, no significant correlation was seen in between cases with a p value of 0.2531.

Table 2: Levels of Prolactin and beta hCG in infertile Female and Healthy control.

	Infertile Female Mean±SD (n=40)	Healthy Control Mean±SD (n=40)	t Value	P Value
Prolactin	33.96±11.46	8.92±2.87	-13.405	<0.0001
Beta hCG	86.38±12.45	6.6±1.988	-40.021	<0.0001



$P < 0.05$

The levels of Prolactin and beta hCG was increased in infertile female as compared to healthy control. In Infertile females the levels of prolactin was 33.96±11.46 and in healthy controls the levels was 8.92±2.87 with a p value of <0.0001 which a significantly indicating Hyperprolactinemia. Serum beta hCG levels was also increased in infertile women's with a p value of <0.0001

Graph 1: Scatter graph showing prolactin levels.

The above scatter graph depicts the levels of prolactin in infertile womens and normal healthy controls.

Graph 2: Scatter graph showing beta hCG levels.

The above scatter graph depicts the levels of beta hCG in infertile womens and normal healthy controls.

Discussion

Human chorionic gonadotropin (hCG), also known as the "pregnancy hormone," plays a significant role in human reproduction. Serum hCG has a circulating half-life of 24 hours. Female infertility accounts for 37% of all infertile couples and most of them are attributed to ovulatory dysfunction and are also correlated with dysregulation of the hormonal network.[17] The existence of abnormally high prolactin values is considered hyperprolactinemia, which is one of the most common endocrinological disorders of the hypothalamopituitary axis affecting fertility.[18-20] Hyperprolactinemia is one of the fertility-influencing endocrinological disorders most severe. The perception that hyperprolactinemia is not only expressed as galactorrhea and amenorrhea but also induces gonadal dysfunction and infertility has contributed to prolactin estimation in infertile females. Hyperprolactinemia influences the reproductive capacity by impairing pulsatile GnRH secretion and interferes with the function of ovarian-level gonadotropins so as to interfere with ovulation.[21,22] Hyperprolactinemia triggers galactorrhea together with menstrual and ovulatory disorders. It is present in females with both galactorrhea and amenorrhea in two thirds. Thus, serum prolactin levels should be estimated in unexplained infertility, any menstrual abnormalities with or without hirsutism, galactorrhea with or without amenorrhea, luteal phase defects, and anovulation.[23] Mild hyperprolactinemia may cause infertility even with normal menstruation.[24] Women with galactorrhea and hyperprolactinemia may be predominantly hypothyroidism. Hypothyroidism induces increased TRH secretion that induces thyrotrophin and lactotrophs, causing both TSH & prolactin levels to rise[25]. Hyperprolactinemia decreases the pulsatile release of the GnRH and impairs the secretion of FSH, LH. It also affects ovarian follicle steroidogenic activity and induces insufficient luteal-phase progesterone secretion[26]. These all result in luteal phase defects, inconstant ovulation, and chronic anovulation. Luteal insufficiency impairs endometrial development and inhibits embryo implantation.[27] It accounts for 3–10 percent of infertility and two-thirds of these women have hyperprolactinemia.[28] In hyperprolactinemic infertility, reduced prolactin secretion with dopaminergic drugs is the best therapy for raising the risk of conception[29].

Conclusion

For nonpregnant people, HCG in the serum rises with age. Consequently, it is concluded that hyperprolactinemia is a major contributing hormonal factor in infertility among infertile women and, as such, prolactin and hCG should be measured in infertile women. Even with normal menstruation, moderate hyperprolactinemia can cause infertility. Hyperprolactinemia is one of the most common female infertility endocrinological disorders and is often associated with hypothyroidism. Present study concludes that all infertile women should be offered serum prolactin estimation at an early stage of infertility checkup rather than going for more costly tests or invasive procedures.

Chondroid Chordoma: An Uncommon Bone Neoplasm

Anita B. Sajnar[1], Neha Bhatt[2], Obaid Noman[3], Pratibha Dawande[4]

[1]Associate Professor, Dept of Pathology, Datta Meghe Medical College, Nagpur, [2]Assistant Professor, Dept of Pathology, Datta Meghe Medical College, Nagpur, [3]Associate Professor, Dept of Pathology, Jawaharlal Nehru Medical College, DMIMSU, Sawangi, [4]Associate Professor, Dept of Pathology, Datta Meghe Medical College, Nagpur

Abstract

Chordomas are rare, slowly growing, locally aggressive neoplasms of bone that arise from embryonic remnants of the notochord. Chondroid-chordoma is an uncommon variant of chordoma. These tumors typically occur in the axial skeleton. Here we report a rare occurrence of chondroid variant of chordoma at sacrococcygeal region in a 60 year old female. Magnetic resonance imaging revealed expansile mass involvingsacrococcygeal region.Gross and microscopic examination confirmed chondroid chordoma.Later patient underwent radiotherapy, doingwell,on a one year follow up. Chondroid chordoma is discussed due to its predilection for occurrence at sacrococcygealregion and its more favorable prognosis compared with that of conventional chordoma.

Keywords: *Chondroid-chordoma, notochord, sacrococcygeal.*

Introduction

Chordoma is rare tumor that grows slowly,locally aggressive, invades surrounding soft tissue and metastasizes infrequently. It accounts for 1%– 4% of all primary malignant bone [(1,2)] Chordoma usually occurs in the sacrococcygeal (50%), spheno-occipital region (35%) and (15%) in the true vertebrae. [(3,4)] Nearly, 33% chordomas in the base of the skull are chondroid in type. [(5)] It is only malignant tumor arising from notochordal elements, more frequent in fifth and sixth decades, affect much more often men than women. Chondroid chordoma is slower growing than conventional chordoma and shows foci of chondroid (cartilaginous) differentiation. It has a better prognosis than classic (non-chondroid) chordoma. Heffelfinger *et al*. described this variant of chordoma indistinguishable from hyaline type chondrosarcoma.[(6)]

Case Report: A 60-year-old female was admitted in orthopaedicward of this hospital with a complaint of numbness and pain in left hip and has increased since 4-8 months period. Magnetic resonance imaging (MRI) findings are showed aapproximately 5.8x4.2x4.8cm, expansile mass involving S4-S5 bodies and coccyx protruding in presacral space. Operative findings revealed tumor mass eroding sacrum below S2 level. It was pink, friable and soft to firm and vascular mass. We received multiple grayish-white to brown pieces which had soft to hard consistency. Hematoxylin and eosin stained sections studied from multiple bits show tumor cells arranged in sheets, cords and nest embedded in myxoid to chondroid matrix. These are small round cells having eosinophilic to vacuolated cytoplasm giving bubbly appearance known as physaliferous cells and round nuclei. Areas of hemorrhage and necrosis seen.

Discussion

Chordomas are usually relatively slow-growing, low-grade malignancies. They arise from the sacrum in approximately 50%–60% of cases, skull base region (spheno-occipital/nasal) in approximately 25%–35% of cases, cervical vertebrae in approximately 10% of cases, and thoracolumbar vertebrae in approximately 5% of cases.[(2)]Genetic studies performed on chordomas include chromosome analysis, telomere reduction and telomere

Corresponding Author:
Dr. Neha Bhatt
Assistant Professor, Dept of Pathology, Datta Meghe Medical College, Nagpur

activity, DNA microsatellite, loss of heterozygosity (LOH), and clonality studies.Clonality studies on eight cases of sacral chordomas indicated a polyclonal origin of the tumor.[7]

Clinical presentation is usually with pain as the cardinal symptom, whereas neurologic deficits tend to vary based on the location of the lesion. Chordomas are divided into conventional, chondroid, and dedifferentiated types. Conventional chordomas are the most common. They are characterized by the absence of cartilaginous or additional mesenchymal components. Chondroid chordomas contain both chordomatous and chondromatous features. The cartilaginous foci of chondroid chordomas resemble those of chondroma or low grade chondrosarcoma. Histologically, they display lobules and vacuolated (physaliphorous), moderately atypical, neoplastic cells across a myxoid stroma separated by fibrous bands.[8]

They have an ectodermal origin, chordomas are not sarcomas; however, they are traditionally classified and approached as sarcomas on the basis of being a primary bone tumor.[9]

In case of diagnositicdelimma, immunohistochemistry stain demonstrates that tumor cells of chondroid chordoma are reactive to epithelial markers like epithelial marker antigen (EMA) and cytokeratin (CK). Chondroma and chondrosarcomas are negative for CK and EMA and are positive for vimentin.[5]

MRI and computed tomography scan are important for pre-operative planning and staging of disease. Tumor can be visualized as midline, lobular, osteolytic foci or an expansile concomitant soft-tissue mass. Technetium-99m bone scan demonstrates hot areas within the tumor showing destructive changes with sclerotic rim and calcification in pre or paraspinal soft-tissue mass.[10]

Though chordoma has been considered of low metastatic potential; but distant metastasis to lung, bone, soft tissue, lymph node, liver, and skin has been reported in up to 43% of patients.[11,12,13] Metastatic disease may be considered of adverse prognostic significance because the median survival time was reported to be <12 months in a series of 28 chordoma patients after the development of distant metastasis.[9]

Surgery continues to be the primary modality in the management of chordomas. Chordomas are considered radioresistant tumors and require doses in excess of 60 Gy. Patients with spinal and sacral chordomas at the Massachusetts General Hospital, with a 5-year local control rate of 53%.[14]Chordomas are not reported to be sensitive to chemotherapy, similar to many other low-grade malignancies. Accordingly, chemotherapy response has been reported in patients with high-grade dedifferentiated chordomas, which represent <5% of all chordomas.[15]

Conclusion

Chondroid Chordomas are uncommon primary bone tumors with a high risk for local recurrence and modest propensity for distant metastasis. Surgery is the primary modality to achieve the best long-term control therapeutic value. Newer techniques and charged particle radiotherapy allow for better dose delivery, and hence better disease control. Chondroid chordoma has better prognosis than conventional chordoma.

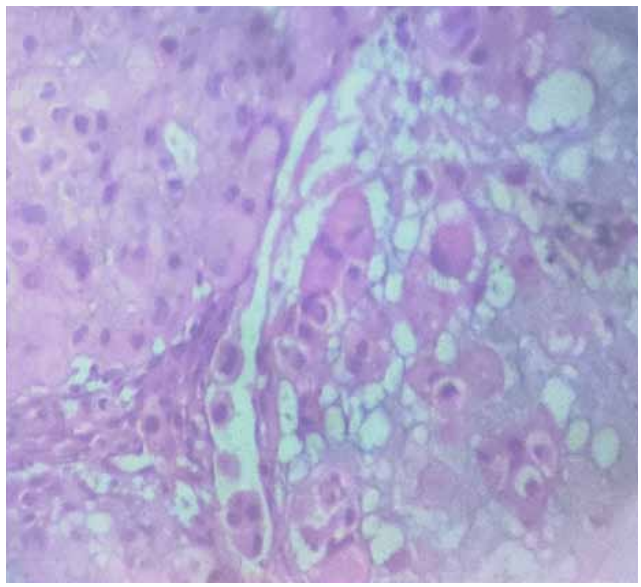

Figure 1: High power view showing small round cells have eosinophilic to vacuolated cytoplasm giving bubbly appearance known as physaliferous cells and round nuclei embedded in myxoid to chondroid matrix. (H and E).

Comparison between Immediate Effects of Post Isometric Relaxation and Reciprocal Inhibition Techniques on Hamstring Flexibility in Patients with Hamstring Tightness: An Experimental Study

Samiksha Sanjiv Sathe[1], Tejal Rajandekar[2], Kirti Thodge[3], Ashwin Chavhan[4]

[1]Assistant Professor, DattaMeghe College of Physiotherapy, Nagpur, [2]Lecturer, Narayana Hrudayalaya College of Physiotherapy, Bangalore, [3]MPT Cardiovascular and Respiratory Physiotherapist, [4]Senior Resident Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Aim: There are studies comparing the effects of post isometric relaxation technique & reciprocal inhibition technique on hamstring muscle flexibility but to the best of our knowledge there is hardly any study that has reported comparative immediate effect of these two techniques. Thus the aim of our study was to evaluate the immediate effect of these two techniques on hamstring muscle flexibility.

Method: The research design used was Comparative Experimental study design. Total 46 participants were screened and those meeting the inclusion criteria (n=40) were included in the study. The participants were randomly divided into two groups- group A - post isometric relaxation and Group B - reciprocal inhibition of 20 each. Pre and immediate post intervention scores were measured in terms of AKET

Findings: Inter group comparison (student's unpaired t test) showed that there was no statistically significant difference between the two groups in terms of AKET. The comparison of pre and post intervention values of the outcome measure in both the groups showed a statistically significant difference.

Conclusion: It can be concluded from the present study that both post isometric relaxation technique & reciprocal inhibition technique have an immediate effect on reducing hamstring muscle tightness. From the mean difference values it is visible that PIR (13.20) is slightly more effective than RI (5.45) although statistically significant difference is not seen.

Keywords: *Post isometric relaxation, Reciprocal inhibition, Immediate effect.*

Introduction

Hamstrings are important muscles of the human body. They contribute to posture stabilization of the body as also to the control of the pelvis region. Hamstring muscles possess the ability to generate high forces rapidly through their eccentric and concentric contractions. A hamstring muscle's length can be changed up to one third as a result of either eccentric or concentric contraction. Usually hamstring muscle is subject to high forces in closed and open kinetic chain activities.[1] Hamstring tightness not only hampers the activities of daily living like running, walking etc. but also causes postural issues and low back pain. Thus treating the hamstrings and relieving the tightness is of utmost importance. Many interventions are available to treat hamstring tightness like passive and active stretches, positional release technique, active release technique, muscle energy techniques etc. Multiple studies have shown the immediate and prolonged effectiveness of Muscle energy techniques in Hamstring tightness [2-4]

Devised by an osteopathic physician, Fred Mitchell, Sr, and polished by Fred Mitchell, Jr Muscle energy technique has been used for the treatment in various aspects. Muscle energy technique involves voluntary contraction of target muscles against a counterforce provided by operator, in a precisely controlled direction.

MET is useful in reducing pain, stretching tight muscles, decreasing muscle tone, improving local circulation, strengthening weak musculature and mobilizing joint restrictions.[6]

Different variations of MET are used in daily practice such as Isometric contraction using antagonist or agonist (with or without stretching), isotonic (concentric or eccentric) contraction, slow eccentric isotonic contraction and isokinetic variation (combined isotonic and isometric contractions) depending on the need.[7]A common explanation proposes that a voluntary agonist muscle contraction, prior to stretching of the muscle, has the effect of reducing reflexive components of that contraction thus causing relaxation, increased muscle length and range of motion of the joint that is in other words causing post isometric relaxation.[7]The second is reciprocal inhibition (RI) mechanism which states that when a muscle contracts isometrically, its antagonist is inhibited, and there is reduced tone immediately after this. Thus the isometric contraction involves two neurological components: Postisometric relaxation (PIR) will follow contraction of the agonist, as a result of Golgi tendon organ mediation and Reciprocal inhibition (RI) whichaffects the antagonist, as a result of spindle mediation. So,once the stretching has actually commenced, biomechanical effectis seen as low intensity force is applied to lengthen the tissues and 'creep' stage begins.[8]However, there is limited documented evidence to find out which technique is the best MET technique on Hamstring function. Thus this study was conducted to find out which of the two widely used MET techniques has a better immediate effect on hamstring muscle function.

Methodology

Study design: A Comparative Experimental study

Sampling method: Simple random sampling

Sample size: Total 40

- **Group A:** 20 subjects received MET (PIR)treatment
- **Group B:** 20 subjects received MET (RI) treatment

Study setting: DattaMeghe College of Physiotherapy, Nagpur

Study duration: 2 months

Inclusion Criteria:

- Patients with knee flexion angle of 15 degrees or more on AKET
- Gender: Male and female both
- Patients willing to participate in the study
- Age group: 25-60 years.

Exclusion Criteria:

- Patients with any low back pathology.
- Patients with history of any recent fracture or surgery of lower limb
- Patients with of knee joint pain or hypermobility
- Patients with any neurological disorder.
- Patients with history of recent hamstring injury

Material Used: Plinth, Stabilising belt, Universal goniometer, Stop watch

Outcome measure –For measuring the hamstring flexibility, the active knee extension test was used in both the groups.

Active knee extension test (AKET) – The patient lies in supine lying with hip flexed to 90 degrees. The patient is asked to perform active knee extension movement and stop when he/she feels strong resistance to the movement. The range of motion of knee joint is measured with the help of goniometer at this end range.

Procedure – The study was carried out at the DattaMeghe College of Physiotherapy, Wanadongri, Nagpur. Ethical approval was obtained from Institutional Ethical Committee & an informed consent was obtained from the participants. Total 46 patients were assessed for the study. Inclusion and exclusion criteria were applied and 6 patients were excluded from the study. The study was conducted on 40 patients fulfilling the inclusion criteria. The participants were randomly divided into two groups by computer generated randomized table into groups of 20 each. Group A received post isometric relaxation technique and Group B received reciprocal inhibition technique. The pre and the immediate post reading of AKET were measured.

Group A – MET (PIR) for Hamstrings tightness: The contralateral leg may be either flexed or may lie

straight on the plinth. The affected leg was flexed at both the hip and knee joints, and then slowly straightened by the therapist until the restriction barrier was identified. The limb was moved a little away from the restriction barrier and the isometric contraction against resistance was introduced. The patients were asked to resist the movement with no more than 25% of strength. The contraction was held for 7-10 seconds followed by complete relaxation of the limb. On exhalation, the knee joint was straightened (extended) towards its new barrier and through that barrier a stretch was applied and maintained for 30 seconds. 3 repetitions of this process were done.[7]

Group B – MET (RI) For Hamstrings tightness: The supine patient was asked to fully flex the hip and knee on the affected side. The affected leg was then slowly straightened by the therapist until the restriction barrier was identified. The calf of the affected leg was then placed on the practitioner's shoulder that stands facing the head of the table on the side of the affected leg. Then the patient was asked to attempt to straighten the lower leg utilizing the antagonists to hamstrings, employing approximately 20 percent of the strength of the quadriceps. This was resisted by the practitioner for 5 to 7 seconds. Appropriate breathing instruction were given. On exhalation, the knee joint was straightened (extended) towards its new barrier and through that barrier a stretch was applied and maintained for 30 seconds. 3 repetitions of this process were done.[7]

Results

MYSTAT 12 software was used in this study. The outcome measure used was Active knee extension test (AKET). Descriptive statistics such as mean and standard deviations were calculated to describe all the variables. The paired t-test and the unpaired t-test were used to confirm differences between pre- and post-intervention. The statistical analysis was conducted at 95% confidence level, and $p<0.05$ was considered statistically significant.

The gender ratio was 12:8 (12 females and 8 males) in Group A – MET PIR group and 10:10 (10 females and 10 males) in Group B – MET RI group. The difference in the mean age of both the groups was statistically not significant (Table 1)

Comparison of the pre and post intervention values (student's paired t test) of the outcome measure showed that there was statistically significant difference in AKET values in both the groups (Table 2 and table 3). Inter group comparison (student's unpaired t test) showed that there was no statistically significant difference between the two groups in terms of AKET (Table 4).

Table 1: Baseline demographic data of both the groups

Group	Group A	Group B	t value	p value	Inference
Age (Years)	39.05±13.91	35.65±13.26	0.76	0.45	Not Significant
Gender ratio (M:F)	8:12	10:10			

Table 2: Mean and SD scores of Group A (Paired t test)

Group A - MET PIR group				
			Paired t test	
	Pre intervention	Post intervention	Mean Difference	p value
AKET	143.10 ± 18.15	156.30 ± 15.54	13.20	0.000

Table 3: Mean and SD scores of Group B (Paired t test)

Group B - MET RI group				
			Paired t test	
	Pre intervention	Post intervention	Mean Difference	p value
AKET	146.75 ± 15.02	152.20 ± 14.68	5.45	0.000

Table 4: Result of post-intervention values of both the groups (Unpaired t test)

	Group A	Group B	Unpaired t test	
	Post intervention	Post intervention	p value	Inference
AKET	156.30 ± 15.54	152.20 ± 14.68	0.39	Not Significant

Discussion

A study done by Bandy et al concluded that the optimal duration for an effective stretch as duration of 30 seconds.[10] In both PIR and RI techniques stretch is maintained for this duration thus leading to increased muscle length with a combined effect of creep and plastic changes occurring in the connective tissue.[5,11] Various studies have shown a positive effect of post isometric relaxation technique on hamstring muscle flexibility.[1,12] A study done by Sambandham et al showed an immediate positive effect of MET on hamstring tightness which upholds the result of our study.[13]

Similarly a study conducted in 2018 by Desai Sonali et al showed considerable improvement in AKET ranges on application of MET on hamstring muscles which supports our study.[4] Ivan et al has stated MET as an effective manipulative technique. MET is said to inhibit the motor activity from the muscle spindles or the Golgi tendon organs.[14]The technique of post isometric relaxation leads to reduction of the muscle tone. The afferent nerve impulses entering the dorsal route associate with the inhibitory motor neuron, stopping the efferent motor neuron impulse discharge. This prevents further contraction and decreases the muscle tone resulting in relaxation of the agonist muscle.[15] In this period lengthening becomes easier as a result of reduced tone. Similar reasons have been discussed by Kuchera et al in their study. [16] In addition Shellock F G et al explained that the inhibitory golgi tendon reflex is said to be activated during isometric contraction of muscles leading to reflex relaxation of the muscle. [17] A pilot study done by Azizi M et al concluded that post isometric relaxation technique can be used to increase the flexibility of hamstring muscle. Visco-elastic changes in muscles or increased tolerance threshold toward stretch are thought to be some of the several possible mechanisms of immediate effectiveness of MET.[18] Furthermore Lederman also explained the viscoelastic changes of the connective tissue to be responsible for the increased flexibility. Thus it can be stated that any reduction in hamstring stiffness after application of MET can be resulted from the viscoelastic changes in musculotendinous unit. In addition Fryer et al in their study have explained that the reasons of increased flexibility after MET may be the result of biomechanical or neuro-physiological changes or increased stretch tolerance.[5]

In the present study we found that there was significant improvement in RI group as well. The amount of literature available on effect and mechanism of working of RI is not as much available. A comparative study of PIR and RI techniques on flexibility of hamstring muscles done by Agrawal S also showed similar results which is in accordancewith our study.[20] The nerve impulses discharged from muscle spindles exciting the agonist muscles' afferent nerve fibers synapse with their excitatory motor neuron in the spinal cord. Simultaneously there occurs inhibition of the motor neuron of the antagonist muscle leading to prevention of its contraction, thus resulting in antagonist relaxation [15]

A study done by Nasiri et al concluded that both PIR and RI techniques are equally effective in increasing the flexibility of hamstring muscle which correlates with our study. Moreover it has been proposed that by virtue of an isometric contraction of antagonist muscle, a muscle can be inhibited prior to stretching.[7]

Conclusion

It can be concluded from the present study that both post isometric relaxation technique & reciprocal inhibition technique have an immediate effect on reducing hamstring muscle tightness. From the mean difference values it is visible that PIR (13.20) is slightly more effective than RI (5.45) although statistically significant difference is not seen.

Prospective Analytical Study of Burn Deaths in Infant and Children Below 6 Year

Tikendra Dewangan[1], Rajesh Babulalji Ramteke[1], Kalpesh C. Patani[2], Ninad Nagrale[3], Shailesh Nagpure[4]

[1]Assistant Professor, Department of Forensic Medicine, Raipur Institute of Medical Science, Raipur Chhattisgarh, [2]Assistant Professor, Department of Forensic Medicine, B.J. Medical College, Ahmedabad Gujarat, [3]Associate Professor, Department of Forensic Medicine, Datta Meghe Medical College, Nagpur, Maharashtra, [4]Associate Professor, Department of Pharmacology, Jawaharlal Nehru Medical College, DMIMSU, Sawangi, Maharashtra

Abstract

Introduction: Burn injury is not only leading health problem in adult but it also cause significant mortality and morbidity in children.Burns can be devastating injuries for children, the immediate effect of which is compounded by ongoing pain, cosmetic and physical disfigurement, impairment, multiple dressing changes and surgical procedures. This prospective analytical study was planned to study the pattern of burn deaths in infant and children.

Material and Method: This Study was carried out in department of forensic medicine and Toxicology, B.J. Medical College, Ahmedabad over the period of 2 year during which 30 cases were studied and analysed. Data was maintained using Microsoft Office Excel and analysed suing test of proportions.

Result: Out of 30 cases studied during this period 18 (60%) cases were males and rest 12 (40%) were females. Most common type of burn was scald in 25 (83%) of cases, followed by electrocution in 3 (10%) cases and most common cause of death was septicaemia in 70% of cases followed by shock due to burns in 6 (20%) cases.

Conclusion: Burn injuries caused to them are because of their curiosity and innocent nature and unable to understand the extent of damage that will be cause by it. As these injuries are accidental and mostly occur in home, they are preventable.

Keyword: *Infant, Children burns, scald, pattern.*

Introduction

Burn injury in infant and children is considerable health problem not only in India but throughout the world. Paediatric burn injury constitutes about one-fourth of the total burn accidents in India.[1] Burns can be devastating injuries for children, the immediate effect of which is compounded by ongoing pain, cosmetic and physical disfigurement, impairment, multiple dressing changes and surgical procedures.[2] Burn injuries have been ranked as second most common cause of accidental death in children younger than 6 years and the most common cause accidental death in the home.[3] It is also called as a man's first double edged sword evidenced throughout the history; it has served as well as destroyed mankind.[4] Burn is a injury which is produced by the application of dry heat such as flames, radiant heat or heated substance over the body surface.[5] Burn injuries have been described as among the most serious injuries that may afflict a human being.[6] A child below 3 years is

too young to understand the danger in the proximity of burn area, so an identification of the risk factors leading to burn injuries is crucial. So this study was planned with aim to study the pattern of burn deaths in children under the age of 6 years brought for post-mortem examination.

Material and Method

This prospective analytical study was carried out in department of Forensic Medicine and Toxicology, B.J. Medical College, Ahmedabad over a period of 2 years from January 2017 to December 2018. A total of 30 cases of burns brought for post-mortem examination at mortuary of civil hospital, Ahmedabad between 0-6 years was included in our study whereas deaths due to chemical burn, lightening, radiation and post-mortem burns were excluded. Detail history of the case was obtained from the patient close relatives, police and other person who were available at the time of incident and those who accompanies the victim at the time of post-mortem examination.

Data was maintained in Microsoft Office Excel and analysed for age, sex, type of burns, percentage of burn and cause of death using tests of proportion.

Result and Observation

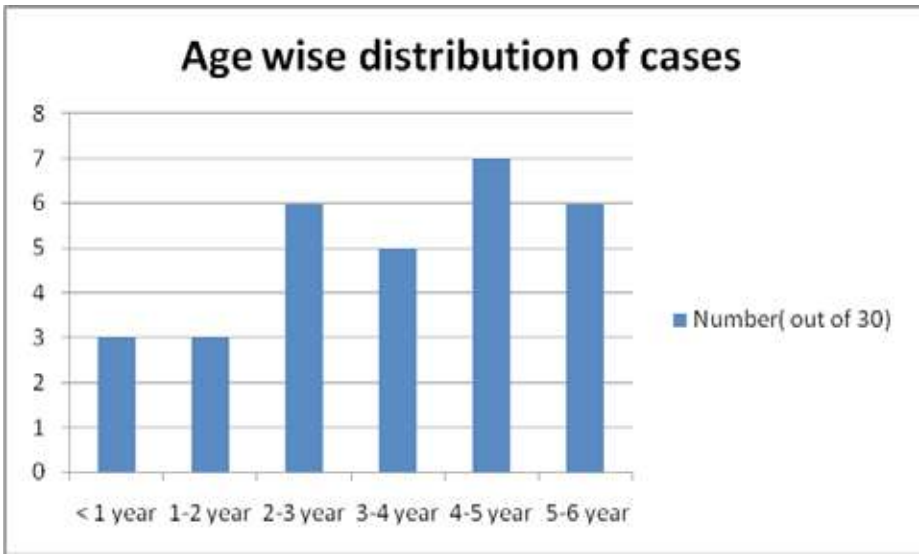

Fig. 1: Showing Age wise distribution of cases included in study

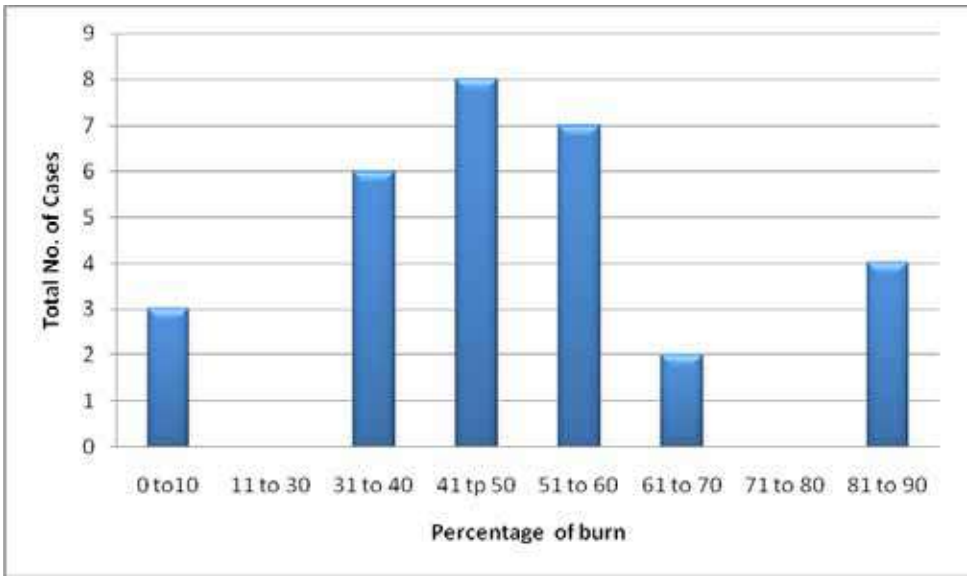

Fig. 2: Showing distribution of cases as per percentage of burns

During the study period total 30 cases were studied, 18/30 (60%) were males and rest 12/30(40%) cases were female showing male predominance. 7/30(23%) cases were found in age group of 4-5 years followed by 6/30 (20%) in age group of 2-3 years and 5-6 years. Age group 1-2 year and <1 year shows 3/30(10%) cases each. (Fig-1).

In majority of cases, 25/30 (83.30%) death was due to scald burns while in 3/30(10%) cases death was due to electrocution where as in 2/30 (6.66%) cases death was due to flame burn.

In our study maximum number of cases i.e. 8/30 (26.66%) cases shows 41-50% burns followed by 7 (23.33%) showing 51-60% burn. Whereas 4/30(13.33%) cases and 2/30(6.66%) cases showed 61-70 % and 81-90% of burns. 3/30(10%) cases shows burns less than 10%. In between 11-30% and 71-80% there were no burns cases. (Fig-2).

Cause of death was septicaemia in 21/30 (70%) cases followed by 6/30 (20%) and 3/30(10%) cases because of shock due to burns and shock due to electric burns respectively.

Discussion

Fire has been known to mankind for about 400,000 years. Although the use of fire was known to ancient man, it is probably the potential fury of an unharnessed fire that made man bow before it. India has an ancient culture where fire is worshiped since the civilization started. Along with water (jal), air (vayu), earth (prithvi), fire (agni) is perceived as one of the four basic components of universe.[7] As per ministry of health and family welfare, Government of India database[8], approximately 70 lakh people sustain moderate to severe burns in India every year. More than 7 lakh burn injuries require admission every year. About 80% of admitted cases are due to accidents at home i.e. kitchen related mishaps. Out of which 1.4 lakh peoples are succumbed to death. Amongst all traumas, burns have highest duration of hospital bed occupancy.[8]

In our study female were less affected than male, as 60% cases are male and 40% cases are female similar findings are also seen in other studies.[9,10] Over activity of male babies as compared to female babies may be the reason of male preponderance. In the study scald burn is more common seen in 83% of cases followed by electrocution in 10% cases and in 7% cases death was due to flame burn. Our this result is comparable with the study done by Lal St et al.[11] in which 54% cases shows scald burn. Scald is caused by boiling water, hot tea or milk. Young children usually sustain this injury due to their curious nature and unsteady movement. Electrocution is probably caused by naked wire carelessly kept in home. Out of two flame burn one was caused by accident while in other case mother burn herself with suicide intention keep baby along with her. All of the case in our study, incident occur in home that too mainly in kitchen. Home remains a dangerous place for children particularly in India due to lack of space to play, cook and storage of hot liquid.

Burns are the frequent cause of injury among children. Pediatrics burn injury can lead to severe physical, social, and psychological impairment. Burn injury results in longer hospitalization and a substantial cost of treatment. Pediatric burn injury can be more severe in comparison to the adults, because the skin is thinner. Even trivial burns in children can lead to dense scarring and contractures.[11]

Conclusion and Suggestions

This study shows that burns injuries can cause major mortality and morbidity to the children. Burn injuries caused to them are because of their curiosity and innocent nature and unable to understand the extent of damage that will be cause by it. As this injury mostly occurs in home, they are preventable. Preventive measures such as

Provision of better housing conditions and reduction of overcrowding, especially in the kitchen or around cooking area.

Improvement of cooking facilities and with provision of raised cooking platform at least 3 feet above the ground level, so that the children cannot reach up to hot utensils.

Burning and lighting agent, kerosene wick, Deepak, candles, should not be left unguarded and should be kept away from the reach of children.

By applying such measures and proper educating the people we can reduce the mortality and morbidity caused by burns in children.

Effect of Exposure of Smartphone Use on Visually Evoked Potential (VEP) in Healthy Adults

Swapnil Bhirange[1], Alka Rawekar[2], Avinash Taksande[3], Komal Meshram[4]

[1]Assistant Professor, Department of Physiology, JNMC, Sawangi (Meghe) Wardha, [2]Professor, Department of Physiology, JNMC, Sawangi (Meghe) Wardha, [3]Associate Professor, Department of Physiology, JNMC, Sawangi (Meghe) Wardha, [4]Associate Professor, Department of Physiology, Datta Meghe Medical College, Nagpur

Abstract

Aims: To assess and compare VEP parameter (amplitude and latency of P100) in healthy adults (MBBS students) using smartphone.

Objectives:

- To record P100 (latency, amplitude) in 1st year MBBS students using smartphone for less than three hours and for more than three hours after sunset
- To record P100 (latency, amplitude) MBBS students using smartphone for duration of less than three years and for more than three years
- To Compare P100 (latency, amplitude) 1st year MBBS students using smartphone for less than three hours and for more than three hours after sunset
- To Compare P100 (latency, amplitude) MBBS students using smartphone for duration of less than three years and for more than three years

Settings and Design: Neurophysiology Lab at the department of Physiology, JNMC, Sawangi (Meghe), Wardha.

Method and Material: A cross sectional study was done in 50 healthy MBBS studentsfrom JNMC.

Results: There is significant difference in the mean values of P100 latencies of right and left eye and in the mean values of P100 amplitude of right and left eye in individuals with exposure of less than three and more than three hours per day after sunset.

Conclusions: We conclude that nocturnal use of mobile phones especially in the bright light exposes an individual to the blue light resulting in various deleterious effects.

Keywords: *Nocturnal smartphone use, VEP (visually evoked potential), Latency.*

Introduction

Use of mobile phone as a token of electronic century and digital world has risen to a very high scale in humans and, especially nowadays, has become an integral part of the young generation. The technology has transformed mobile phones extensively since its inception as analogue phones and later being replaced, over the years, by digital ones, more precisely, the smartphones. Smartphone has voided the tools like calculator, mp3 player, Microsoft office, dextop browsers, book readers etc., and has taken over their places. Thus using smartphone has indirectly become the essential commodity.

The operating power of analogue phones is higher than digital phones, emitting more electromagnetic radiation (EMR). Operating frequencies of mobile phone are 450- 900MHz (analogue systems), 1800-1900MHz (digital systems) and 1900-2200MHz (Universal Mobile Telecommunications System).(1) Peak power output of

mobile phone antenna ranges from 8-15 W (450 MHz), 2W (900 MHz) and 1W (1800 MHz).[2] The "Specific Absorption Rate" (SAR) is the rate at which energy is absorbed by the human body. In the USA and India, the maximum level of SAR for smartphones set by governmental regulating agencies is 1.6W/Kg, averaged over a volume of 1g of tissue.[3,4]

Younger generation has become habitual to the smartphone and the usage starts from the morning till the person goes to sleep. Thus the smartphone is used almost continuously throughout the day and also after the sunset. During the use of smartphone, especially in the dark condition than the illuminated environment, electromagnetic radiations from antenna during a phone call and electromagnetic waves and bright light (especially the blue light) from the screen of smartphone during browsing causes more photo-mechanical damage, photo-thermal damage, and photo-chemical damage[5,6] make eyes more vulnerable to adverse effects because of their anatomy and composition (they are having a few blood vessels).[7,8] Blue light is an important factor emitted from smartphone and is known to generate poisonous molecules in the light sensitive cells of the eye and leads to macular degeneration and age related changes.[9] So it becomes a need of time to determining the deleterious effects of electromagnetic radiations generated from smartphone on the human visual system.

P100 latency prolongation appears to be the most reliable indicator of clinically significant abnormality, being least affected by technical factors and degree of patient co-operation. It appears to be generated by the pyramidal cells in layer IV of area 17.[10] Imaging studies point to the source of the early phase of the P100 peak as being in dorsal extrastriate cortex of the middle occipital gyrus, whereas the late phase of P100 appears to be generated by the ventral extrastriate cortex of the fusiform gyrus.[11] These results suggest the cortical generation of VEP waveforms. Thus VEP is useful in detecting the site of lesion when the conduction disturbance is in the anterior visual pathway.

The present study was planned to assess the effect of duration of usage of MP on human visual system by recording of pattern reversal visual evoked potentials (PRVEP).

Aim: To assess and compare VEP parameter (amplitude and latency of P100) in healthy adults (MBBS students) using smartphone.

Objectives:

1. To record P100 (latency, amplitude) in 1st year MBBS students using smartphone for **less than three hours and** for **more than three hours** after sunset
2. To record P100 (latency, amplitude) MBBS students using smartphone **for duration of less than three years and for more than three years**
3. To Compare P100 (latency, amplitude) 1st year MBBS students using smartphone for **less than three hours and** for **more than three hours** after sunset
4. To Compare P100 (latency, amplitude) MBBS students using smartphone **for duration of less than three years and for more than three years**

Materials and Method

Study Set-up: The present study was undertaken in the Neurophysiology Lab at the department of Physiology, JNMC, Sawangi (Meghe), Wardha.

Study Design: It was a cross sectional study, in which effect of exposure of smartphone was assessed in MBBS students using visually evoked potential (VEP).

Sample Size: A total of 50 subjects were studied.

Study Protocol: The subjects were selected by random method of sampling and studied after obtaining the approval from institutional ethics committee to carry out the research work at Jawaharlal Nehru Medical College (JNMC) and Acharya Vinoba Bhave Rural Hospital (AVBRH), Sawangi (Meghe), Wardha. The study group consisted of MBBS students from JNMC. Every Subject included in the study was examined in details after taking a detailed clinical history and brief general examination.

Inclusion Criteria:

- Apparently healthy MBBS students including Males and females.
- Age group between 18-23 years.
- Subjects with normal visual acuity or corrected by the glasses.

Exclusion Criteria:

- Presence of any illness that could influence visual evoked potentials.

- Best corrected visual acuity worse than 6/60.
- Extreme pupil sizes.
- History of major illness like diabetes, hypertension, etc.
- Any evidence of diabetic retinopathy, optic atrophy, glaucoma, etc.
- Alcoholics, smokers, tobacco users or with any other addictions.

Subjects were grouped in four categories based on duration of exposure of smartphone as

Group IA: Duration of exposure of smartphone less than three hours after sunset

Group IB: Duration of exposure of smartphone more than three hours after sunset

Group IIA: Duration of exposure of smartphone less than three years

Group IIB: Duration of exposure of smartphone more than three years

All the subjects selected for study were subjected to a detailed history taking by means of planned questionnaires including special enquiries regarding complaints of dimness of vision, tingling, paresthesia, addiction to alcohol, smoking, tobacco chewing. All the subjects underwent brief ocular examinations like general examination of eyes, recording of visual acuity and ocular tension. Subjects underwent careful systematic neurological examination for the evidence of peripheral neuropathy. Motor power and reflexes were checked for motor neuropathy. Previous reports, if any, for any ailment were assessed.

For the best results of VEP testing, subjects were explained about the test in a language he/she can understand to ensure the full co-operation. The usual glasses were, if any, were asked to put on during the test. The results of ocular examination were reviewed before starting the test. Subjects were advised to come without applying oil to the scalp. Preparation of the scalp skin was done with 'Nuprep® skin prep gel' before the study. The subjects were instructed to avoid any meiotic or mydriatic drug, if any, 12 hours before the test.

Running the Test: VEP was performed on Neuro-**MEP-4 : 4-channel NCS, EMG and Multi-modality EP system Neurosoft** machine.

Stimulus parameter (Pattern Reversal Stimulus):

- **Type and method of generation** – Computer generated patterns on a video monitor.
- **Type of pattern** – Black and white checkerboard pattern
- **Size of pattern element** – 32 minutes
- **Size of stimulus field** – 20 degrees
- **Stimulus type** – Full field stimulation with fixation point in the centre and pattern extending to both the sides equally.
- **Mode of pattern presentation** – Mode of stimulus presentation was pattern reversal in which dark and light pattern elements were alternately reversed
- **Stimulus rate** – 1.71 Hz (cycles per second)
- **Mono-ocular versus Binocular stimulation** – Mono-ocular stimulation was performed with each eye tested separately
- **Distance between the subject and the screen** – 100cms

Recording Parameters:

System Bandpass – 2-200 Hz

Analysis Time – 250 ms

Amplifications- 20,000-1,00,000

Recording Electrodes – Standard disc surface electrodes

Electrode placement – International 10-20 system placement with Active electrode (Oz), Reference electrode (Fz) and Ground electrode (Fpz)

Number of Epochs – 100

Replications – Two responses were recorded and superimposed for the reproducibility of the waveform. The replicated response measurements with P100 latency, within a 2.5 ms difference and peak-to-peak amplitude of N75-P100 or P100-N145, within 15% difference were accepted. (12, 13)

Methodology

The subject was explained about the procedure. After the preparation of scalp skin by abrading and degreasing properly, the electrodes were placed at O, Fz, and Fpz sites using the 'Nuprep® skin prep gel' as

per 10-20 international system. Uniform illumination was maintained for every subject studied. Distance between the TV screen and the subjects eye was kept constant at 100 cms. Subject was instructed to fix his gaze at the central spot on the TV screen. Mono-ocular stimulation was done and each eye tested separately with an eye-patch covering the other eye. With the preset stimulus and recording conditions as mentioned above and keeping the electrode impedance <5 KΩ, the recording procedure was started. Two responses from each eye were recorded and superimposed to ensure the reproducibility.

Statistical Analysis: All the data was expressed as mean ± S.D. The significance of difference between groups was calculated by Fisher's Exact Test of analysis on SPSS software version 24.

Observations and Results

Table 1. Comparison of Latency and amplitude in individuals with exposure of smartphone for less than three and more than three hours per day after sunset

Parameters	Duration of exposure in Hours per day		Significance
	<3Hrs/day Exposure	>3Hrs/day Exposure	
P100 Latency (Right Eye)	98.41	109.56	0.000
P100 Latency (Left Eye)	98.72	110.12	0.000
P100 Amplitude (Right Eye)	7.96	4.56	0.004
P100 Amplitude (Left Eye)	7.96	4.13	0.000

Table 2. Comparison of Latency and amplitude in individuals with exposure of smartphone for less than three and more than three years.

Parameters	Duration of exposure in years		Significance
Duration of exposure	<3Years of Exposure	>3 Years of Exposure	
P100 Latency (Right Eye)	103.41	104.24	0.696
P100 Latency (Left Eye)	103.86	104.72	1.000
P100 Amplitude (Right Eye)	6.67	6.00	0.741
P100 Amplitude (Left Eye)	6.48	5.72	1.000

Table 3. Inter-ocular differences in Latency and amplitude

Parameters / Duration of exposure	P100 Latency (Right Eye)	P100 Latency (Left Eye)	P100 Amplitude (Right Eye)	P100 Amplitude (Left Eye)
<3Hrs/day Exposure	98.41	98.72	7.96	7.96
>3Hrs/day Exposure	109.56	110.12	4.56	4.13
<3Years of Exposure	103.41	103.86	6.67	6.48
>3 Years of Exposure	104.24	104.72	6.00	5.71

From the results, it is obvious that there is significant difference not only in the mean values of P100 latencies of right and left eye as well as in the mean values of P100 amplitude of right and left eye in individuals with exposure of less than three and more than three hours per day after sunset. Our study is consistent with the findings of a study done to assess the effect of exposure of smartphone for less than three per day after sunset.[14-18] But our study couldn't find any significance in comparing the mean values of P100 latencies of right and left eye as well as in the mean values of P100 amplitude of right and left eye in individuals with exposure of less than three and more than three years of exposure.

Also we could find the inter-ocular differences in the values P100 latencies and P100 amplitude and the findings are consistent with many studies. [19-23]

Discussion

VEP stands to be an important procedure for assessing visual function. Though VEP can detect abnormality along the visual pathway ranging from the eye, retina, the optic nerve, optic radiations, upto the occipital cortex,[24] it appears to be highly sensitive to lesions of the optic nerve and anterior chiasm[25] *i.e.* to optic neuropathies (26), demyelination[27], multiple sclerosis [28, 29]. The activation of visual cortex primarily occurs by the central visual field.

The latency of VEP components is indicative of extrastriate source of defects rather than primary visual pathways. For instance, difficulties in motion detection, or "optic flow", seem to be especially prominent and may be explained by parallel defects in primary magnocellular stream and extrastriate visual processing. [30-31] The commonest cause of prolonged P100 latency is demyelination in the optic pathways.[32] A power density dependent decrease in latency of some of the late components of thalamic evoked potentials by affecting multisynaptic neural pathways. The amplitude of P100 has a wide inter-individual variability reducing its clinical utility.Conditions leading to axonal loss such as ischemic optic neuropathy produce decreased amplitude.

The inter-ocular asymmetry can be attributed to small differences in visual acuity, dominance of eye, changes in the alertness, and eye movement during the recording. These differences are usually small. Intraocular amplitude and peak latency analysis increases the sensitivity of the VEP to monocular diseases since each subject serves as his own control and may reveal abnormality.[19,20] The disparities between the dominant and the non-dominant eyes seem to be the presence of lateralization in the Central Nervous System [21] and neuro-anatomic asymmetries of the human striate cortex. [22] Proximity of the right eye to the cell phone and feeling greater heat and more radiation power also has been found to be the reason for inter ocular asymmetry.[23] (Table no. 3).

That blue light has a greater tendency to affect living organisms by disrupting biological processes that rely on natural cycles of day and night Therefore, light rich in short-wavelength (blue) light should be avoided in the late evening to promote a healthy night-time lighting environment. Apoptosis plays a major role in retinal visual cell loss.[38-44] The caspase-dependent as well as caspase-independent pathways, over stimulation of Poly [ADP-ribose] polymerase 1 (PARP-1) through oxidant-induced DNA damage, cleavage of PARP-1 inhibiting the enzyme responding to DNA damage along with Retinal endo-illuminator toxicity can induce apoptotic cell death.

Conclusion

Thus we conclude that nocturnal use of mobile phones especially for more than three hours per day for more than three years at least and especially in the bright light exposes an individual to the short wavelength light (blue light) resulting in various deleterious effects. Hence, combating the unhealthy effect of blue light from smartphone displays at night does not simply mean turning off the smartphone, but rather using well designed surge protection devices (SPDs), using smartphone at the proper distance, optimally adjusting the brightness setting in a dark room and the proper intensity of smartphone displays to see better where and when required while protecting people's health and circadian rhythm. Similarly if the blue light in smartphone displays in the night, if controlled finely, can have a greater impact on reducing the unhealthy effect like disturbed circadian rhythm due to decreased melatonin secretion. As this is a pilot study and sample size is small, further research in this regards is necessary.

Metabolic and Cardiovascular Responses to External Weights During Treadmill Walk in Overweight Young Adults

Swapnil Bhirange[1], Dalia Biswas[2], Avinash Taksande[3], Prerana Agarwal[1]

[1]Assistant Professor, [2]Professor and Head, [3]Associate Professor, Department of Physiology, JNMC, Sawangi (Meghe), Wardha

Abstract

Aim and Objective: Compare the physiological responses within bouts of aerobic exercise varying in intensity and the presence of wearable weights.

Study Design: Interventional study

Settings: Exercise Physiology Lab at the department of Physiology, JNMC, Sawangi (Meghe), Wardha.

Method and Material: Forty (18 females, 22 males, mean age = 22.23 ± 1.32) healthy volunteers were tested for aerobic fitness on a treadmill to determine VO2. Participants completed eight 30-minute walking trials on a treadmill and oxygen consumption (VO2) and heart rate (HR) were monitored while walking at different speeds and with varying combination of upper and lower body external weights. The design included two intensities (slow walking and brisk walking) and four conditions (no weights, arm weights, leg weights, and arm and leg weights) for a total of eight experimental trials.

Statistical Analysis Used: ANOVA and pair-wise comparisons on SPSS software version 24.

Results: VO2 was significantly lower without the wearable weights in comparison to wearing both upper and lower weights in the slow walk trial ($P < 0.001$; ES = 0.74) and also during the brisk walk trial ($P < 0.001$; ES = 0.35). HR was significantly higher during the brisk walk trials with external weights on both the arms and legs (P=0.018, ES=0.37).

Conclusions: Findings suggest that the metabolic responses were significantly increased wearing external weights on both the arm and leg during walking exercise on treadmill and increasing energy expenditure (burning additional calories) over the 30 minute session and have minimal impact on heart rate.

Keywords: *External weights, VO_2Max, Heart rate, treadmill.*

Introduction

Obesity has become one of the major health issues over the world. Worldwide obesity has nearly tripled since 1975. In 2016, more than 1.9 billion adults, 18 years and older, were overweight. Of these, over 650 million were obese. 39% of adults aged 18 years and over were overweight in 2016, and 13% were obese.[1]

Overweight and obesity have become the major health problem, in addition to physical inactivity, in almost all the age groups particularly in urban areas with serious medical and psycho-social consequences, replacing the more traditional public health concerns. Though low prevalence of obesity among Indian children (3-2%) may be surprising, but the relatively high prevalence of overweight (14-9%) is alarming.[2]

Overweight children often become overweight adults[3] and overweight in adulthood is a health risk. Large cohorts from various populations have demonstrated the important influence of childhood BMI on future cardiovascular health. Juvenile obesity is particularly alarming because it is considered to be a key predictor for obesity in adulthood[4], and its prevention

and treatment have a remarkable clinical relevance [5]. Several disorders have been linked to overweight and obesity in childhood. Obesity results in considerable morbidity and mortality, of which cardiovascular disease and type 2 diabetes mellitus remains one of the principal causes.[2]

Physical activity has been the integral part of human body and it should naturally be part of our everyday life. Because of a more modern and demanding lifestyle, physical activity has declined, becoming less important than other activities such as work, family, or social responsibilities. Regular physical activity is associated with various health benefits. Active individuals can lower their risk of coronary heart disease, hypertension, colon cancer and diabetes by being active for thirty minutes a day. Exercise also helps maintain a healthy weight, stronger bones, muscles and joints, reduce body fat and increase lean muscle. Also regular exercise can decrease anxiety and depression while improving mood[6].

Methodology

Study design: Interventional study

Settings: Neurophysiology Lab at the department of Physiology, JNMC, Sawangi (Meghe), Wardha.

Participants: 40 participants (22 boys and 18 girls) ranging from 18-25 years were recruited. Each participant was asked to walk on the treadmill to determine the exercise intensities for subsequent exercise trials.

Familiarization with the external weights included instruction on proper size, location, and fit for the ankles and wrists. The purpose of this portion of the trial was to provide exposure to the external weights prior to the experimental manipulation to limit the perceptual impact of wearing a novel device.

Following setting workload and familiarization, the participants was informed about the exertion assessment scale that was to be used throughout the research study. Borg's 6-20 Rating of Perceived Exertion scale (RPE) [7] was explained in full detail to each participant, and the participants were then required to confirm that they understood the tool clearly.

Sample size: Sample size was calculated as fourty (40) using formula $4PQ/L^2$ where prevalence of overweight adults has been taken as 11.3% [8]

Description of Laboratory Visits:

Visit Description:

1. Screening to include a physical exam, informed consent, and resting assessments
2. Maximal treadmill test
3. Setting Workload and Familiarization with treadmill and external weights
4. 4-7 Experimental exercise trials

Screening (Visit 1): The screenings included a comprehensive health history, pre-participation physical exam administered by a physician, completion of the informed consent document, and assessment of resting heart rate, weight, height, and blood pressure.

Maximal Exercise Testing (Visit 2): Each participant was complete a graded exercise maximal treadmill test that included measurements of heart rate, blood pressure, perceived exertion, and metabolic gas exchange. The "Health and Exercise Science (HES)" protocol[9] was used for this test consists of a starting speed of 3.0mph on the treadmill with speed increases of 0.5 every minute afterward. Heart rate and RPE were recorded every minute; blood pressure was recorded every three minutes. When participants reached a speed of 7.0 (females) or 8.0 (males) on the treadmill, the incline was then increased by 2% every minute thereafter, with no additional increases in speed. Participants were encouraged to go until maximal effort and exhaustion was achieved.

Setting Workload and Familiarization (Visit 3): Each participant was asked to walk on the treadmill to determine the exercise intensities for subsequent exercise trials.

One workload corresponds to a "slow walk" which was designed to replicate walking that was associated with activities of daily living.

The second workload corresponds to a "brisk walk" which was designed to replicate walking that was purposeful and associated with fitness. Workload establishment of the two separate speeds lasted approximately 30 minutes with 15 minutes designated to each walking speed. Collectively, the two workloads were self-selected and were intended to reflect public health recommendations related to lifestyle physical activity.

Familiarization with the external weights included instruction on proper size, location, and fit for the ankles and wrists (3 Kgs, **AURION** Wrist/Ankle External weights Home Gym Weight Bands commercially available on **AMAZONE**) [10, 11]. The purpose of this portion of the trial was to provide **exposure to the external weights prior to the experimental manipulation to limit the perceptual impact of wearing a novel device**. Following setting workload and familiarization, the participants were informed about the exertion assessment scale that was to be used throughout the research study. Borg's 6-20 rating of perceived exertion scale (RPE) was explained in full detail to each participant, and the participants were then required to initiate that they understood the tool clearly.

Experimental Exercise Trials (Visits 4-7): The four experimental trials were allowed for both exercise intensities to be tested across four equipment conditions. The two exercise intensities examined were the "**slow walk**" and "**brisk walk**". The four equipment conditions included: no external weights, ankle and wrist external weights, wrist external weights only, and ankle external weights only (see Table).

Prior to each exercise trial, the metabolic cart was properly calibrated by the research team. A heart rate monitor was supplied for each participant upon arrival to the laboratory. A warm-up of 30 seconds was preceded every exercise trial at a speed of 2.5 mph on the treadmill. At the conclusion of the warm-up, the speed was adjusted to either to a self- selected "slow" or "brisk" walking pace as previously determined, and was dependent upon what condition the participant will be assigned for that day. Every six minutes heart rate and rate of perceived exertion for the ankles, chest/breathing, and overall were assessed. At minute 24 of the exercise trial maximal heart rate achieved and perceived exertion of the ankles were recorded from minute 24 to minute 29 at an interval of 1min.

At 30 minutes, a 30 second cool down at 2.5mph on the treadmill was transpired. Once the treadmill was stopped by the research team, immediate post exercise perceived exertion was taken and again ten minutes afterwards.

Thus Heart rate and oxygen consumption were investigated across self- selected two intensities (slow and brisk) with four different combinations of External weights (Table 1) and eight balanced experimental trials (walking for thirty minutes at a self- selected slow or brisk speed with either no togs, arms only, legs only, or both arm and leg togs) were incorporated.

Table 1: Experimental Trial Conditions

Intensity		External weights			
Slow Walk	Brisk Walk	None	Wrist & Ankle	Ankle Only	Wrist Only

Inclusion Criteria:

- Age between 18-25 years
- BMI 23 – 24.9 kg/m^2 [12]
- Participants not doing regular physical exercise
- Participants giving consent

Exclusion Criteria:

- Age between <18 and >25 years
- BMI between < 22.9 and >25 kg/m^2
- Participants having cardiovascular, metabolic, pulmonary diseases and related symptoms
- Participants doing regular exercise
- Patients not following the guidelines of this study
- Participants not giving consent

Outcome Measures:

- Cardiovascular – Heart rate
- Metabolic - VO_{2max}

Statistical Data Analysis: The research design utilized two intensity namely slow walk and vigorous walk and four conditions namely no external weights, wrist and ankle-external weights, ankle-external weights only, wrist-external weights only. Repeated measures ANOVA test for statistical analysis was applied. Each participant served as their own control. Each p-value will be<0.05.

Results

Table 2: Demographic profile of the participants (n = 40)

	Minimum	Maximum	Mean ± SD
Age	18	25	22.23±1.32
Height (inch.)	59	71	64.84±2.11
Weight (lbs.)	116	194	161.0±23.9
BMI	23.82	24.87	24.35±0.65
Slow speed	1.8	3.1	2.45±0.55
Brisk speed	3.2	4.6	3.91±0.70

Table 3: $VO2_{max}$ Data: Descriptive statistics (n = 40)

Treadmill speed–external weights	Mean ± SD
Slow-none	12.11 ± 1.43
Slow-arms	12.81 ± 1.45
Slow-legs	11.98 ± 1.81
Slow-both	12.83 ± 1.42
Brisk-none	14.97 ± 2.12
Brisk-arms	15.64 ± 2.32
Brisk-legs	15.92 ± 1.98
Brisk-both	16.12 ± 2.69

Table 4: Follow-up Comparisons (VO2)

Variable 1	Variable 2	P-value	Effect Size
Brisk-none	Brisk-both	<0.001	0.35
Brisk-none	Brisk-arms	0.876	0.39
Brisk-none	Brisk-legs	0.006	0.34
Brisk-both	Brisk-arms	0.001	0.56
Brisk-both	Brisk-legs	0.372	0.98
Brisk-arms	Brisk-legs	0.001	0.76
Slow-none	Slow-both	<0.001	0.74
Slow-none	Slow-arms	0.546	0.09
Slow-none	Slow-legs	0.008	0.33
Slow both	Slow-arms	<0.001	0.34
Slow-both	Slow-legs	0.006	0.87
Slow-arms	Slow-legs	0.328	0.45

The results showed that comparison between "VO2 during the "slow" walk with and without external weights on the **arms**." (p=0.546); "VO2 during the "brisk" walk with and without external weights on the **arms**" (p=0.876); "VO2 during the "brisk" walk with external weights on both the **arms and legs** and that with external weights on the **legs only**" (p=0.372); and "VO2 during the "slow" walk with external weights on the **arms** that with external weights on the **legs**" (p=0.328) had no significant difference.

But the results showed that comparison between "VO2 during the "slow" walk with and without external weights on the **legs**" (p=0.008); "VO2 during the "brisk" walk with and without external weights on the **legs**" (p=0.006); "VO2 during the "slow" walk with and without external weights on both the **arms and legs**" (p<0.001); "VO2 during the "brisk" walk with and without external weights on both the **arms and legs**" (p<0.001); "VO2 during the "slow" walk with external weights on both the **arms and legs** that with external weights on the **arms only**" (p<0.001); "VO2 during the "brisk" walk with external weights on both the **arms and legs** and that with external weights on the **arms only**" (p=0.001), and lastly "VO2 during the "slow" walk with external weights on both the **arms and legs** and VO2 during the "slow" walk with External weights on the **legs only**" (p=0.006) showed a significant difference.

Heart Rate:

Table 5: HR Data: Descriptive statistics (n = 40)

Condition	Mean±SD
Slow-none	96.87±10.34
Slow-arms	97.23±12.01

Slow-both	103.26±14.980
Brisk-none	116.87±11.89
Brisk-arms	117.12±10.87
Brisk-legs	119.11±14.68
Brisk-both	119.95±13.48

Table 6: Follow-up Comparisons (Heart Rate)

Variable 1	Variable 2	P-value	Effect Size
Brisk-none	Brisk-both	0.018	0.37
Brisk-none	Brisk-arms	0.656	0.23
Brisk-none	Brisk-legs	0.002	0.26
Brisk-both	Brisk-arms	0.044	0.65
Brisk-both	Brisk-legs	0.621	0.81
Brisk-arms	Brisk-legs	0.035	0.19
Slow-none	Slow-both	0.003	0.21
Slow-none	Slow-arms	0.629	0.96

Variable 1	Variable 2	P-value	Effect Size
Slow-none	Slow-legs	0.041	0.65
Slow both	Slow-arms	0.034	0.21
Slow-both	Slow-legs	0.214	0.36
Slow-arms	Slow-legs	0.023	0.73

The results showed that comparison between "heart rate during the "slow" walk with and without external weights on the **arms**." (p=0.629); "heart rate during the "brisk" walk with and without external weights on the **arms**" (p= 0.656); "heart rate during the "brisk" walk with external weights on both the **arms and legs** and that with external weights on the **legs only**" (p= 0.621); and "heart rate during the "slow" walk with external weights on the **arms** that with external weights on the **legs**" (p=0.083) had no significant difference.

But the results showed that comparison between "heart rate during the "slow" walk with and without external weights on the **legs**" (p= 0.041); "heart rate during the "brisk" walk with and without external weights on the **legs**" (p= 0.002); "heart rate during the "slow" walk with and without external weights on both the **arms and legs**" (p<0.003); "heart rate during the "brisk" walk with and without external weights on both the **arms and legs**" (p<0.019); "heart rate during the "slow" walk with external weights on both the **arms and legs** that with external weights on the **arms only**" (p< 0.034); "heart rate during the "brisk" walk with external weights on both the **arms and legs** and that with external weights on the **arms only**" (p= 0.044), "heart rate during the "slow" walk with external weights on **arms only** and that with external weights on the **legs only**" (p=0.023) and lastly "heart rate during the "brisk" walk with external weights on **arms only** and that with external weights on the **legs only**" (p=0.035) showed a significant difference.

Discussion

The present experiment is designed to examine the cardiovascular and metabolic responses of walking with external weight worn on the wrists and ankles. Results showed a significant increase in oxygen consumption while wearing External weights during exercise. Wearing these additional weights while walking elicited a linear rise in oxygen consumption, and more specifically, the largest responses were seen during trials with External weights on both the arms and legs.

An approximate 13% increase in energy cost was seen during the "slow" walk when both sets of external weights were added to the body while about 16 extra calories were burned throughout the walking trial. Furthermore, about 12% increase in energy cost was also seen when adding arm and leg external weights during the "brisk" trials. When walking at a "brisk" speed with no external weights, participants burned, on average, about 184 calories. When arm and leg External weights were added, it resulted in an average of 23 more calories burned over thirty minutes. But there was a little change in heart rate while wearing External weights. From resting heart rate to maximal heart rate, heart rate increased about four times, and the resting oxygen consumption had increased up to sixteen times during the brisk walking trials. Thus the significant increase in heart rate is relatively difficult to see. It still suggested the metabolic adjustments produced by the addition of External weights. [10] There was significant increase in heart rate and oxygen consumption with wrist weights, explaining that walking with wrist weights increased the energy cost more than the ankle weights.

Wearing external weights during exercise by an overweight individual can easily overcome the discouragement he/she experiences from the amount of maintenance required to stay healthy and fit leading to higher self-efficacy in the exerciser. This also prevents further weight gain by making small increases in physical activity.

As we are solely looking at a low-risk healthy population of young adults ranging 18years to 25years, therefore the findings cannot be generalized to other groups such as the elderly, adolescent or hypertensive. Thus we recommend for further research on individuals with different fitness levels and using a more intense exercise modality like running or cycling. Also, the External weights implicate small changes for those individuals who are sedentary, and may not provide a large metabolic response due to the little amount of weight that they add. Therefore, it is difficult to consistently report such a sensitive amount of change in oxygen consumption.

Conclusion

The metabolic responses were significantly increased wearing external weights on both the arm and leg during walking exercise on treadmill and burn additional calories over the 30 minute session, eliciting an approximate 12% improvement over exercise sessions

when no external weights were worn. Significant increase in oxygen consumption and caloric expenditure was observed by wearing the external weights, but the cardiovascular responses were not significant at both the slow and brisk speeds. External weights can thus be a practical and promising tool to be implemented into the fitness industry and rehabilitation centers.

Abstract

Introduction: Diabetes and its complications impose significant economic consequences on individuals, families, health systems and countries. People living with diabetes and their families feel the impact of diabetes most directly, often through the expenses of diabetes treatment and loss of family income when diabetes interferes with work.

Objective: To assess the financial status of adult diabetic patients attending the diabetic clinic of Bankura Sammilani Medical College, Bankura.

Materials and Method: It is an Institution based, Cross-sectional, descriptive Study. Complete enumeration of all patients attending Diabetic clinic of Bankura Sammilani Medical College and hospital, Bankura, West Bengal was done. Eligible consenting of adult patients (> 18 years of age) who were diagnosed as a case of diabetes at least 1 year back and on treatment were interviewed with review of medical record and Out-of pocket expenditure information was collected in terms of INR. It views the cost of NCDs as the sum of several categories of direct and indirect costs. The study was preceded after obtaining ethical clearance. Data were entered in MS Excel spread sheet. Calculation was done with the help of software SPSS 22.0 free version.

Results: Majority of annual treatment expenses of study subjects were in Drugs and consumables (66.73%) followed by Investigation cost 15.19% and others. The average INR for annual total diabetes care was 13,733.17±13,389.86.

Conclusion: Drugs and consumables, investigation and transportation cost leads to more than 90.0% of out-of pocket expenditure causing financial burden on both adult diabetic patient and its family.

Keywords: *Adult diabetic, direct cost, indirect cost, out-of pocket expenditure.*

Introduction

All types of diabetes are on the increase, type 2 diabetes in particular: the number of people with diabetes will increase by 55% by 2035. In human as well as financial terms, the burden of diabetes is enormous, provoking 5.1 million deaths and taking up some USD 548 billion dollars in health spending (11% of the total spent worldwide) in 2013. In India the total number of diabetic population in 2013 is 65.10 millions and estimated around 109.00 millions in 2035 (20-79 years)[1].

Diabetes affects all segments of the population and

Corresponding Author:

e-mail: magicofkaran@gmail.com

is one of the leading causes of premature morbidity and mortality, and requires life-long healthcare services. Poverty, low education, and gender discrimination adversely affect women with diabetes. About 90% of all respondents did not test their blood glucose regularly and suffered from several complications with low medication adherence and poor clinic attendance. Information on the availability, cost, and quality of medical care for diabetes is generally not available[2].

Diabetes and its complications impose significant economic consequences on individuals, families, health systems and countries[3]. People living with diabetes and their families feel the impact of diabetes most directly, often through the expenses of diabetes treatment and loss of family income when diabetes interferes with work[4].

Besides the health expenditures, other measurements have also been used to assess the economic impact of diabetes. First, diabetes also imposes a large financial burden on people with diabetes and their families. The size of this burden depends on their economic status and the social insurance policies of the countries in which they live. Second, at the societal level, diabetes leads to loss in productivity and economic growth. Finally, the largest economic burden caused by diabetes is the monetary value associated with disability and loss of life as a result of the disease itself and its related complications, including heart, kidney, eye and foot disease[5].

The National Rural Health Mission[6] (NRHM) launched in 2005 and the new pilot National Programme for prevention and control of Diabetes, Cardiovascular diseases and Stroke[7] (NPDCS) offer opportunities for improving care for diabetes and other non-communicable diseases through service provision at the primary and secondary levels of care.

Availability and affordability of anti-diabetic medication is another problematic aspect, in spite of "The National List of Essential Medicines" identifying glibenclamide, metformin, and insulin (soluble and lente) as anti-diabetic drugs that need to be available universally[8]. The availability of glibenclamide in public health facilities, for example, varied from 100 percent in Karnataka to 3.8 percent in West Bengal[9]. Given the uncertainty of availability of medicines, and the lack of pricing control over the private sector, compliance with medication becomes a serious issue[10-14].

Materials and Method

An Institution based, Cross-sectional, descriptive Study was done in Diabetic Clinic of Bankura Sammilani Medical College and hospital, Bankura, West Bengal which runs once in a week on every Thursday and approximately 20 to 30 patients attend the OPD day per week. Total duration of study was of 20 months from May 2014 to December 2015. Patients who were diagnosed as a case of diabetes in private clinic or other department of the B.S.M.C and hospital and/ or on treatment on anti-diabetic drugs were enrolled as a new patient on first visit of the patient in Diabetic Clinic. Adult patients (> 18 years of age) attending Diabetic clinic and who were diagnosed as a case of diabetes at least 1 year back and was on treatment are study subjects. All eligible patients who give informed or verbal consent attending the Diabetic clinic are taken in the study during data collection period. On an average of 5-6 patients were newly enrolled in register per week on Diabetic clinic. During the data collection period all eligible patients attending the diabetic clinic, were taken as study population and 150 study subjects were taken. The study was proceeded after obtaining ethical clearance from the institutional ethics committee and Diabetic clinic under Medicine Department. Pretesting of Schedule was done in 20 patients attending medicine OPD and were excluded from the final data collection. Any difficulty that arose during pretesting was corrected in the final questionnaires.

Result

84.0% of subjects did not have to pay for annual Consultation charges. 16.0% of subjects had to payfor Consultation charges at private clinic. Even 2.7% of them had to pay INR of ≥2000/-. The Mean INR for annual consultation charges was 221.61±593.65 with arange of 0.00-3500/-INR.

Majority of the subjects (43.3%) had to pay 1000-2000 rupees every year for investigations (outdoor annually) due to diabetes and associated conditions. The Mean INR for annual investigation cost was 1972.33±1788.43/- with a range of 0-12000/-INR.

One fourth of study subjects had to (27.3%) pay for more than 10,000 rupees in a year for Drugs and Consumables(outdoor annually). The Mean INR for annual cost on Drugs and Consumables was 8931.93±10554.39/-and a range of INR for annual cost on Drugs and Consumables was 0-96000/-.

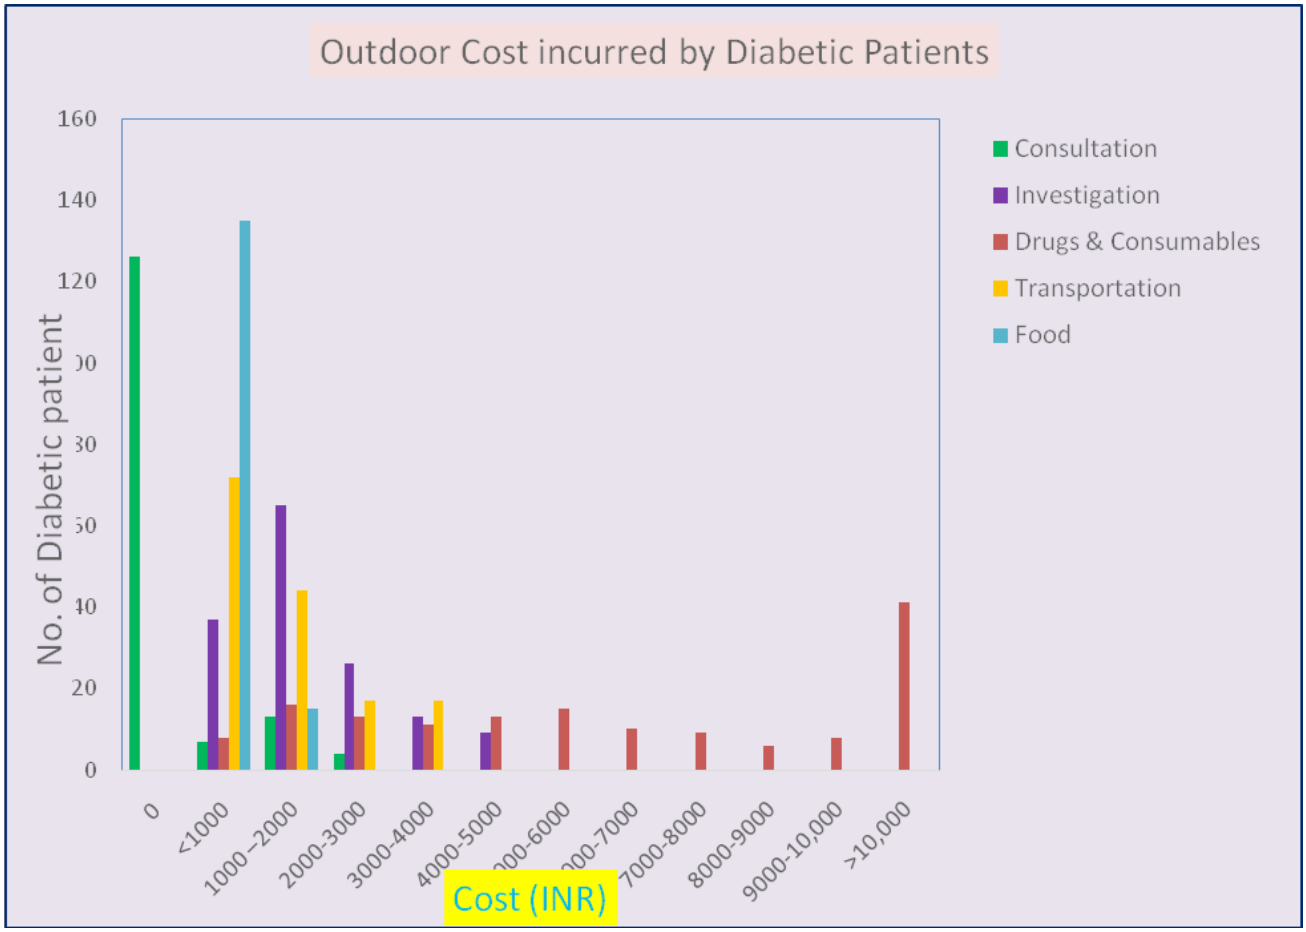

Figure 1: Distribution of study subjects according to annual expenditure on different outdoor cost by Adult Diabetic Patient (n=150)

Table No. 1: Distribution of study subjects according to Total annual cost (outdoor) (n=150)

Treatment	Outdoor Cost (INR)	Indoor Cost (INR)	Total Cost (INR)	Percentage
Doctor Consultation cost	33,020/-	0.0	33,020/-	1.59
Investigation cost	2,95,850/-	19,250/-	315100/-	15.19
Drugs and consumables cost	13,39,790/-	43,670/-	1383460/-	66.73
Transportation cost	2,42,676/-	20,870/-	2,63,546/-	12.72
Food cost	59,220/-	17,990/-	77,210/-	3.72
Surgical cost	0.0	1000/-	1000/-	0.05
Total cost	19,70,556/-	1,02,780	20,73,336/-	100.0

Majority of annual treatment expenses of study subjects were in Drugs and consumables (66.73%) followed by Investigation cost 15.19%, Transportation cost 12.72%, Food cost was 3.72% and least by Consultation cost was 1.59%. The mean INR for annual total diabetes cost was 13,733.17±13,389.86/-, the median INR was 10,520.00±9,682.50/- and the range of INR for annual total diabetes cost was 520-1,21,200/-.

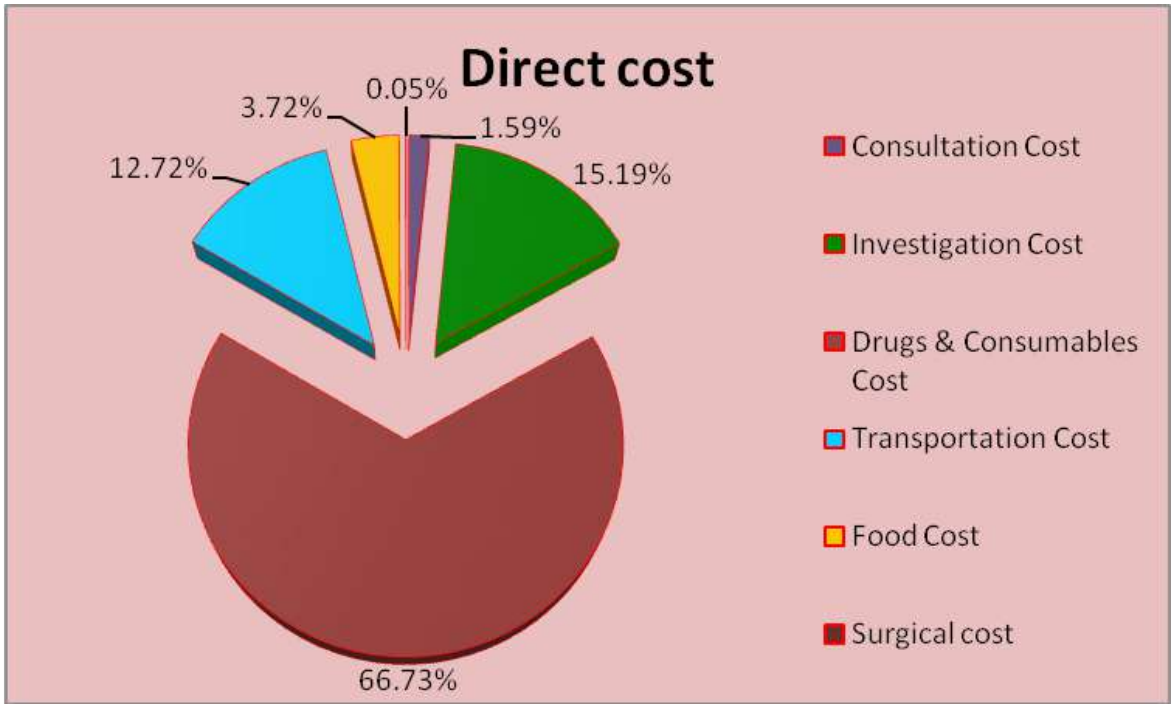

Figure 2. Distribution of study subjects according to Total Direct cost (n=150)

Majority of treatment expenses were in Drugs and consumables followed by Investigation cost 15.01% and then Transportation cost was 12.31%. Only 10.0% of subjects were hospitalised during the last one year for diabetes associated complications. According to duration of stay in hospital, 66.7% of subjects were admitted to hospital for 1-7 days in the last one year.

Table No. 2: Distribution of study subjects according to Total Hospital admission cost in last one year (n=15)

Treatment	Cost (INR)	Percentage
Investigation cost	19,250/-	18.72
Drugs and consumables cost	43,670/-	42.48
Transportation cost	20,870/-	20.30
Food cost	17,990/-	17.50
Surgical cost	1,000/-	1.0
Total cost	1,02,780/-	100.0

During hospitalization due to diabetes and associated complication, 42.48% of cost was spend on Drugs and Consumables followed by 20.30% in transportation and 18.72% for investigation and 17.50% for Food cost. The mean INR for hospitalization due to diabetes and its complication was 643.33±2411.06/-, the Range of INR for hospitalization was 0.0 -17,000/-.

Majority of 58.67% subjects had Man days lost of them and their companions in last one year. Total Man days lost of them and their companions in last one year was 1538 days. Mean of Man days lost of them and their companions in last one year was 17.48±11.79 days. Range of Man days lost of them and their companions was 4-72 days. Majority of subjects had loss of more than 2,000 rupees in last one year from Wages of them and their companions due to diabetes. Total INR wages lost of study subjects and their companions annually was 1,30,750/-. Mean INR wages lost by study subjects and their companions annually was 2,563.73±2,792.59/. Range of INR for wages lost of study subjects and their companions annually was 240-18000/-.

Table No. 3: Distribution of adult diabetic patients according to Total Direct Cost and diabetic complications (n=150)

Cost	Variables		N	Median±IQR	Mean rank	Mann-Whitney U Test (p value)
Total Direct cost (INR)	Diabetic Complications	Present	51	10,200.0±9,760	74.15	2455.5 (0.784)
		Absent	99	10,600.0±10,570	76.20	
	Comorbid conditions	Present	98	10,300.0±10850	73.81	2382.5 (0.513)
		Absent	52	11,212.0±33180	78.68	
	Absenteeism	Present	51	10,320.0±10445	76.45	2644.0 (0.749)
		Absent	99	10,840.0±9810	74.15	

The median score of Total cost was less when Diabetic complications was present than when it was absent and the difference was statistically not significant (p >0.05).The median score of Total cost was less when Comorbid conditions was present than when it was absent and the difference was statistically not significant (p >0.05).The median score of Total cost was less when Absenteeism was present than when it was absent and the difference was statistically not significant (p >0.05).

Discussion

In this study 150 adult diabetic patients attending the diabetic clinic were interviewed along with review of medical records. In this study physical assessment was done by comparing with diabetes complication, comorbid conditions and financial assessment of annual expenditure was done by collecting data of recent three months expenditure on diabetes care by the study subjects for both direct and indirect costs. Physical and financial status association was seen with socio-demographic characteristics and health services related factors, utilization of health facilities and among themselves also.

Proportion of female (51.3%) was more than male (48.7%) in present study and similar finding was found in study done in Saudi Arabia[17].

In present study the mean age of female was 50.00±12.69 years and the mean age of male was 52.40±12.64 years whereas the overall mean age of the participants was 54 ± 12 years in a study conducted in Oman[18].

In present study 80.6% of study subjects had good drug compliance whereas 19.4% had poor drug compliance whereas a multicentric study in India, revealed 79.4% were compliant with their medication[19]. But other studies revealed poor drug compliance[20-23, 9].

79.3% of study subjects skipped the drug when it was finished. Only 5.3% of study subjects had supply of drug from hospital fully but rest of them had to buy the drug from the shop. 50.0% had to buy all the antidiabetic drugs from the shop and 44.7% were dependent both on shop and hospital for anti-diabetic drug. 52.0% of study subjects had irregular supply of drug from hospital whereas 48.0% of subjects had regular supply of drugs.

Diabetes was diagnosed in 6.0% of study subjects below 20 years of age. The proportion of diagnosed case of diabetes increased up to 50 years of age and then decreased. The Mean age of diagnosis of diabetes was 45.92±13.58 years in study subjects, Median age of diagnosis was 47.0±21.0 years and Range was from 14-87.5 years. In Diab-Care Asia, a multi-country study in Asia, the mean age of diagnosis among Indian respondents was 43.6 years[24].

Majority of study subjects attending the diabetic clinic had 1-5.99 years (67.3%) of duration of diabetes and only 13.3% of subjects had more than 11 years of duration of diabetes. In present study Median year of duration of diabetes was 3.0 (1-32) years whereas a study in Oman showed a median year of duration of diabetes was 7 (4-10) years[25].

Majority of annual treatment expenses of study subjects were in Drugs and consumables (66.73%) followed by Investigation cost 15.19%, Transportation cost 12.72%, Food cost 3.72% and Consultation cost was least at 1.59%. In present study drug costs accounted for more than half of the total direct costs which was similar to other studies conducted in India[26-33].

Conclusion

Antidiabetic drug were not regularly available in hospital so all most all had to purchase drug from the shop when not available at hospital.

Drugs and consumables, investigation and transportation cost leads to more than 90.0% of out-of pocket expenditure in both in-door and out-door care causing financial burden on both adult diabetic patient and its family. Majority of study subjects had Man days lost of them and their companions in last one year was approximately 4 years.

Total INR wages lost of study subjects and their companions annually was also a financial constraint for follow-up of hospital by subject.

Assessment and Comparison of Knowledge and Awareness about Hand Hygiene among Health Care Workers from PHC and Medical College

Amit Pasari[1], Pratibha Deshmukh[2], Sweety Agrawal[3]

[1]Assistant Professor Department of Nephrology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences Sawangi, Wardha, Maharashtra, [2]Professor & Head, [3]Assistant Professor, Dept. of Anaesthesiology, Datta Meghe Medical College, SMRC Hospital Hingana Nagpur

Abstract

Objectives: Present study was conducted to assess and compare the knowledge of hand hygiene (HH) according to WHO guidelines among healthcare workers (HCW) from medical college hospital and primary health care centre (PHC). Improvement in knowledge of HH was assessed after training.

Method: Cross-sectional study was conducted in two groups comprising of 167 HCW from a medical college hospital (GROUP A) and from PHC (GROUP B). The WHO "Hand Hygiene Knowledge Questionnaire" was used to collect data. Multiple choice questions were given to participants before and after training program for HH.

Results: Eighty & eighty seven HCW were recruited in group A & B respectively. Before HH training program, both the groups had very few people with good knowledge of HH (8.7% in group A & 5.7% in group B). After attending the HH training program, there was significant increase in the number of individuals having good knowledge of HH practise (52.5% & 35.6 % in group A and B respectively, $p<0.001$ for the groups).There was significant increase in the mean scores in both groups after HH training from 57.638+ 12.52% to 75.66 + 12.45%, $p <0.001$ in GROUP A & 46.66 +18.7% to 64.59 + 18.97%, $p<0.001$ in Group B.

Conclusions: There was low level of awareness about HH practices in studied population. Regular awareness program must be conducted to improve the knowledge of HH. Medical colleges should consider conducting such program for all HCW including PHC HCW at regular interval.

Keywords: *Hand hygiene, PHC, HCW, HH, WHO.*

Introduction

Healthcare workers (HCW) play a significant role in transmission of nosocomial pathogen.[1] Improper hand hygiene by health care worker is responsible for about 40% of nosocomial infections.[2] Health care associated infections (HCAI) are major cause of increasing morbidity, mortality and health care cost among hospitalized patients. Hand hygiene (HH) is an effective way of preventing the spread of infectious diseases and antimicrobial resistance.[3] Improved compliance with HH, with proper use of alcohol-based hand rubs (ABHR) can reduce the nosocomial infection rate by as much as 40%.[1] Practicing HH, either washing the hands with water and soap or using ABHR, is a simple effective way to prevent infections.

Compliance with recommended HH procedures for HCWs has been poor, with mean baseline rates as low

as 5% and an overall average of 38.7%.[4] In our study, HCW's awareness and knowledge regarding hand hygiene before and after educating them with WHO guidelines was studied with the help of questionnaire. HCWs working in a medical college & those working in primary health care centres in Vidarbha (India) were randomly recruited for the study. Aim of our study was to assess and comparison of knowledge of hand hygiene according to WHO guidelines among healthcare workers from medical college hospital and primary health care centre workers. Also comparing the knowledge of HH among HCW before and after educating them by comprehensive awareness and training programme.

Material and Method

Research design and setting: This cross-sectional study was conducted in two groups. Group A comprised of HCW from medical college hospital and Group B comprised of HCW from primary health care centres (PHC). Both the groups included doctors and nurses.

Ethics: Ethical committee clearance was taken from institute. Health care workers were explained about the content and nature of the study.

Sample size and sampling: As per previous studies, 8-10.6% HCW had a good knowledge of hand hygiene practice (i.e. score ≥75%).[5,6] Considering 9% prevalence of good knowledge of HH practice in our population and 95% confidence level, we calculated sample size of 80 in each group.

Exclusion Criteria: HCWs who refused to give consent for participation were excluded. Incompletely answered questionnaire were also excluded from final analysis.

Methodology and Data Collection: The World Health Organization (WHO) "Hand Hygiene Knowledge Questionnaire"-revised 2009 edition was used to collect data. The questionnaire contained questions on the participant's profession, years of the experience working in hospital, attendance in previous HH programme and awareness about 7 steps and 5 moments of HH as described by WHO. Twenty one multiple choice questions were given to participants in English & Marathi. These questionnaires were filled by participants before and after taking educational hand hygiene training programme. Educational hand hygiene programme was conducted by medical college and primary health care centre workers between March to May 2020. All the participants were randomly assigned to 30 batches each comprising of 5-6 HCW for training. Training was conducted in the form of audio visual presentation and HH demonstration. To identify the level of knowledge, scores were given to responses from the participants. For the scoring, "1" point was given for a response that indicated a "good level of knowledge" and "0" point was given for a response that indicated a "poor level of knowledge".[3] A score of 75% and above was considered good, 50-74% was considered moderate, and below 50% was considered as poor knowledge of HH practice.[5-6]

Statistical Analyses: Statistical analysis was done with the help of SPSS version 16. Paired T test was used for analysis of pre & post test scores of individual respondents. Unpaired T test & Mann Whitney U test were used for comparing mean scores of two groups. Chi square test was used to compare categorical variables. P value of < 0.05 was considered significant.

Results

Total 167 HCWs which included doctors and nurses were enrolled in the study. HCWs were divided into two groups, 87 health care workers working at primary health care centre and 80 healthcare workers working at medical college. The demographic characteristics of the HCW are shown in Table 1. In group B, 42 were doctors and 45 were nurses while in group A42 were doctors and 38 were nurses. Median experience of HCWs was 3 years in group A & 4 years in group B. Out of 167 participants 115 had attended hand hygiene training in last three years.

Table 1: Demographic parameter of Group A and Group B Participants

Profession	Group A (%)	Group B (%)
Doctor	42(52.5%)	42(48%)
Nurse	38(47.5%)	45(51%)
Median experience working in hospital (years)	3	4
Attended any hand hygiene programme in last 3 years	55 (68.8%)	60 (68.9%)

There was significant increase in the mean scores in group B after HH training (from 46.66 +18.7% to 64.59 + 18.97%, $p<0.001$) Table 2.

There was significant increase in the mean scores in group A after HH training 57.638 %(+ 12.52) 75.66 % (+ 12.45) Table 2.

Table: 2 Comparison between pre-test and post test score for awareness and knowledge about Hand hygiene among group A and B participants.

	Group A		Group B	
	Mean±SD (%)	P Value	Mean±SD (%)	P Value
Pre Test Score	57.638 +12.52	< 0.001	46.66 +18.7	< 0.001
Post Test Score	75.66 +12.45		64.59 +18.97	

Mean increase in the scores after attending the HH program was comparable in both the groups. (18.62+19.89 % vs. 18.02+11.40 % group B vs. group A respectively, p= 0.733) Table 3.

Table: 3 Comparison between growths in percent score between both groups

Groups	Growth in Percent (Mean±SD)	P value
Group A	18.02±11.40	0.733
Group B	18.62±19.89	

Before HH training program, both the groups had very few people with good knowledge of HH (8.7% in group A & 5.7% in group B). After attending the HH training program, there was significant increase in the number of individuals having good knowledge of HH practise (52.5% & 35.6 % in group A and B respectively, p<0.001 for the groups).

Before HH training, poor score i.e. < 50% was found in 19(23 %) and 40 (45 %) participants in group A and B respectively. There was significant reduction in the number of participants having poor score after HH training program. 2(2.5 %) and 19(21.8%) participants in group A and B respectively) Table 4.

Table: 4 Comparison of the participant's knowledge level in both groups.

Hand Hygiene Knowledge	Group A		P value	Group B		P value
	Pre Test N (%)	Post Test N (%)		Pre Test N (%)	Post Test N (%)	
Good (≥75%)	7(8.7%)	42(52.5%)	p<0.001	5(5.7%)	31(35.6%)	p<0.001
Poor (< 50%)	19(23%)	2(2.5%)	p<0.001	40(45%)	19(21.8%)	p<0.001

Discussion

Nosocomial infections constitute a major challenge of modern medicine. On an average, infections complicate 7% to 10% of hospital admissions.[7] Transmission of microorganisms from the hands of HCW is the main cause of nosocomial infections, and hand washing remains the most important preventive measure.[8] There is evidence that hand antiseptics reduce the transmission of health care associated pathogens and the incidence of Health Care Associated Infection (HCAI).[9]

Several hand hygiene studies have been conducted among medical students and nursing students and HCW including doctors and nurse from tertiary health care centre.[5-6, 10-14] In developing country like India, primary health care centre is the first point of health care contact for many patients. There are no previous studies conducted on knowledge and awareness about hand hygiene among health care workers from PHC. In our study we tried to assess the awareness and knowledge of HH in HCW working in a medical college & PHCs.

Rezaee et al had carried out an interventional study to assess the effect of an educational program on HH to medical students. The medical students were participating in a one-day teaching workshop about the importance of HH. The participants filled out the questionnaire before attending, on finishing, and 3 months after the

workshop. There was a significant difference between the pre-test and the late post-test scores in knowledge and performance categories.[10]

Ansari et al compared the level of knowledge attitude and practice (KAP) regarding hand hygiene among doctors and nurses, training sessions were conducted for 100 healthcare workers (56 doctors and 44 nurses) and their assessment for knowledge, attitude and practice was done through pre-test and post-test questionnaire. They found that there was a significant improvement in the KAP score for both doctors and nurses after the training session.[11]

In our study we conducted training session for health care workers from medical college and primary health care canters. Pre-test and post-test questionnaire were given to assess knowledge about HH. At baseline, very few HCW had good knowledge about HH (< 10% of the participants in both the groups). Our findings are similar to those observed in previous similar studies.[5]

We also observed that mean scores at baseline were significantly higher for the HCW working in medical college as compared to those working in PHC. This may be attributed to repeated training programs in medical colleges & presence of signage highlighting importance of hand hygiene being prominently displayed in the wards. There has been no published study comparing HH awareness between HCW in medical college & PHC.

After attending the training program, there was significant improvement in scores in both the groups. There was also a significant increase in the proportion of HCW having good knowledge of HH. Mean increase in the scores after training program was comparable in both the groups. This shows that, conducting HH awareness program in medical college as well as PHCs will lead to better awareness of HH practices in healthcare settings. Improving HH practices in HCW working in PHC can result in reducing HCAI at primary healthcare level. This can help reduce the spread of MDR organisms in the health care setting ultimately leading to reduced healthcare expenditure.[15]

Hence our study shows that training program is needed for both HCWs from medical college and PHC. A well conducted program can bring about remarkable improvements in HH awareness among HCW. We also suggest that such program should be conducted more frequently by medical colleges for HCWs. Regular reinforcement of HH practices among HCW will result in improved compliance and reduction in rate of HCAI.

Conclusions

All HCW should be educated about hand hygiene. Regular awareness program must be conducted to improve the knowledge of HH. Emphasis should be given on HH training programs for PHC HCW. Medical colleges should consider conducting such program for all HCW at regular interval.

Limitation: We conducted this study in one hospital and PHC workers from a small area. A larger study in wider geographical location may give better insights on the subject. Awareness of HH practice should be reassessed at longer time interval after training program to assess the long term retention of HH practices.

Myositis Ossificans Traumatica of the Wrist in Elderly: A Description of an Unusual Case

Suvarn Gupta, Pratik Kawde, Aashay Kekatpure, Sonal Karmore, Romil Rathi

[1]Assistant Professor, [2]Senior Resident, [3]Associate Professor, [4]Senior Resident, Department of Anaesthesia, Jawaharlal Nehru Medical College, Wardha, [5]Associate Professor, Department of Orthopaedics, Datta Meghe Medical College, Wandongri, Nagpur

Abstract

Myositis ossificans commonly involves muscles and subcutaneous tissues in people of younger age group. The myositis ossificans is commonly seen around the muscles of elbow joint but occurs less commonly in muscles around hands and wrist. We report a case of Myositis ossificans involving the wrist in a 65 year old lady.

Keywords: *Myositis Osificans, Wrist Joint, Myositis in Elderly.*

Introduction

Myositis ossificans commonly involves muscles and subcutaneous tissues in people of younger age group.[1] The disease is usually found in muscles but less commonly changes are seen in subcutaneous tissues, tendons, fascia and periosteum. The myositis ossificans is commonly seen around the muscles of elbow joint but occurs less commonly in muscles around hands and wrist. This is a case report of myositis ossificans in a 65 year old women involving muscle and tendons around wrist joint.

Case Report: A 65 years old lady came to Out-patient department with a history of injury to right wrist 4 year earlier. She had fall of a heavy object over her right wrist sustaining an injury to right wrist. The patient was advised massage from a practitioner for 5–6 weeks, there-after mobilization of wrist was started. She then incidentally noticed lump around her right wrist after 6 months which was of the size of a pea. The swelling gradually increased for next 12 months, also there was wrist joint movement was restricted. Since past 1 year, patient has pain localised to right wrist and has aggravated since past 6 months. On presentation, patient now has restricted right wrist movements. No history of constitutional symptoms. Single spherical swelling of size 3x3cm was present on the dorsum of right wrist along the ulnar border, with smooth surface, ill defined edges, tender on touch, hard in consistency, attached to the underlying bone was seen. Movements of involved wrist were reduced to 10 degrees of dorsiflexion and palmar flexion. Movements at Distal radio-ulnar joint like supination and pronation were restricted to 0°-30°only. Visual analogue scale was 8/10 and Mayo wrist score was poor (52). Distal vascular status of hand was preserved.

Antero-posterior (AP) and lateral radiographs of the right wrist (As shown in Fig. 1) revealed ossification around dorsal aspect of distal end of ulna in the areas of the extensor tendons. This radiological finding was in favour of traumatic myositis ossificans.

Clinically, the patient had history of trauma followed by massage and radiographically there was ossification around distal ulna. Based on above 2 findings, a provisional diagnosis of myositis ossificans (secondary to trauma) was made. This was confirmed by subsequent Magnetic resource imaging of right wrist joint (Fig. 2) which showed lobulated calcified mass around anterior, posterior and lateral border of distal ulna. The mass was surgically excised (Fig. 3) and histopathological examination confirmed the diagnosis. There was an improvement in the Post-operative Visual analogue scale and Mayo wrist score which was 2/10 and good (84) respectively.

Fig. 1: Antero-posterior and lateral radiographs of the right wrist showing ossification around dorsal aspect of distal end of ulna.

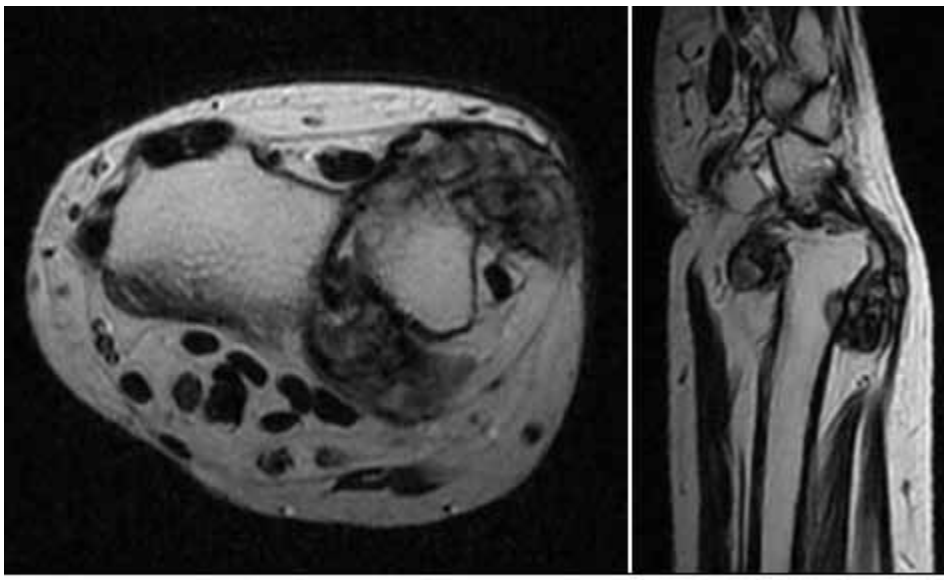

Fig. 2: MRI of right wrist joint showing calcified mass around anterior, posterior and lateral border of distal ulna.

Fig. 3: Intra-operative picture of the mass

Discussion

The term "tendonitis ossificans traumatica", a broad term for calcification or ossification in or around tendons was coined by Rothberg[2]. The majority cases of myositis ossificans, mentioned in literature are of non-traumatic cause involving in the muscle and subcutaneous tissues of the hand often mimicking as a neoplasm[3]. In this case, the patient had myositis ossificans which was secondary to trauma and involving extensor tendon sheaths around wrist making it as a rare presentation.

The hypothesis behind ossification can be proliferation of mesodermal tissues as a reaction to traumatic stimulus[4]. Increased vascularity and metabolism with calcium brought to the injured part by the hyperaemia of the injury results in new bone formation. It is difficult to differentiate between calcification and ossification in a tendon radiologically. The histopathological examination is considered to be accurate in these cases.

Foreign-body granuloma, osteoclastoma, atypical fibroxanthoma and nodular fasciitis are some of the differential diagnosis with similar features. Kai Y [5] et al reported pseudo-malignant myositis ossificans of the hand in 35 years old male without any history of trauma. The histopathological examination revealed central zone of fibroblastic tissue with multinucleated giant cell and intermediate zone of mixture osteoblasts and fibroblasts.

The benign and self-limiting nature of this disease, the treatment of choice can be conservative for a majority cases. However, severe pain with compressive symptoms and loss of function of the joint may require aggressive surgical intervention.[6]

Conclusion

In immediate post traumatic phase, hyperaemia due to massage should be prevented and there is definitive role of cryotherapy[2] in prevention of post traumatic myositis ossificans.

Prevalence of Different Resistance Pattern in Staphylococcal Aureus Isolates From Tertiary Care Hospital

Dhruba Hari Chandi[1], Dr. Nandkishor Bankar[2], Ranjit Ambad[3], Brij Raj Singh[4], Karan Jain[5]

[1]Assistant Professor, Department of Microbiology, Jawaharlal Nehru Medical College, Sawangi (M), Wardha, Maharashtra, [2]Assistant Professor, Department of Microbiology, Datta Meghe Medical College, Wanadongri, Hingna Road, Nagpur, Maharashtra, [3]Associate Professor, Department of Biochemistry, Datta Meghe Medical College, Wanadongri, Hingna Road, Nagpur, Maharashtra, [4]Professor, Department of Anatomy, Datta Meghe Medical College, Wanadongri, Hingna Road, Nagpur, Maharashtra, [5]Statistician, Department of Microbiology, Datta Meghe Medical College, Wanadongri, Hingna Road, Nagpur, Maharashtra, India

Abstract

Introduction: Staphylococcus aureus is common isolated pathogen from clinical specimen with increasing trend of antimicrobial resistance. Staphylococcus aureus and Coagulase-negative Staphylococci (CoNS) infections have become common among both hospitalized and non-hospitalized patients.

Aim: The aim of this study was to determine the inducible clindamycin resistance among the MRSA and MSSA.

Material and Method: This study was prospective study which includes the entire sample obtained in the Department of Microbiology laboratory from Tertiary Care Hospital with bacterial infection and confirmed by positive culture. The standard microbiological protocol for detection of inducible clindamycin, Disc approximation method (D–test) was performed.

Result: Out of 124 Staphylococcus aureus isolates, 17 (13.7%) were inducible clindamycin resistant; 6 (35.29%) from (cefoxitin susceptible) MSSA and 11 (64.71%) from (cefoxitin resistance) MRSA.

Conclusion: The incidence of inducible clindamycin resistance among the Staphylococcus aureus was high. This high rate screen among the MRSA and MSSA provokes the necessity of performing the D- test before starting the antibiotic therapy.

Keywords: *Inducible Clindamycin Resistance (ICR), Staphylococcus aureus, MRSA, MSSA, D-test.*

Introduction

Staphylococcus aureus and Coagulase-negative Staphylococci (CoNS) infections have become common among both hospitalized and non-hospitalized patients. Staphylococcus aureus is one of the pyogenic bacteria most often infecting humans[1]. The development of Staphylococcoi resistance to antimicrobial agents is a growing concern.Staphylococcus aureus is known for acquiring antimicrobial resistance promptly after the introduction of new antibiotics[2].Reports of methicillin resistance in Staphylococcus aureus followed rapidly upon the introduction of methicillin in 1961. MRSA are present worldwide today, and most are resistance to multidrug[3]. Study of early isolates of MRSA showed that a key genetic component responsible for resistance, *mecA,* is not native to the *Staphylococcus aureus* genome. The cassette mec (SCCmec) of Stapylococcal chromosome has been characterized as a novel, mobile

resistance factor which differs from both transposons and bacteriophages[4].

MRSA usually spreads by clones; however, the mec gene is known to have been transmitted between Staphylococcus aureus strains, and probably between other staphylococcal species. Nevertheless,it is noteworthy that some forms of SCCmec bear various additional genetic elements (Tn554, which encodes resistance to macrolides, clindamycine and streptogramine B; and pT181, which encodes resistance to tetraclines) which may confer resistance to additional groups of antibiotics; these genetic elements are especially common in HA-MRSA[5]. Additionally, strains that are resistance to erythromycin will easily become Clindamycin resistance due to inducibility of resistance. Clindamycin, a protein synthesis inhibitor, is a frequent therapeutic choice for staphylococcal infections, especially infections of the skin and soft tissue, and as an alternative in patients with penicillin allergies[6].

As for the central nervous system, it does have exceptional tissue penetration[7]. The drug accumulates in abscesses, and no changes to renal dosage are needed. Good oral absorption makes it convenient for outpatient prescription or as follow-up drug after intravenous therapy [6]. Resistance to this drug, however, is yet another problem. Staphylococcal resistance to clindamycin can be either inducible or constitutive (iMLS $_B$ - inducible Macrolide-Lincosamide-Streptogramin B resistance). It is known that treatment with clindamycin in patients harboring iMLS B Staphylococci leads to the production of constitutive resistance, which in turn leads to therapeutic failure[8]. Inducible clinamycin resistance test can be detected by simple test known as Disk approximation test or D-test[9]. The optimal inter disk distance between the antibiotics is not yet clear, and the Clinical and Laboratory Standards Institute (CLSI) suggests a range of 15 to 20 mm separation of the disc[10].

Aims and Objective: The aim of the present study is to know the inducible clindamycin resistance among the MRSA and MSSA isolates from Tertiary Care Hospital.

Material and Method

Study Site and Population: This study was conducted in Department of Microbiology at Shalinitai Meghe Hospital and Research Centre, Wanadongri, Nagpur in collaboration with Jawaharlal Nehru Medical College (Datta Meghe Institute of Medical Sciences), Wardha, from November 2019 to April 2020.

This study was prospective study which includes all the sample obtained in the Department of Microbiology laboratory from the patients attending OUT patient Department and IN patient Department of Shalinitai Meghe Hospital and Research Centre with bacterial infection and confirmed by positive culture.

Isolation, Identification and AST of Staphylococcus aureus: The samples received in the microbiology lab were inoculated on Blood agar and Mac Conkey's agar, incubated for 24 hours at 37^0C for staphylococcal isolation.

Patients with clinical infection but organisms not grown in the culture or organism expect Staphylococcus auresus, who has taken antibiotic before sample collection, were excluded from the study. Total of 124 Staphylococcal species were isolated and confirmed by gram stain and various biochemical tests like catalase test, oxidase test, coagulase test, mannitol salt agar, etc. Antibiotic susceptibility test (AST) was examined on Mueller-Hinton agar (MHA) plateby using modified Kirby-Bauer disc diffusion method following CLSI guidelines[11] with commercial antibiotic discs (Hi Media).

Detection of MRSA and MSSA: Screening of Methicillin Resistant was performed by Cefoxitin (30µg) disc diffusion method and interpreted according to CLSI guideline[11]. The isolates which gave zone of inhibition(ZOI) $\leq$ 21mm were Methicillin Resistant (MRSA) and isolates with ZOI $\geq$ 21 mm were Methicillin Susceptible (MSSA).

Detection of inducible Clindamycin (D-Test): For detection of inducible clindamycin, Disc approximation method (D – test) was performed as ruled by CLSI 2019. Clindamycin disc was placed at a measured distance (between 15-26 mm) from erythromycin disc and incubated.Appearance of flattening of the clindamycin zone adjacent to the erythromycin disk ['D' shape] was classified as D-test positive.[9]

Quality Control: Quality of each test was performed by using standard protocol Staph *aureus* ATCC 25923 an *Escherichia coli* ATCC 25922 were respectively used as positive and negative control

Result

Prevalence of Inducible Clindamycin-resistance: The prevalence of Inducible Clindamycin Resistance

was found to be 13.7% among the *Staphylococcus aureus* isolated.

Frequency of Clindamycin Resistant isolates: There was no any observation of constitutive clindamycin resistance among the *Staphylococcusaureus* isolates. However, erythromycin-induced clindamycin-resistance (ICR) was observed among 17 isolates (13.7%): six (35.29%) of those ICR positive or D-effect positive (D+) isolates were susceptible to cefoxitin (MSSA) and eleven (64.71%) were resistant to cefoxitin (MRSA). However, distribution of inducible clindamycin resistance among MSSA and MRSA was statistically insignificant (p value > 0.05).

Table No. 1: Distribution of Inducible clindamycin resistance among MSSA and MRS

Methicillin-resistance	ICR screening		Total	P value
Screening	D+	D-		
MSSA	6	62	68	0.018
MRSA	11	45	56	
Total	**17**	**107**	**124**	

Discussion

Staphylococcus aureus is one of the common human pathogens capable of causing a large variety of infection.The incidence of invasive infections has been raising with emergence of community acquired (CA) and hospital-acquired (HA) methicillin-resistant Staphylococcus aureus (MRSA)[12]. In particular in penicillin-allergic patients, clindamycin is an alternative option for mild to moderate MRSA infections. Sub inhibitory concentration of erythromycin,however, is a common resistance inducer to inducible clindamycin resistance (ICR)[13,14].

The recent studies reveal that clindamycin has become an excellent drug of choice for the staphylococcal infections specially skin and soft tissue infections. It has been used as alternative drug for the penicillin allergic patients[6].

However, the differentiation of inducible-clindamycin resistance (iMLSb phenotypes) from other type of resistance is a critical issue because of the therapeutic implications of using clindamycin to treat a patient with an inducible clindamycin-resistant *Staphylococcus aureus* isolate. Clindamycin resistance may be either of *Erm*-mediated or M*srA*-mediated. *MsrA-mediated* resistance is due to efflux-pump mechanism. *ErmA-mediated* resistance of clindamycin may be either constitutive or inducible[6].

But when induction test was performed, 17 (13.7 %) of the isolates showed D-effect, i.e. they were inducible clindamycin resistant strains (iMLSB phenotype). Sixof those strains were MSSA and eleven were MRSA. Absence of constitutive resistance but still presence of 13.7 % of inducible resistance to clindamycin provokes the importance of D test, if clinical failure is not anticipated[15]. The observation of D-effect to be more among MRSA in comparison to MSSA indicate that clindamycin may not be suitable to be used as empirical therapy against.

In the study of Michael Z. David et al[16] showed prevalence of MRSA among adult 32.81% and among children 17.49% which is greater than this study as shows prevalence of MRSA was 13.7%. Iraj Sedighi et al[17] studied reported Inducible clindamycin resistance of 37.5% of CA-MRSA isolates at the time of admission and 22.2% of HAMRSA isolates at discharge whereas in this study showed 13.71% Inducible clindamycin resistance of MRSA AND MSSA.

Another study of Pal N et al[18] showed Inducible clindamycin resistance of 43.56% in MRSA (Methicillin resiatant staphylococcus aureus), 6.93% MSSA (Methicillin sensitive staphylococcus aureus), 43.56% MRCNS (Methicillin resiatant coagulase negative staphylococcus aureus) and 6.0% MSCNS (Methicillin sensitive coagulase negative staphylococcus aureus) whereas this study showed 35.29% MSSA and 64.71% MRSA out of total Inducible clindamycin resistance. According to the study of Naima Fasih et al[19] showed Inducible clindamycin resistance of 62% among MRSA staphylococcal isolates which was greater than this study.

A studied done by Mukesh Patel et al[20] showed the presence of MLSBi in 212 (52%) of the isolates overall, with 139 (50%) MRSA and 73 (60%) MSSA isolates exhibiting MLSBi which was greater than this study as this study showed showed 35.29% MSSA and 64.71% MRSA out of total Inducible clindamycin resistance[21].

Conclusion

The incidence of inducible clindamycin resistance among the Staphylococcus aureus was high. This high rate screen among the MRSA and MSSA provokes the

necessity of performing the D- test before starting the antibiotic therapy. The observation of D-effect to be more among MRSA in comparison to MSSA indicate that clindamycin may not be suitable to be used as empirical therapy against.

Abstract

Neuropathic joints, which is also known as Charcot's Arthropathy, is a destructive joint pathology resulting from loss or decrease in proprioception, pain and temperature sensations. Patients suffering from diseases associated with neuropathy like diabetes mellitus, syringomyelia and syphilis are said to be prone to the disease. Patients with syringomyelia commonly suffer with arthropathy involving shoulder. We report a case of 35 year old male patient with syringomyelia and charcot's arthropathy involving left elbow.

Keywords: *Charcot's Arthropathy; Syringomyelia; Elbow.*

Introduction

Charcot's arthropathy which was first reported by Jean-Martin Charcot in 1868[1], is a destructive joint pathology resulting from loss or decrease in proprioception, pain and temperature sensations[2-4]. The etiological factor of Charcot arthropathy includes Tabes dorsalis, syringomyelia, traumatic spinal cord injury, leprosies, congenital pain insensitivity, diabetes mellitus, chronic alcoholic intoxication, and so on. Although Charcot arthropathy associated with above mentioned factor has been mentioned in the literature, but a very less number of cases describing Charcot arthropathy of elbow caused by syringomyelia and Chiari malformation associated with scoliosis have been reported.

Case Presentation: A 35 years old male patient reported to our hospital complaining of weakness in right hand since the last 12 years and swelling over his left elbow since 3 years. Weakness was associated tingling and numbness in left upper limb. Swelling over the elbow joint was painless, diffuse and was gradually progressive. Patient underwent incision and drainage 2 years back carried out by a local practitioner and after the drainage, swelling did not subside and a gradual increase in size was noted. Patient gave a history off and on fever with loss of appetite and weight loss of around 15 kg in 3 years. Patient had no history trauma, comorbidities or any surgical history in the past.

On clinical examination, Diffuse swelling of size 5 x 6 cm approximately, non-adherent to bone or underlying structures, smooth over the lateral surface and irregular over the medial surface was present around the elbow joint and valgus deformity was present. Wasting of left forearm and hand muscles was seen. Elbow range of motion was 0-130 degrees and pain-free with full supination and pronation with medial and lateral laxity at the elbow joint. Bony crepitus was noted while performing elbow range of movements. On clinical examination of cervical spine, there was weakness in finger grip of left hand with sensory hypoesthesia over the dorsal aspect of left hand. Motor power of bilateral shoulder, elbow and wrist joints were normal. Examination lumbar spine and other limbs was normal.

Haematological examination in the form of complete blood count with Erythrocyte sedimentation rate, fasting and post meal blood sugar levels, C reactive protein levels, veneral disease research laboratory tests, uric acid, liver function test and kidney function test were carried out and found to be within normal limits except ESR level was slightly raised.

Joint aspiration was also done to rule out infection but culture did not find any organism growth.

Radiographs of Antero-posterior and lateral view of left elbow jointshowed degenerative changes in left elbow with decrease in joint space, flattening of articular margins of olecranon with marginal osteophytes at the olecranon process with periarticular sclerosis was seen. Loose bodies are seen near the radial head. Radiographs of Anteroposterior and lateral views of cervical spineshowed scoliosis at the cervico-dorsal spine with primary curve having convexity towards left side and secondary curve having convexity towards right side.

MRI of cervical spine showed a syrinx from the level of upper border of C1 vertebra till lower border of C2 vertebra. Sagittal section of T2 weighted image was suggestive of Chiari malformation with tonsillar herniation.

Patient was sent to neurosurgery department and patient was treated with posterior fossa decompression. From Orthopaedic point of view, swelling was aspirated and patient was immobilized with above elbow slab for 15 days and non-steroidal anti-inflammatory drugs were started. Swelling gradually subsided after 15 days of conservative treatment and above elbow slab was removed. Rather than pain, instability was the chief complaint. Hence, Patient was given customised Dynamic Hinged Elbow Braceand Elbow was mobilised using the brace. At the end of 1 year, patient remained asymptomatic and able to do his day to day activities.

Discussion

Charcot's Arthropathy of elbow is usually rare condition with few case report and case series being reported in literature.[6-17] Only 3% to 8% neuropathic joints, reports involvement of elbow joint. In the literature, two theories were postulated by the researchers that describe the pathogenesis of this condition, they are the neurotraumatic and neurovascular theory. As described Johnson in 1967, the neurotraumatic theory suggest the cause to be repetitive trauma to the affected joint which has lost sensations. The neurovascular theory described by Allman et al suggests active bone resorption due osteoclasts after sympathetic dysfunction and hyperaemia leading to joint destruction.[4]

On the basis of Underlying aetiology, joint involvement pattern can be identified like patients with Diabetes Mellitus are prone to develop this pathology in the ankle and foot while in Patients with syphilis, hip and knee joint involvement is common. In cases with syringomyelia, the upper limbs joints are seen to get commonly involved. Thus, in our case report underlying etiology and pattern of joint involvement resembles the literature findings.

Syringomyelia is characterized by cavitation of the spinal cord which can translates into a progressive clinical syndrome and can thereby lead to loss of neurologic functions. 16 one of the underlying aetiology of syringomyelia can be Chari malformation which was first described by H. Chiari in 1891. It was described as herniation of inferior lobe of cerebellum with elongated tonsils into the spinal canal. Thorough neurosurgical examination and investigation for consideration of surgical management should be obtained, as was carried out in our case.[18,19]

The treatment of choice for charcot's arthropathy has not been very clearly described in literature. The recent study derived guidelines suggests analgesia, elbow immobilization till swelling subsides followed by physiotherapy, and management of patient expectations.

Surgical Arthrodesis with external or internal fixation has resulted in variable surgical outcomes to some researchers.[15,16,17]. Kwon et al[15] reported a case series of 6 neuropathic elbows, out of which 3 cases were managed surgically developed post-operative complications which required additional surgery. A septic neuropathic elbow was managed with surgical debridement and external fixation resulted in instability in further follow-ups.[7] Elbow arthrodesis which was a treatment of choice after tubercular elbow is rarely performed today[20]. Arthrodesis is suggested only when there is no other reasonably reconstructive option available.[20]

As there was lack of valid guidelines for neuropathic elbow in the recent literature and patient wanted to have some function at elbow for daily activities, a trial of conservative management was considered in our case. Immobilisation of elbow with above elbow slab for 15 days was advised and as swelling was reduced, elbow was mobilised with dynamic hinge elbow brace for 3 months. At the end of 1 year follow-up, patient was asymptomatic and patient was able to perform daily activities.

The case of neuropathic elbow joint secondary to syringomyelia with chiari malformation with scoliosis has rarely been reported in the recent literature.

We conclude that the maintenance of function of a joint, rather than immobilization, is the 'motto' of treatment of neuropathic joint. We managedour patient conservatively, as suggested by the majority of theliterature, and the patient was satisfied with the treatment.

After a thorough literature search, we can say that, this is the first report of neuropathic joint of elbow, secondary to syringomyelia with Chiari Malformation with scoliosis on the Indian subcontinent.

Influence of Anxiety and Claustrophobia on Blood Pressure and Heart Rate during MRI Scan

Haydar A. Al-Shimmery[1], Alyaa. Raheem[2]

[1]Lecturer, MSc, Medical Radiological Physics. UK, [2]Ass. Lecturer, Middle Technical University, Collage of Health and Medical Technology; [2]MSc in Radiography. SHU. UK, Ass. Lecturer at [2]Middle Technical University, Collage of Health and Medical Technology/Baghdad, Iraq

Abstract

Aim: To assess the effect of anxiety and claustrophobia on human blood pressure and heart rate during MRI scan.

Method: Samples of 48 patients who need MRI scan service were chose. A questionnaire and scales were used to evaluate the patients' anxiety group and claustrophobia. Blood pressure and heart rate were determined in before and after the scan in the same circumstances and method.

Results: The majority of the patients were female. The relation between anxiety scale and gender revealed that majority of the female have the high anxiety scales (68.57%). Alternatively, the minority of male have high anxiety level (40%). The relation between anxiety and claustrophobia with the systolic pressure before and after MRI scan, approved a statically significant difference with t-test = 3.007 and P value <0.05. No significant association was found of diastolic pressure and heart rate at the same time and circumstances with anxiety levels and claustrophobia.

Conclusion: This study represents significant evidence for an association of high blood pressure with high anxious and claustrophobic patients, measured before and after the MRI scan. While diastolic blood pressure and heart rate did not change during MRI exam.

Keywords: *Claustrophobia, blood pressure, heart rate, diastolic.*

Introduction

Magnetic resonance imaging (MRI) is vital medical equipment that has been steadily used as it gives image with high quality by using non ionizing radiation. For this procedure, the patients need to be scanned by a long narrow tube for approximately several minutes without movement, because technical issues which need to provide image free artifacts[1,2]. This period of MRI procedure which includes fear, noises, stress, nervousness, stability and unfamiliar environment could make challenge to manage the scan typically with anxious or claustrophobic patients. These are common problems which occurs with the patients during the MRI scan[3]. Anxiety is a indistinct and still vague[4]. It has been reported that 25% to 37% of the patients undergoing MRI scan experienced substantial anxiety[5,6]. What is more, the fear of enclosed spaces is called claustrophobia. Which is a common specific phobia with a prevalence of 1.0% to 15% in the general patients [7]. The American Cardiology Association emphasize that it should be important for the physician, dentist and medical staff to deal with complications that may take place in patients who have hypertension [8]. In addition to the light-headedness, nausea, fainting, fears of actual harm, the blood pressure and heart rate increasing

aliaman@yahoo.com

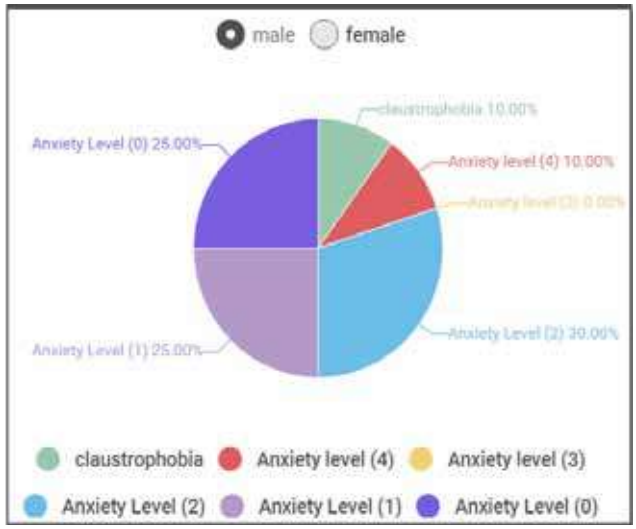
may present with anxious and claustrophobic patient. [9]. This leads to necessity to avoid possible adverse reaction for cardiovascular disease like hypertension which could be occur with such psychological status. Recently the Global Health Risks shows that arterial hypertension remains the primary cause of mortality and morbidity in the world [10,11].

This study aims to evaluate the influence of anxiety and claustrophobia on the blood pressure and heart rate before and after the MRI scan. For this purpose, a questionnaire based on a rating scale was designed to capture the emotions feeling before the MRI scans. Blood pressure and heart rate recorded for the patients ten minutes before and after the imaging procedure in the same conditions.

Method

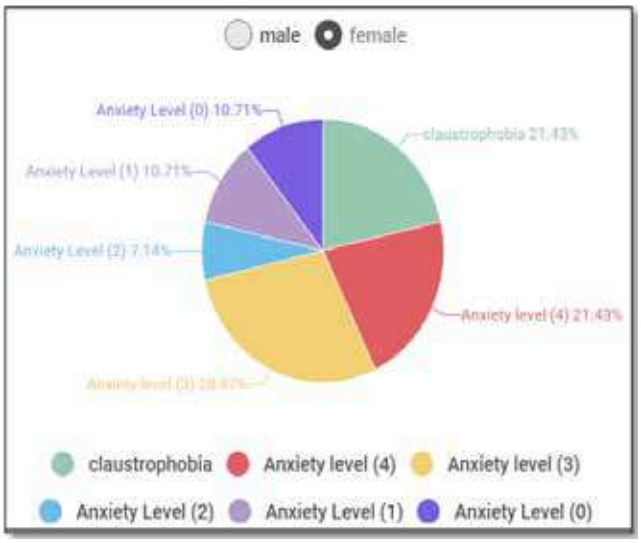
This experiment was to assess the potential for claustrophobia, anxiety and clinical relevance with MRI. All patients who agreed in participating received information about the study procedure, with free to withdraw from trail at any time before or after the MRI scan.

Eighty four patients with an age ranged between 25 to 50 years were selected in this experiment in Baghdad hospital during the period from May to October in 2015. The patients with cardiac disease were excluded to avoid solely based on arterial hypertension changes which found with their history previously[11]. For this reason, it is noteworthy that subjects who had any of the hypertension were included for the evaluation of the HR and PB.



All patients were interviewed and evaluated face to face in the next room of the MRI scan. Then they asked to answer a general health questions by the same examiner to exclude any blood pressure disorders, previous history to the hypertension or any cardiac diseases following the instructions and any drugs which were taken by the patients through 24 hours before the scan that would affect the sensitivity of results were excluded [12].

The blood pressure and heart rate measured by a digital cardiologic stethoscopein two separate times. First measurement, when the patient in the waiting room, trying to characterize the BP and HR two minutes before the MRI scans. The second measurement is taken two minutes after the scan in the same place and techniques of the first measurement. To evaluate the patients' phobia and anxiety level, before the MRI examination, patients were informed with a description of how to rate the intensity of anxiety and claustrophobia if present by using four points numerical scale; the following values were established: A=0, B=1, C=2, D=3, E=4.

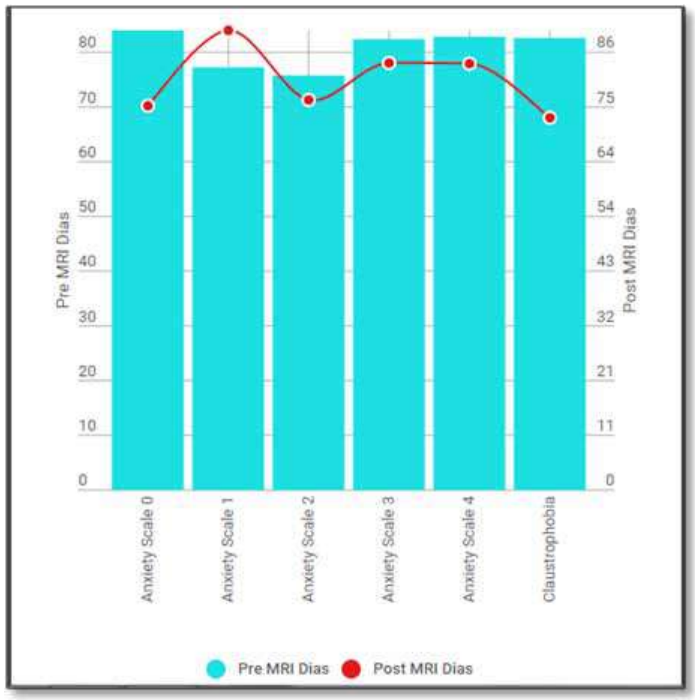


The scale was used and consists of four questions with five possible answers, which characterize the patient anxiety level in response to different situations that involve a visit to the MRI exam room and it is applied before the scan.

The sum of the values assigned to each answer, the possible interval score may vary between 4-20 points. The level of anxiety classified in naught, mild, moderate and exacerbated groups. The collected data were firstly stored in an Excel® worksheet and then we held a descriptive statistical analysis using the SPSS®, accompanied by a form containing issues about patient identification, harmful habits, diseases, frequency to MRI visit and cardiovascular parameters. For the claustrophobic group which was detected by using a claustrophobia questionnaire according to (CLQ)[13].

Results

(a) Female patients



(b) Male patients

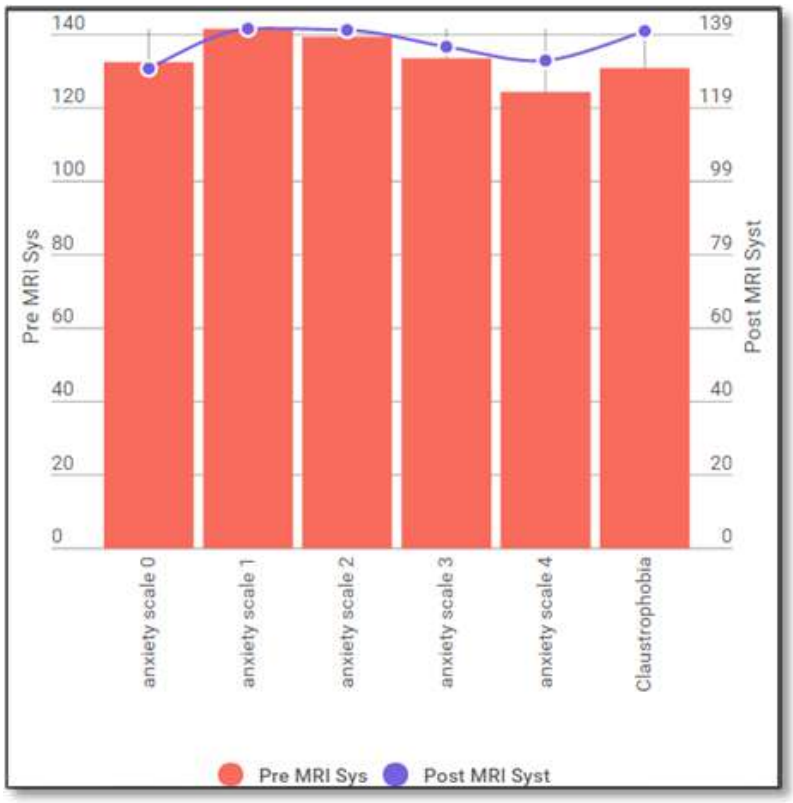


Figure (1a, 1b) anxiety scale percentages and claustrophobia across sex and age groups where

Figure (1) shows 48 volunteers participated in this research, (58.3%) belonged to the female with a mean age of 38 years and incomplete high education, (41.7%) belonged to male with a mean age 39. According to the aspects related to health, most of them did not have the habit of smoking, but presented a family history of systemic diseases, such as diabetes Mellitus, hypertension, cancer, heart disease, pulmonary emphysema. During the period of the patient's follow-up no systemic change that could interfere with the results of the study was detected. The relation between anxiety scale and gender revealed that majority of the female have the high anxiety scales with Claustrophobia. On the otherhand, the majority of male have mild or no anxiety level (25%), female had mild anxiety only (10%). The data obtained from the relation between anxiety scales and the age group revealed thereno significant relation could be detected.

It can be clearly seen that first and second anxiety scales groups show no functional relation between there systolic pressure and the experiment. While patients with higher anxiety scale with level 3 there are obvious upwards. Figure (2, a) Illustrates the statistically significant difference concerning to systolic BP with patients with high anxiety levels and claustrophobic group with (mean ± standard deviation) in the pre and post MRI scan whereas levels of anxiety and claustrophobia t-test=3.007 and P value <0.05). Figure (2,b) shows the difference (mean ± standard deviation) of diastolic BP in accordance to the anxiety scale and claustrophobia pre and post the MRI scan, in different measures, considering the different anxiety level observed.

(a)

(b)

Figure (2): Association of blood pressure with anxiety levels and Claustrophobia. (a) The relationships of pre- and post MRI scans systolic BP with 5 groups (b) the relationships of pre- and post MRI scans diastolic BP with 5 groups.

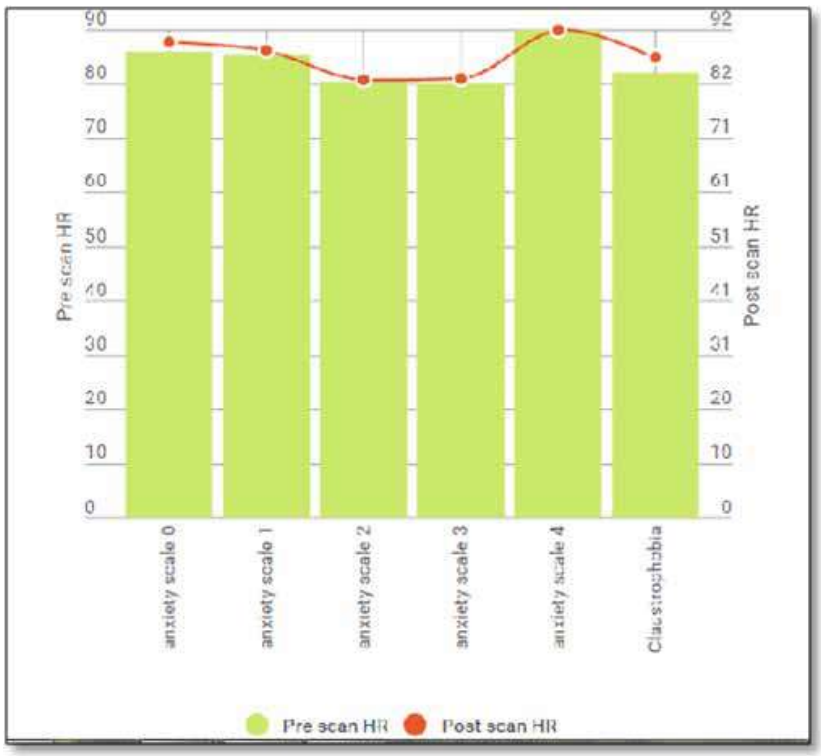

Figure (3) Association of heart rate with anxiety levels and Claustrophobia plots with pre and post MRI scan

Figure (3) shows the HR of volunteers in the two mentioned periods. We can detect that the HR virtually does not change as a function of claustrophobia or anxiety scales. There is a minor alteration after MRI scan for the non-noxious with increasing the difference till plunge in the group 3 and returning to rise again with higher anxious and claustrophobic patients. This is non-significant changes according to the difference of (mean ± and standard deviation).

Discussion

The purpose of this research was to study the relationship between the influence of anxiety and claustrophobia with the bloodpressure and heart rate before and after MRI scan. This section discusses the findings that were observed with the psychophysical questionnaire and vital signs correlation. The study shows three major results about the influence of the anxiety and claustrophobia on; systolic, diastolic blood pressure and heart rate. The authors made this MRI developed anxiety scale in relay on Corah NL. to diagnose the state of anxiety in dental patients [14]. This scale was developed to our study because of the capability to be applied in count for helping as a predictor for the workers in the MRI room in compare with other anxiety scales. Patients during MRI scan are commonly undergoing negative emotions. The unfamiliar environment, unknown staff and noises can incite fear and anxiety as result they cannot complete the scan or motion artifacts will appear in the images[15].

The description provided by radiological technologist and researcher before and after MRI scan is efficient for those patients who presented with mild and non-anxiety level, because we noticed reduction of the patients expectation in relation to the scan performed. This finding reinforces the importance of MRI questionnaireto verbalize so early and safe to the patient about the procedures to be performed in each visit, thus avoiding the fear of the unknown procedures of the scan [6,16].

Keen patients to MRI scan with no anxiety or mild level are found more with younger or educated patients. The result suggests that it is associated with the fact the patients relate the MRI scan to the feeling of fear and anxiety, perhaps to have previous negative experience[17]. Most of the previous studies on MRI associated anxiety and claustrophobia focus on psychological aspects [18]. So this pilot study as our knowledge is the first in related with main vital signs in MRI procedures. Thus, the questionnaire had been prepared to evaluate the patient reactions and to place psychological strategies to reduce the anxiety of the same. In this study, the volunteers received information about the steps and the procedures that were performed, as recommended by other authors[5,12].

The percentages in Figure (1) of this study were approved by other researchers which explained this variation in relation to different reasons for example: the age, gender and circumstances, background and even gene defect [19]. The different individuals have different thresholds for the anxiety sensitivity[20]. Similarly, the difference claustrophobic reactions of MRI patients are affected by body part examined, gender and positioning in the MRI tube [21].

The pie charts illustrate the primary percentages of having different anxiety scale and claustrophobia. It is clear that the main factor influencing their various percentages is the gender difference.

Femalehad higher anxiety levels about 21 % for claustrophobia and anxiety level scale 4; also around 28 % have anxiety scale 3. This result was also found by other study [22]. Whilethe male have lower anxiety level but, the total percentage of less anxious and feared female are fewer than 25%.

In comparison, male percentage shows proportion of the high anxiety scale 4, 3 and claustrophobia of 10%, 0% and 10% respectively. The reasons might belong to anxiety and phobia occurs more often in female than in male [23]. Reckelhoff,et al have shown that BP is less in woman than in men at similar ages. After menopause period, conversely, the BP increases in female more than in male[24].

Sledge and Vinger-hoets; approved interoperation which the first phase of reaction with anxiety and specific types of phobia which leads to increase the systolic pressure and heart rate [25]. Supporting to this study, figure (2-a) illustrates the actual (mean±) values in the five levels groups. Where after the third anxiety level there were significant change between the systolic pressure and the anxiety and rising gradually with moderate, exacerbated levels and claustrophobia. In result, the systolic mean values of the groups raising influence by two factors: the increase in anxiety scales and the present of claustrophobia.

In contrary, significant changes in the diastolic and HR were not found in relation to the five groups during the MRI examination. These results were in the same line, with previous pilot study were found the phobia, anxiety and panic attack do not associated with diastolic and heart rate [26]. In spite of the gigantic improvement in the aspects of arterial hypertension detectionnumerous fields of blood pressure measurement require further rigorous study, such as blood pressure measurement in distinct clinical situation and population [10].

Conclusion

The study results revealed that there was a substantial relation between systolic to anxiety and claustrophobia. On the other hand, the diastolic and heart rate did not change before and after the MRI scan in relation to the anxiety levels recorded with the patients. It is recommended that further research should be conducted in this field. Therefore, according to these results, patient with high blood pressure and/or heart diseases measures his blood pressure before the scan and calm he down should be a mandatory technical step before MRI.

Molecular Study of Antibiotic Resistance *Mycobacteriumtuberculosis* Isolated from Clinical Samples in Baghdad City

Heba Firas Saeed[1], Muhammad Fulayyih Tarif[2]

[1]M.Sc. Student, [2]Prof., Middle Technical University, Collage of Health and Medical Technology/Baghdad, Iraq

Abstract

Background: Drug-resistant TB is the most important issue that threatens to interrupt the improvements achieved in tuberculosis control. Multidrug-resistant (MDR) tuberculosis is defined as resistance to both rifampicin and isoniazid.

Objectives: To find molecular feature via DNA extraction for genes in charge of drug resistance in pulmonary tuberculosis patients with hyperglycemia and role of the Xpert MTB/RIF Ultra molecular test efficacy in DR-TB cases detection.

Method: 106 pulmonary TB patient sputum and blood samples were collected in the Institute of Chest and Respiratory diseases in Baghdad and Medical City Hospital from December 2018 - July 2019, 52 were drug resistances TB patients. All patients were examined by conventional method such as direct examination (AFB test), Gene-Xpert test, FBS and HbA1c test were carried out for all cases.

Results: GeneXpert/ultra results revealed 43 cases were Rif resistance in which it was highly significant. The GeneXpert/ultra quantity was mostly medium in the bacillary load. The Rif's resistance cases were mostly registered in the age group (20-59) and in male population. The most frequent patient's type was New MDR. The GeneXpert/ultra quantity and HbA1c levels results showed that most elevated HbA1c cases had a medium to high bacillary load. The DST results were significant in which 95.3% were Rif's resistance and 62.8% were STR's resistance. The LPA on 23 DR cases showed the following; 13 patients were MDR cases in which a deletion in the band WT8 and mutation in the MUT3 band of the gene rpoB and deletion in the inhA WT1 band of the inhA gene were the most notice.

Conclusions: Molecular method had showed that mutations in the *rpoB* gene especially 530 and S531L codon are responsible for majority of RMP resistance in MTB while mutations at the -15/-16 *InhA* codon and 315 of *KatG* codon responsible for most INH-resistance cases.

Keywords: *Antibiotic resistance; Mycobacteriumtuberculosis: clinical samples.*

Introduction

Tuberculosis (TB) is the leading cause of death due to an identifiable infectious pathogen worldwide[(1)]. TB is one of the top 10 causes of death and the leading cause from a single infectious agent (above HIV/AIDS). Millions of people continue to fall sick with TB each year[(2)]. Drug resistance is a natural phenomenon increased by man. Resistance is initiated by a genetic mutation that makes a drug unsuccessful against the mutant bacteria. There is an increased risk of developing resistant bacteria in patients with a large bacillary load because more spontaneous mutations arise in a big population. Then the inadequate treatment permits for

the selection of a drug-resistant strain to become the dominant strain in patients infected with TB, which can spread from person to person in the same manner as drug-sensitive TB[3]. Multidrug-resistant (MDR) TB is defined as disease due to M. tuberculosis resistant to at least rifampin (R) and isoniazid (H), the vital elements of TB treatment(4). MDR-TB progresses in otherwise curable TB when the course of antibiotics is interrupted and the levels of the drug in the body are inadequate to kill the bacteria 100%[6]. An estimated 600,000 individuals infected with multidrug-resistant (MDR) forms of tuberculosis (TB) in 2016, including 110,000 with rifampicin-resistant TB (RR-TB). Only 153,000 cases of MDR-TB were identified and only 130,000 people began MDR-TB treatment. An expected 240,000 individuals deceased from MDR/RR-TB in 2016[7]. Multi drug resistant TB is a serious public health problem, as it has been associated with higher rates of failure and mortality than drug-susceptible TB, especially in human immunodeficiency virus (HIV) confected patients[8].

Method

Study was conducted at National Reference Laboratory of Tuberculosis/Baghdad from December 2018 to July 2019. 106 TB specimens were collected in this study, 54 of them were new cases and sensitive for RIF and INH; while the other 52 of specimens were DR, 30 of those 52 were hyperglycemia. Their history was taken including the sex, age, history of the symptoms.

The direct examination (AFB) was done by Ziehl-Neelsen stain. The stain was prepared according to the guidelines of laboratory manual guidelines in Iraq[11], the culturing was done on Lowenstein-jensen medium (L.J) solid media, while drug susceptibility test was also carried as instructed in the Laboratory manual guidelines in Iraq(11). Molecular Method for Screening Drug-Resistant TB [12] included **Gene Xpert System MTB/ RMP or Xpert MTB/RIF Ultra**(13-16). and **Line Probe Assays**[17] the Genotype MTBDR *plus* test (Hain Lifescience GmbH, Nehren, Germany)[18] is based on the DNA-strep technology[19] in which they were carried outaccording to the guidelines of laboratory manual guidelines in Iraq.[11]

Result

106 TB specimens were collected in this study, 54 of them were new cases and sensitive for RIF and INH; 19 female and 35 male, while the other 52 of specimens were DR cases 14 female and 38 male, 30 of those 52 were hyperglycemia. The patients were arranged according to age into four groups.

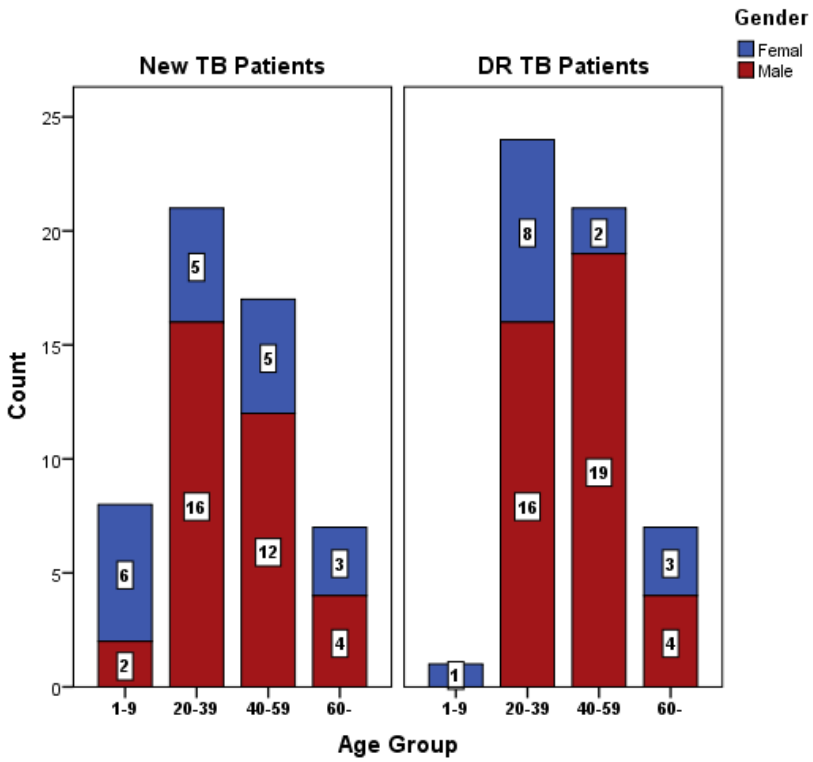

Figure (1): The age group and gender distrubution acording to the TB type

In this study the most recorded cases were in the age groups of (20-38)y in which (38.9%) patients were new TB cases while (46.2%) were DR TB cases and the age group of (39-57)y in which (33.3%) patients were new TB cases while (38.5%) patients were DR TB cases. The P value of age was (0.126) and the mean age of patients was (40.4) years old. Males subjects were more innumerable than female in TB cases according to results, which showed that males were 35 (64.8%) in New TB cases (control), 19 (35.2%) in DR TB cases.

Table (1): Distribution of DR-TB patients according to their DST results:

		New DR		Retreat DR		New MDR		Retreat MDR	
		N=5	100%	N=10	100%	N=21	100%	N=16	100%
Streptomycin	Resistant	2	40.0%	3	30.0%	12	57.1%	12	75.0%
	Sensitive	3	60.0%	7	70.0%	9	42.9%	4	25.0%
Isoniazid	Resistant	1	20.0%	9	90.0%	21	100.0%	16	100.0%
	Sensitive	4	80.0%	1	10.0%	0	0.0%	0	0.0%
Rifampicin	Resistant	4	80.0%	1	10.0%	19	90.5%	16	100.0%
	Sensitive	1	20.0%	9	90.0%	2	9.5%	0	0.0%
Ethambutol	Resistant	2	40.0%	3	30.0%	11	52.4%	12	75.0%
	Sensitive	3	60.0%	7	70.0%	10	47.6%	4	25.0%

Out of the 52 cases ((21/52) (40.38%) new MDR, (16/52) (30.76%) retreated MDR.

The 5 new DR cases (4/5) (80%) RIF's resistance. While the retreated DR cases showed that (9/10) (90%) were INH resistance. The new MDR cases were 21 in which (21/21) (100%) were INH resistance, (19/21) (90.5%) were RIF's resistance. The 16 retreated MDR cases (16) (100%) were INH resistance, (16) (100%) were RIF resistance.

Table (2): The Gxpert/Ultra results distribution according to age, gender, type, HbA1c Level, Zeheel Nelson and Gxpert/Ultra Quantity:

	GeneXpert/Ultra Result				P value
	RR		RS		
Variables	N=43	100%	N=63	100%	
Age Group					0.256
< 20 y	1	2.3%	8	12.7%	
20-39	20	46.5%	25	39.7%	
40-59	15	34.9%	23	36.5%	
≥ 60y	7	16.3%	7	11.1%	
Gender					0.869
Female	13	30.2%	20	31.7%	
Male	30	69.8%	43	68.3%	
Type					<0.001
New	0	0.0%	53	84.1%	
Retreat	0	0.0%	1	1.6%	
New DR	4	9.3%	1	1.6%	

	GeneXpert/Ultra Result				P value
	RR		RS		
Variables	**N=43**	**100%**	**N=63**	**100%**	
Retreat DR	2	4.7%	8	12.7%	
New MDR	21	48.8%	0	0.0%	
Retreat MDR	16	37.2%	0	0.0%	
HbA1c Level					<0.001
Normal(4.6-6.5)	18	41.9%	58	92.1%	
Abnormal	25	58.1%	5	7.9%	
Zeheel Nelson					0.147
Positive	43	100.0%	60	95.2%	
Negative	0	0.0%	3	4.8%	
GeneXpert/Ultra Quantity					0.016
High	17	39.5%	10	15.9%	
Medium	17	39.5%	35	55.6%	
Low	8	18.6%	10	15.9%	
Very low/Scanty	1	2.3%	8	12.7%	

The study is showing that the most age group cases with RR lies in the (20-39) group as 20(46.5%) patients followed by the (40-59) group of TB patients by 15(34.9%) The male patients are also dominant in number in the both RR cases as well as the RS cases, males 30 (69.8%) out of 43 cases with RR results. The 43 RR cases present most patients are new MDR with 21 (48.8%). While the 63 RS cases mostly are new TB patients with 53(84.1%), 8 (12.7%) retarded DR cases and 1(1.6%) retreated and new DR respectively.

Table (3): The Gxpert/Ultra results distribution according to the TB patients symptoms:

	GeneXpert/Ultra Result				P value
	RR		RS		
Variables	**N=43**	**100%**	**N=63**	**100%**	
Productive cough					0.011
Present	26	60.5%	52	82.5%	
Absent	17	39.5%	11	17.5%	
Night Sweating Fever					<0.001
Present	4	9.3%	41	65.1%	
Absent	39	90.7%	22	34.9%	
Weakness					0.134
Present	31	72.1%	53	84.1%	
Absent	12	27.9%	10	15.9%	
weight loss					0.609
Present	28	65.1%	44	69.8%	
Absent	15	34.9%	19	30.2%	
Hemoptysis					0.343
Present	3	7.0%	8	12.7%	
Absent	40	93.0%	55	87.3%	

The night sweating fever were the most symptom with significant P < 0.001 followed closely by productive cough symptom the P value being 0.011. While the most common symptoms were weakness present in 31 (72.1%) RR cases and 53 (84.1%) RS cases, P value 0.134.

Table (4): Gexp/Ultra distribution according to culture on LG and DST (SIRE) results

Variables	GeneXpert/Ultra Result				P value
	RR		RS		
	N=43	100%	N=63	100%	
Culture on LG					---
Positive	43	100.0%	10	100.0%	
Negative	0	0.0%	0	0.0%	
Streptomycin					0.014
Resistance	27	62.8%	2	20.0%	
Sensitive	16	37.2%	8	80.0%	
Isoniazid					0.884
Resistance	38	88.4%	9	90.0%	
Sensitive	5	11.6%	1	10.0%	
Rifampicin					<0.001
Resistance	41	95.3%	0	0.0%	
Sensitive	2	4.7%	10	100.0%	
Ethambutol					0.108
Resistance	25	58.1%	3	30.0%	
Sensitive	18	41.9%	7	70.0%	

All the 53 samples culture result were positive except with 3 of them were subjected to contamination and had to be re-cultured. DST culture results for RIF resist showed 41 (95.3%) positive results on LG out of the 43 RR Gexp/Ultra cases with highly significant P value < 0.001.

Table (5): The LPA results distribution according to the TB patients types:

Discussion

The current study showed a broad range of patients' age with tuberculosis which suggests that all ages can be susceptible to the infection with MTB. These results were compatible with that being reported by studies in Baghdad by AL-Khafaji[23] and in Sulaimaniyah, Iraqi Kurdistan (24) and another which involve almost seven countries[13].

The results also showed that the most prevalent age groups are (20-38) and (39-57) years old of TB patients. and this was also found in the other studies in Iraq such as Kareem *et al.,*[25] and study from 2009- 2012 by Al-khazraji.; et al[26], also The results of study expressed by AL-Khafaji in [23] displayed a large-scale age range of TB patients (> 10 to more than 60 years old) and reveal that the predominant age groups were (21-30) and (41-50) years old of TB patients, the low percentage of TB cases among age group less than 14 years may be due to the BCG vaccine which is given at young age, vaccination give good protection for children however this immunity decline with age.

The Difference results showed in this study of TB cases between men and women may reveal physiological differences (i.e. sex differences) in the epidemiology of TB, differences in the social positions of female and male that affects the risk of exposure and/or gender differences in access to care.

The results of the Genexpert/ultra assay with the HbA1c were of highly significant and it goes with results of the study by Ali RH.; et al which conducted in the developed countries, that the most TB cases were found in Europe; it was more prevalent in elder people due to diabetes mellitus and among immune-compromised patients.[34].

Conclusion

Molecular method had showed that mutations in the *rpoB* gene especially 530 and S531L codon are responsible for majority of RMP resistance in MTB while mutations at the -15/-16 *InhA* codon and 315 of *KatG* codon responsible for most INH-resistance cases. Also Diabetes Mellitus is a recognized risk factor for TB (DR-TB) cases in Iraq. TB patients with diabetes mellitus had shown a rather high bacillary load in molecular test. Some DM-TB patients (with uncontrolled DM) may not respond to the anti-TB treatment and more likely to develop into drug resisting (DR) cases.

Assessment of Risk Factors of Asthma in Health Institutions in Maysan Governorate, Iraq

Ali Abdulwahed Abdul Jabbar[1], Buthaina Ateyah Rashid[2]

[1]M.Sc. Student, [2]Assist Prof., Middle Technical University College of Health & Medical Technology, Baghdad, Iraq

Introduction

Background: Asthma is a common chronic lung disease in which the airways (bronchi) become inflamed and are abnormally sensitive to certain triggers. Asthma can affect people of all races and ages and although there is no known cure, there are many ways to control it. The symptoms of asthma include coughing, shortness of breath, wheezing and chest tightness.

Materials and Method: This is A case-control study conducted in Consultation Center for Chest and Respiratory Diseases at Al-Sadr Teaching Hospital in Maysan Governorate Data was collected over a period of five months between the 1st of November 2019 to the 1st of April 2020.

Results: The commonest risk factors that had been found causes asthma in cases was family history of asthma with OR=5.127, CI=(2.77-9.49), upper respiratory tract infection with OR=5.059, CI=(2.29-8.76), active smoker with OR=2.145, CI=(1.18-3.91)Occupational exposure to dust with OR = 4.660, CI= (2.68-8.10), skin allergy with OR =2.77, CI=(1.28-6.03).

Conclusion: Significant association was found between **(**Family history of asthma, upper respiratory tract infection, active smoking,occupational exposure to dust, chemical, fumes and gases, allergies and the used of NSAIDs before the onset of asthma) and asthma in adults in maysan governorate.

Keywords: *Risk Factors; Asthma; chronic lung disease; Maysan.*

Introduction

Asthma is a common chronic respiratory disease and is a major public health problem worldwide and affects people of all races and genders. Reports indicate that the number of asthma sufferers worldwide may exceed 334 million, according to a report published by the World Asthma Network in 2014**(1)**. Many studies have shown that the prevalence of asthma varies between countries and within countries and is directly proportional to different allergies, where different lifestyles are adopted and societies become civilized and this trend is expected to continue during the next two decades**(2)**. For people who suffer from asthma, it can cause them a major disability and affect the quality of life significantly**(1)(2)**. The significant increase in the prevalence of asthma and other allergies (for example, eczema) cannot be explained over the past several decades by relying on genetic factors alone and this leads to an increased focus on other risk factors such as environmental exposure, for example and it is expected that cases will rise Asthma to over 400 million cases globally in 2025**(3)**. due to climate change, increased exposure to air pollution, urbanization, changing the immune response and changing lifestyle**(3)(4)**. in the UK receiving approximately 4.3 million adults treating from asthma**(5)**.

Aim of Study: To assess the major risk factors of asthma in adult in health institutions in maysan governorate.

Patients and method

A case-control study was conducted in Consultation Center for Chest and Respiratory Diseases at Al-Sadr Teaching Hospital in Maysan Governorate(one of the 18 Iraqi governorate located in south of Iraq the number of persons 1 million and characteristics with Marshes and oil) It is a center for the diagnosis and treatment of

respiratory diseases and is located in the center of the city of Amara and provides care and treatment to respiratory patients from all its districts and aspects of Maysan Governorate. The center provide services to average 50 patients daily with respiratory diseases of them about 2-3 patients with asthma daily for 5days in a week. The daily center activities include history taking, clinical examination, laboratory investigations, management, the follow-up to asthma patients, health education, also different respiratory cases for management and follow up. Data was collected over a period of five months between the 1st of November 2019 to the 1st of April 2020.

Statistical Analysis: Analysis of data was carried out using the available statistical package of SPSS-25 (Statistical Packages for Social Sciences- version 25).

Finding: The results in table 1 showed the distribution of age and gender among cases and controls and there was no statistically significant difference between the two groups (p >0.05) the higher percentage of cases was in age groups (40-49) years (27.5%). the higher percentage of controls was in the age group (30-39) years (30.8%). Predominantly males (36.7%) and females (63.3%) in both cases and controls.

Table (1): Distribution of cases and controls according to age and gender.

		Asthmatic patients		Controls		P value
		No	%	No	%	
Gender	Male	44	36.7	44	36.7	
	Female	76	63.3	76	63.3	
Age (Years)	<20 Years	7	5.8	4	3.3	0.356
	20---29	12	10.0	21	17.5	
	30---39	30	25.0	37	30.8	
	40---49	33	27.5	27	22.5	
	50---59	20	16.7	18	15.0	
	=>60 Years	18	15.0	13	10.8	

The results in (table 2) shows persons that used electrical heating system protected from asthma with low significant association OR=0.553, CI=(0.32-0.95). Persons that use oil heating system at risk (5 times) to have asthma with highly statistical significant OR =4.846, CI=(2.40-9.80). Regarding dampness on the wall, the percentage of the cases was 73.3% and controls were 65.0%, with no statistical differences between the two groups (p-value= 0.162).). Regarding household pets, the percentage of cases was 19.2% and controls were 15.0% with no statistical significant P-Value =0.162. persons that allow pets in bed at risk 5 times to have asthma with significant association OR=5.46, CI=(1.24-24.09).

Table (2): Distribution of cases and controls according to heating system inside the house, dampness on the wall and household pets.

Type of heating system inside the house		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Electrical	Yes	34	28.3	50	41.7	0.030*	0.553 (0.32-0.95)
	No	86	71.7	70	58.3		
Oil	Yes	108	90.0	78	65.0	0.0001*	4.846 (2.40-9.80)
	No	12	10.0	42	35.0		

Type of heating system inside the house		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Is there dampness on the wall	Yes	88	73.3	78	65.0	0.162	1.481 (0.85-2.57)
	No	32	26.7	42	35.0		
You have household pets	Yes	23	19.2	18	15.0	0.391	1.344 (0.68-2.64)
	No	97	80.8	102	85.0		
Allow pets be in bed	Yes	12	52.2	3	16.7	0.019*	5.46 (1.24-24.09)
	No	11	47.8	15	83.3		

This table shows the persons that have a family history of asthma at risk 5 times to have asthma compared with none with highly significant association OR=5.127, CI=(2.77-9.49). the high percentage of family history in cases was 18.3% in mother and in controls was 7.5% in sister.

These results shows persons that have upper respiratory tract infection at risk five times to have asthma with highly significant association OR=5.059, CI=(2.29-8.76). this table shows persons that have an infection from 6-11 months at risk 8 times to have asthma with highly significant association OR=8.25, CI=(1.80-37.91), persons that have infections =>12 months at risk 4 times to have asthma with highly significant association OR=4.29, CI=(1.48-12.41).

Table (3): Distribution of cases and controls according to family history and upper respiratory tract infection.

		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Family history of asthma	Yes	57	47.5	18	15.0	0.0001*	5.127 (2.77-9.49)
	No	63	52.5	102	85.0		
The relationship with the person in the family has asthma	Brother	3	2.5	3	2.5		
	Father	17	14.2	2	1.7		
	Grandfather	4	3.3	-	-		
	Mother	23	18.3	3	2.5		
	Sister	3	2.5	9	7.5		
	Sons	-	-	1	0.8		
	Uncle	7	5.8	1	0.8		
Have URT infection before asthma onset	Yes	86	71.7	40	33.3	0.0001*	5.059 (2.29-8.76)
	No	34	28.3	80	66.7		
Duration of infection	<6 months	40	46.5	33	82.5	0.001*	-
	6---11	20	23.3	2	5.0		8.25 (1.80-37.91)
	=>12 months	26	30.2	5	12.5		4.29 (1.48-12.41)

The results in table 4 show persons that are an active smoker before the onset of asthma at risk 2 times to have asthma from non-smoker with significant association OR=2.145, CI=(1.18-3.91) the high percentage of cigarettes packet/day was 56.4% of cases and 72.7%of controls were in 1 packet/day, With statistically no significant (p-value = 0.433). the high percentage of the duration of smoking of cases was 43.6% in duration

(=>15 years), for controls were 40.9% in duration (10---14 years). Regarding second-hand smoke, the percentage of cases was 50.8% and controls were 49.2% with statistically no significant (p-value = 0.796).

Table (4): Distribution of cases and controls according to smoker and second hand smoke.

		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
Smoker before onset asthma	Yes	39	32.5	22	18.3	0.012*	2.145 (1.18-3.91)
	No	81	67.5	98	81.7		
Cigarettes packet/day	1	22	56.4	16	72.7	0.433	
	2	15	38.5	5	22.8		
	3	2	5.1	1	4.5		
Duration of smoking	<5 years	5	12.8	1	4.5	0.530	
	5---9	7	17.9	4	18.2		
	10---14	10	25.6	9	40.9		
	=>15 years	17	43.6	8	36.4		
Second hand smoke	Yes	61	50.8	59	49.2	0.796	1.069 (0.64-1.77)
	No	59	49.2	61	50.8		

The results in (table 5) show persons that are overweight that have BMI(25-29.9) at risk 1 time to have asthma but with no significant association OR=1.42, CI=(0.78-2.58). Persons that are Obese I that have BMI (30-34.9) at risk 3 times to have asthma with significant association OR=2.54, CI=(1.15-5.63). persons that are Obese II that have BMI (=>35) at risk 5 times to have asthma with significant association OR=4.89, CI=(1.77-13.53).

Table (5): Distribution of cases and controls according to BMI.

		Asthmatic patients		Controls		P value	OR (95% CI)
		No	%	No	%		
BMI (Kg/m^2)	Normal (18.5-24.9)	33	27.5	51	42.5	0.005*	-
	Overweight (25-29.9)	45	37.5	49	40.8		1.42 (0.78-2.58)
	Obese I (30-34.9)	23	19.2	14	11.7		2.54 (1.15-5.63)
	Obese II (=>35) Total	19120	15.8100	6120	5.0100		4.89 (1.77-13.53)

Discussion

Regarding the age, the results in this study demonstrated that the higher percentage was in the age group between (40-49) years with no significant association (p-value =0.356). it disagrees with the study that reported by Abdulhussian, 2015 in Basrah that found most of the study samples were among age group (30-44) years with no significant association (p-value =0.730)[6]. In the current study, this results demonstrated that the higher percentage of gender in females 63.3% in compared with males 36.7%.which is in agreement with the result that done by Abdulhussian, 2015 in Basrah that found most of the study samples were among females 62.5% in compared with males 37.5%[6].

Regarding the type of heating system inside the house the results of current study shows that the higher percentage was 90.0% in cases and 65.0% in controls were oil, which it disagrees with the result of study done by Esmaeil Idani,2019 in Iran which found that the higher percentage of cases was 98.3% and controls were 98.4% were Gas[7] . This disagreement may be due to the type of fuel available in Iraq compared to other countries, Also, it may be due to economic and environmental matters.

In this study regarding dampness on the wall, this result demonstrate that the percentage of the cases was 73.3% and controls were 65.0%, with no statistical differences between the two groups (p-value= 0.162). which is in agreement with the result of study done by Esmaeil Idani,2019 in Iran that found that the percentage of cases was 51.1% and controls were 49.2% with no statistical differences between the two groups (p-value= 0.433)[7].

regarding household pets, the current study demonstrate that the percentage of cases have household pets was 19.2% and controls were 15.0% and this results shows the percentage of allowing pets in bed was 52.2% in cases and 16.7% in controls with statistical significance (p-value = 0.019).which is in agreement with the results of study done by Esmaeil Idani,2019 in Iran that found the percentage of cases have household pets was 8.5% and controls were 7.9% and the percentage of allowing pets in bed was 2.8% in cases and 0.9% in controls with statistical significance (p-value <0.001)[7].

The present study demonstrate that the percentage of cases have family history of asthma was 47.5% and for controls 15.0%,which is in agreement with results of study that done by Elfaki NK, 2017 in Saudi Arabia. That found that the percentage of cases have family history of asthma was 66.8%. and for controls 40.2%[8].

The current study demonstrate that the percentage of cases have upper respiratory tract infection was 71.7% and for controls were 32.5% with highly statistically significant (OR= 5.253, CI=3.03-9.11) . which is in agreement with the results of study that reported by Al-Mazam, A., 2001 in Saudi Arabia that found that the percentage of cases have upper respiratory tract infection was 61.8% and for controls were 13.6% that found to be an independent risk factor for bronchial asthma (OR=10.5, CI=5.11-21.89)[9].

Regarding active smoker this study shows that the percentage of the active smoker was 32.5% among cases and 18.3 among controls,which is in agreement with the results of study done by Elfaki, N. K., 2017 in Saudi Arabia. that found the percentage of cases are active smokers was 26.6% and for controls were 22.8%[8].

Regarding second-hand smoke, this study shows that the percentage of cases was 50.8%,and for controls were 49.2%. which is in agreement with the results of study done by Elfaki, N. K., 2017 in Saudi Arabia. that found the percentage of cases was66.3% and for controls were 56.0%[8].

Regarding BMI(Body Max Index) this study shows that the higher percentage of cases was 37.5% were overweight (25-29.9) and the lower percentage of cases was 15.8% were obese II(=>35). which is in agreement with the results of study done by Muhammed, S. M et al,2012 in Baghdad which found that the higher percentage of asthmatic patients was45.7% were overweight (25-29.9). and the lower percentage of cases was 2.3% were obese II(=>35)[10]. But, it is disagreed with the results of study done by Rönmark, E.et al,2005 in northern Sweden that found that the higher percentage of cases was 42.1% were normal (20-24.9)[11]. This disagreement may be due to a different lifestyle in Iraq than in other countries.

Conclusions

Statistically significant was found between the type of heating system inside the house and asthma in adults. Also, between patients who had a family history of asthma and asthma in adults so Positive association was found between upper respiratory tract infection and asthma in adults.

Atherogenic Index of Plasma Levels in Iraqi Diabetic and Diabetic Nephropathy Patients

Sulaiman M. Hasan

Ph.D. Clinical Biochemistry, Department of Biochemistry, Collage of Dentistry, Al-Farahidi University/Iraq

Abstract

The study aimed todetermine the Levels of HbA1c %, urea, createnine, albumin,total cholesterol, triglyceride,high density lipoprotein (HDL-c), low density lipoprotein (LDL-C) and very low-density lipoprotein (VLDL) in diabetic and diabetic nephropathy patients and to compare the results with that of control group. Then, to compare Atherogenic Index of Plasma levels in these groups that may be predict prone of patients to cardiovascular illness. This study has selected one hundred fifty participates who were consideredto be enrolled in this research with aged ranged (40-65) years that divided into three groups as follows: group one (G1) consists of 50 healthy individuals as a control group, group two (G2) consists of 50 patients with diabetes and group three (G3) consists of 50 patients with diabetes and nephropathy as complication.

This study illustrated significant increased were found in Total Cholesterol and low-density Lipoprotein in G2 comparing to G1, while there was highly significant increase in total cholesterol and low-density lipoprotein in G3 comparing to G2 and in G1. Results, also, revealed highly significant increase in triglyceride and very low density in G2 and G3 comparing to G1. Data demonstrated highly significant decrease in high density lipoprotein in G2 and G3 comparing to G1. Also, demonstrated highly significant increase in Atherogenic Index levels in G2 and G3 comparing to G1, while no significant increased observed in G3 comparing to G2. Sothe study concluded that Atherogenic Index is elevated in diabetic and nephropathy diabetic patients who could be used as a marker for predict cardiovascular disease in patients groups.

Keywords: *Diabetic Nephropathy, Lipid profile and Atherogenic Index (AIP).*

Introduction

Diabetic nephropathy is the most common cause of chronic kidney disease and represents a large and ominous public health problem. Patients with diabetic kidney disease have exceptionally high rates of cardiovascular morbidity and mortality. In fact, the excess mortality among patients with diabetes appears to be largely limited to the subgroup with kidney disease and explained by their high burden of cardiovascular disease [(1)].

Obesity increases the risk of many diseases such as heart disease, type 2 diabetes, obstructive sleep apnea, cancers and osteoarthritis**[(2)].** There is a seven times greater risk of diabetes in obese people in contrast with healthy weight, with a threefold increase in risk for overweight people. Also, body fat distribution is an important determinant of increased risk of diabetes **[(3)].**

The atherogenic index of plasma (AIP), defined as logarithm [log] of the ratio of plasma concentration of triglycerides to high-density lipoprotein (HDL) cholesterol, has recently been proposed as a predictive marker for plasma atherogenicity and is positively correlated with cardiovascular disease risk. Also, AIP correlates with the size of high-density lipoprotein and

Lecturer, Ph.D. Clinical Biochemistry, Department of Biochemistry, Collage of Dentistry, Al-Farahidi University/Iraq
e-mail: drnihadkhalawe@gmail.com

low-density lipoprotein particles and with the fractional esterification rate of cholesterol by lecithin: Cholesterol acyl transferase in plasma. This ratio accurately reflects the presence of atherogenic small low-density lipoprotein and high-density lipoprotein particles, is a sensitive predictor of coronary atherosclerosis and cardiovascular risk and a useful surrogate for insulin resistance [4].

Materials and Method

One hundred fifty individuals with age ranged between (40-65) years were enrolled in this study. They divided into three groups as follows:-

1. Group (G1) that consists of 50 healthy individuals as control group.
2. Group (G2) that consists of 50 diabetic patients.
3. Group (G3) that consists of 50 diabetic nephropathy patients.

Blood samples were collected from all groups after a period of fasting 12-14 hours. The study was conducted between March 2020– June 2020 in the diabetic & endocrinology center in Al- Yarmouk Teaching Hospital/Iraq.

Whole blood was used in determination of HbA1c. The HbA1c was determined by HPLC method. A hemolyzed whole blood was mixed with a weakly binding cation-exchange resin. The nonglycosylated hemoglobin (HbA0) linked to the resin, leaving (HbA1) free to remove by a resin separator. The percent of HbA1 was measured by evaluation of the absorbance values at 415nm of HbA1 fraction and of the total Hb fraction,by calculating the ratio of absorbances (R). This ratio comparing was compared to the ratio of a glycohemoglobin standard that obtained from the same procedure[5]. The urea level was estimated after enzymatic hydrolysis by urease enzyme. Indophenol compound was generated from Salicylate and Hypochlorite as shown in below . The intensity of the green complex is proportional to the urea found in the sample[6]. Creatinine in the sample was reacted with picrate in alkaline medium forming a coloured complex (Jaffe method)[7]. The method for determination of albumin was based on the specific binding of bromocresol green (BCG), an anionic dye and the protein at acidic pH with the resulting shift in the absorption wavelength of the complex. The intensity of the color formed was proportional to the concentration of albumin in the sample[8]. Serum glucose was measured by using kits from (Randox Company, United Kingdom) which based on the PAP enzymatic determination of glucose[9]. Total cholesterol[10],triglyceride [11]and HDL-c [12]were measured by enzymatic method from (Human Gesellschaft fur biochemical and Diagnostica mbH, Germany.). The levels of LDL-C and VLDL-C were analyzed by using Friedewald equation as follows[13]:

$$\text{LDL} - \text{C}\left(\frac{mg}{dl}\right) = Total\ cholesterol - HDL - \frac{TG}{5}$$

Serum VLDL-C can be calculated by:

$$\text{VLDL} - \text{C}\left(\frac{mg}{dl}\right) = \frac{TG}{5}$$

The atherogenic index of plasma (AIP) was calculated according to Milada formula equation as display below[14]:

$$\text{AIP} = \frac{logTG}{HDL}$$

Statistical Analysis: The results expressed as mean± SEM. Students t-test was applied to compare the significance of the difference between DN, Diabetic patients and control groups. p-value ($P \geq 0.05$), ($P \leq 0.05$), ($P \leq 0.001$) considered statistically nonsignificant, significant and highly significant respectively. The correlation coefficient (r) test is used for describing the association between the different studied parameters.

Findings: Results in table (1) illustrated levels of (FBG, HbA1C%, urea, creatinine and albumin) in G1, G2 and G3. Results in table (1) reveled a significant elevation in FBG, HbA1c%, urea and creatinine levels in G2 comparing to G1. Results, also, showed a highly significant elevation in these parameters in G3 comparing to G1 and G2. While results display a significant decrease in albumin levels in G2 and G3 comparing to G1 and in G3 comparing to G2.

Table 1: Descriptive Parameters for G1, G2, G3

Parameters	(G1)	(G2)	(G3)	T-Test G1 vs G2	T-Test G1 vs G3	T-Test G2 vs G3
FBG (mg/dL)	90.62±7.223	177.62±25.742	230.67±50.974	S	S	S
HbA_{1C} (%)	5.32±0.475	8.42±1.068	11.77±1.47	S	S	S
Urea (mg/dL)	20.31±3.4	33.67±4.62	107.37±57.2	S	S	S
Creatinine (mg/dL)	0.47±0.11	0.92±0.164	3.94±2.42	S	S	S
Albumin (mg/dL)	4.029±0.3	3.97±0.215	2.4±0.836	NS	S	S

Table (2) shows the levels of total cholesterol, triglyceride, high density lipoprotein (HDL-c), low density lipoprotein (LDL-C), very low density lipoprotein (VLDL) and AIP levels for G1, G2 and G3. Results revealed a significant elevation in levels of total cholesterol, triglyceride, low density lipoprotein and very low density lipoprotein in G2 and G3 comparing to G1 while a significant decrease was found in HDL levels in G2 and G3 comparing to G1. Results, also showed a significant elevation in (TC, TG, LDL-c and VLDL-c) in G3 comparing to G2,while nosignificant was found in G3 comparing to G2 in HDL levels. Result in this table, also, demonstrated highly significant elevation in Atherogenic Index levels in G2 and G3 comparing to G1, while no significant increase observed in G3 comparing to G2.

Table (2): Lipid profile (TC, TG, HDL-c, LDL-c, VLDL-c) and AIP levels for all studied groups.

Parameters	(G1)	(G2)	(G3)	T-Test G1 vs G2	T-Test G2 vsG3	T-Test G1 vsG3
TC (mg/dL)	187.4±6.1	193.5±6.6	271.47±5.5	N.S	S	S
TG (mg/dL)	105.04±20.111	177.01±52.8	228.5±6.8	S	S	S

AIP	0.54±0.017	0.82±0.024	0.89±0.017	S	N.S	S

Diabetic dyslipidemia comprises a triad of raised triglycerides, decrease HDL-c and excess of small, dense low density lipoproteinparticles, which is in agreement with the present study[15]. The dyslipidemia are found in diabetes patients due to insulin resistance or deficiency affect key enzymes and pathways in lipid metabolism[16].

In individuals with type 2 diabetes, metabolic syndrome and the combined dyslipidemia, cardiovascular risk is elevated by a clustering of risk factors such as abdominal obesity, impaired fasting glucose, increased blood pressure, low HDL-cholesterol (HDL-C), elevated triglycerides (TGs) and an elevated in small, dense LDL particles. The current increase in the incidence of type 2 diabetes in the population perhaps poses the most urgent cardiovascular risk. Although insulin resistance is crucial to the pathogenesis of the disease, the associated atherogenic lipoprotein phenotype considerably enhances the risk. Hence there is an ongoing intense search for a medication capable of modifying the atherogenic lipid profile as well as lowering glucose. Medications of the thiazolidinedione class traditionally used for glycemic control in patients with type 2 diabetes seem to hold promise in this respect[17].

Atherogenic Index may be an important tool for analyzing the results of clinical trials. The association of triglycerides and high density lipoprotein in this simple ratio theoretically reflects the balance between risk and protective lipoprotein forces and both triglycerides and high density lipoprotein are widely measured and available[18].

In summary, Atherogenic Index provides

information about the atherogenicity of plasma and quantifies the response to therapeutic intervention[19].

Conclusion

The study concluded that Atherogenic Index is increased nephropathy diabetic patients more than diabetic and control group that could be used as a marker for predict CVD in patients' groups.

Evaluation of Serum Level of Serum Catalase and SOD as a Predictive Factors in Preterm Labor Patients

Sura Zeki Salih[1], Mutaz S. Ahmied[2], Israa H. Abdulkareem[2]

[1]M.Sc. Student, [2]Assist Prof., College of medicine, Tikrit University, Tikrit, Iraq

Abstract

The study is a comparative case control study conducted on 45 preterm delivery between (28-37 week) of gestation as cases group and 45 term delivery between (37-42 week) of gestation as control group, at obstetrical and gynecology department of Salah Alden general hospital in Salah Alden city from 20th of November 2019 to 15th February 2020. The blood sample taken from participated women and the oxidative stress parameter (F2-8-isoprostan and protein carbonyl) was measured by ELISA technique. The cases were Single and twin pregnancy with cervical dilatation >3 cm and fully effaced cervix, and/or rupture membrane, Uterine contraction 3per 10 min and Indicated labor pregnancy like bleeding, DM, hypertension, pPROM, fetal destress, fetal death. But uncertain gestational age, elective term cesarean section, liver disease, renal disease and hepatitis infected women were excluded.

Result: Mean age of participants was (26.05±6.59 years) with a range of (14-45years) and mean weight was (74.84±6.728 Kg), range of (60-95 Kg) and mean height of participated (156.14±5.3 cm) and range of (150-170 cm).Superoxide dismutase and catalase showed significant decrease in preterm labor (mean±stander error) (529.161 ± 35.87 U/ml) (1.637 ± 0.12 pg/ml) respectively in compare with (mean± stander error) (1.637± 0.12U/ml) (529.161± 35.87 pg/ml) in preterm labor.

Conclusion: This study showed that catalase and superoxide dismutase significantly decrease in preterm labor group.

Keywords: *Serum catalase; SOD; Predictive Factors; Preterm Labor Patients.*

Introduction

A preterm birth (PTB) defined as a labor occurring before 37 weeks (259 days) of gestation. PTB are usually classified into three categories: medically induced (25% of all PTB), spontaneous preterm labor (50% of all PTB) and preterm premature rupture of membranes (pPROM) (25% of all PTB). Preterm birth are divided into four degrees of prematurity: extremely preterm (less than 28 weeks), very preterm (28 – 31^{+6} weeks), mild preterm (32 – 33^{+6} weeks) and moderate preterm (34 – 36^{+6} weeks)[(1)]. Preterm birth, depending on one's point of view, may be considered as an adverse gestational outcome (where a fetus is incapable to achieve its in utero growth potential) or a favored outcome (e.g., where an abortion or non-viable prematurity has been successfully prevented). Even healthy women with low-risk pregnancies, a fraction of babies can be probably born preterm[(2)].

The most popular definition of free radicals is {molecules or molecular fragments that contain one or more unpaired electrons in the atomic or molecular orbitals}. The free radicals are uncharged, short-lived molecules and very reactive. Human body contain about 10,000–20,000 free radicals which attack each individual cell of human body. Numerous of these radicals are beneficial in that they effort for immune cells responsible

e-mail: drnihadkhalawe@gmail.com

for bacterial cells killing and toning the smooth muscles, which in order regulate the normal function of blood vessels and the internal organs. Uncontrolled generation of the free radicals in human body may cause various harmful effects like heart and neurodegenerative diseases, autoimmune diseases, cancers, etc.[3].

Preterm labor is a complex condition resulting from multiple etiologic factors, but it is well documented and accepted that both inflammation and infection represent highly significant risk factors for PTB. However, despite the public health and clinical significance of PTB and recent research achievements, the relations between infectious agents, immunological or molecular pathways and triggering factors for spontaneous PTB remain poorly understood reflecting the complexity of this obstetrical problem. It has been widely acknowledged that OS may involve in the pathogenesis of human disease and represent a major topic in all areas of medicine [4]. In this regard, there is emerging evidence that an imbalance between oxidants and antioxidants may play a role in PTB [5].

This study is designed to evaluate the association of catalase and SOD with preterm labor.

Patient and Method

This study is case control study carried out in Salah Alden city from 20th of November 2019 to 15 February 2020. The study included 90 pregnant women attend Salah Alden general hospital department of obstetrics and gynecology for labor, 45 of them are preterm (between 28 and 37 weeks) as cases and 45 of them complete term (between 37 and 41 weeks) as control, the patients included Single and twin pregnancy, cervical dilatation >3 cm, fully effaced cervix, and/or rupture membrane, uterine contraction 3per 10 min and indicated labor like bleeding, DM, hypertension, pPROM, fetal destress and fetal death. The exclusion criteria include uncertain gestational age, elective term cesarean section, liver disease, renal disease and hepatitis infected women. Ablood sample was taken from them and an interview was carried out with these patients using questionnaire form designed by the investigator including their demographic characteristics, age, weight, length. etc. The antioxidant parameter (catalase and SOD) was measured by ELISA technique and colorimetric methodrespectively.

Results

The results showed that mean age of participants was (26.05±6.59) years with a range of (14-45) years and mean weight was (74.84±6.728) Kg, range of (60-95)Kg and mean height of participated (156.14±5.3)cm and range of (150-170) cm. The participants include 32 urban females and 58 rural and they deliver 51 male babies and 39 females. 22 of the participants are prim gravitas and the other 77 are multigravida.

The study groups include 15 prim gravida women and 30 multigravida in preterm group and 7 prim gravida and 38 multigravida in term group.

The study groups include 10 women with positive history of abortion and 35 women with negative history in preterm group and 8 women with positive history of abortion and 37 women with negative history in term group.

Catalase Activity: Comparison between study groups regarding serum catalase activity level was performed using anova test. Cases were compared with controls. There was a statistically significant difference in the serum mean catalase activity level for cases group (mean±S.E) (529.161± 35.87) pg/ml and control group (mean±S.E) (739.284± 17.60) pg/ml, p value <0.001. Table (1).

Table (1): Serum catalase activity level comparison between term and preterm groups

Catalase (pg/ml)						
Group	**N**	**Mean**	**S.E**	**Minimum**	**Maximum**	**P value**
Term	45	739.28	17.60	365.13	992.08	*<0.001
Preterm	45	529.16	35.87	27.78	902.08	

*The result was highly significant.

Superoxide dismutase activity: Comparison between study groups regarding serum SOD activity level was performed using anova test. Cases were compared with controls. There was a statistically significant difference in the serum mean SOD activity level for cases group (mean±S.E) (1.637±0.12) U/ml and control group (mean±S.E) (2.251± 0.14) U/ml, p value 0.002. Table (2).

Table (2): Serum SOD activity level comparison between term and preterm labor

Superoxide Dismutase (*U/mL*)						
Group	**N**	**Mean**	**S.E**	**Minimum**	**Maximum**	**P value**
Term	45	2.25	0.14	0.63	3.78	*0.002
Preterm	45	1.637	0.12	0.06	3.57	

*The result was highly significant.

Comparison of serum mean level of SOD between patient complain of contraction (mean±S.E) (1.655±0.23) U/ml and patient not complain of contraction (mean±S.E) (1.603±0.19) U/ml within preterm group show no statistical significant with p value 0.364.

Comparison of serum mean level of SOD between patient complain of pPROM (mean±S.E) (1.515±0.30) U/ml and patient not complain of pPROM (mean±S.E) (1.681±0.27) U/ml within preterm group show no statistically significant with p value 0.174.

Comparison of serum mean level of catalase between patient complain of contraction (mean±S.E) (572.039±67.11) pg/ml and patient not complain of contraction (mean±S.E) (446.705±24.67) pg/ml within preterm group show no statistically significant with p value 0.213.

Comparison of serum mean level of catalase between patient complain of pPROM (mean±S.E) (534.534±98.97) pg/ml and patient not complain of pPROM (mean±S.E) (527.243±87.23) pg/ml within preterm group show no statistically significant with p value 0.947.

The study show that the comparison of serum means level of catalase and SOD between prim and multigravida in preterm group no statistically significant. Table (3)

Table (3): Comparison Oxidative stress level between prime and multi gravida in preterm group

No. of previous pregnancy (in preterm group)		**Catalase (pg/ml)**	**SOD (U/ml)**
Prim gravida	Mean	542.56	1.38
	S.E	69.04	0.28
Multi gravida	Mean	522.19	1.76
	S.E	42.08	0.11
P value		*0.76	*0.16

*The result was non-significant.

The study show that the comparison of serum catalase and SOD mean level between prim and multigravida in term group no statistically significant Table (4).

Table (4): Comparison Oxidative stress level between prime and multi gravida in term group.

No. of previous pregnancy in term group		Catalase (pg/ml)	SOD (U/ml)
Prim gravida	Mean	773.94	2.24
	S.E	47.55	0.36
Multi Gravida	Mean	733.34	2.25
	S.E	19.04	0.15
P value		*0.42	*0.97

*The result was non-significant.

The study show that the comparison of serum means level of catalase and SOD between women with negative history of abortion and women with positive history of abortion in preterm group no statistically significant. Table (5).

Table (5): Comparison Oxidative stress level with history of abortion in preterm group

History of abortion (in preterm group)		Catalase (pg/ml)	SOD (U/ml)
Negative	Mean	532.62	1.58
	S.E	41.42	0.15
Positive	Mean	516.16	1.81
	S.E	67.85	0.12
P value		*0.85	*0.45

*The result was non-significant.

The study show that the comparison of serum means level of catalase and SOD between women with negative history of abortion and women with positive history of abortion in term group no statistically significant. Table (6).

Table (6): Comparison Oxidative stress level with history of abortion in term group

History of abortion (in term group)		Catalase (pg/ml)	SOD (U/ml)
Negative	Mean	739.54	2.15
	S.E	21.32	0.15
Positive	Mean	738.22	2.66
	S.E	16.14	0.24
P value		*0.97	*0.15

*The result was non-significant.

The study show that the comparison of serum mean level of catalase and SOD between women with positive history of preterm labor and women with negative history of preterm labor in preterm group no statistical significant. Table (7).

Discussion

Spontaneous preterm birth (sPTB) is a common major pregnancy complication leading to perinatal morbidity and mortality as well as short- and long-term sequelae [(6)]. The biologic mechanisms leading to PTB are incompletely understood. Oxidative stress may represent one possible mechanism. Oxidative stress biomarkers have been associated with adverse pregnancy outcomes [(7)] and several studies have shown that oxidative stress biomarkers are increased among women who go on to experience PTB or shortened gestation. However, the strength of association remains inconsistent across studies and discrepancies may in part be due to differences in biomarkers used to measure oxidative stress.[(8)]

Catalase enzyme is one of most abundant antioxidant enzymes which represent first line of antioxidant defense against free radical. [9]

In this study catalase activity was measured in both preterm and term groups and the results revealed that its serum levels is significantly low in preterm groups in comparison with term group. This inverse association of catalase enzyme and preterm labor was proved in other studies [10, 11]. This results may be due to increase in antioxidant defense as compensatory mechanism against increase oxidative stress in term group. Tiffany A. Moore, et al. found no differences in catalase levels in preterm maternal or cord blood samples between preterm and term pregnancies [12].Ramkumar Menon, et al measure catalase level in maternal plasma and found its levels was high in preterm labor in comparison with term labor [13]. These deferent results remain inconclusive, but indicate that a deferent finding in deferent studies may be caused by deferent studies circumstances, environmental factor, personal characteristics, diseases and other factors.

SODs are endogenous antioxidant enzymes that are catalyze the dismutation of O2• to H2O2 and O2.[14]

In this study the SOD activity was measured in maternal serum of preterm and term groups and the results show significant high level in term group in comparison with preterm. That's agree with the result of other studies [13, 11] This results may be due to increase in antioxidant defense as compensatory mechanism against increase oxidative stress in term group, Or due to normal increase in SOD level in this period of pregnancy [15] In other reviewed studies, researchers measured SOD in the preterm mothers. Herway et al. study EcSOD in maternal serum and did not showed significant differences between term and preterm birth [16]. Gunko, Pogorelova and Linde find minor expressions of Cu/Zn-SOD in women with preterm birth in comparison with women with term birth [17]. In the other studies, the researchers did not find significant differences in EcSOD levels between TB and PTB in cord blood [18] or in protein expression for Cu/ZnSOD in the myometrial tissue [19]. These inconclusive results indicate that SOD may be associated with race/ethnicity, personal factors, disease and environmental factors.

By comparing SOD level between pregnancies presented by pPROM and pregnancies presented by uterine contractions the results revealed decrease its level in pPROM pregnancies the same as Ramkumar Menon, et al study [13]. That due to increase oxidative stress which cause decrease antioxidant. In other study by Eryn H. Dutta et al. SOD1 measured in fetal membranes and show higher level in PTB than in pPROM whereas SOD2 showed no significant difference between the two groups [20].

Catalase level was compared between pregnancies presented by pPROM and pregnancies presented by uterine contractions the results revealed no significant deference between two groups, this results may be due to increase oxidative stress in two groups that cause decrease in antioxidant level. Ramkumar Menon measure serum catalase and found that its level in pPROM pregnancies was higher than spontaneous preterm labor which highlights the ambiguity associated with marker analysis of oxidative stress.[13] Eryn H. Dutta et al. found that catalase was not significantly different in fetal membranes of pPROM and PTB. [20]

Also, Soydinc *et al.,* did find lower catalase levels in the vaginal wash fluid in pPROM compared to a matched control group. [12]

Davut Sinan KAPLAN, et al. study total oxidative status and total antioxidant status in maternal colostrum of primiparous and multiparous mothers. and No significant differences were determined between two groups. [21]

Abstract

Ayurveda explains disproportion in the three doshasvata, pitta and kapha singly or all of them together can cause Apasmar. Aggravated doshas get accumulated in hridaya and create the features based upon Doshic predominance, which cause illusion of the mind and visual hallucination and seizures (tonic spasms and clonic jerks). Often it is presented with outwarding of tongue, deviation of the eyes, dribbling of saliva with froth, tonic and clonic movements of limbs. Epilepsy is characterized by recurrent, episodic, paroxysmal, involuntary clinical events related with alternation of cerebral function. An epileptic attack is anrapid and unwarranted electric discharge of cerebral neurons. Saraswat Churna is a popular Compound drug which is successfully used in Psychological disorders. It is mentioned in "Unmada Prakaran" of well known Ayurvedic book of " Bhaishgya Ratnawali" that Saraswat Churna consists of different types of Medhya Rasayana herbs like Vacha, Shankhapushpi etc. and Brahmi Swarasbhawna is given to it for three times. Phenytoin (Diphenyl Hydantoin or Dilantin) is highly effective and widely prescribed anticonvulsant drug used in the treatment of grand mal and psychomotor epilepsy. Phenytoin has been used to treat thought, mood and behaviour disorders, cardiovascular disorders, neuro muscular disorders, gastrointestinal disorders, Endocrine disorders. As Dilantin showed adverse reactions like urticarial like skin rashes, gastric irritation, resulting in nausea, vomiting, hyperplasia and hypertrophy of the gums noted in 90% of patients was not noted in patients treated with Saraswat Churna.

Keywords: *Apasmar, Epilepsy, Saraswatchurna, Dilantin, Diseases, Treatment, Adverse Reactions.*

Introduction

Since time in memorable with existence of human being disease is associated. "Dis-ease" when a human being suffers from uncomfortableness or any alternation in normally; he is said to be diseased. Hippocrates is to modern system of medicine what Sushrut and Charak are to Ayurveda, But at least Hippocrates had bit of previous work to develop upon while Charak and Sushrut have done everything first hand and their work is pioneering, as well as astronomical. Transient loss of memory or loss of memory of convulsions is known as Apasmar[1,2]. In this disease patient gets convulsions, attacks of falling down and frothing from mouth. After convulsions patient is again normal. According to Ayurveda constituents of body are divided into two types 1st Sthula and 2nd Sukshma. Dosa, Dhatu and Mala are of sthula type and Atma, Indriya Mana are of Sukshma type. According to Ayurveda; Apasmar is a psychosomatic disorder. In more or less proportion Apasmar found in almost all countries. Being prevalent in both sexes, all age groups

and any socio-economic condition, it has predilection for children. In all types of medical therapies we get description about disease which is similar to Apasmar and treatment of the disease. But still this disease remains the challenge for the therapists[3,4]. Through strong tranquilizers and sedatives of modern therapy are effective, they have adverse effect on mind. Hence an effective drug. Dilantin which is a drug of choice for all types of epilepsy is used by all Allopaths. In this study effects of Saraswat Churna in Apasmar are studied as against the allopathic drug Dilantin. In this study Saraswat Churna is used as a treated drug & Dilantin is used as a standard drug.This present thesis is an outcome of the above mentioned studies[5,6].

Material and Method

Selection of drug: Uptil now all the research work has been done on reinstate or reject whatever has been stated in the texts written thousands of years ago by the Acharyas.

There is no literature in which Saraswat Churna has been used up till now. According to Unmada Prakarma of Bhaishagyaratnawali daily intake of Saraswat Churna causes potentiating of Budhi, Dharanashakti, Dhairya and Smurti sequentially. Apasmar is defined as transient expression due to derangement of memory, intelligence and mind. Therefore I decided to work over use of Saraswat Churna in Apasmar.

Vacha the main ingredient of Saraswat Churna according to Ayuved has Medhya, Sangyasthapana, Akshepshamaka & Vedanasthapana action on central nervous system. According to Modern Science Vacha is Stimulant, antispasmodic & sedative in action.

Shankhapushpi according to Ayurved is Medhya, Balya for Brain & Nerves has Nidrajanana property.

Sunthi has stimulant & analgesic action.

Marich has antispasmodic & stimulant action on Nervous system.

Pippali is Stimulant & Medhya.

Ajamoda is balya for Brain & Central nervous system.

Kushtha is akshepshamak & avasadak.

Jeeraka is Vatanulomak & balya for brain.

Ashwagandhan is akshepshamak & analgesic.

After preparing churna of all twelve ingredients of 'Saraswatchurna' the mixture is given **Brahmi swarasbhavana** thrice. Brahmi is kaphavatshamak & has Apasmar & Unmadshamakprabhava. Brami is Kaphavatshamak & has Apasmar & Unmadshamakprabhava. Brami is also Medhya, Smaranshkti-wardhak (improve memory) Mastishka-Dharanashakti.

Thus according to Ayurved classics following are the qualities of the drugs used in 'Saraswat Churna' :- Antispasmodic, increases memory, tranquilises the over activity, sedative, hypnotic, brain tonic & Apasmarhara (antiepiteptic).

Therefore I have used Saraswat Churna for my research work.

Dilantin (Diphenylhydantoin): This is a major drug in the treatment of a variety of epileptic seizures with the exception of petit mal. Dilantin is a drug of choice, used by all Allopaths. In this study effects of Saraswat Churna in Apasmar are studied against the allopathic drug Dilantin.

Therapeutic Uses: This is important drug in the T/t of grand mal epilepsy, psychomotor seizures. Drug often controls focal cortical epilepsy but does not completely abolish the seizure activity.

Materials and Method:

A. Settings: A total 30 patients of Apasmar were randomly selected for the present study, from the Kayachikitsa OPD of Pakwasa Samnwaya Hospital and Bajaj Anusandhan Centre, Nagpur.

B. Research design: A Randomized Control Trial

1. Participants:

- Patients – Diagnosed patients of Apasmar(Epilepsy)
- Gender-Both Male and Female
- Age- From 15yrs-75yrs of age.

2]. Sampling procedure:

Random sampling

Grouping:

Groups	No. of patients	Age	Sex	Intervention	Dose/day	Duration
Group A Study Group	15	15 yrs to 75 yrs	Male and Female	Saraswat Churna	1 gm t.d.s. with Honey	6 months
Group B Control Group	15	15 yrs to 75 yrs	Male and Female	Dilantin	100mg t.d.s. with Plain water	6 months

4. Sample size: Sample size was taken 30

5. Population: Patients of Apasmar(Epilepsy) were selected from O.P.D. of Pakwasa Samnwaya Hospital and Bajaj Anusandhan Centre, Nagpur.

C. Data collection tools and process: Patients fulfilling inclusion criteria and willing to give written consent will be enrolled for study. The selected patient will be informed about possible outcome and side effects of interventional drug.

a. Inclusion criteria:

- Subject is between 15 and 75
- Ability to provide informed consent (or assent if under the age of 18)
- Ability to keep accurate seizure diaries
- Subject had prior neuroimaging with report available
- Diagnosed patients of Apasmar

b. Exclusion criteria:

- Subjects with significant progressive disorders or unstable medical conditions requiring acute intervention
- Change in AED regimen in the last 28 days
- Subject is currently taking > 3 concomitant AEDs
- Subject has had status epilepticus within the past 2 years

c. Specific Investigations:

- Manas Parikshan
- E. C. G.
- CBC
- C. S. F. Examination
- X- Ray Skull

d. Assessment Criteria:

1. Severity of attack

a. Grade 0: Myoclonic tremors

b. Grade 1: Multi focal clonic tremors

c. Grade 2: Generalized tonic tremors

d. Grade 3: Frothing + tongue biting

2. Frequency of convulsion

a. Grade 0: No convulsion

b. Grade 1: 1 episode/15 days

c. Grade 2: 1 episode/7 days

d. Grade 3: 1 or more episodes/day

3. Duration of convulsion attack

a. Grade 0: No convulsion

b. Grade 1: 5–15 s

c. Grade 2: 15–30 s

d. Grade 3: >30 s

4. Ictal features

a. Grade 0: No any features

b. Grade 1: Headache

c. Grade 2: Headache + drowsiness/delirium

d. Grade 3: Paresis + other complaints

D. Methodology: This is a Randomized Control Trial. The study was conducted at O.P.D. of Pakwasa Samnwaya Hospital and Bajaj Anusandhan Centre, Nagpur of Kayachikitsa department, as per inclusion criteria.

Written consent will be obtained from each patient. Total 30 patients were selected and they were divided

in two equal groups by random sampling method using lottery technique.

Preparation of Drug:

A. Contents of Saraswat Churna: Saraswat Churna contains mainly 12 types of herbal drugs in which eleven ingredients i. e. Kushtha, Patha, Ashwagandha, Shankhapushpi, Shunthi, Maricha, Pippali, Jeeraka, Krishna jeeraka, Ajmoda and Saindhav-lavana were taken in equal parts i.e. one part of each ingredient was taken and Vacha was taken in equal proportion of above drugs. Therefore eleven parts of Vacha & eleven parts of other drugs were taken. Fine powder of each ingredient was made by grinding method. Then the powder is mixed well after grinding. Then the mixture was given Brami Swarasbhavana thrice. And thus Saraswatchurna was ready for research work.

Comparative study of Rasa, Gun, Virya, Vipaka & Prabhava of contents of Saraswat Churna:

Table 1A

Name	Rasa	Guna	Virya	Vipaka	Prabhava	Doshaghnata

B. Dilantin: Dilantin which is a drug of choice for all types of epilepsy is used by all Allopaths. In this study effects of Saraswatchurna in Apasmar are studied as against the allopathic drug Dilantin.

Total no. of fifteen patients were treated by Saraswat Churna and fifteen patients were treated by Dilatin. The results obtained are represented graphically.

Statistical Data: In the present clinical study the response of Saraswatchurna and Dilantin on 15 patients each was observed. The data collected during the course of study is recorded below**.**

Table 2. Prakruti (According to Sharirik Dosha)

	Treated Group		Standard Group	
	No. of Patients	Percentage	No. of Patients	Percentage
Vata-pittaj	5	33.34	6	40
Vata-kaphaj	7	46.66	5	33.34
Pitta-kaphaj	2	13.33	2	13.33
Vata-pitta-kaphaj	1	6.67	2	13.33

Table 3. Prakruti (According to ManasikDosha)

Hrillasa	2	33.33	2	33.33
Nidrarthah	6	100	5	83.33
Cheshtalpata	6	100	6	100
Shuklagurusnighdharupadarshanam	4	66.66	3	50

Observation and Results

It has been opined in A.P.I. that a final say regarding the relief to the patient can only be given after the period of five years follow up. Therefore in the present study the assessment of the results of the treatment in the terms of cured, markedly improved etc. is avoided.

An assessment of severity of symptoms recorded before and after treatment is used here to evaluate the efficacy of the treatment

Group 1:

Total no. of patients was 15.

Disturbance of intelligence, memory & orientation had shown better results compare to other clinical features

Symptomatic relief in percentage is as follows:

1. Disturbance of intelligence – 68.75% relief.
2. Disturbance of Orientation – 66.34 % relief.
3. Disturbance of memory – 65.81% relief.
4. Tongue bite – 52.33% relief.
5. Sphurat Sakthihprantam, muhurmuhurh – 35.29% relief.
6. Shukla guru snigdharupadarshanam – 19.78% relief.
7. Vishamrudan – 18.18% relief
8. Dantankhadan – 15% relief
9. AsamanVilapam – 15% relief
10. Chestalpata – 13.33% relief
11. Kampa – 12.05% relief

In Group 2:

The total no. of patients was 15.

In this Kampa, Dantan Khadan, Sphurat Sakthihprantammuhurmuhurh & seizure activity; drug had shown better results

Symptomatic relief in percentage is as follows:

1. Dantan Khadan– 78.28%
2. Kampa – 68.75%
3. Sphuratskhthihprantammuhurmuhurh -64.91%
4. Tongue bite-60%
5. Vishamrudan- 52.63%
6. Chestalpata – 44.44%
7. Asaman Vilapam-26.61%
8. Disturbance of intelligence- 24.44%
9. Shukla guru snighdharupadarshanam- 23.52%
10. Disturbance of Memory- 19.72%
11. Disturbance of orientation -19.04%

Therefore Saraswatchurna in following Clinical features is more effective than Dilantin:

1. **Disturbance of intelligence**-44.31% more effective than Dilantin.
2. **Disturbance of memory**-46.07% more effective than Dilatin.
3. **Disturbance of orientation**-47.30% more effective than Dilantin,

While in following Clinical features Dilantin; is more effective than Saraswatchurna:

1. **Dantan Khadan –** 58.28% more effective than Saraswatchurna.
2. **Khampa-** 56.25% more effective than Saraswatchurna.
3. **Visham rudan-**34.45% more effective than Saraswatchurna.
4. **Sphurat Sakthihprantammuhurmuhurh** – 29.72% more effective than Saraswatchurna.
5. **Cheshtalpata -** 21.11% more effective than Saraswatchurna.
6. **AsamanVilapam-** 11.61% more effective than Saraswatchurna.
7. **Shukla guru snighdharupadarshanam-** 03.74% more effective than Saraswatchurna.
8. **Tongue bite-** 7.67% more effective than Saraswatchurna.

Discussion

In this study entitled comparative clinical study of role of Saraswat Churna in Apasmar was conducted on 30 patients grouping them into two groups of 15 each (Treated group and Standard Group)[7,8.]

Group A administered by Saraswat Churna treated group and group b administered by Dilantin standard group and clinical investigation conducted before and after the starting of the treatment with the above drug for a duration of six months. And the findings were recorded monthly intervals and comparison made between before and after completion of treatment.Maximum patients were between 20 to 40 years. Maximum patients i.e. 36.66% were belonging to 31-40 years and 26.66% were belonging to 41-50 years.Maximum patients were Male i.e. 60%. 73.33% of patients were married and 26.66%of patients were unmarried. Majority of patients were having mixed vegetarian diet i.e. 70%. 50% of patients were Businessmen. 70 % were of middle class. Addiction of alcohol is one of the precipitating causes of epilepsy. From 30 patients 11 were male had addiction of alcohol[9,10,11]. 36.66% patients were of Vata-pittajprakruti, 40% patients were of vata-kaphajprakruti, 13.33% patients were of pitta-kaphajprakruti, 10% patients were of vata-pitta-kaphajprakruti. Prakruti indicated that Rajasik Prakrutiwere exhibited in majority of patients and disease is mainly causes by the predominance of Raja and Tama.80% patients were having duration of illness from 10-20 years[12-16]. As Dilantin showed adverse reactions like urticarial like skin rashes, gastric irritation, resulting in nausea, vomiting, hyperplasia and hypertrophy of the gums noted in 90% of patients andthese adverse reactions were not noted in patients treated with Saraswat Churna.

Conclusion

In Ayurveda system of medicine the diseases are classified according to Doshicpredominance as well as signs & symptoms. In the present Clinical study a detailed description of Apasmar by various Ayurvedic Acharyas

and the trial drug Saraswatchurna is selected from an authentic Classical text. Saraswatchurna is compared with standard drug Dilantin by clinical symptoms and signs as recorded by Ayurvedic system, investigations in Apasmar patients to find out whether is superior or not in comparison to standard drug therapy.

The result of Saraswat Churna is insignificant.

Ethical Clearance: Taken from institutional ethics committee.

Source of Funding: Self.

Conflict of Interest: Nil.

Critical Appraisal of Communicable Diseases in the Perspective of Ayurveda

Punam Sawarkar[1], Gaurav Sawarkar[2]

[1]Associate Professor, Department of Panchakarma, [2]Associate Professor, Department of Rachana Shareer, Mahatma Gandhi Ayurved College Hospital and Research Centre, Salod (H), Wardha, Datta Meghe Institute of Medical Science (DU), Wardha, Maharashtra, India

Abstract

Current situation of COVID -19 pandemic demands for search literature about in *Ayurveda* to generate various preveative & treatment modalities to over come over it. Considering this need, review regarding communicable disorders from available Ayurved literature was done extensively & elaborated under heads of concept of airborne communicable diseases in Ayurveda,its etiology, pathology & symptomatology with recommended various treatment measures given in Ayurvedascripctures. It is observed that COVID -19 can be corelated with various *Aoupasragic Rogas* or *Janapadodhwnasa Vyadhi* which has similar symptomatology similar with *Vata kapahaja Jwara*. Treatment modalieties of this *Jwara* & some preventives measures such as *Davuavayapasharaya* (spiritual practices like *Homa, Havana & Yoga*, *Dhoopana*), *Yuktivyapashara (Dinachrya, Rutucharya, Vyayam*, *Ayurvedic* drugs & herbs, *Upakrama* of detoxification, *Rasayana Chikitsa, Dhoopana*) *& Satvajaya Chikitsa (Sadvrutta & Achara Rasayana)* can be adopted in such condition.

Keywords: *COVID-19, Aoupasargic Roga, Pathophysiology, Davuavayapasharaya, Yuktivyapashara, Satvajaya Chikitsa.*

Introduction

COVID -19 is an entity among highly communicable disorder which generally spreads through air. There is no any successful pharmacological or non-pharmacological remedy is yet discovered till date. However, current dreadful outnreak of this dieases demands for such intervention & it is also necessary to check compatability of such modalities in the present era.

Persuing this aim, encouragement for researchs in vulnerable & sensitive area of COVID -19 with its prabable effective remedies in *Ayurveda* is really need of hour in current scenario. *Ayurveda* i.e. an ancient science of life & health, ever evolved throughout the globe & playsan imperative role in elaborating this concept of communicable diseases. As COVID -19 not directly elaborated by *Ayurveda* but considering it in a concept of *Anukata Vyadhi* given by *Acharya Charak*, explaration of COVID -19 can be possible with the help of different causative factors responsible for their generation & transmission, group of persons vulnerable for it, pattern & type of evolving symptoms, organs or structures involved in this disease, pathology involved, type of response given by patient on the basis of some fundamental principles of *Ayurveda*. As this exploration of these factors may help to establish some affirmative guidelines regarding preventative & curative aspect of COVID-19 in *Ayurveda* by breaking its basic pathology by doing root cause analysis. Through this paper, sincere efforts are done to compile the same to search effective & safe modalities in our ancient science.

A extensive literature search was done to review concept of communicable disorders, various clinical entities involved with *Pranavaha Srotas* (respiratory

Mob: 9860667023, 8956977899

System) i.e. disorders of *Shwasanavaha Sansthana* with their causative factors, symptomatology by using available various *Ayurvedic* sculptures including *Samhita*, *Nighantu*, various research articles from different databases such as Google scholars, PubMed, *Shodhaganga.* Many P.G. & Ph.D. dissertations from different institutes till April 2020 are also reviewed. All these sources were screened & information related topic is identified & an attempt has done to compile this scattered information under different heads.

Observations and Results

As information collected from above different sources was observed in scattered form, therefore; it is narrated under heads of causative factors, various mode of transmission, organs or structures involved, *Samprapti* (probable mode of pathology), pattern, types symptoms regarding concept of airborne communicable diseases, treatment strategies in Ayurveda. All these heads will be explained one by one as follows:

Fundamental concept of airborne communicable diseases in *Ayurveda:* A many clinical conditions similar to COVID-19 are described in varius *Ayuvedic* manuscripts under the terms of *Janpadohwasna* or *Aupsargikarogas Roga* (diseases which are communicable in nature i.e, *Kushtha, Skin diseases, Jwara (Fever*) which are quite similar to epidemic disease which are caused due to vitiation of some factors such as air, water, location and seasons[1].

Causative factors & various mode of trasnmission: According to *Acharya Charaka, Adharma*[2] i.e. *Pradnyaparadh* which compromises of failure to follow *Dincharya & Ritucharya* (daily & seasonal regimen), *Vegavidharan (*suppression of urges*), Paapkarma (*sins*)* are the maincausative factors for such epidemic condition[3]. Apart from these, there are ample references of causative factors described in the form of *Dhatu Kshaya* (wasting), *Vega Sandharana (*suppuration of natural urges*), Ruksha Padartha Sevan* (intake of dry food), *Ati Vyayama* (excercise), *Rajasa* & *Dhooma Vatabhyam (*exposure to dust & smoke), *Atisheetambupana Sevana (*excessive intake of cold water*),* Vitiation of *Ama, Shuddhi Atiyoga* which are responsible for vitiation of *Pranavaha Strotas i*.e. respiratory system which are described in various *Ayurvedic* compendium in scattered form. Ultimately, all these factors play important role in the pathogenesis of various airborne communicable diseases[4].

Hetu Sevana

(contact with etiological factors i.e. *Rogotthan, Abhighata, Bhutabhisanga, Jantu-Kitta* transmission through *Mansahara* i.e. non-veg diet)

⇩

Strotovaigunya in *Vata* dominant *Kapha, Dushya i.e. Amashaya (Stomach) & Moolasthana of Pranvaha Strotas (*Lungs +Heart+Bronchi*)* & vitiation of *Vayu* + obstruction of *Vata* in the lower region

⇩

Upward movement of *Vata*

⇩

Vitiation of Pranavaha, Rasavaha Strotasa

⇩

Disturbed function of *Udana Vayu Dushti+ Agni Mandya*

⇩

Sama Rasa Dhatu+ Vitiation in in *Mukha, Kantha* & *Nasa* (throat, chest &oral cavity & nose which are main site of *Kapha* & *Udan Vayu* which results affected Mucosa of nose & mouth, conjunctiva of eyes exposed to potential respiratory droplets)

⇩

Pranavaha & *Rasavaha Strotasa Dushti Lakshana (*Symptoms of airborne diseases*)*

⇩

Dry or with phlegm/ *Vata Kaphaja Jwar* (Symptoms of corona) [8]

Fig. - 1: Pathophysiology of COVID-19.

While *Acharaya Sushruta* narrated different modes of transmission of such communicable disorders from person to person which consists of physical contact, expired air, eating with others in same plate, sharing bed (sexual contact also) using clothes, garlands and paste (*Anulepa* or cosmetics) [5] In addition to these, he further quoted that this transmission takes place by *Krumi*or *Jantu* which have appearance i.e. *Sukshma* (microscopic) & are *Ashukari* (rapid in action) in nature. This concept of *Sushruta* for causative factors of communicable diseases is highly matched with aetilogy of Covid -19 induced by Corona virus in contemporary science[6].

Pathology: *Pranavaha* & *Rasavaha Srotas*are mainly involved in pathogenesis of COVID-19. As *Hridaya*, *Mahasrotas* and *Murdha* are *Moolasthana* of *Pranavaha Srotas* and *Rasavaha Dhamani* are involved in transportation of *Pranvayu*[7] in the body which are also affected in this disease. Considering the various organs involved in this diseases & symptomolgy evolved, probable pathology of COVID -19 as per Ayurveda can be described in fig.no. 1 as follows:

Symptoms: The causataive organism of COVID-19 mainly attacks over respiratory & gastrointestinal system, so symptoms related with these two different systems are prominatly observed in this disease. Specific symptoms such as *Pratishyaya* (running nose), *Mookhpaka* (Sore throat), *Sakapha* or *Shushka Kasa* (wet or dry cough), *Angamarda* (Body ache), *Shirshoola* (headache) and Sneezing (*Kshavayu*) which are described by *Ayurveda* in various clinical eltities related with respiratory disorders, systemic disorders like *Jwara* (fever), *Shiroroga*, etc, All these symptoms generally reflects in COVID-19 also. There is a quite similarity between symptoms of communicable diseases which are airborne in nature with disorders of *Pranavaha Strotas*occurs due to its vitiation of this channel because symtoms such as shortness of breath, fever, sore throat, nasal congestion, rhinitis, chest pain, hemoptysis, diarrhea & fatigue described in viral communicable diseases are also observed as *Alpalpam* (short respiration) or *Shwasa, Jwara, Swarabheda, Pratishyaya, Uraha Shula, Rakta Stheevana*, *Atisara* & *Dourbalya* respectively.

Some symptoms mentioned under term of *Pranavaha Strotas Dushti Lakshana* e.g.*Atisrishtam* (Respiratory act is too long) *Atibaddham* (restricted respiration), *Kupitam* (agitated) *Alpalpam* (Shallow or short breaths) *Abhikshnan* (Frequent, or repeated, increased) *Sasabdam* (Stertorous) *Sashoola* (Painful respiration) & which are occurred due to vitiation of this*Strotas* may observed in severe complication of this COVID-19[8, 9].

In addition to these, *Vata-Kapahaja Jwara* can be correlated with COVID -19 due to similarity in symptoms such as *Pratishyaya (*cold or nasal congestion), *Kasa (*cough & sore throat), *Jvara (*Fever), *Shwvasa (*difficulty in breathing/breathlessness) & *Shirograha (*Headache) [10].Same opinion is given by Commentary *Chikitsa Tatwapradipika* also.*Shirshoola* & *Hrullas* which ocuured as a result of *Agnimandya* in *Vata-Kaphaja Jwara* are alsoexplained in modern science as headache & nausea.

Treatment strategies in *Ayurveda:* Till date; no any drug has specific claim to treat COVID 19, therefore, exploration of traditional remedies are highly needed in current scenario. In *Ayurveda*, all *Aacharya* insisted to take into consideration about nature of *Vyadhi* (disease) through *Dosha,* the *Sthathan Sanshraya* (site of manifestations), *Hetu* (etiological factor), *Adhisthan* (location), *Samsthana* (clinical feature), *Yoni* (site of origin), *Atmanam* (cardinal symptom) before adopting any treatment measures in any clinical conditions especially for *Anukta Vyadhi* i.e. diseases which are not mentioned directly with respect to its treatment or symptoms[11] & treatment should initiated only after assessment of these factors.

Generally due to close similarity in appearance of symptoms, treatment modalities of *Vata-Kaphaj Jwara* such as *Amapachaaka*, *Jwaraghna* & *Vatanulomana Chikitsa* can be applied here[12].Drugs having properties Drugs with properties such as *Vatakaphahar,* antioxidants, anti-inflammatory, immunomodulator, anitiviral, antimicrobialcan be used in this dieases. While concept of *Dhoopana* checks over the transmission of diseases from one person to another due to its antiseptic, antimicrobial & disinfectant properties[13][14][15].

According to *Chakrapani*, as *Vyadhibala Kshamatva* i..e immunity plays important role to prevent such diseases, its maintaince plays imperative role in prevention of this disease.immunity of body can better improved with the help of some hoilistic principles of *Ayurveda* such as *Dincharya* & *Rutucharya* through with matainanace of *Agni* can be done.As vitiation of *Agni* is main culprit for any disease, its maintaince imposes to avoid infection.Regular use of judicious use of *Panchakarma* therapies by healthy person is

also recommmded by *Achrayas* to main the health[16]. All these therapies have Antioxidants action which fight against cell damage & protects the body from oxidative stress. To maintain healthiness, physical as well mental health is equally important. To acuire mental helath, various remedies in the form of *Yoga, Achararasayana* & *Sadvrutta* are suggested[17].

In nutshell, three types of strategies i.e. *Daivayayapashraya, Yuktivayapashraya* & *Satavavajaya Chikitsa* are recommended by our ancient *Acharyas* for management of *Aoupasargic* & *Janpadodhwansa Vyadhi* such as COVID -19.

Discussion

The concept of communicable diseases along with theirvarious mode of spread has been very well elaborated by *Acharya Sushruta*.According to modern science, Bacteria, Virus, Fungi & Parasites are main causative factors for developing various communicable diseases like COVID-19.Corona virus (Jantu) is originated from the animal-like snake and bats.This fact is already quoted by *Ayurveda*before thousands years ago & there are such statements representing that many *AoupasargikRogas* (infectious diseases) have origin from different types of Worm (*Krumi*), Insect (*Kittak*), Virus (*Jantu, Raksha* or *Graha)* whichare *Sukshma* (microscopic), *Ashukari* (rapid in action) & they induces *Jvaraupanna* (Fever), *Snayudurbala* (muscle weakness or bodyache, fatigue ness, generalized weakness) . Basically all these organism generates such diseases due to vitiation of *Air (Vayu), Water (Jala), Time (Kala)* & *Region (Desha)* .This statement about the development of symptomatology by above causative factors in Ayurveda is also supported by modern science by stating that that most of diseases occurring due to Virus e.g.Viral fever have bodyche, general weakness & fever as chief symptoms. Along with that, such disorders are quick spreading in nature i..e highly contagious in nature.

All components of *Pradnaparadha*or *Adharma* are responsible for hampering immunity of an individual. Causative pathological factors described in *Samhita* in context of *Shwasa, Kasa, Hikka, Pratikshaya* can be taken into consideration while treatment of COVID-19 .*Ayurveda* has greatly appreciated for prevention of any disease rather than its treatment .Keeping this fact in mind, various preventative strategiesi.e avoidance of *Pradnaparadh* or *Adharma* or *Hetu* of some diseases such as *Shwas, Kasa, Pratishayay, Shroroga, Nasa Roga, Jwara (Abhishangaj)* through properadption of *Dincharya* & *Ritucharya*can be highlighted & planned for management of pandemic like COVID-19 because these strategy maintains sound health by boosting immunity. Through different modes of treatment & prevention, *Ayurveda* accepts the presence of micro - organism & most emphasis is given to maintain equilibrium of the internal environment & to avoid exposure to causative organism. For prevention, *NidanaParivarjana* in the form of*Dhoopana*, with *Bhootanashak Dravyas* (antimicrobials) has important role to remove causative factors by purifying the air.

While treating airborne infections such as COVID-19, etiopathological factors of *Vatashleshmak Jwar*, its *Chikitsa* in *Ayurveda* should be kept in mind. These causative factors are quite similar as told by contemporary science. There is an one major difference between treatment modalities of *Vatasleshmak Jwar* & COVID-19 that there is great emphasis is given to correct first *Agnimandya* (digestive as well as metabolic (fire) in Ayurveda.

Considering the season i.e. present environmental conditions, Physical and mental health, diet should be planned. Fruits, vegetables, cereals included in diet helps to maintain the health properly and they can feel light and further it help to proper digestion, it also leads to burn fats, calories, which will lead to healthy body and help to maintain to immunity .Various Ayurvedic herbs with antiviral, antioxidants, immunomodulatory, antitussive, antipyretics and bronchodilators properties & having capacity to strengthen the respiratory systemto improve the immunity in the form of *Rasayana* can be highly appreciated for prevention purpose in covid-19 outbreak[18][19][20].

Considering the basic pathology, causative & risk factors, specific clinical manifestations (sign & symptoms) for COVID -19 in terms of *Ayurveda*; rational use of *Davuavayapasharaya (*Spiritual practices like *Homa, Hvana & Yoga*, *Dhoopana*) [21], *Yuktivyapashara (Dinachrya, Rutucharya, Vyayam*, *Ayurvedic* drugs & herbs, *Upakrama* of detoxification, *Rasayana Chikitsa, Dhoopana) & Satvajaya Chikitsa (Sadvrutta & Achara Rasayana)* can be planned for prevention & management of communicable diseases like COVID-19.

Conclusion

As contemporary science has limitations in treatment modalities of COVID-19 & an extensive review of background of an essential and compulsory factors involved in pathogenesis of COVID-19 according to *Ayurveda*, it is possible to prevent & overcome over such similar clinical conditions with the rational application of the basic principles in this ancient science i.e. *Ayurveda* with its proper understanding.

Study of Fresh Versus Frozen Embryo Transfer with Reference to Early Pregnancy Loss

Deepti Shrivastava

Professor in Department of Obstetrics and Gynaecology, Director of Wardha Test Tube Baby Centre, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi, Wardha

Abstract

Background: Etiology of Increased rate of early abortions associated with pregnancies happened after In Vitro Fertilisation are not understood fully till date. 'Freeze all embryos' is a new dictum of improving the overall success of In Vitro Fertilisation,although it's effect on early pregnancy loss is controversial in existing literature .So many studies stated that vitrification and thawing process although improves the positive pregnancy rate but cause early pregnancy losses after implantion, but other studies contradict it. Hence in present study we wish to find out the difference of early pregnancy demise in frozen thaw embryo transfer cycles in comparison to fresh embryo transfer cycle.

Trial Design: This is a cross sectional study which will be conducted in Wardha test tube baby centre, Acharya Vinoba Bhave Rural Hospital.

Method: 20 consecutive women conceived after In Vitro Fertilisation, either Fresh or Frozen embryo transfer and will be followed up further for rate of early abortions amongst them.

Expected Outcomes: Frozen embryo transfer cycles may have more chances of successful clinical pregnancies at 6-7 weeks of gestational age, but later on may result in early pregnancy losses.

Keywords: *Frozen, Embryo Transfer, Early Pregnancy Loss.*

Introduction

Presently frozen embryo transfer is one of the most recommended procedures in advanced treatment of infertily. As the success of In Vitro Fertilisation, is still limited in spite of so many advancements in all the fields of reproductive biology, frozen embryo transfer is a viable alternative to fresh embryo transfer considering that the endometrium and ovaries of fresh stimulation cycles are not properly prepared for implantation[1]. In frozen embryo transfer there could be better control of both endometrium and ovaries hence pregnancy rates are proposed to be increased and perinatal outcomes should be better than fresh embryo transfer, In few studies the rate of clinical abortion and biochemical pregnancy was reported around 20% after frozen embryo transfer [2].

Previously clinical indications for frozen embryo transfer (cryopreservation) were to help the cancer patient undergoing treatment, patients who have premature ovarian failure, to overall delay the fertility procedure for so many social factors[5].

Now days all freeze strategy is almost replaced the standard fresh assisted reproductive technique hence frozen embryo transfer is an important part of assisted reproductive technology. Previous studies suggested

Corresponding Author:

e-mail: deepti_shrivastava69@yahoo.com

that procedure of frozen embryo transfer reduces the number of transferred embryos as well as also reduces the risk of multiple pregnancies, risk of Ovarian Hyper Stimualation Syndrome and ectopic pregnancies[1].

Elective frozen embryo transfer has been shown higher live birth rate than a fresh embryo transfer amongst the women with poor ovarian reserve or polycystic ovarian syndrome[4].

In spite of many advantages of vitrification and slow thawing process in frozen embryo transfer, there is a rising concern of increased number of early pregnancy losses and more chances of aneuploidy and abnormal genotype associated with it.

There is some controversy regarding the early positive pregnancy rates due to better implantation versus take home baby outcome of patient undergoing with healthy babies in frozen embryo transfer.

With this background, we would like to conduct the present study to compare the early pregnancy losses and their associated factors in fresh versus frozen embryo transfer.

Aim: This study aimed to find out the rate of early pregnancy losses in frozen and fresh embryo transfer cycles of in vitro fertilisation.

Objectives:

1. To compare serum β–Human Chorionic Gonadotrophins level on day 14th in post embryo transfer in fresh and frozen embryo transfer women.
2. To confirm presence or absence of sac in both the groups.
3. To compare the appearance of cardiac activity and other early foetal parameters in both groups
4. To compare early pregnancy losses in both the groups.
5. To compare late complications of pregnancy in both the groups.
6. To compare final outcome of pregnancy in both the groups.

Method

Study Design: Cross sectional study

Setting and Location: The study will be conducted in the rural area of Central India which caters up to 30 kms surrounding area.

Wardha Test Tube Baby Centre is the only centre providing advanced infertility care in whole of the district. This centre is associated with tertiary care fully equipped rural hospital

In Vitro Fertilisation lab, Acharya Vinoba Bhave Rural Hospital, Sawangi.

Period of recruitment and relevant dates will be decided before planning the stimulation protocol for these infertile women that is June 2020 onwards for 6 months and exposure will be for 10- 12 days.

The Follow up will be up to 12 weeks after conception

Analysis and Data Collection will be done after 9 months of the study. Subjects will be explained about the nature and purpose of the study after assuring confidentiality and taking informed consent the details of the patient will be entered in data forms the proforma of the subjects will be preserved comprising of demographic details, past medical, surgical and comorbid conditions. Personal and family history which might affect early pregnancy losses.

Participants:

Inclusion Criteria:

- Couples suffering from primary/secondary infertility fulfilling the indications of In Vitro Fertilisation .
- Patient with history of pregnancy loss with fresh embryo transfer.

Exclusion Criteria:

- Patient with abnormal semen parameter.
- Patients not giving consent for research.
- Patients having uterine agenesis.
- Patients not fit for In Vitro Fertilisation having viral infections like Human Immune deficiency Viral disease, Hepatitis B S Antigen etc.
- Patients with known history of early pregnancy losses.

Sources: Infertility patients at outpatient department of Acharya Vinoba Bhave Rural Hospital for seeking In Vitro Fertilisation treatment.

Method of Selection: All the women whose beta human corionic gonadotrophin, will come positive after 14 days of embryo transfer.

Outcome Parameters:

Primary Outcome:

1. To compare beta human corionic gonadotrophin level on day 14th in post embryo transfer in fresh and frozen Embryo Transfer women. [COMPARABLE]
2. To confirm presence or absence of sac in both the groups. [COMPARABLE]
3. To compare the appearance of cardiac activity and other early fetal parameters in both groups [EXPECTED TO BE LESS IN NUMBER IN Frozen Embryo Transfer]
4. To compare early pregnancy losses in both the groups.

Secondary Outcome:

1. To compare late complications of pregnancy in both the groups.
2. To compare final outcome of pregnancy in both the groups.

Predictors:

1. Abdominal pain after gestational sac visibility
2. Bleeding per vaginum after gestational sac visibility

Confounders:

1. Advanced Maternal Age
2. Ante Mullerian Hormone
3. Number of embryos formed

Diagnostic Criteria:

Signs and symptoms of inevitable abortion.

Bias:

1. Blinding is not possible because of cost and time duration.
2. Method bias.
3. Confounding bias.

Study Size: 8-15 cycles per month are carried out in Wardha Test Tube Baby Centre, Out of which 60 % are self stimulation cycles 70 % of In Vitro Fertilisation cycles will suit to eligibility criteria considering dropout rate So average comes out to be 4-5 patients per month

Sample size Calculation:

$N = \aleph^2 * N * p(1-p)/C^2(N-1)+\aleph^2 p(1-p)$

Total population = N=20 during 12 months

$\aleph^2$ = Chisquare value for 1 degrees at some desired probability level. This is 3.84 at 5% level of significance.

P = 50% proportion

Q = 100-p

= 50

C = Confidence interval of the one choice (95% CI)

= 0.05

$N = 3.84*20*0.5*0.5$

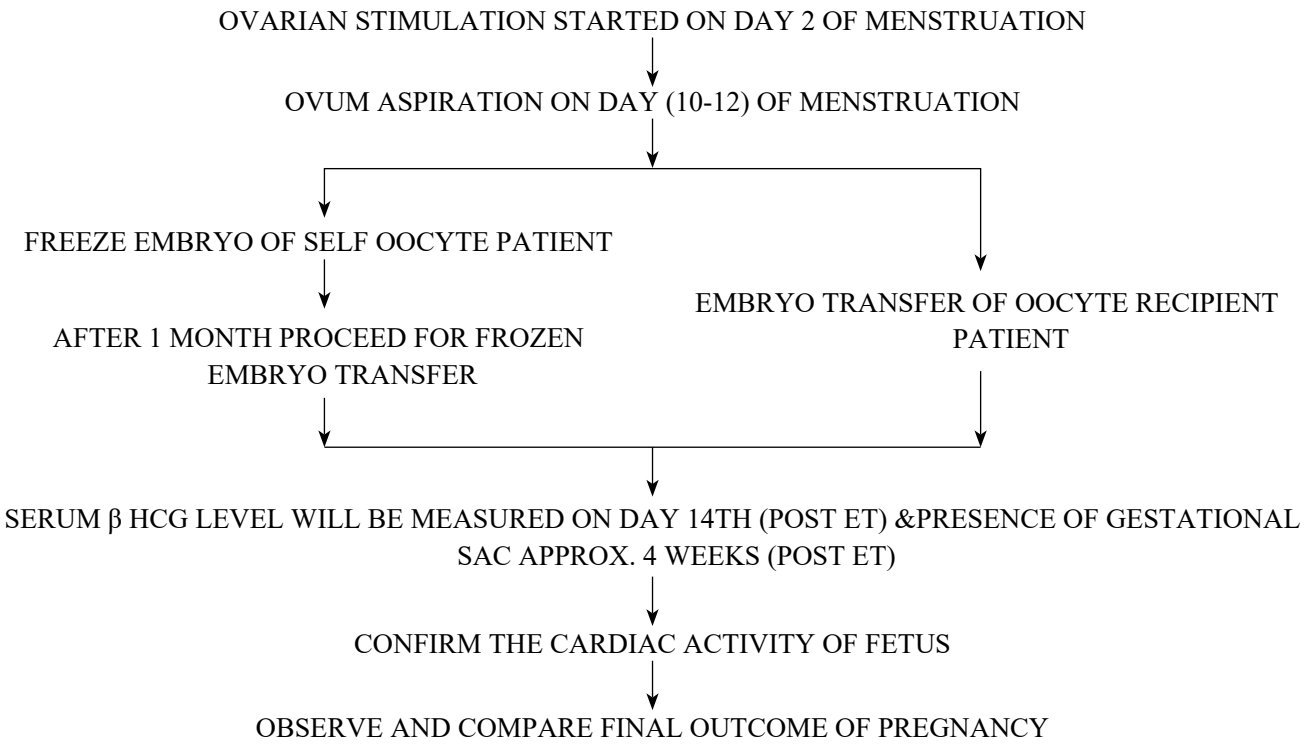
$(0.05)^2 *24+3.84*(0.5*0.5)$

= 23.52 = 19

Quantitative Variables:

Not applicable

Statistical Method: The statistical analysis will be carried out using the SPSS 22 software package (SPSS Inc., Chicago, IL).



The method used is Chi Square test

Expected Results:

1. The β -HCG level on day 14th in post embryo transfer in fresh and frozen Embryo Transfer women would be COMPARABLE without stastical significance.
2. Presence or absence of gestational sac in both the groups would be COMPARABLE without stastical significance.
3. The appearance of cardiac activity and other early fetal parameters in both groups is EXPECTED TO BE LESS IN NUMBER IN Frozen Embryo Transfer cycles.
4. Early pregnancy losses may be more in Frozen Embryo Transfer groups.

Secondary Outcome:

1. The late complications of pregnancy would be COMPARABLE without stastical significance in both the groups.
2. The final outcome of pregnancy would be COMPARABLE without stastical significance in both the groups.

(DAIGRAMATIC REPRESENTATION OF RESEARCH METHODOLOGY)

Discussion

Hyper stimulation of ovaries in In Vitro Fertilisation is started to make gonadotropins level in the body at supraphysiological level which may influence the genetic makeup of oocytes and subsequently the embryos formed, so also reduce the endometrial receptivity for transferred embryos may be leading to failure of In Vitro Fertilisation treatment, hence by transferring the embryo in frozen cycle may lead body to come to normal endocrinal status and may improve the success of In Vitro Fertilisation by restoring the endometrial receptivity and selecting genetically normal embryos after thawing. Whether combined effect of both may increase or reduce the early pregnancy losses after successful In Vitro Fertilisation treatment will be studied .With this background we wish to conduct this study the pregnancy rate in frozen-thawed embryo transfer cycles is usually lower than that of fresh transferred embryos.[1]

There was an increased risk of loss after frozen Embryo Transfers versus fresh among women younger than 38 years in a study done by Hipp et all. [2]

In contrast to fresh cycle, women who received frozen cycle embryo had a significant increased risk of early miscarriage (P <0.001), while frozen cycle was linked with lower risk of late miscarriage (P =0.045) according to Lingminet all. [3]

According to study done by Zhang B et al. the risks of gestational diabetes mellitus, preterm birth, and small for gestational age were comparable between the frozen and fresh embryo transfer groups in both singleton and twin births. However, singleton infants born after frozen embryo transfer were more likely to be large for gestational age (25.2% vs. 17.5%; relative risk 1.44, 95% confidence interval 1.01-2.07, P=.044) than those born after fresh embryo transfer. [4]

In a study done by Basirat et all however,no significant differences between biochemical pregnancy rate (23% versus 18.8%, OR 1.301; 95% CI .95-1.774), gestational sac (95.6% versus 100% in Frozen Embryo Transfer, OR 0.60; 95% CI 0.54-0.67), and fetal heart activity (87.2% versus 93.6% OR .46; 95% CI .16-1.32) in fresh embryo transfe and Frozen Embryo Transfer cycles, respectively. P< 0.05 was considered statistically significant for all measures.[5]

Apart from fresh and frozen transfer, the study done by A Kaluarachchia stated that The success rate was analysed according to the duration of embryo freezing.

This showed a gradual decline in the implantation rate according to the duration of freezing.[6]

There was an increase in the risk of obstetric complications in pregnancies resulting from Frozen Embryo Transfer when compared to those emerging from fresh embryo transfers according to Roque et all.[7]

Review on *Dhatryadi Churna*: An Ayurvedic Antipyretic Polyherbal Formulation

Sanket Shelke[1], Bharat Rathi[2]

[1]Assistant Professor, [2]Professor, Department of Rasashastra & Bhaishajya Kalpana, Mahatma Gandhi Ayurved College and Hospital and Research Centre, Salod (H), Wardha.(Maharashtra). Datta Meghe Institute of Medical Sciences (Deemed to be University), Sawangi (M) Wardha

Abstract

Introduction: In almost all Samhitas Jvara chikitsa is described with single or compound herbal drugs. Dhatryadi Churna is one such polyherbal churna formulation indicated in jvarachikitsa. But no data is available to know about its efficacy.

Aim and Objectives: To review *Dhatryadi Churna* w.s.r. to its antipyretic activity.

Material and Method: Relevant references were reviewed with respect to Dhatryadi Churna described in Samhitas and various Ayurveda texts such as Brihatrayee, Laghutrayee bhaishajyaratnavali etc. All the references were collected and reviewed thoroughly.

Observation and Results: Total 7 references with the name Dhatryadi Churna and Amalkyadi churna are recorded in various Samhitas and Ayurveda texts indicated in jvara chikitsa. Out of the total 5 ingredients, significant antipyretic activity in experimental animals in different dosages found in *Emblica officinalis, Terminalia chebula, Piper longum and Plumbago zeylenica.*

***Conclusion**:* Based onPharmacological properties and experimental studies conducted on individual drugs proved that Dhatryadi churna is a effective antipyretic formulation and can be used safely for treating Jvara.

Keywords: *Jvara, Dhatryadi Churna, Antipyretic activity.*

Introduction

In the Ayurvedic classics various forms of formulations are portrayed to achieve healthy and balanced life. *Panchavidha kashaya kalpana* represents the basic preparations upon which, in later period, many pharmaceutical method were developed for various medicine preparation to compete with need of all time availability, palatability, longer shelf life and efficacy. [1-2] There are more than 30 forms of formulations which are used by physicians in daily practice. Among them, herbal powder is one of the most accepted classical dosage form of Ayurvedic formulation advocated in various disease conditions. *Churna* in general is the fine powder of a completely dry drug, which is filtered through a clean cloth.[3]

In almost all Samhitas Jvara chikitsa is described with single or compound herbal drugs which includes various forms of formulations such as avaleha, arishta, vati etc. Dhatryadi Churna (DC) is one such compound powder formulation described in Ayurveda compendia. This formulation contains fine powders of *Amalaki*

(*Emblica officinalis* Gaertn.), *Haritaki* (*Terminalia chebula* Retz.), Saindhav (Rock salt), *Pippali* (*Piper longum* Linn.) and *Chitraka* (*Plumbago zeylenica* Linn.) in equal proportion and indicated in the treatment of fever. There are many other references available where DC is described for treating fever and various other conditions such as loss of appetite,lack of digestive fire, eye diseases and constipation. Hence attempt is made in this paper to review DC described in various Samhitas and Ayurveda texts w.s.r. to its antipyretic activity.

Material and Method

Relevant references were reviewed with respect to DC described in Samhitas such as Brihatrayee and Laghutrayee andvarious Ayurveda texts such as Yoratnakar, Bhaishajya ratnavali etc. Published research papers related to pre clinical and clinical studies showing antipyretic activity of DC and individual drugs were searched. References were also searched for Amalkyadi churna and Amalkyadi gana as Amalki and Dhatri is synonymous.

Observation and Results

During the literary search total seven references were identified with the name DC and three were found as Amalkyadi churna (AC). The very first reference of Dhatryadi churna is found described in Sushruta Samhita in Dravyasangrahniya Adhyaya. Later it is described in other Samhitas and Ayurveda texts such as Sushruta samhita, Astanga Hridaya, Astanga Sangraha, Bhavprakash and. In Sushruta Samhita it is described with the name as *Amalakyadi gana*,in Sharangdhara Samhitait is described under the name *Amalakyadi churna* and in Bhaishajya Ratnavali as *Amalakyadi kwatha.* The ingredients and indications are compiled in Table 1.

Table 1: References of *Dhatryadi churna* in various Samhitas and Ayurveda Texts.

S.N.	Reference	Name	Ingredients	Indications
1.	Sushruta Samhita[4]	Amalkyadi Gana	Amalaki, Haritaki, Chitrak, Pippali	Jvara, Mandagni Netrya, Kaphanashak
2.	Ashtang Hriday[5]	Dhatryadi churna	Amalaki, Haritaki, Saindhav, Chitrak, Pippali	Jvara, Mandagni
3.	Ashtang samgraha[6]	Dhatryadi churna	Amalaki, Haritaki, Saindhav, Chitrak, Pippali	Jvara, Mandagni Vibandha
4.	Sharangdhar samhita[7]	Amalakyadi churna	Amalaki, Haritaki, Saindhav, Chitrak, Pippali	Jvara, Arochaka, Deepan, Pachana
5.	Yogartnakar[8]	Dhatryadi churna	Amalaki, Haritaki, Saindhav, Chitrak, Pippali	Jvara, Mandagni
6.	Bhavaprakash[9]	Dhatryadi churna	Amalaki, Haritaki, Saindhav, Chitrak, Pippali	Jvara, Mandagni Vibandha
7.	Bhaishajya ratnavali[10]	Amalakyadi kwatha	Amalaki, Haritaki, Chitraka, Pippali	Jvara, Deepan, Pachan, Kaphahar

Table 2: Pharmacological properties of Ingredients of *DC*

S.N	Ingredient	Rasa	Guna	Veerya	Vipak	Karma
1.	Amalaki [11] (Emblica officinalis.Burm.)	Pancharasatmak except lavan rasa	Laghu, Ruksha	Sheeta	Madhura	Vayahsthapana (C.S) Dahaprashaman Rasayan (B.P)[12]
2.	Haritaki[13] (Terminalia chebula. Retz)	Pancharasatmak except lavan rasa	Laghu, Ruksha	Ushna	Madhura	Shothahara, Kushthaghna Vishamjwaraghna (B.P)[14]
3.	Saindhav[15] (Sodii chloridum)	Lavan, Madhura	Snigdha, Sukshma Laghu	Sheeta	Madhura	Sukshma, Avidahi[16]
4.	Chitrak[17] (Plumbago zeylanica Linn.)	Katu	Laghu, Ruksha, Tikshna	Ushna	Katu	Deepaniya, Shulaprashaman Padushan[18]
5.	Pippali[19] (Piper longum Linn.)	Katu	Laghu, Snigdha, Tikshna	Anushna	Madhura	Deepaniya viryavardhak, pittashamak [20]

Researches on ingredients of DC.

Table 3: Experimental studies conducted on individual drugs of DC.

S.N	Drug Name	Part used	Type of Study	Reference
1.	*Emblica officinalis.*Burm.	Fruit powder	Experimental study- anti-pyretic and analgesic activities	Perianayagam, J.B et al[21]
2.	*Terminalia chebula.* Retz.	Fruit powder	Experimental study -*antipyretic activity*	Shukla P. et al [22]
3.	*Plumbago zeylanica* Linn.	Leaf extract	Experimental study *analgesicanti-pyretic activity*	Mittal V et al [23]
4.	*Piper longum* Linn.	Fruit powder	Experimental study -*anti-pyretic activity*	Evan Prince Sabina et al[24]

Pharmacologicalstudies:

Emblica officinalis. **Burm (Amalaki):** Study conducted by Perianayagam *et al*., on extracts of *Emblica officinalis* fruits observed potent anti-pyretic and analgesic activities. An ethanolic extract and aqueous extract (500 mg/kg) administered in a single dosedemonstrated considerable reduction in temperature in rats induced by brewer's yeast. Both the extracts brought outprominent inhibitory outcome on acetic acid-induced writhing response in mice in the analgesic test. The contents likephenolic compounds, tannins, alkaloids, carbohydrates and amino acids are established to be having antipyretic effect.[21]

Terminalia chebula. **Retz (Haritaki):** The flavonoids content of Terminalia chebula may also be responsible for its antipyretic activity by inhibiting prostaglandin synthesis in hypothalamus.

Shukla P*et al*., assessed the antipyretic activity of ethanolic extract of *Terminalia chebula* (EETC). The antipyretic activity was assessed by Brewer's yeast-induced pyrexia in Albino rats (120-130 g) of either sex. Single dose administration of 400 mg/kg and 600 mg/kg EETC showed substantial antipyretic activity, as compared to the standard paracetamol group. Thus this study proved significant antipyretic activity with ethanolic extract of *Terminalia chebula* Retz.[22]

Plumbago zeylanica **Linn*. (Chitrak):*** Mittal et al studied the antipyretic activity of ethanol extracted from dried callus and roots of *Plumbago zylenica*. Both the extracts were administered in mice at doses of 100,200 and 400 mg/kg to evaluate the peripheral and central analgesic activity by glacial acetic acid induced writhing and tailimmersion model respectively. Root extract significantly (P<0.01) reduced the writhing count at a dose 200 mg/kg whereas callus extract modified the pain threshold appreciably at 400 mg/kg. Root extract enhanced the reaction time significantly (P<0.01) in tail immersion model at 400 mg/kg. while callus extract failed to change the reaction time significantly during the observation period.[23]

Piper longum **Linn. (*Pippali*):** Extracts of *Piper longum* fruits possess potent anti-pyretic activities. The pyrexia was induced in experimental animal Mice by yeast injection. Piperine (20 and 30 mg/kg) and indomethacin (10mg/kg) were administered in single dose showed a significant (p<0.05) reduction in rectal pyrexia, similar to standard drug indomethacin without any adverse effects.[24]

Discussion

Total seven references were found with the name Dhatryadi churna or Amalakyadi churna. As Dhatri and Amalaki is synonymous. All the reviewed Samhitas described DC or AC with five ingredients as *Amalaki* (*Emblica officinalis* Gaertn.), *Haritaki* (*Terminalia chebula* Retz.), Saindhav (Rock salt), *Pippali* (*Piper longum* Linn.) and *Chitraka* (*Plumbago zeylenica* Linn.) in the treatment of fever and associated symptoms such as loss of appetite, lack of digestive fire and constipation.

Jvarahara drugs are known as antipyretics in medical science. Drugs which reduce the elvated body temperature by inhibition of prostaglandin synthesis are termed as antipyretic drugs[25]. In Ayurveda Samprapti (pathogenesis) of fever is described on the basis of state offactors responsible for digestion and metabolism/ transformation and dosas. According to Sushruta, Dosas aggravates due to consumption of causative factors and during respective time spreads to entire body and produces fever. Aggravated Dosas enters the Amasaya and combines with Agni, accompanying the Rasa, blocks the channels of Rasa and Sweda, impairs the function of Agni and expels out the Agni from the site of digestion and spread to all over body and gives rise to

Jvara. Dosas exhibit its exacerbated symptoms and signs and brings abnormality in the skin, nail, eyes, tongue, urine and faeces[26]. Acharya Charaka recommended *Langhana* (fasting therapy) as a first line of treatment for Jvara followed by digestive drugs[27].DC is such a polyherbal formulation with a perfect blending of *deepana, pachana* and *jvarahara* drugs. Antipyretic action of Dhatryadi Churna can be well understood by knowing the pharmacological properties and antipyretic experimental studies of its ingredients.(Table 2 and 3)

Probable mode of action of *Dhatryadi Churna* in *Jvara:* *Dhatryadi Churna*prominently consists of *Katu-Tikta-Lavan* rasa*, Madhura Vipaka*, *Sheeta Veerya* and *Laghu*, *Ruksha*, *Snigdha, Tikshnaguna*. Its *Katu-Tikta-Lavan*rasas digest and pacify Kaphapradhana doshas present in rasadhatu and correct aruchi (loss of appetite) and vishamagni (The state in which the action of Agni is rendered erratic either excessive or decreased, variable from time to time, due to the dominant influence of Vata). Due to its katu rasa and tikshna *Guna* it causes amapachana (substances having capacity to digest uncooked food material) and due to its laghu and tikshna property it causes srotoshodhana (purification of structural or functional channels meant for the transportation of Dhātus undergoing transformation) of rasagata doshas. Being ushna and tikshna, it acts as Svedajanana (substances that causes excessive sweating)[28]. Saidhava lavan commonly known as rock salt acts as a catalyst, help to enhance the action of other drugs in the formulation by deep penetration in the body after administration of drug. It also helps in developing the taste in the mouth[29]. Thus through all these properties of *DC*, Agni becomes normal leading to the subsidence of fever.

No clinical studies were found on DC regarding its antipyretic activity. Instead the individual ingredients of DC are reported to have antipyretic activities as depicted in table no 3. Hence combination of all these ingredients as DC may show synergistic effect and strong antipyretic activity. Various scientific studies conducted on individual ingredients of DC/AC showed that plants possess a range of phytochemicals such as alkaloids, flavonoids, glycosides, terpenoids, steroids, proteins and tannins which could lead to potential antipyretic activity[30]. Nabanita Roy et al conducted a study on phytochemical analysis of Amalkyadi churna revealed the presence of proteins, saponins, phenols, glycosides, tannins, alkaloids and fixed oil[31]. Mradu Gupta et al also confirmed in his research that flavonoids and its related compounds present in Jvarahar mahakashay preparation exhibit inhibition of archnoid acid Peroxidation which helps in decreasing prostaglandin levels thus reducing the fever. The results of the literary search of individual drugs of DC show antipyretic activity.However further studies are required on DC to elucidate the mechanism of inhibiting prostaglandin synthesis in hypothalamus which is responsible for reducing fever.

Conclusion

Literary review revealed that *Dhatryadichurna* is a compoundpolyherbal preparation containing *Katu tikta Lavan rasa, Madhura Vipaka*, *Sheeta Veerya* and *Laghu*, *Ruksha*, *Snigdha* and *Tikshnaguna*. Pharmacological properties and experimental studies conducted on individual drugs proved that *Dhatryadichurna* can be a potent antipyretic poly herbal formulation and useful for treating *jvara* safely.

Case Report on Oligohydramnios

Lalhriatpuii[1], Manjusha Mahakalkar[2], Manoj Patil[3]

[1]M.Sc Nursing 1st Year, Department of Obsterics & Gynecology Nursing, [2]Asst. Professor, Department of Obsterics & Gynecology Nursing, Smt. Radhikabai Meghe Memorial College of Nursing, Sawangi (Meghe), Wardha, Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, [3]Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

Introduction: Oligohydramnios is an extremely rare condition where there is a deficiency of liquor amnii in the amount of less than 200Ml at the time of delivery. Sonographically, it is amaximum vertical pocket of liquor is < 2 cm or the amniotic fluid index is < 5 cm (less than 5 percentiles) is specified.

Patient History: A 23years old ANC & 8months mother was admitted on 11.9.2019 with the complaints of reduced fetal movements and abdominal discomfort.

Past History: Patient has history of blood transfusion 3months back and has history of cervical cerclage at 7months of pregnancy.

Clinical Findings: Reduced fetal movements, abdominal discomfort, leaking of the amniotic fluid, low amniotic fluid on ultrasound, low maternal weight gain, pre labor rupture of membranes.

Investigations: Ultrasonography (AFI=5cm), Hb% - 9.1gm%, MCV-74, MCH-23.5pico/gm, HCT-28.5%, Total WBC Count – 8000/cu.mm, Lymphocytes- 20%.

Surgical Management: Patient does not have any past surgical history.

Medical Management: Tab. AFI plus BD, L- Arginitrate sachet 5gm/BD/orally, Tab. iron OD, Tab. Calcium OD.

Nursing Management: Assess both maternal and fetal conditions carefully, fetal heart rate and vital signs should be assessed properly. During labor, an amnio-infusion should be given via intrauterine catheter. Fluid should be administered via amniocentesis before giving birth. The level of amniotic fluid may help by increasing the amount of oral fluid intake.

Conclusion: Patient was admitted to AVBRH and was diagnosed as oligohydramnios and got appropriate treatment and her condition has improved.

Keywords: *Oligohydramnios, amniotic fluid, cervical cerclage, amniocentesis.*

Introduction

Oligohydramnios is a disease characterized by an amniotic fluid deficit during pregnancy. Oligohydramnios is an extremely rare condition where there is a deficiency of liquor amnii in the amount of less than 200Ml at the time of delivery. Sonographically, it is a maximum vertical pocket of liquor is < 2 cm or the amniotic fluid index is < 5 cm (less than 5 percentiles) is specified[1].

Patient Identification: An ANC mother of 23 years old with 32.2 weeks gestational age from Hinganghat was admitted to ANC 12, AVBRH on 11th sept, 2019 with a complaints of reduced fetal movement, pain in abdomen and lower back area. After all the investigations, she was diagnosed as oligohydramnios.

Present History: Patient was apparently admitted in AVBRH on 11/9/2019 with a chief complaints of pain

in abdomen, pain in the lower back and reduced fetal movement.

Past History: Patient has history of mild anemia 3 months back where she has undergone the blood transfusion and she has history of cervical cerclage in 7 months of pregnancy for which the patient was hospitalized, she complaints pain in lower back and reduced fetal movement since 1 month back and came to AVBRH for further management.

Past interventions and outcome: My patient was diagnosed as oligohydramnios at 7 months of pregnancy where cervical cerclage has done at that time, from that time onward patient was admitted to hospital time to time for treatment. The treatment was found effective as the patient does not develop complications till then.

Obstetric History:

Menstrual History:

Age of menarche- 14 years

Duration of menstrual period- 3-4 days

Duration of cycle in days- 28 days

Regularity- regular

LMP – 28/6/19

EDD – 4/3/2020

POG – 32.2 wks

Antenatal assessment-

Weight – 45 kgs

Height – 15 cm

Edema – absent

Previous no. of antenatal visits – 2 visits

Treatment – patient has taken 2 doses of TT injection, and she's taking iron and calcium tablets.

Clinical Findings: Reduced fetal movements, abdominal discomfort, leaking of the amniotic fluid, low amniotic fluid on ultrasound, low maternal weight gain, pre labor rupture of membranes.

Etiology:

1. *Fetal conditions*- fetal chromosomal or structural anomalies, renal agencies, obstructed uropathy, spontaneous rupture of the membrane, intrauterine infection, post maturity, intrauterine growth retardation.
2. *Maternalconditions* - hypertensive disorders, uteroplacental insufficiency, dehydration, idiopathic.

Investigations:

1. CBC
   - HB% - 9.1 gm%
   - Total RBC Count – 3.87 mil/cu.mm
   - Total WBC Count – 8000/cu.mm
   - Total platelets count – 1.83 lacs/cu.mm
2. LFT
   - Total bilirubin – 0.6 mg/dL
   - SGPT – 20 U/L
   - SGOT – 40 U/L
3. USG
   - Single cell uterine fetus with 32.2 wks with oligohydramnios
   - AFI = 5CM

Therapeutic Intervention:

1. First trimester – counselling, serial USG
2. Second trimester – counselling, consider amnioinfusion, serial USG, termination of pregnancy SOS
3. Third trimester – deliver post term cases, serial USG & Doppler in IUGR, conservative management for protein pre-labor rupture of membranes till 34 weeks.

Medical Management:

- Tab. AFI plus BD
- L- Arginitrate sachet 5gm/BD/orally
- Tab. iron OD
- Tab. Calcium OD

Nursing Management:

- Assess both maternal and fetal conditions carefully, fetal heart rate and vital signs should be assessed properly. During labor, an amnio-infusion should be given via intrauterine catheter.

- Fluid should be administered via amniocentesis before giving birth.
- The level of amniotic fluid may help by increasing the amount of oral fluid intake.

Discussion

The patient 23 years old was apparently admitted in AVBRH on date 11/09/2019 . patient complaints of pain in the lower abdomen, lower back and decreased fetal movement, as she has complaints all this things patient was undergone several investigations like blood investigation, ultrasonography. After all this investigation patient was diagnosed as oligohydramnios where her amniotic fluid index(AFI) was 5cm. The condition of patient was improved after getting care by various multidisciplinary health care team. She was admitted in the ANC ward for further management[2,3].

Aclinical trial on oligohydramnios during the third trimester of pregnancy was done in 2012 at Moradabad city, U. P. The results shows that 24. 583. 99 SD was the patient mean age and out of these 46. 15% were the age between 21-25 years. 36%were primigravida and 64% patients were multigravida. Among 78 pregnant women 74% wasmild oligohydramnios and 25% was severe. Around 68% were preterm delivered which means who delivered before completing 37 weeks of gestational age. 72% cases were delivered by caesarean section, out of all these 51% were due to fetal distress, 33% were normal Cardiotocography (CTG) and 66% were abnormal at the time of admission. The normal colour of the amniotic fluid was found in 69% cases at the time of membrane rupture whereas 31% cases meconium stained was found. Mostly, in severe oligohydramnios the chances of caesarean section was high than the mild and moderate oligohydramnios group. Perinataloutcome like Apgar score, weight of the baby, meconium aspiration syndrome, respiratory distress syndrome and neonatal ward admission.65% cases were found to be low birth weight baby among 78 newborn babies. Among 78 babies, 21 babies APGAR score was less than 7 at 5 minutes. Respiratorydistress syndrome was suffered by 15% babies and 10% were suffered meconium aspiration syndrome. Due to all these complications 15 babies were admitted to NICU[4,5].

Oligohydramniosis well known to be associated with high adverse risk during the perinatal period. However, it is a poor indicator for the adverse effects during this period. But it is also used as a predictor for delivery[6,7]. So, closely monitoring of the volume of amniotic fluid during antenatal period is very helpful to find out the risk of the adverse effects during perinatal period.[8,9.]

Conclusion

Oligohydramnios is one of the most common complications during the pregnancy which can cause maternal mortality and morbidity. But if it is diagnose in early stage and if it is treated properly we can reduce the maternal and fetal complications. My patient has received proper care and her conditions also improved as evidenced by the patient conditions and the treatment is still going on till my last date of care.

Abstract

Background: Labor has been defined as that of the initiation of periodic painful contractions of progressive deletion as well as dilation of a cervix, followed by a decent part going to lead to the expulsion of its fetus & placenta from the uterus of mother. Post - natal treatment was its individualized treatment provided that meet the needs of the baby and mother after delivery/childbirth.

Case Report: Mrs. Nikita Matram 25-year-old female was admitted in AVBR Hospital with the complaint of pain in abdomen and increased the fetal movement on date 4/01/2020 and she delivered female baby on date 6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness. but the patient has a previous history of abortion after marriage of four month two and half month of baby was abort. That time dilatation and curettage was done.

Patient delivered female baby throughout the vaginal delivery and baby and mother was normal after delivery baby was kept with mother on same bed and initiate breastfeeding within one hour after delivery.

Conclusion: Case report conclude that after normal delivery and post-natal care mother and baby was normal.

Keywords: *Full term normal delivery, post-natal care, newborn, delivery.*

Introduction

Giving birth, commonly defined of labor and birth, seems to be the conclusion of pregnancy once an or maybe more kids exit the mother via going through the womb or even the caesarean delivery and, throughout delivery, a baby is released through the womb. There are different forms of vaginal delivery. Supported vaginal and instrumental vaginal birth, accidental vaginal delivery, triggered vaginal birth, natural vaginal delivery.

Treatments that are consistent to protection. Given medical and scientific innovations through managing complex health problems, this same current setting with maternity services had also increased rates for healthy mothers and infants. There have been fears all around the community that evidence-based strategies and procedures across labour and childbirth are standard occurrence.[1] There is significant mis-use of advantageous techniques, over-use of detrimental or inefficient method, or lack of desire and over consequences of insufficiently measured method.[2] Enhance the efficiency with maternity services for both developed and emerging nations is an essential part with efforts to reduce maternal and infant mortality and morbidity.

Case Presentation: Mrs. Nikita Matram 25-year-old female diagnosed with G2,A1, with 38 .2 wks. of gestational age with full term normal delivery was admitted in AVBR Hospital with the complaint of pain in abdomen and increased the fetal movement on date 4/01/2020 and she delivered female baby on date

6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness.. Before pregnancy the patient menstrual cycle was regular 28 days of cycle and duration was 3-4 days and Last menstrual period was 11/04/2019 and Expected date of delivery was 16/01/2020.

Mrs. Nikita Matram has a previous history of abortion after marriage of four month & two and half month of baby was aborted. That time dilatation and curettage was done.She has not used any contraception method & no any medical history like DM, Hypertension, TB, Asthma.she livesin joint family in their family five member are living together including newborn and she was belonging from middle class family and intheir houses all facilities are available like electricity, water supply from municipality etc. her monthly income was 25000/- per month. Mrs. Nikita and her family members were psychological stable. She maintains good interpersonal relationship with others. She is taking only vegetarian diet. She doesn't have any allergic reaction from any food and no any history of any bad habits like chewing tobacco, smoking etc.

Patient general examination was state of health was unhealthy, conscious, Body built thin, Posture erect, hygiene was good. general parameter height was 154 cm,weight 45 kg. Vital sign is Temperature 98˚c, Pulse 84 b/m, Respiration – 20 b/m, BP – 120/80 mmHg. In breast some changes occur because of pregnancy enlargement of breast, nipple was large erectile and discharge was present of milk secretion. In abdomen linea nigra, striae gravidarum present. Lochia rubra was present.

Investigations:

- CBC

  Hb 12.7 gm %

  Total RBC 3.92 million/cu mm

  Total WBC 13900 cu.mm

  Total platelet counts 2.69 lacs/cu.mm

  SGOT 31

  Albumin 3.6 g/dl

- USG –

  Fetal no. – single

  Lie – variable

  Placenta – anterior, grade –II

  Presentation – variable

  Fetal movement – present

  Liquor – adequate

Impression of USG–single intrauterine live fetus of average gestational age of 27 weeks 1 day and corresponding to weight of 999GMS.

The drugs are used Inj. Metrogyl 100cc, I.V., TDS. Action–Metronidazole injection is also to prevent infection when used before, during, and after colorectal surgery. Metronidazole injection is in a class of medications called antibacterial. It works by killing bacteria and protozoa that cause infection, Inj. C-Tax 1 gm, I.V.,BD.,Action - C Tax 1gm Injection is an antibiotic medicine used to treat bacterial infections in your body. It is effective in infections of the brain, lungs, ear, urinary tract, skin and soft tissues, bones and joints, blood and heart. It is also used to prevent infections during surgery, Inj. Oxytocin 10 IU.Oxytocin is a uterine stimulant, prescribed for the initiation of uterine contractions and induction of labor in women as well as stimulation of contractions in cases where the uterus does not contract enough during labor.

If any complication occurs during normal delivery than patient refer for lower segment Cesarian section. Mother should take care of self and self-care mayinclude Rest and ambulance-early ambulation after delivery, hospital stay, diet, perineal care, care of bladder, care of bowel, sleep, care of breast, rooming in, aseptic and antiseptics, immunization post-partum exercise, follow up, daily observation and care of newborn. After normal delivery mother and baby should come for check up and follow up after discharge of six weeks, and explained the client about if any sign of infection and side effect of medication immediately informed to the doctors. Immunization of baby follow up is necessary.

Discussion

Present case reveals that the antenatal patient come in hospital with the complaint of pain in abdomen and increased the fetal movement on date 4/01/2020 and she delivered female baby on date 6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness. After delivery mother and baby was normal Apgar score was ten and

baby was kept with mother in same bed it will help to initiate breast feeding, thermoregulation, create bonding between mother and child, mother learn how to provide the care to baby etc. after that pain was manage by painkiller. Condition of baby and mother was good.

Most broadly, the phrase 'natural life' in scientific research and healthcare policy refers to conception without and with minimal surgical intervention. The 2007 systematic review by both the prenatal care Planning Group, Making Natural Childbirth a Fact, provided for such a uniform approach of hospital birth to improve trust for auditors or tracking practice patterns A subsequent description defined natural delivery or non-assisted vaginal delivery without intervention of labour; epidural, spinal and general anaesthesia or episiotomy. Unlike many other meanings, an interpretation with Werkmeister has been restricted to a pregnancy and birth and it does not apply to birth outcomes like vertical presentation as well as intact perineum.[3]

This same delivering of a full-term baby originally referred with service only at gestational age of 37-42 weeks, even though defined by last menstruation cycle or through ultrasound dating as well as assessment. A Naegel rule is indeed a frequently was using formula besides predicting a due date focused mostly on date from the last menstruation cycle. Its legislation states a 28-day menstruation periods as well as a mid-stage ovulation. Ultrasound dating will be much more accurate, especially because once implemented early in the pregnancy and used to substantiate or adjust a due date focused on last menstruation cycle. About 11 per cent of singleton birth is pre-term and 10 per cent of all births are post-term. As a result, nearly 80 per cent of babies are born on even a full-term basis, but only 3-5 per cent of births arise mostly on expected delivery date.[4]

Healthcare offers patient care, encourages convenience, listens to emotional needs through a comprehensive wellbeing paradigm, and teaches nutrition or self-care. Even so, in today's popular health care setting, postnatal nurses are very often responsible to devices or for mothers and babies. It is critical that organizations develop trust and expertise in order to make a transition towards a humanizing birth feasible. This topic problem in such a major nursing review offers important resources to help caregivers encourage, endorse and defend regular birthsNursing staff have a special and significant role to play in deciding the treatment procedures encountered by women. Unfortunately, nursing staff may well be functionally removed from important method of data interchange as well as from making a contribution to a treatment plan. This can influence the ability of nursing to successfully encourage, help or secure regular births. Since medicalized conception presents a threat of iatrogenic damage to the both mothers and infants, nurses have a duty obligation to encourage natural delivery in order to improve patient health.[5] Studies on Prenatal diagnostic and treatment modalities were reviewed [6-7].

Conclusion

After delivery mother and baby was normal. Apgar score was ten at birth. Condition of baby and mother was good after pain management pain was reduced.

Case Report on Obsessive-Compulsive Disorder

Samuel Vanlalpeka[1], Jaya Gawai[2], Manoj Patil[3]

[1]M.Sc. Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Wardha Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, [2]Associate Professor, Dept. of Mental Health Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Wardha Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, [3]Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

Introduction: Obsessive-compulsive disorder is an anxiety disorder in which people have recurrent, undesirable thoughts, ideas or sensations (obsessions) that make them feel compelled to go and do something (compulsion) repeatedly. Repetitive habits, such as washing hands, inspecting items or bathing, can substantially interfere with the everyday routines and social experiences of a individual.

Symptoms: Behavioral changes like hyperactivity, impulsivity, repetitive movement, perfectionism and social isolation. Mood changes likes anxiety, anger and apprehension. Psychological changes like sleep disturbance, fear, repeatedly going over thoughts and narcissism.

Investigation: Hb% - 13 mg/dl; Glucose plasma random – 86 mg%; Serum Globulin– 3.2gm %; serum-Protein- 7gm %; HIV, HCV, HBsAg, VDRL, all of these tests were negative.

Surgical Management: Patient have no past surgical history.

Medical Management: Patient was treated with Ativan (Lorazepam) 3mg q6hr per oral and Therapies like Aversion therapy and Group Psychotherapy was also used.

Nursing Management: Assess for physical, psychological and social data. Aware for Impact of obsessions and compulsions on physical health, mood, self-esteem and natural capacity to cope. Remember that the defense mechanisms used, the nature or structure of the feeling, the suicidal risk, the capacity to work and the space accessible for social support services.

Conclusion: Patient was admitted to AVBRH and was diagnosed to have Obsessive-compulsive disorder. The got appropriate treatment and therapy and his condition has improved well.

Keywords: *Obsessive-compulsive disorder, anxiety, compulsion, obsession, lorazepam, narcissism.*

Introduction

Individuals with obsessive-compulsive personality disorder are very serious and Obsessive-compulsive personality disorder is very severe and formal, and has emotional difficulty. They are highly rigid, perfectionist, and keen on law. They are resistant to change about how tasks will be handled, and dedicate themselves to success to the exclusion of personal satisfaction. An extreme fear of making mistakes leads to a challenging decision-making process. The disease is relatively widespread and appears more often in men than in women. It appears to be most common in the oldest children within the family group.[1]

The obsessive-compulsive disorder is, according to ICD9, a state in which "the outstanding symptom is a feeling of subjective compulsion which must be resisted - to carry out some action, to dwell on an idea, to recall an experience, or ruminate on an abstract topic. Unwanted thoughts, which include the insistency of words or ideas are perceived by the patient to be inappropriate or

nonsensical. The obsessional urge or idea is recognized as alien to the personality, but as coming from within the self. Obsessional rituals are designed to relieve anxiety, e.g. washing the hands to deal with contamination. Attempts to dispel the unwelcome thoughts or urges may lead to a severe inner struggle, with intense anxiety."[2]

Patient Information: A male patient 47 years from Halwadi, Wardha was admitted to Psychiatric Ward, AVBRH on 10th January 2020 with acase of Obsessive-compulsive disorder.

Present Medical History: My patient was apparently asymptomatic 2 years back when he was working in a private company while he was firing from his job due to his lack of responsibility according to his employer. Since then, he started maintaining self-disciplined and directing himself to his work with fear of loosing the new job again. His behavior getting very excessive that leads to difficulty in coping with family and the society. He was brought to AVBRH by his wife on 10/01/2020, when he was diagnosed with Obsessive-compulsive disorder.

Past Medical History: My patient was apparently asymptomatic 2 years back when he was fired from his job due to lack of responsibility. He started devoting himself to his new job, maintaining new job self-disciplined that eventually leads to excessive behavior disorder like sleep disturbance, lack of interaction**,** perfectionist, difficulty in completing task due to perfectionism and strict standards, maintaining extreme hygiene of self and surroundings.

Family History: My patient belongs to a nuclear family, middle class living with his wife and two sons in their own house in Halwadi, Wardha. He is working as aa clerk in a private school and is a breadwinner of the family. His two sons, one is 11th standard and the other is 9th grade. His wife has a small grocery store in their house.

Clinical Findings: Behavioral changes like hyperactivity, impulsivity, repetitive movement, perfectionism and social isolation. Mood changes likes anxiety, anger and apprehension. Psychological changes like sleep disturbance, fear, repeatedly going over thoughts and narcissism.

Predisposing Factors: From a psychoanalytical point of view, one of overcontrol is the parental style in which the adult with obsessive-compulsive personality disorder was reared. Such parents want their children to live up to and reject their set standards of behaviour if they do not. Praise is bestowed on the child with far less frequency than punishment for unwanted behaviors. Individuals are specialists in this setting of knowing what they can not do to escape retribution and criticism, rather than what they should do to gain respect and praise. They learn to follow strict rules and regulations. Significant accomplishment are expected, taken for granted and acknowledged only occasionally by their parents, whose responses and decisions are restricted to pointing out transgressions and infringement of the rules.[1]

Pathophysiology: Anxiety, obsessive-compulsive,most likely and associated disorder arecaused by multiple factors. A graphic description of this multiple association hypothesis is provided in the Stress/Adaptation Transactional Model.

Mental Status Examination: A mental status examination was performed on my patient and it was found out that there was an impaired in the stream of thought and in the insight, the score was 2 i.e. the client denies of him having mental illness.

Diagnostic Assessment: Hb% - 13 mg/dl; Glucose plasma random – 86 mg%; Serum Globulin– 3.2gm %; serum-Protein- 7gm %; HIV, HCV, HBsAg, VDRL, all of these tests were negative.

Therapeutic Intervention: Tab Ativan (Lorazepam) 3mg PO x q6h. Therapies like Aversion therapy and Group Psychotherapy was also used.

Discussion

A male client of 47 years old from Halwadi was admitted to Psychiatric ward, AVBRH on 10th January 2020 with a complaint of strict personality and disciplined, which cause him to interact or cope with his family or society (according to the patient). According to the patient's wife, the patient was an extreme self-disciplined, perfectionist, and he also wanted to change the bedsheet, clothes, shoes and blankets every day and he was very violent when they disobey him and this behavior had started in the past 2 years ago. He was diagnosed as Obsessive-compulsive disorder. As soon as he was admitted to hospital investigations were done and appropriate treatment were started. After getting treatment, he shows great improvement and the treatment was still going on till my last date of care[2,3].

A study was done on, "An epidemiological study and severity assessment of obsessive-compulsive disorder in Warangal region, India". The study aimed at to clinically assess the prevalence and assess the severity of obsessive-compulsive disorder (OCD) in Warangal region, India. A prospective observational study was done for a duration of 6 months i.e. from July-December 2013 at various Neuropsychiatric Centres in Warangal region. A total of 113 patients (male: 65, female: 48) were screened using specially designed data collection form to collect and record demographic data. Structured interviews were conducted to obtain Yale Brown Obsessive- Compulsive Scale (YBOCS) scores. All the data were analysed by ANOVA and Chi Square test using Statistical Package for Social Sciences (SPSS) software version by dividing the patients into age groups of decades from 11 to 60. It was found out This obsessive-compulsive disorder was more common in subjects between the ages of 21 and 30 (46%) and literate in patients (98.2%). More patients were married (61.6%) than single patients (38%). The most prevalent obsession was fear of harming (81.25%) while of the most prevalent compulsions was repeating (76.1%). Based on YBOC scale, OCD severity was categorized into subclinical (2.7%), mild (23.9%), moderate (41.6%), severe (23%) and extreme (8.9%). The study concluded that the prevalence of OCD condition was more among the age group of 21 to 30 years and among literates. Sociodemographic factors like age, socioeconomic status and urban were risk factors in assessing the severity of OCD.[3] Fewarticles related to various aspects of prevalent psychological problems and associated factors were reviewed [4-11].

COVID 19–Laboratory Scenario

Anmol Taneja[1], Sunita Vagha[2]

[1]Resident, Department of Pathology, [2]Professor and Head,Department of Pathology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha, Maharashtra, India

Abstract

Background: Coronavirus is RNA virus, positive stranded, and is enveloped was first isolated in 1965, can cause symptoms like common cold, severe respiratory symptoms,gastrointestinal,liver and CNS symptoms. WHO announced the original name of coronavirus as COVID19. This virus has been named as Severe Acute Respiratory Syndrome Cov-2 currently and WHO has now declared this virus as emergency of public health concern. More than seventy thousand people in the China and 25 other countries have been infected.

Materials and Method: Various lab investigations like CBC, Real Time-PCR, d-dimer levels, cell culture, electron microscopy, Low platelet count, ESR, CRP levels, Chest CT, Xray, Liver and Kidney Function tests, SOFA (sequential organ failure assessment) score have been useful in diagnosing the causative agent.

Conclusion: Since no antiviral treatment has been effective till now so transmission can be slowed down by preventive measures like self-quarantine,isolation, maintaining distance from one another and use of personal equipment.

Keywords: *Coronavirus, COVID 19, SARS cov 2, Low platelet count, Real Time PCR.*

Introduction

Structure: Corona virus belong to family *Coronaviridae* is an RNA virus, positive stranded, and is enveloped of ca. 27000 - 31500 nucleotides present[(1)], For an RNA virus, this family is the largest known genome[(2)]. Corona means crown in Latin, so this virus when visualised under electron microscopy gives the appearance of coronavirus virions, membrane of virus gives projections in form of spikes, which gives the resemblance of a crown[(2)].

Coronavirus in humans was first isolated in 1965 from discharge of nasal cavity of patient having common cold and termed as B 814.[(2)]

This virus shares similarities regarding organisation and expression of the genome, in open reading frame encodes 16 non structural proteins. At the 5' end, 1 a/b is present, followed by/proteins mainly :Spike Protein, Envelope Protein (E), Membrane Protein (M) and Nucleocapsid (N) encoded by other open reading frames at the 3' end.[(2)]

Different strains known to infect humans are currently 6 including: Human coronavirus 229 E, OC 43, NL 63, HK U1, SARS coronavirus and MERS coronavirus[(2)].

SARS cov 2 shares similarities to some of virus generas, mainly beta subtypefound in bats.[(3)]

229 E and OC 43 are the viruses from alpha and beta lineage that cause fifteen to twenty nine percent of all common cold[(2).]

Coronavirus can cause symptoms like common cold, severe respiratory symptoms, gastrointestinal, liver and CNS symptoms.[(3)]

History: WHO used a term novel coronavirus on December 29 2019, in reference to virus that was responsible for affecting the respiratory system of patient in Wuhansuffering from Pneumonia and officially, Novel coronavirus as Coronavirus disease (COVID 19) was announced by WHO and Severe Acute Respiratory Syndrome cov 2 (SARS- Cov-2) as the current name of virus[3].

It was confirmed by WHO that the local seafood market place in China, Wuhanwas associated with the outbreak of coronavirus epidemic but no specific animal was identified in association with this disease [3].

Epidemiology: During mid December 2019 in Wuhan, the outbreak of this disease started and up to February 18, 2020,more than seventy thousand people in the China and 25 other countries had been infected.[4].

2.2 to 3.3 is estimated basic reproductive number and 2.3 % as its mortality rate. Five thousand five hundred and forty four cases have been reported as of March 6, 2020, including 159 death[5].

The confirmed cases of Covid 19 Infection, up to 14th April, 2020 in India were 11,487 and out of which 393 have been deceased [6].

Most number of cases were found to be confirmed in Maharashtra (2,684). [6]

Animals like camels, cattles, cats, bats probably serve as hosts for coronavirus [3].

Mode of Transmission: Animal coronaviruses don't spread among humans generally with the exceptions of some like Severe Acute Respiratory Syndrome cov 2 and MERS which transmit mostly via respiratory droplets(via coughing or sneezing) through close contact with infected people[3].

Three main routes have been described as a route of transmission for Covid 19 according to new guidelines from health authorities in china as following :

1. Droplet transmission
2. Transmission through contact
3. Aerosol

One study indicated the potential transmission route for this virus infection as the digestive system in addition to these routes [3]

Laboratory Scenerio: Laboratory findings and investigations play a very important role in diagnosing the disease.

Molecular Profile :

Procedures suggested for suspected patientsare: Real Time PCR (RT-PCR)-for detection of the viral RNAin samples of lower respiratory tract like in sputum, throat swabsetc[3].

Specimen collection should be done and all specimens should be regarded as potentially infectious. Respiratory material should be collected at minimum .

Microbiological Profile:

Upper respiratory tract specimen:

1. Nasopharyngeal swab.
2. Oropharyngeal swabs and
3. Washes in patients who are able to walk about but not bedridden

Lower respiratory specimen:

1. Sputum for endotracheal aspirate.
2. BAL[3].

Blood, stool, urine specimens should also be collected[6]. Specimens should be transported to test centre immediately after sample collection with correct handling during transportation lab testing and confirmation with NAAT should be done followed by serological testing viral Sequencing and viral culture.[7].

Hematological Profile:

1. Complete Blood Count.
2. Platelet count
3. ESR levels

Biochemical Profile:

1. CRP
2. Lipid profile.
3. D- dimer level.
4. Procalcitonin.
5. Liver Function Test (LFTs)
6. Kidney Function Test (KFTs)
7. Potassium level.

Pan et al conducted a study, involving twenty one patients (71% women, from age ranging from 25 to 63 years) and frequent abnormalities reported as : Increased values of CRP, ESR, LDH and D dimers[8].

Wang et al studied the behavior of 6 laboratory parameters in 138 patients having Covid 19 infection and out of them, 33 were having a severe disease and noted significant differences between patients who needed ICU admissions and those who did not encompassing: High WBC count, Neutrophilia, lymphocytopenia, High LDH, Total Bilirubin, Creatinine, D-dimer and Procalcitonin[8].

Biomarker which is independently associated with severeity of the disease and mortality risk is Platelet count . It is also very simple as well as readily available[9].

In up to fifty five percent of patients in disease outbreak, low platelet count was found and it was considered as a risk factor regarding risk of mortality risk[9].

G Lippi et al conducted a metaanalysis including 1779 patients, 399 with severe disease and concluded that the patients who didn't survive had a significantly lower platelet count than the survivors[9].

Investigations like potassium levels can be a reliable, in time and sensitive biomarkers in patients with severe infections[10].

D Chen et al conducted a study and found that body temperature, CK,CK-MB, LDH and high levels of CRe active Proteins were significantly associated with a severity of low levels of potassium[10].

Some findings like high SOFA score (a score for assessment of sequential organ faliure), d-dimer levels > 1 microgram per mililitrecan tell about poor prognosis at an early age[11].

Fei Zhou et all conducted a study in which 191 cases were taken and divided them into two groups: survivors = 137, non survivors = 54 and concluded that old age, high SOFA score and d dimer levels more then 1 microgram per ml were associated with high risk of mortality[11].

Findings associated with death were like: Lymphopenia, lymphocytosis, Elevated LDH, cardiac markers like cardiac troponin 1, Creatinine Kinase, d dimer levels, Serum Iron, Interleukin 6, Prothrombin time and Procalcitonin[11].

An important investigation in suspicion of Covid 19 infection are the levels of CRP. The extent of lung lesion and disease severity are reflected by levels of C Reactive Proteins providing an important clinical evaluation index.[12].

L. Wang et al conducted a study in 27 positive patients and found that levels of C Reactive Proteins were correlated positively with lung lesions and reflected the severity of disease at early stages of the disease[12].

Radiological Profile:

1. Chest CT should be recommended in suspected cases of Covid 19 cases, for follow upas well as for initially revaluation, because respiratory system is primarily involved [12].
2. Chest X ray- Even before the onset of symptoms, CT findings may be present, so Chest X Ray have little diagnostic values at early stages.

Chest radiographs show features of ARDS, ranging from intermediate to advanced stages[12]. Lung and immune system damage are the main pathological changes.

Fibrin exudates of serous type, clear membrane formation in lung alveoli, with the congestion and edema[12].

In early stages, CT imaging reveals small, multiple patchy shadows, stromal changes with lung exudates, which develop as multiple ground glass and infiltrating shadows in both lungs[12].

Sana Salehi et all conducted a study in which 919 patients were taken for study and found characteristic pattern and distributed of CT findings as Ground Glass Opacities (88%), both lungs involvement (87.5%), and Multilobular involvement (78.8%).

Terlobularthickening of septa, Bronchiectasis, thickening of pleura with involvement of subpleura were Other CT findings. In setting of strong clinical suspicion for Covid 19 diagnosis, chest CT along with laboratory testing may be beneficial.

Sensitivity of CT Scan alone for the diagnosis was 76.4 %[12].

Cynthia S goldsmith et al gave a report which describe the events in which virus was isolated as well as identified by electron microscopy.

This study tells about various lab findings and investigations which have been used for diagnosing the etiological agent and also tells about various important investigations which should be done for screening for better outcome of the patients suffering from this disease.

There is no specific treatment confirmed to be effective against this virus till date, so symptomatic treatment with supportive care has been recommended regarding the patients which have been infected with Covid19 [3], along with some preventive measures to slow down the transmission of infection like isolation of cases,, disinfection of environment and use of personal equipments for safety[3].

Conclusion

This study give a brief idea about the disease including its epidemiology, mode of transmission, various lab investigations and findings, preventive measures etc.

Most studies have given their views on epidemiological and potential causes and many more studies are still trying to explore the prevention, safety and control measures.

However further research should be done to provide reliable and valid measures to face this type of problem in short term as well as long term.

A Study of Lipid Profile and Estradiol for Evaluation of Cardiovascular Risk in Pre- and Post-Menopausal Women

Prajakta Warjukar[1], Rakesh Kumar Jha[2], Prakash Kute[3]

[1]Assistant Professor Dept. of Biochemistry, [2]Tutor Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur-441110, [3]Assistant Professor Dept. of Biochemistry, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi, Meghe, Wardha-442001

Abstract

Introduction: Following menopause, decreased oestrogen production from ovaries leads to lipoprotein profile derangement, drastic alterations in the metabolism of glucose and insulin, distribution of body fat, coagulation and fibrinolysis and vascular endothelium dysfunction. Oestrogens include many cardioprotective mechanisms that alter the vascular tone by enhancing the levels of nitrous oxide. Endothelial cells are stabilized by oestrogens, they augment antioxidant potential and alter fibrinolytic proteins. These are all cardio-protective mechanisms that are reduced with beginning of menopause.

Objectives: To evaluate the relation of oestradiol hormonal variation with plasma lipid concentrations in pre- and post- menopausal women.

Material and Method: 50 premenopausal women and 50 postmenopausal female were selected as subjects. Data were obtained via clinical assessment from laboratory investigations and questionnai.

Results: Serum levels of Total Cholesterol (TC), Triglycerides (TG), LDL-cholesterol, and VLDL-cholesterol in postmenopausal women were significantly elevated when matched with premenopausal women. For postmenopausal women, the level of HDL-cholesterol declined substantially. The concentration of estradiol in post-menopause women was significantly lower ($p<0.001$).

Conclusion: Menopause results in alterations in the lipid profile by reducing HDL and increasing total cholesterol (TC), triglycerides (TG), LDL-cholesterol and VLDL-cholesterol, thus raising the chances of cardiovascular disease. These shifts are due to decreased amounts of oestrogen that are observed in menopause.

Keywords: *Menopause, Oestrogen, Cardiovascular disease, Plasma lipids, Coronary heart disease.*

Introduction

Menopause refers to a state of complete menstruation cessation at the end of reproductive life because of loss of ovarian follicular function and menstrual cessation. There are numerous hormonal changes that occur after menopause in women and result in variations in lipid metabolism and increase the chances of coronary artery disease in women[1,2,3].

There are alterations in the metabolism of glucose and insulin, coagulation,distribution of body fat, fibrinolysis, and dysfunction of the vascular endothelium[3,4]. Coronary artery disease (CAD) is the major reason of death for women after the menopause. Post-menopausal women are 4 to 8 times more likely to die from CAD than from any other disease[5]. Framingham study results indicate

e-mail: ambad.sawan@gmail.com

that female CAD morbidity levels escalate faster than male morbidity rates after 45 years of age[6]. Numerous risk factors have been reported as responsible for CAD progression.

The incidence of CAD in women is lower up to the age of 50 years, but then the incidence in both men and women is similar[7]. As average lifespan in women is rising in terms of age and menopause remains relatively unchanged, so females are now spending more of their lives in post-menopause period. In India, 60 million women are over 55 years of age[8].

Oestrogen improves the permeability of the vessels by increasing production of nitrous oxide. Adequate Protein, Vitamins and Minerals intake is required for a healthy pregnancy[9]. It maintains a balanced profile of lipoprotein. It helps to maintain the endothelial cells, improves the antioxidant effect and changes the fibrinolysis protein. In menopause, all such cardioprotective functions are missing. Postmenopausal women face an elevated risk of developing cardiovascular disease and pre-eclampsia.[2,3,10]

A woman today, after the menopause, will live about a third of her life. After menopause the ovaries fail to produce significant quantities of oestrogen; thus, symptoms and diseases related with an oestrogen deficiency are of growing in significance for women's health[11].

Inadequacy of estrogen is a crucial factor that contributes in postmenopausal women's lipid metabolism derangement that is linked to increased cardiovascular risk[2,12]. Post-menopausal women currently account for over 30 per cent of India's female population at risk of CAD[13].

Low-density lipoprotein has been involved in coronary heart disease (CHD) progression. A predisposing factor for CHD is the accumulation of fatty plaques on the arterial walls (arteriosclerosis)[14].

Given comprehensive research on the effect of progestogens and oestrogens on lipoprotein and lipid metabolism[3,15,16]. It is not yet certain if changes in sex steroid levels are correlated with variations in lipid concentrations correlated with menopause period. Coronary artery disease (CAD) is evidently polyfactorial, and data of endogenous hormones could improve our assessment of CAD[17].

Our research aimed at finding variations in lipid status in menopause women and in regularly menstruating females and investigating the relationship between menopause status and associated hormonal variability with plasma lipid concentrations.

Material and Method

This cross-sectional study was carried out at Datta Meghe Medical College,Nagpur in collaboration with Jawaharlal Nehru Medical College Sawangi (Meghe) Wardha & Datta Meghe Institute of Medical Science (Deemed University) Maharashtra, India,between August 2019 to July 2020.

For this study, groups of 50 premenopausal women and 50 postmenopausal women were chosen randomly. The postmenopausal females who were studied were those with a history of natural menopause, who had menstrual cessation for at least one year. Those who had regular menstruation were premenopausal women who were studied.

Exclusion Criteria:

1. People with hypertension,
2. Cardiovascular disease,
3. Diabetes mellitus,
4. Hepatic,
5. Metabolic and renal disease
6. Those on exogenous hormones or hormone replacement therapy,
7. Lipid reduction medications.
8. Smokers,
9. Alcoholics,
10. Sedentary women
11. Skilled athletes or sports people

The research had been accepted by the Institutional ethical committee. Following a 12-14 hour overnight fasting, venous blood samples were obtained from subjects after obtaining their informed consents. But this was achieved for the premenopausal community on the 7th day of the last menstrual cycle. Samples were centrifuged, the plasma was separated, and analyzed.

The total cholesterol, triglyceride and HDL were estimated by an enzymatic method and serum LDL and

VLDL were calculated by using Friedewald's formula VLDL= TG/5.0 and LDL = TC - HDL - TG/5.0 (mg/dL)[18].

Oestradiol was estimated by using Chemiluminescence Immunoassay kit, which is a two step competitive binding immunoassay for the quantitative determination of 17-beta–oestradiol. Body Mass Index (BMI), as a measure of body fat was determined, based on height and weight of Pre-and Post-menopausal women It was calculated by following formula. Height was measured in Meter and weight was taken in Kgs.

Statistical Analysis: Data collected was entered into Microsoft Excel Worksheet and statistically analysed by using SPSS (Statistical Package for Social Sciences) version 23.0. For quantitative data, calculated values were processed by using: arithmetic mean, standard deviation and Student's 't' test. P value of< 0.05 was considered as statically significant.

Results

Table 1: Comparison of Plasma Lipids in Premenopausal and Postmenopausal Women

Plasma Lipids (mg/dl)	Pre-menopausal n=50	Post-menopausal n=50	P-Value
TC	151.42 ± 16.38	209.26 ± 27.48	< 0.001
TGL	126.3 ± 13.32	126.3 ± 13.32	< 0.001
HDL	47.56 ± 6.19	26.8 ± 5.4	< 0.001
VLDL	21.18 ±1.32	24.3 ± 2.40	< 0.001
LDL	84.76 ±20.32	159.38 ±29.42	< 0.001

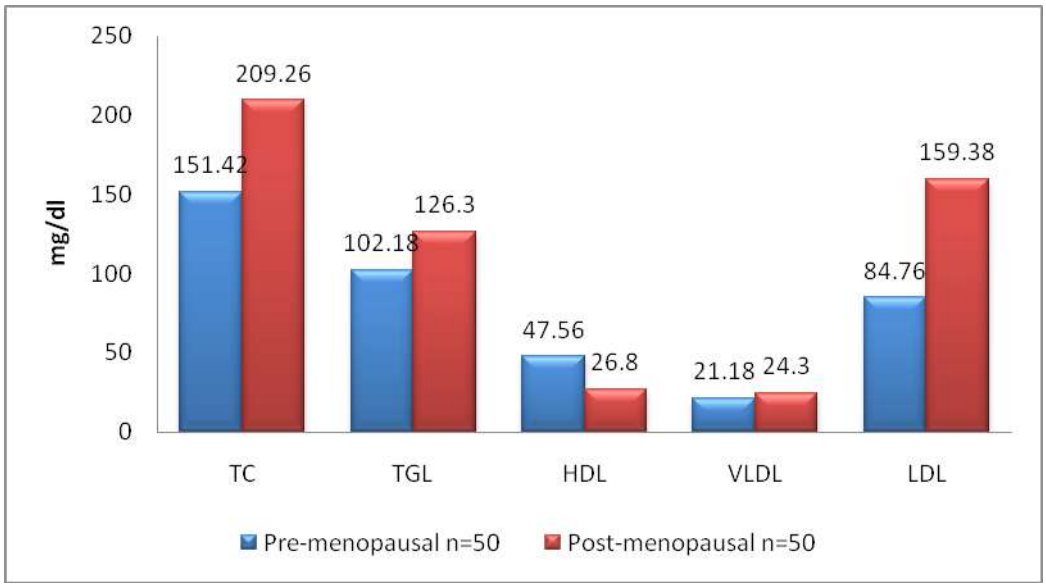

Fig-1: Comparison of lipid profile in pre and post menopausal women

In postmenopausal women, we found a significant rise in serum levels of Total Cholesterol (TC), Triglycerides (TG), LDL-cholesterol and VLDL-cholesterol compared with those in premenopausal women (p<0.001). The level of HDL-cholesterol in postmenopausal women was significantly reduced relative to that in premenopausal women (p<0.001) (Table 1 and fig 1).

[Table 2]: Comparison of Estradiol and BMI in Premenopausal and Postmenopausal Women

	Pre-menopausal n=50	Post-menopausal n=50	P-Value
Estradiol (Pg/ml)	168.48±41.28	42.32±11.20	< 0.001
BMI (kg/m^2)	20.7±4.3	23.9±4.12	>0.05

In our study, estradiol concentration in pre menopausal women (168.48 ± 41.28) was observed to be significantly higher (p<0.001) than post menopausal women (42.32 ±11.20) [Table-2].

According to the results of this study, there was no significant difference (p>0.05) in BMI between postmenopausal women (23.9±4.12) and pre-menopausal women (20.7±4.3) [Table 2].

Discussion

In postmenopausal women, we found a significant rise in serum levels of Total Cholesterol (TC), Triglycerides (TG), LDL-cholesterol and VLDL-cholesterol compared with those in premenopausal women (p<0.001). The amount of HDL-cholesterol in postmenopausal women was significantly lower than in premenopausal women (p<0.001).

Postmenopausal women in our cohort have demonstrated more significant dyslipidaemia than premenopausal women, in line with previous studies[19,20].

Our finding was comparable to the Ifueko (2013) analysis in which TC, TAG and LDL-C in postmenopausal women were significantly increased with "P" value < 0.001 than in premenopausal females[21]. Similarly, Shenoy and Vernekar (2015) observed a considerable increase in TC, TAG, and LDL-C but the HDL-C was not significantly increased in postmenopausal women compared to premenopausal females[22].

Our study results are consistent with other studies carried out by Kalavathi et al., where TC is shown to increase in postmenopausal females due to estrogen deficiency relative to premenopausal females and is statistically significant (P < 0.001) [12].

In our study, postmenopausal women had high TG and were statistically relevant (P < 0.001), relative to premenopausal women. Such results are consistent with other research carried out by Welty, Hallberg, and Svanborg[5,23]. For postmenopausal females, there is increased fat accumulation and increased release of free fatty acids into circulation, and excessive free fatty acids provide a substrate for hepatic TG synthesis[24].

In our study, in contrast with premenopausal women, postmenopausal women had elevated rates of LDL and were statistically important (P < 0.001). Those results are consistent with other studies[12]. Circulating estrogen regulates lipoprotein lipase (LPL). LPL catalyzes VLDL's hydrolysis to form intermediate-density lipoprotein and subsequently, LDL.

Regulation of various LDL receptors in Liver, is carried out by effect of Estrogen on lipid metabolism. Estrogen works on the hepatocytes on these LDL receptors and contributes to greater clearing of LDL-C particles[25]. By this process the serum LDL-C levels are regulated. Lack of Estrogen following menopause increaseshepatic TG and plasma LPL activity causing plasma LDL to concentrate and also contributes to LDL receptor down-regulation[26,27]. In our study, the VLDL was elevated and statistically significant (P < 0.001) in post-menopausal females relative to pre-menopausal females, and these results are consistent with studies by Welty [5].

Lack of Estrogen in postmenopausal women induces relative accumulation of small VLDL particles with cholesterol esters (CE) either due to elevated VLDL catabolism resulting in higher number of VLDL residual particles or increased cholesterol ester transfer protein activity[28]. The VLDL remnants are highly capable of interacting with smooth arterial muscle cells[29]. It is well known that VLDL alone constitutes a risk factor for cardiovascular diseases.

Anticipating the factors that impact the post-menopausal female's lipid profile will improve their cardiovascular risk profile by implementing strategies to control these mechanisms through modifying the relative risk factors during menopause transition.

The HDL was increased in premenopausal women relative to postmenopausal women in our study, and was statistically relevant (P < 0.001). These results

correspond to studies performed by Shenoyand Vernekar (2015)[22], and Sapkota et al. in 2015[23].

Estrogen raises HDL-C which is considered good cholesterol for CVS by raised hepatic synthesis of Apolipoprotein -A and decreased hepatic removal of HDL2 cholestrol by decreasing hepatic lipase enzyme activity. Because estrogen is reduced during menopause and this contributes to both of these functions being hampered[30].

The protective mechanism involving HDL could be due to its role in the transport of reverse cholesterol, resulting in the redistribution of cholesterol away from the artery wall and suppression of monocyte adhesion and antioxidant activity, which may avoid LDL oxidation[31]. In our analysis, we excluded the factors that could alter the lipid profile. BMI tests in pre- and postmenopausal women (P>0.05) do not indicate any important difference. So we concluded that those changes observed in these postmenopausal women's lipid profile are due to hormone estrogen deficiency and not linked to BMI. Similar findings have also been found in numerous other studies[12].

Conclusion

In the study,adverse changes in the lipid profile of postmenopausal women suggests that this group of people is at augmented risk of cardiovascular problems in the near future. Menopause contributes to increased lipid profile thus increasing the risk of cardiovascular disease. Postmenopausal females are at elevated risk of developing cardiovascular disease due to changes in lipid pattern and the loss of oestrogen's cardioprotective impact.

The decreased cardiovascular protective HDL is an indicator that menopause is an independent risk factor for the development of cardiovascular disease. Thus, it is necessary to encourage each and every postmenopausal woman to undergo screening for an abnormal lipid profile. Specific health education approaches are needed to prevent postmenopausal women from developing cardiovascular diseases.

In this high-risk population early and timely identification and primary prevention will reduce morbidity and mortality.

Comparison of Quality Enhancing Method of Modern & Ayurvedic on Tulasi (Ocimum Sanctum)

Dhiraj A. Zade[1], Prakash Tathed[2], Sambhaji Tike[3], M.K. Rehman[4], Swanand Pathak[5]

[1]Associate Professor, Department of Dravyguna, DMAMCH & RC, Wanadonagari, Nagpur, [2]EX-Dean, YMT Ayurvedic College, Hospital & R C, Kharghar, Navi Mumbai, [3]HOD, Professor, Department of Dravyaguna, YMT Ayurvedic College, Hospital & R C, Kharghar, Navi Mumbai, [4]Ex-HOD, Professor, Department of Dravyaguna, YMT Ayurvedic College, Hospital & R C, Kharghar, Navi Mumbai, [5]Professor Dept. of Pharmacology Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha

Abstract

Modern civilization, Industrialization and the population explosion has shrunken forests as well as the land available for cultivation in our country which has badly affected the availability of medicinal plants as the quantity of medicinal plants is reduced the quality also is compromised. The green revolution was brought about by the use of chemical treatments on the seeds, plants, used of the pesticides and chemical manures. It would be worthwhile to study whether similar pattern can be employed to increase the no. of plants and their quality in the field of cultivation of medicinal plants. Although, plant breeding appears to be the principal way of improvement, and can give good results in terms of resistance to pathogens, active component content and yield; the agronomical and the technological approaches are also very important. An agronomical method to improve the quality & quantity of the plants includes treatments of seeds & the growing plants with Bio-engineered herbal products along with the use of organic manures. The scientist in the field of botany and agriculture have developed some method of quality enhancing by treating seeds, seedlings or young shoots or buds in plant breeding with some suitable chemical treatments. These method have given satisfactory results in the form of increase in the yield. Hoping that the quality also improves it would be worthwhile to grow medicinal plants on the similar lines. The relevant literature reveals that Colchicine treatment on seeds or seedling or emerging buds for quality enhancing of medicinal plants will be worth studying.

Keywords: *Ocimum sanctum, Cholchicine, decoction.*

Introduction

Colchicine is a toxic natural product and secondary metabolite, alkaloid originally extracted from plants of the genus *Colchicum luteum i.e.* Colchicum luteum. Since chromosome segregation is driven by microtubules, Colchicine is also used for inducing polyploidy in plant cells during cellular division by inhibiting chromosome segregation during meiosis[1,2,3,4] half the resulting gametes therefore contain no chromosomes, while the other half contain double the usual number of chromosomes (i.e., diploid instead of haploid as gametes usually are), and lead to embryos with double the usual number of chromosomes (*i.e.* tetraploid instead of diploid)[5] While this would be fatal in animal cells, in plant cells it is not only usually well tolerated and properties of the plants can be enhanced. This necessitates to the plant with chemical treatments by suitable chemicals or organic materials on the seeds before sowing.

Ocimum sanctum (O. sanctum) is of family labiatae regarded in Ayurveda as a kind of 'elixir of life' and believed to promote longevity.

To generate the scientific evidences a comparative study of morphological and phytochemical of O. sanctumand O sanctum grown after treating it's seeds with O. sanctum decoction and colchicine and Colchicum luteum was studied.

Material and Method

Material:

1. *O. sanctum* seeds.
2. The materials used for treating the *O. sanctum* seeds
   i. Decoction of *O. sanctum*
   ii. Cholchicine
   iii. Colchicum luteum

Method

Sample A: *O. sanctum* plant grown after soaking *O. sanctum* seeds in distilled water for 24hrs.

Sample B: *O. sanctum* plant grown after soaking *O. sanctum* seeds in O. sanctum decoction for 24hrs.

Sample C: *O. sanctum* plant grown after soaking *O. sanctum* seeds in Colchicine solution for 24hrs.

Sample D: *O. sanctum* plant grown after soaking *O. sanctum* seeds in weak infusion of *Colchicum luteum* for 24hrs.

B. The **Decoction** was prepared as per the method mentioned in **Sharangadhar Samhita** which was used for treatment of seeds for 24hrs.

C. The Colchicine solution was prepared by dissolving 100mg of the powder of the chemical in 100ml of distilled water (1000ppm) and the 5ml of this solution was added to 5ml of distilled water to make it 500ppm. This solution was used to soak the seeds of O. sanctum for 24hrs.

D. The dried tuber of *Colchicum luteum* plant was crushed to obtain fine powder. 100mg of this powder was added to 100 ml of distilled water and mixture was churned for about 1hr. The mixture thus prepared was strained with fine cloth. The solid was discarded and the fluid was used in quantity of 5 ml to which 5ml of distilled water was added and the seeds of O. sanctum were soaked in this weak infusion for 24hrs.

The seeds thus germinated in the pattery dishes were transferred to the not manure soil. The plants of all the groups thus grown were sufficiently watered and were observed daily. After the appearance of inflorance i.e. after 2 months the plants were studied for following tests.

Morphological appearance, Phytochemical, HPTLC studies of all the groups.

1. **Morphological appearance:** Height of the plant, length of the root, charchaterstics of the stem and leaves were observed.

Solvent System: Toluene: Ethyl acetate: Formic acid: Methanol (3: 2: 0.4:0.4) was used as solvent system.

Chromatographic Development: Precoated TLC plates was used for Chromatography.

Observations and Results

Results of Morphological Charchacter of Tulasi: On the Comparison of Morphological features of the group A, B, C and D, the variation observed was significantly more than the control group A in all the three group of plants which were grown after treating the seeds with O. sanctum decoction (Group B), Colchicine solution (Group C) and weak infusion of *C. luteum* (Group D).

Table 1: Morphological Observation

Treatment	Observation Morphological Features
1. Control (A)	Height 11.2 cm shoot length 7.3 cm root length Secondary roots 16 no Stem color slightly purplish Stem clothed with soft silky hair but occurred frequently. Petiole length 2.1 cm Leaf Elliptical slightly acute, apex, margins slightly serrated. Leaf with 8-9 subveins.
2. T-1 Decoctions (B)	Height 22.2 cm Shoot length 12.1 cm root length Secondary roots length no33 Tertiary roots are also found. Petiole length 2.3-2.6 cm. Stems clothed with silky hair Leaves with elliptic ovate blade Apex acute.
T-2 Colchicine	Height 18.2 cm shoot length 19.1 cm root length Secondary root length no 24 Tertiary roots are also found. Stem colour dark purplish with abundant silky hairs. Secondary branched develop, petiole length 1.5 to 1.9 cm. Basal leaves with emarginated leaf apex, while upper ones are acute at obtuse leaf apex.
T- 3 Colchicum luteum (D)	Height 18.6 cm Shoot 9.2 cm root Secondary roots – 20 Leaf, petiole length 1.6-1.0 cm, margins Deeply surrounded with acute apex. Main vein with 8-9 subveins. Stem colour – slightly purplish Silky hair abundantly found

Table 2: Morphological character of all samples

Sample	Shoot	Root	Sec. Root	Petiole
A	11.2.	7.3	16	2.1
B	22.2	12.1	33	2.3-2.6
C	18.2	19.2	24	1.5-1.9
D	18.6	9.2	20	1.6-1.0

Table 3: Phytochemical Study of Samples

A, B, C and D of O. Sanctum

Sr.No.	Parameter↓/Samples→	A	B	C	D
1	Foreign matter %	0	0	0	0
2	Total Ash value %	7.87	6.34	7.35	8.59
3	Acid insoluble Ash %	0	0	0	0
4	Water soluble extractive %	68.75	69.88	68.98	69.45
5	Alcohol soluble extractive %	78.64	79.77	78.95	79.56
6	Total % of Alkaloids	24.65	26.82	26.45	26.55
7	pH	6.75	6.79	6.92	6.8

8. Colchicum luteum	0.40	0.4	0.45	312.3	32.11	0.50	3.0	8161.2	37.14	0.30

Table 5

Samples	Eugenol Area	Eugenol %
Control (A)	6725.2	0.24
Decoction (B)	7877.4	0.29
Colchicine (C)	8099.1	0.29
Colchicum luteum (D)	8287.9	0.30

Discussion

These studies the plants were grown by treating the seeds of O. sanctum by O. sanctum decoction group B, colchicine and Colchicum luteum. The plants were grown for two months till inflorescence appeared. The morphological characters of all the groups were studied along with the chemical composition.

O. sanctum is having maximum medicinal and healing properties commonly occurred in near about all the regions of the India and mostly tropic & subtropics regions of the world. It is necessity to increase the quality and quantity of this valuable drug.

To provide a scientific basis for quality enhancement it decided to undertake four groups labeled as ‘A’ ‘B’ ‘C’ ‘D’. A - Control group, B – Decoction treated, C – Colchicine treated, D – Colchicum luteum treated. A

comparative study of all these samples was carried out. Some of them are mentioned Ayurvedic Pharmacopeia of India and Qualitative analysis of ICMR while the remaining are standard operative procedure explained by the experts.

Morphological character: It is observed that the height of plants group B is practically doubled (22.2cm) than that of control Group A (11.2 cm), where as that of group B grew 22.2cm Group C grew 18.2cm and Group D grew 18.6cm. It seems that the average growth in length of the shoot is maximum in group B followed by Group D & C in comparison with control Group A. The height of shoots is significantly more in the treated group.

The length of root of the control group A is 7.3 where as that of Group B is 12.1, Group C is 19.2 and Group D is 9.2 which indicates that the length of root of group C is largest than that of Group B, Group D and Group A but roots of group B and D are also longer than the control group. Roots are meant for giving the stability to the plant and providing nutrition this being one season plant stability is not much required and the roots are hardly used for medicinal purposes.

The numbers of secondary roots also highest in group B that is 33 and that of group C has 24, Group A has 16 and group D has 20 which suggest that the group B instead of growing in length grow in number suggesting that the nutrition provided to the plant is more.

The length of the petiole is also more in group B than that of group A group C and D are comparable with the control.

In comparison to control group A (7.87%) it was observed that the **Total Ash value%**content of sample C is 7.35 which is similar that of sample D is 8.59 which is significantly more than that of control group A. Ash value of group B is 6.34% which is significantly less than that of control group A and also of group C and D. Ash being an inert material lesser value of ash indicates that the organic material which is active is more in that sample implying that the plant which has lesser ash is more active hence it is concluded that the plants of group B are of better quality than control group A and other groups C and D.

The values of **acid insoluble ash** is zero % which if compared with the normal range i.e. not more than 3 % shows good quality of the samples. Acid insoluble ash denotes presence of siliceous matter in the drug which in lesser amount indicates better quality of the herbal drug. All the sample shows 0% acid insoluble ash indicating that the medicinal value of all the samples is good.

In comparison to control group A 68.75 % it was observed that the **water soluble extractive%**content of sample C is 68.98, sample D is 69.45 and that of sample B is 69.88 which is shows that the water soluble extractive is maximum in Group B which is significantly more than that of control group A and group C and D. the group C and control Group A are comparable where as group D it is significantly more.

It can be safely said that water soluble amino acids, carboxylic acid and vitamins are more in plant which has more water extractive values denoting greater activity therefore it can be concluded that in comparison with control and other groups, group B plant is more potent.

The presence of alkaloids, glycoside, steroids, anthraquinones and triterpenoids are estimated by alcohol soluble extractive values. It was observed that the **Alcohol soluble extractive%**content of sample C is 78.95, sample D is 79.56 and of sample B is 79.77 in comparison with control group A shows increase in the Alcohol soluble extractive% meaning there by the above said chemicals are comparable in the treatment groups but are significantly more than that of group A 78.64 indicating better availability of these chemicals.

In comparison to control group A 24.65 it was observed that the **alkaloids content** of sample C is 26.45, sample D is 26.55 and that of sample B is 26.82 which is showing improvement in the alkaloids in all th e treatment groups in comparison with group A treated groups are comparable with each other but are significantly more than that of control group A. Alkaloids are the major active ingredients of any plant. Their increase suggest better activity of the drug[6-16].

The drugs with low **pH** (acidic pH) have better absorption in intestine, as absorption of drug is dependent on pH of intracellular and extracellular fluid. So, the pH of the drug should be low and when the values were Compared to control group A it was observed that the pH Values of group C is slightly more where as that of Group B and D are similar to group A. It seems that there is no difference in pH of plant extracts in the treated groups.

It was noticed from the graph that **Eugenol %** in all the plants in the treated groups is significantly higher than that of control group A whereas there is negligible Difference among Eugenol % in B, C and D. eugenol being volatile oil is considered as active principle of the plant O. sanctum which is mostly used in respiratory tract disorder. Increase in eugenol after different indicates increase the potency of the plant.

So, considering this it can be said that decoction treatment & Colchicum luteum treatment to plants especially O. sanctum is equally effective as Colchicine used today. So, New Decoction & Colchicum luteum treatment can be considered as new options for quality enhancement in plants.

Ethical Clearance: Taken from institutional ethics committee.

OBE implies a paradigm shift toward supporting high levels of learning for all students. It focuses on what students can do and how do students relate to teaching (Biggs and Tang 2007).

That is, the instructor should provide guidance for students to achieve their outcomes by choreographing specific learning activities and assessment tasks (Van Schalkwyk 2007). Considering the above the most important aspect of OBE is to determine the learning outcomes[5].

"Pretorius (1998) has also laid down several characteristics of OBE:

- It is a learner-centered approach based on the philosophical assumption that all learners are achievers if allowed sufficient time to do so.
- There is freedom and flexibility for self-motivated learners to engage in enriching activities in order to attain the required outcome.
- Learners are focused on what is expected of them since they are exposed to the outcome right from the onset.
- Learners become accountable for their own learning when having to attain outcomes.
- An opportunity for flexible teaching strategies is offered to teachers since the emphasis is not only on whether the learner attains the selected outcome, but also on procedure.
- Learner success is established purely on whether the learner has attained the required outcome or not–and not in terms of the achievements of other learners.
- A variety of opportunities are offered to learners to demonstrate whether the outcome has been attained.
- Learner progression is based on demonstrated achievements.
- It is a long-term commitment based on the premise of continuous improvement.
- The notion of "great expectations for all to succeed", is emphasized.
- It focusses on the future and is able to address the changing needs of the community more readily.
- Community requirements tend to be addressed more directly because, in determining the required outcomes, there is the involvement of an extensive range of stakeholders such as parents, teachers and business leaders.
- The focus is on skills needed in everyday living and the requirements of the career environment, rather than on memorizing factual knowledge.

Rationale: There are very few studies related to OBE in Indian context with respect to analyzing the awareness, understanding,the reluctance and implementation of OBE practices in professional educational institutions.

Unemployment statistics of Indian youth especially in the days of reaping benefits of demographic dividend, has put forward a need to restructure the educational scenario.

This study makes a modest effort to give a visualization of the current scenario in educational sector by providing results about OBE quotient amongst faculty members,their perspective on application of the OBE and the effectiveness of OBE.

Literature Review: In a study conducted by Botha (2002), the research concluded that OBE is concerned with what students have learnt and how well they have learnt rather than what they were supposed to learn.

The shift in focus from teacher to student has led to constructivism in higher education (Ertmer and Newby 1993) where constructivism emerges from philosophy, psychology, sociology and education (Carlson 2003). It lays emphasis on knowledge as a social endeavor (Otting 2000).

In OBE teachers are stimulators of meaningful knowledge rather than mere transmitters of existing knowledge (Harris and Alexander 1998 in Kember 1997).

Black and Wiliam (2009) argue that every instruction is aimed at achieving some goals such as improving learning skills.

Transmission approach to knowledge delivery leads to superficial learning while an approach focused on students leads to in-depth learning. It is thus important to use appropriate method to transform superficial learning to in-depth learning (Trigwell et al. (1999).

Ebrahim (2010) and Allawneh and Mallah (2008) highlighted in their study that administrators incorporated the outcome based education concept in their system without adequate training to the members of faculty

on how to execute these concepts and render student centric learning. This leads to inability of the members of faculty to develop and enhance their teaching skills.

Further to this (Mc Alpine et al., 2006) stated that there was a lack of alignment between course goals, plans and classroom activities may be due to the lack of understanding of OBE by the administrators similar to the members of faculty.

Recent trends in higher education industry reflect that for assurance of quality in education focus should be on identification of outcomes of the course or program to be taught and alignment of these learning outcomes with the teaching pedagogy and assessment strategy in a manner to maximize the achievement of these outcomes. It's a process that begins with identification of outcomes i.e. what the students should be able to do at the end of the program, then organizing the curriculum accordingly, defining instruction and pedagogy and finally the assessment to ascertain that the intended learning has actually taken place. (Baron & Boschee, 1996; Deneen, 2009; Spady, 1994; Webb, 2009).

Laguador, J. M., & Dotong, C. I. (2014) in this study found out that faculty members may possess appropriate knowledge in certain area of the OBE implementation but not being practiced. Continuous participation of the faculty members in training and seminars is highly encouraged to provide them updates of the OBE process. Faculty members with high level of knowledge and understanding on the implementation of OBE have also higher possibility to contribute in the realization of the objectives of OBE through practice.

Research Methodology

Questionnaire Design: Structured close ended questionnaire has been used to collect data for the research. The questionnaire was developed based on literature review and objectives of the research. It takes into account the major components of OBE i.e. PO, CO, Pedagogy and Assessment.

The data is analyzed using both descriptive & inferential statistics

The study uses Convenience sampling method for data collection and data was collected based on the availability and willingness of the respondents.

Objectives:

Objective 1: To assess the knowledge of OBE amongst the faculties (Mgt & Engg)

Objective 2: To understand if OBE quotient differs with Gender and Age.

Objective 3: To understand the relationship between knowledge of OBE and acceptance/Reluctance of Teachers towards implementing/practice of OBE

Objective 4: To analyse the impact of OBE on teaching effectiveness of Faculty members.

Prominent Variables used in the research: OBE literacy quotient: OBE literacy quotient is the extent of knowledge pertaining to OBE concept and practices.

Items related to assess the OBE Quotient:

1. I have the conceptual knowledge of OBE.
2. I have gained the knowledge of OBE through the Seminars/Workshops/Self study
3. I understand how the Program Outcomes and Program Educational Outcomes of the College were formulated
4. I am aware of the process to formulate Course Outcomes using Bloom's Taxonomy
5. I understand the relationship between Course outcomes and Program outcomes.
6. I have clear understanding on how to do the OBE assessment
7. I understand the use of the direct assessment techniques in assessing the course outcomes.
8. I can assess the students by using Activities, Exercises, Projects, assignments to attain the course outcomes.
9. I understand the principle of making and using the rubrics for assessment.
10. I am ready to apply the OBE curriculum in the delivery of my instructions
11. I have used different techniques related to OBE in the delivery of my instructions
12. I was involved in implementing OBE at my college/ institute.

13. I understand the difference between PO, PSO, PE and GA
14. I can comfortably map COs with POs.
15. I can measure attainment of my course.

Teaching Effectiveness: Teaching Effectiveness is the result of the application of OBE practices and getting a positive evident learning outcomes.

Items related to Teaching Effectiveness: I find the students more engaged.

The students are able to think out of box.

The Teaching-Learning has become two way interactive process.

Higher order thinking skills of the students have improved

Clear teaching objectives and predefined expectations have inspired students to become creative and innovative thinkers.

Students understand WHY they are learning.

Increased student involvement allows students to feel responsible for their own learning

Students gained real world experience

Students are able to recall and implement/execute the concept.

Students are inspired and motivated about the subject

Hypothesis 1:

Context: The concept of OBE was first adopted in Engineering Colleges in India soon after India became a signatory member of Washington accord and later percolated to the various programs. So the researchers found it imperative to find if there was any difference in the OBE knowledge of the faculties in Management and Engineering colleges.

Ho1: There is no significant difference between the OBE Literacy Quotient of Various faculties of technical education (Engineering, Management)

Ha1: There is a significant difference between the OBE Literacy Quotient of Various faculties of technical education (Engineering, Management)

Hypothesis 2:

Context: It is well established from the Literature review that OBE knowledge is the need of the hour. But merely having knowledge will not suffice. So it was essential to explore the relationship between OBE quotient and acceptance of the faculties/teachers to implement the OBE practices in their classroom.

Ho2: There is no significant relationship between knowledge and acceptance of Teachers towards implementing/practice of OBE

Ha2: There is significant relationship between knowledge and acceptance of Teachers towards implementing/practice of OBE

Hypothesis 3:

Context: The employability of the students will enhance only if the teaching is effective especially if the students are able to apply the concepts taught by the teachers. Thus it was necessary to explore whether there exists any relationship between OBE literacy quotient and teaching effectiveness.

Ho3: Teaching effectiveness is independent of OBE literacy quotient.

Ha3: Teaching effectiveness is dependent on OBE literacy quotient.

Sample Size: 75 faculty members of Engineering & Management institutions (across Maharashtra).

Data Analysis & Interpretation

Descriptive and interferential statistics have been used, by applying SPSS 21 software package. Descriptive statistics have been used for summarizing the data to draw a meaning from the data.

Mean & Standard Deviation were computed to describe all the variables and Cronbach's Alpha test was performed to check the reliability of the data.

Reliability Statistics: Inferential statistics have been used for testing the hypothesis and drawing conclusions. T-Test was used to generalize the results of the sample for the complete population.

Analysis 1:

Test of normality

Shapiro-Wilk Test of Normality: To assess whether the data is normally distributed, Shapiro-Wilk Test of Normality is used for both data collected from Members of Faculty. The test reveals whether sample data are drawn from a normally distributed population or not.

Table 1: Applying Shapiro-Wilk test of normality to mean values determined and results obtained

Tests of Normality							
	Teaching in	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
		Statistic	df	Sig.	Statistic	df	Sig.
OBE quotient	MBA	.150	47	.010	.947	47	.033
	ENGG.	.144	25	.195	.949	25	.235

The statistical value (p value) for the data is .235. Assumed level of significance is .05. Since the *p* value is greater than .05 (p>.05) the results are significant which means that the data is normally distributed.

Analysis 2:

OBE Quotient:

Table 2: The OBE quotient was calculated and the mean score was found as under:

Independent Samples Test										
		Levene's Test for Equality of Variances		t-test for Equality of Means						
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
									Lower	Upper
OBE literacy Quotient	Equal variances assumed	.614	.436	.462	73	.646	.06276	.13596	-.20820	.33372
	Equal variances not assumed			.491	60.670	.625	.06276	.12772	-.19267	.31819

The significance value is greater than .05, which means that the null hypothesis is accepted. There is no significant difference between the OBE Literacy Quotient of Various faculties of technical education (Engineering, Management).

Independent Sample T-test was used to study the difference in the understanding of OBE by gender & Age of Members of Faculty (Teachers).

Analysis 3:

Table 3: Understanding of OBE differs by gender

Independent Samples Test										
		Levene's Test for Equality of Variances		t-test for Equality of Means						
		F	Sig.	t	df	Sig. (2-tailed)	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
									Lower	Upper
OBE literacy Quotient	Equal variances assumed	.614	.436	.462	73	.646	.06276	.13596	-.20820	.33372
	Equal variances not assumed			.491	60.670	.625	.06276	.12772	-.19267	.31819

Independent sample test was conducted to generalize the results of the sample for the population. The results show that understanding of male members of faculty (3.88) did not show statistically significant difference to the understanding of female members of faculty (3.81), t (75) =.462, p = .646

Results are significant when calculated p value is less than assumed p value. Since $p > 0.05$, the null hypothesis is accepted & hence we conclude that understanding of OBE does not differ by gender of members of faculty.

Analysis 4:

Table 4: Different age groups shows different levels of OBE understanding.

Descriptives				
OBE quotient				
	N	Mean	Std. Deviation	Std. Error
20-30	8	3.55	.5574	.19710
30-40	31	3.711	.5857	.1052
40-50	27	4.068	.4878	.0938
50+	9	4.000	.4386	.14620
Total	**75**	**3.8578**	**.5573**	**.0643**

A Turkey Post hoc test revealed that the group with experience of 40-50 years showed higher level of understanding compared to 20-30 years & 30-40 & 50 above groups.

The graph clearly shows that members of faculty with experience between 40-50 years shows higher level of understanding of OBE compared to other members of faculty from the other two groups.

Analysis 5:

Table 5: Relationship between knowledge (OBE literacy quotient) and acceptance of Teachers towards implementing/practice of OBE

Correlations			
		OBE quotient	**Acceptance for practice of OBE**
OBE literacy quotient	Pearson Correlation	1	.293*
	Sig. (2-tailed)		.011
	N	75	75
Acceptance for practice of OBE	Pearson Correlation	.293*	1
	Sig. (2-tailed)	.011	
	N	75	75

*.Correlation is significant at the 0.05 level (2-tailed).

The p value is 0.011)which is less than 0.05, it means that we reject the null hypothesis and the correlation is significant and looking at the correlation quotient (r=0.293) the value of r is positive which means that there is a positive correlation between OBE Quotient and Acceptance of the Teachers to implement OBE practices.

Table 6: Interpretation

	Alternate Hypothesis	**Statistical Tool**	**Interpretation**
Ha1	There is a significant difference between the OBE Literacy Quotient of Various faculties of technical education (Engineering, Management)	T-test	The null hypothesis is accepted. There is no significant difference between the OBE Literacy Quotient of Various faculties of technical education (Engineering, Management)
Ha2	There is significant relationship between knowledge and acceptance of Teachers towards implementing/practice of OBE	Bi Variate Correlation	The alternate hypothesis is accepted
Ha3	Teaching effectiveness is dependent on OBE literacy quotient.	Bi Variate Correlation	The alternate hypothesis is accepted

Conclusion

The findings have demonstrated that some of the faculties lack the understanding of OBE which leads to monotonous teaching and less teaching effectiveness. It is a well-established fact that OBE is the need of the hour considering the fact that traditional education system is yielding unemployable youth due to a wide gap between the theory taught & practical knowledge required[6,7]. Members of faculty have also depicted low level of understanding of OBE which in turn leads to inadequate application of the concept in the education system and reluctance to implement OBE. The findings of the study also suggests that there is a clear linkage between Understanding the concept of OBE,Implementation of OBE in classroom teaching and Effectiveness in teaching. Proper training programs should be organized for the teachers in all technical programs.

Impact of Outcome Based Education (OBE) on Teaching Effectiveness of Faculty Members of Professional Program

Vaishali Rahate[1], Sujit Metre[2], Ranjit Ambad[3], Swapnil Bhirange[4]

[1]Associate Professor, Datta Meghe Institute of Management Studies, Nagpur, [2]Principal, Shree Binzani City College, Nagpur, [3]Associate Professor Dept. of Biochemistry Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Nagpur, [4]Assistant Professor Dept. of Physiology Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

The growth and development of a country relies heavily on the Higher education which powers the supply of skilled and technologically advanced manpower.

Outcome based education is potentially successful curricular innovation for educational institutions as it not only overcomes the lacuna of traditional learning process but also it has the advantage of being future driven. OBE aims at assessing the learners on understanding, critical thinking, reasoning, reflection and action. It aims at ensuring that the students have an integration of knowledge and learning relevant and connected to real-life situations. Looking at the growing importance of Outcome based Education (OBE), This study is conducted to find the OBE literacy quotient of the faculty members in Management & Engineering colleges. A preview is generated with respect to the acceptance and/or reluctance of faculty members towards implementing OBE practices. The study also postulates the relationship between OBE knowledge and teaching effectiveness.

The data is analyzed through descriptive and inferential statistics.

The outcome of the research would be significant for the policy makers and administrators in determining the means to improve quality of education by proper implementation of OBE practices.

Keywords: *Outcome based Education (OBE), OBE literacy quotient, teaching effectiveness.*

Introduction

Looking at the fast changing global environment, it has become imperative to make changes accordingly in the teaching learning process. The regulatory bodies in India had proposed the outcome based education format earlier for the Engineering and Medical Institutions and now have percolated the policies in all the educational institutions[1].

It is a task to change the mindset of the teachers who have been following the traditional classroom instructional pedagogy for years together. Thus there is a necessity to create awareness, train the faculty members, motivate them to design activities which targets towards the outcomes. The role of the teacher has to be changed from merely a instructor to a facilitator. Active learning rather than passive learning is the need of the hour for the students to sustain in the competitive world[2,3].

According to Pretorius (1998) and Genis (1997) OBE is a system that is relevant and appropriate to address future needs in a better manner compared to traditional approach. It also intend to implement the changes in technology and work environment more effectively[4].

A to Z Activities for Engaging School Going Children During Lockdown

Archana Dhok[1], Devendra Punewar[2], Ranjit Ambad[3], Lata Butola[4]

[1]Professor and HOD Dept. of Biochemistry Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences Sawangi Meghe Wardha-442001, [2]Branch Manager Nipon Mutual Fund Indore, [3]Associate Professor Dept. of Biochemistry Datta Meghe Medical College, Shalinitai Meghe Institute of Medical Sciences, Nagpur-441110, [4]Tutor Dept. of Biochemistry Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences Sawangi Meghe Wardha-442001

Abstract

Pandemic of Novel Corona Virus disease is rampant and self-isolation or quarantine is one of the core strategies in flattening the curve of infection rates. It means that schools are going to be closed for relatively longer time. Such thought of staying at home with kids during the lockdown has built up a certain amount of stress and anxiety among parents. For them, it has become essential than ever to spend time with their kids and plan their day. Parents are suddenly getting confused for resources to keep their kids engaged in productive activities. With schools shut, children are also bound to feel more agitated and confused than ever, causing them to react in ways that may be new for parents. As such, it becomes important for parents to strike a balance between work and spending time with their kids, and understanding the ways in which the lockdown experience can be made simpler and healthier for the entire family.

Keywords: *Pandemic, quarantine, skill development, Covid-19.*

Introduction

The government of India Initially has declared a total lockdown, in the wake of Covid-19 pandemic, for 21 days which has extended further. Even the most tolerant people will have their limits tested as they are forced to stay indoors. Parents are wondering about lockdown activities to keep kids occupied[1,2,3]. Children are the most vulnerable section of society right now as schools across the country are closed and they are forced to be at home day in and day out. They dislike staying indoors too long and like to go out and play and interact with their mates. It is, therefore, the responsibility of the parents to keep children engaged during lockdown with productive quarantine activities. Zafirakou says it is important to limit screen time while children are learning at home[4,5.]

This can be done by engaging them in activities that are fun learning opportunities.

Ensure that the play area is hygienic and safe for your kid to plays alone there. Kids can be supervised through CCTV Camera.

Here are A to Z activities to keep kids busy during lockdown:

A. Art and Craft: By involving your kids in art and craft, you will not only be helping them pass the time easily but also be giving wings to their creativity. By making easy and simple craft projects helps the children to sharpen their artistic talents and whet their minds. Provide them lots of craft supplies such as paper sheets, glue, tapes, kid-friendly scissors, glitter, craft kits, etc. for setting up a creative space. Encourage your kid to create something new every day using those supplies.

Dr. RanjitAmbad
Associate Professor Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Institute of Medical Sciences, Nagpur-441110

B. Build with Lego: Lego toys are so popular among children as it gives lot of fun but artfully, they also teach the fundamentals of physics. Start with simpler structures and as your kid begins to get hold of the concept and then move towards more advanced ones. This exercise alone will keep your kid occupied for hours and is perfect for beating boredom.

C. Chat with friends: It's really important for the children to communicate with their friends. Parents can set up online meetings with their children's friends. Not every day, but during the week, there should be some way they are connected with somebody else that's not you, and not another adult. They want their space and parents should allow them to talk with their friends to share their ideas.

D. Do It Yourself: Apart from the most obvious advantage of getting our children away from screens and gadgets, creative projects help children with inspiration, imagination and good motor skills. Getting messy sometimes and creating things is actually as important as outdoor play and reading. It helps to develop bilateral coordination, Fine motor skills,and Self regulation. It acts as a esteem booster and encourage self expression. 1

E. Exercise: A 2019 study published in the journal Proceedings of the National Academy of Sciences found that serotonin, a mood-regulating chemical the body produces, increases during exercise and can boost the energy and also associated with feelings of well-being, heightening of appetite, and lessening of mental depression. Combining regular physical activity with a healthy diet is the key to a healthy lifestyle. It should be variety of age-appropriate activities and with fun, so kids will come back for more. 2,3,4

F. Fancy dress celebration: Fancy dress also helps children develop emotionally, being a channel where children can freely express themselves. It also helps children communicate with others, and by playing the characters that they love they learn control their emotional responses. Fancy dress helps children develop their imagination. You can share these photographs to relatives and friends. 5

G. Gardening: A garden provides the opportunity to make a positive environmental impact. Planting a garden provides enjoyment. Watching your garden go from bare ground to ripe produce or beautiful plants offers a sense of satisfaction. It makes your child responsible and caring. Some gardeners find the activity relaxing and stress-relieving, for overall mental health benefits. Caring for the plants gives the entire family a chance to work together. Gardening also offers a form of moderate outdoor exercise.[6]

H. Helping in household chores: Children can learn a lot many things from doing household chores. Doing chores helps children to care for themselves, a home and a family. They **learn skills** they can use in their adult lives, like preparing meals, cleaning and organizing the home. It helps for easing family stress,and breaking away from gender stereotypes. Being involved in chores also gives children **experience of relationship skills** like communicating clearly, negotiating, cooperating and working as a team. When children contribute to family life, it **helps them feel competent and responsible**. Even if sometimes they don't enjoy it, when they keep on doing they get the feeling of satisfaction that comes with finishing a task[6,7.]

Here are some ideas for chores for children of different ages.

Toddlers (2-3 years):

- Pick up toys and books.
- Put clothes on clothes hooks.
- Set placemats on the dinner table.

Preschoolers (4-5 years)

- Set the table for meals.
- Help put clean clothes into piles for each family member, ready to fold.
- Help with grocery shopping and putting away groceries.
- Hand you wet clothes to be hung out to dry.

School-age children (6-8 years)

- Water the garden and indoor plants.
- Feed pets.
- Clean the bathroom sink, wipe down kitchen benches, mop floors or take out rubbish.
- Help hang out clothes and fold washing.
- Put away crockery and cutlery.
- Help with choosing meals and shopping.

- Help with meal preparation and serving, under supervision.

I. Indoor Games: By playing games, students become more motivated to learn, pay attention and participate in set tasks. Games help students to become a part of a team as well as take responsibility for their own learning. There are so many indoor games like chess, carrom, playing cards, UNO Snakeladder, Ludo and many more .Playing these games with family is really a great joy.[8]

J. Jigsaw puzzles: Jigsaw puzzles exercise the left and right sides of your brain at once. It improves your short-term memory and improves your visual-spatial reasoning. Jigsaw puzzles are a great meditation tool and stress reliever. Starting a jigsaw puzzle and keeping it on a table in your living room or kitchen is an invitation for the whole family to participate, whenever they have a few minutes to sit down and focus. It's a tactic that parents of teens can use for starting a conversation while working toward a shared goal.[9]

K. Kid's Recipes: This quarantine is a great time to teach your little chefs some simple dishes that they can make for themselves. Your child could be next master chef who knows?

If you want to get creative and need a little help, there are plenty of online sources that offer cooking classes and if you're confident in your skills, start your own online account and help others learn as well.

L. Learn a new language: Knowing a secondary or tertiary language can be really beneficial. It will open up new horizons for your kids. With the online world being just a touch away, learning a new language has never been this easy.There are plenty of apps online that teach new languages and are designed in the form of a game so that your children can have fun while learning.

M. Meditation: *Dr. Bryan Bruno, Founder and Medical Director at Mid City TMS explain, "*Meditation is one of the healthiest activities that a parent can do with their child. Meditation affects different parts of the brain, including the parietal lobe. Activity in the parietal lobe slows down during meditation, and children are able to process information more clearly."

Andrea Gurney, Licensed Clinical Psychologist, states "Kids who practice meditation and mindfulness reap a host of benefits, including but not limited to increased focus, self-control, coping strategies, emotional regulation, and better relationships."

These Changes Include:

- Kids feel calmer and can control their emotions better
- Kids have an increased emotional capacity to deal with stressful events
- Behaviour is improved
- Lower levels of depression and anxiety
- Improved memory

N. News Reading: There is a separate section for the kids at one page of newspaper where Sudoku, puzzles,riddles, tongue twister etc are published. These type of mind games helps in improving the vocabulary skills of children. Newspaper reading enhances the vocabulary of students. It is important for students, as early as Kindergarten, to start learning to read and gather information from newspaper. They help students develop daily reading habits that will last their entire lives. Studies have shown that students who learn using newspapers become more active citizens as adults.[10]

O. Online Activity Classes enrollment: Take time and try to understand the interest and hobbies of your kids. Accordingly, you can enroll them in different activity e-classes such as General Knowledge, Art and Craft, music classes, etc. Give them a specific fun task to do to base on what they have learnt in the activity class. This will help to channelize their energy while doing something creative and productive. You can also subscribe to an audio app for children like Audible, where children stories are shared in a fun and engaging way. They can even dance to their favourite songs or take up physical activity e-classes to keep their bodies active. Help your child pick a hobby in which he/she is genuinely interested.

P. Picture Stories: Orbis Pictus from 1658 by John Amos Comenius was the earliest illustrated book specifically for children. It is something of a children's encyclopedia and is illustrated by woodcuts. A Little Pretty Pocket-Book from 1744 by John Newbery was the earliest illustrated

storybook marketed as pleasure reading in English. For young readers, picture books are an important part of learning how to read. The rhythm and rhyme of picture books makes them easy to understand and fun to read aloud, allowing children to learn words quickly.[11]

Q. Quilling: Quilling is the art of rolled, shaped, and glued paper that results in creating a unified, decorative design. The name quilling is thought to come from the origin of the art; birds' feathers, or quills, were used to coil the strips of paper around. Quilling is also a great craft for kids as it teaches them fine motor skills and is a great craft to train their hand-eye coordination.[12]

R. Riddles: Young minds need to be fostered with something that gives them an opportunity to think over. Children are the buds in which we can instill our hopes for a great future. They are the ones that will make the world a better place to live in. Riddles for kids are the best form of solutions that helps to enhance their vocabulary. When you are sharing and solving riddles with children, it gives them an opportunity to bond with you and stay connected. Also, it helps them to break out of their comfort zone and mingle with others.

Riddles can help children form associations, link ideas and think, be creative and make conclusions; all of which are good ways of learning and remembering things quickly and with ease.[13]

S. Story Telling: Storytelling is used as a tool to teach children the importance of respect through the practice of listening. As well as connecting children with their environment, through the theme of the stories, and give them more autonomy by using repetitive statements, which improve their learning to learn competence. Vocabulary, comprehension, sequencing, memory and creative writing are all benefits from storytelling.[14,15]

T. Treasure Hunt: Hide a certain treasure in the house something that your kid will enjoy upon unearthing and lay out some clues to the hidden treasure. It would not only help you and your kid to pass the time during this period of quarantine but will also give you an opportunity to spend some quality moments together. Needless to say, the whole process of searching for clues will sharpen the mental faculties of the kids and help them grow.

Treasure Hunt play is essential to the healthy development of children; play helps them discover and explore, solve problems, test new ideas and experience friendship, cooperation and teamwork.[16]

U. Understanding of the situation: It is very important to explain the current situation to the children. They should understand the need of the lockdown. Parents should explain them what all precautions has to be taken by each of us during this situation. Try to solve the quarries arises in their mind.

V. Video call with relatives: Video conferencing helps to improve communication and re-establish relationships. During a video conference you get to see the body language and facial expressions of the participants. This leads to a more effective and faster collaboration. Modern technology provides new options to stay involved with your family. Video calling is now one of the most effective ways of staying in touch, and making these calls isn't a task that should be overlooked. In fact, it is absolutely vital that you find a way to stay connected.[17]

W. Writing the experience/letter: Online messengers and chat rooms may be the popular mode of communication these days, but nothing beats the charm of a letter. Besides serving as excellent memory archives and having great sentimental value, letters are great for teaching the art of penmanship to your young ones. Letters force the writer to be concise and clear and therefore, improve the thought process and help in developing clear thinking skills. Tell your kids to write their experiences or give them any theme to write.

X. X-mas tree making and decoration: Santaclaus is a favorite character of kids .Ask them to prepare the Christmas tree and decorate it. They would love it. Provide them all necessary things for decoration sometimes many things are available at home only.

Y. Yoga: One of the easiest and healthiest things you can do with your kids is to make them practice Yoga daily. The age-old discipline is great for improving overall health and keeps the energy levels high a necessity during these times!

It is also a great opportunity to teach your children the importance of having good health. If they learn to follow the discipline young, they will stay healthy all their lives.

Z. **Zumba dance:** Zumba Jr. is a great way for kids to have a good time while learning to exercise for an hour. They get a great workout in, meet some fun new friends and learn some hot dance moves while listening to various cultural music artists. Zumba is really fun way to spend quality time together as per the The National Association for Sport and Physical Education. There are so many benefits of zumba for kids.

- Improved Endurance
- Better Body Coordination, Gross Motor Skills & Control Over Their Body
- Teaches kids to incorporate fitness as a natural part of their lives
- Promotes an overall healthier lifestyle
- Develop teamwork respect confidence and cultural awareness

Parents can encourage creativity of children by

Teach them life skills: The most important thing is that now is a really good time to teach children things you want to be done. Not all lessons need to be academic – they can be life lessons we want our children to learn as well. Even how they should fold their clothes, mop up or vacuum. Take an hour out and show them how you want them to do it. Usually, life is very fast, and we have no time for this type of teaching. But they are invaluable skills.

Enjoy family time: In the evening, there should be family time. So everyone's devices go away, every household with children can now guarantee there is going to be family time.

Try and limit screen time: Research has linked screen time with an increased amount of sedentary behavior in children and teens. It is your job to encourage healthy behaviors and limit unhealthy ones sometimes this means making unpopular decisions like limiting your children's screen time. Let's get them reading books, drawing on toilet rolls, cooking, in the garden building things because they can't be the generation that's in front of screens learning, otherwise it will have a huge effect on them.

Proper and regular communication with kids can help them in understanding what is expected out of them during your work hours.

Encourage them to play independently: Train your children to be independent so that they are not always looking for you or someone else to accompany them at all times. This will make them confident and will also allow you to focus better on work. Focus on quality rather than quantity when it comes to spending time with our child. With clear communication and understanding, plan his/her activities for the day or the week.

Share the responsibility: We need to jointly plan and give them that sense of responsibility. It's quite powerful for them to take control of what they'd like to do. And if that's being in their room drawing, then give them that time, make them exhausted from doing that, because they will get bored very soon. And when they want to do other things, that are where, as a parent, you've already got all these resources and ideas ready to go.

Be Patient and Co-operative: There are going to be interesting, diverse scenarios taking place in homes at the moment. Don't get exhausted but calm and quite. Just remember that your children are transitioning as well. We need to use lots of conciliation and give and take. Every parent is concerned because we are taking up a new role here, which we have never had to do before. The positive thing is, we are going to get to know our children more[8,9.]

Quarantine doesn't have to mean boredom. There are plenty of activities that you can organize for your children which will not only keep them from getting bored but will also help them grow.

Stay positive, productive and proactive!

Yoga Helps to Improve Immunity & Fight Against Infection During Covid19

Pravin Pande[1], Vaishali Tendolkar[2], Shaini Suraj[3], Ashish Anjankar[4]

[1]Assistant Professor, Medical Surgical Nursing Dept, Dmcon, [2]Professor, Mental Health Nursing Dept, Dmcon, [3]Counsellor, Dmcon, [4]Associate Professor Dept. Of Biochemistry Jawaharlal Nehru Medical College, Datta Meghe Institute Of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Corona is a pandemic disease but other than the corona also so many viruses and organisms effect on the respiratory system and harm on immune system of the body. Yoga plays a important role in the life. Yoga, perhaps, is one amongst the foremost effective and tried resistance boosters that we will adopt for a healthier life. Yoga could be a holistic follow that strengthens our body physically similarly as mentally. As a result, the body's defense conjointly improves in such a condition. A healthy life may be simply achieved if we have a tendency to learn to adopt a healthy modus vivendi, healthy food decisions and regular follow of yoga and meditation. Ayurveda, yoga, and meditation square measure the perfect factors to measure a healthy life. Surya Namaskar or Sun Salutation could be a sequence of twelve powerful yoga poses. Besides being an excellent vas physical exercise, Surya namaskar includes all 12 asanas and it will help to the growth of the physical body as well as mental peace. Surya Namaskar is additionally legendary to possess an associate vastly positive impact on the body and mind.

Keywords: *Corona, Yoga, Asanas, Pranayama, Surya Namaskar.*

Introduction

Corona is a Pandemic disease but other than corona also so many viruses that effects on the respiratory or the immune system of the body. A virus infects the body by getting into healthy cells. There, the encroacher makes copies of itself and multiplies throughout your body. The new coronavirus latches its high-pitched surface proteins to receptors on healthy cells, particularly those in your lungs. Specifically, the infective agent proteins bust into cells through ACE2 receptors. Once within, the coronavirus hijacks healthy cells and takes command. Eventually, it kills a number of healthy cells[1].

Coronaviruses square measure an oversized family of viruses that square measure common in folks and lots of totally different species of animals as well as camels, cattle, cats, and bats. Rarely, animal coronaviruses will infect folks and so unfold between folks like with MERS-COV, SARS-COV, and currently with this new virus (named SARS-COV-2).

The globe Health Organization declared an official name for this malady that's inflicting the 2019 novel coronavirus eruption, 1st known in the city, China. The new name of this malady is coronavirus malady 2019, abbreviated as COVID-19. In COVID-19, "CO" stands for "Corona", "VI" stands for "Viruses" and "D" for "Disease".There square measure many sorts of human coronaviruses as well as some that unremarkably cause delicate higher tract malady, like coronaviruses 229 E, NL 63, OC forty-three or HKU1 however SARS-COV-2 could be a new strain of coronaviruses that haven't been antecedently known in humans[2,3.]

The Clinical spectrum of COVID-19 ranges from delicate malady with non-specific signs and symptoms of acute respiratory disease to severe respiratory disorder with metabolic process failure and septic shock. There have conjointly been reports of symptomless infection with COVID-19. Current estimates of the time period vary from one to fourteen days, in step with the WHO and therefore the America Centers for malady

management and precautions. The median time period has been calculable to be five days. Transmission is also potential throughout the time period[4].

Virus Effects on Respiratory System: The virus moves down your tract. That's the airway that features your mouth, nose, throat, and lungs. Your lower airways have additional ACE2 receptors than the remainder of your tract therefore COVID-19 is additional doubtless to travel deeper than viruses just like the cold lungs may become inflamed, creating it robust for you to breathe this will result in respiratory disorder, associate infection of the small air sacs (called alveoli) within your lungs wherever your blood exchanges chemical element, and carbonic acid gas[5].

Yoga: Yoga plays an essential role in our life, word yoga was derived from the Sanskritic language word Yuj which suggests 'to join' or 'to unite'. This union isn't, merely, concerning your nose touching your knees as you bend to the touch your toes! The union spoken is that of your mind together with your body. You integration together with your surroundings and nature. And, finally, your individual consciousness with the universal consciousness.

The earliest recorded mention of the word 'yoga' is within the ancient Indian text, the Rig sacred writing - this body of data dates back to around 1500 BC! within the Atharva sacred writing, once more (dating to 1200-1000 BC), there's a mention of the importance of the management of breath. it's tough to pinpoint precise dates as a result of within the starting, the Vedas were, only, orally passed on from one generation to a different. Written records came to a lot of later.

Lord Mahavira and Lord Buddha's teachings shaped the first basis for Yoga Sadhana. whereas Lord Mahavira spoke of achieving salvation and freedom through meditation, Lord Buddha spoke of specific postures and meditation to realize enlightenment.

The most powerful Granth Bhagavad Gita conjointly came into existence during this amount. This text could be a dialogue between Lord avatar (universal consciousness) and aristocrat mythical being (human consciousness). Here, the Lord explains the ideas of Hindu deity, fate yoga (generous actions), devotion yoga (dedicated and caring actions), and Jnana yoga (knowledge)[6,7].

Maharshi Patanjali, thought-about the daddy of Yoga was the primary one to order the practices of yoga in, what's believed to be, the second century B.C.. Through his Yoga Sutras, he disseminated the means of yoga, and therefore the data it's to supply. This yoga was referred to as Raja yoga. He developed the Astanga yoga or the eight limbs of yoga, including yamas, niyamas, asanas, pranayama, pratyahara, Dharana, dhyana, and samadhi.

The idea of victimization yoga for treatment of diseases, fitness and to realize freedom from stress could be a fashionable, and rather, superficial perspective. In the past, yoga wasn't simply a method to get rid of diseases as an example, the stress on hygiene and cleanliness was a gift in the past similarly. But, this failed to talk over with solely brushing, laundry, and general morning ablutions. It enclosed keeping your mind, and by extension, your thought method conjointly, pure and clean. In different words, it junction rectifier to all-around well-being[8].

Yoga–The Resistance Booster: As the season's amendment, the possibilities of falling sick rise sharply. It's tough for our body to stay the pathogens unfree once the immunity levels square measure down and folks around America square measure sneeze and coughing. tho' we have a tendency to cannot shun from being connected with people who square measure sick, we will definitely work our thanks to strengthening our defense.

Antibiotics and different medicines do facilitate the body pass through the malady however they don't facilitate improve the body's immunity. Yoga, perhaps, is one amongst the foremost effective and tried resistance boosters that we will adopt for a healthier life it's an associate ancient art that strengthens the body and conjointly relaxes the mind. Let's have a glance at a number of easy yoga poses which will assist you to place up a robust resistance consequent time influenza season comes around:

Yoga could be a holistic follow that strengthens our body physically similarly as mentally. As a result, the body's defense conjointly improves in such a condition. A healthy life may be simply achieved if we have a tendency to learn to adopt a healthy modus vivendi, healthy food decisions and regular follow of yoga and meditation. Ayurveda, yoga, and meditation square measure the perfect factors to measure a healthy life[9].

Yoga isn't an alternative to medicines however rather a preventative live to stay diseases unfree. So,

let's not wait for this point for influenza to return knock at our door however rather beat it with ease.

Surya Namaskar: Surya Namaskar or Sun Salutation could be a sequence of twelve powerful yoga poses. Besides being an excellent vas physical exercise, Surya namaskar includes all 12 asanas and it will help to the growth of the physical body as well as mental peace. Surya Namaskar is additionally legendary to possess an associate vastly positive impact on the body and mind.

Surya Namaskar is best done early morning on an associate empty abdomen every spherical of Sun Salutation consists of 2 sets, and every set consists of twelve yoga poses you may realize many versions on the way to follow Sun Salutation. However, it's well to stay to 1 explicit version and follow it often for best results. Besides healthiness, Surya Namaskar conjointly provides a chance to precise feeling to the sun for sustaining life on this planet.

12 Steps of Surya Namaskar (Sun Salutation): Surya Namaskar (Sun Salutation) consists of twelve totally different postures. These 12 asanas are more beneficial for to improve the immunity and protect from infection and helpful for the physical growth.

Daily atleast 20 sryanamskar for beginner and more than 100 also performed by trained person.

1. **Pranamasana (Prayer Pose):** Pranamasana is that the 1st posture within the yoga sequence. To accomplish this create, stand upright on your mat and make sure that your feet square measure placed getting ready to one another. Next, take a deep breath, expand your chest, and relax your shoulder throughout inhalation, raise your arms from the facet and whereas eupnoeic be a part of each your palms along as if you're praying. The prayer posture or 1st salutation is complete.
2. **Hasta Uttanasana (Raised Arms Pose):** Ensure that your palms square measure joined along, a bit like within the previous prayer creates. Take a deep breath, elevate your arms, and slightly bent backward. Your striated muscle should keep getting ready for your ears.
3. **Hasta Padasana (Standing Forward Bend Pose):** Breathe out and bend forward from your waist. attempt to bit the ground together with your hands. However, make sure that your spine remains straight. whereas performing arts this creates, you must exhale slowly and completely.
4. **Ashwa Sanchalanasana (Lunge Pose):** Bend your knees slightly, in order that the palms will rest on the ground beside your feet. Take a deep breath, bring your right knee towards the proper facet of your chest, and stretch your left leg backward. Raise your head and appearance forward.
5. **Chaturanga Dandasana (Plank Pose):** Inhale and produce your right leg back similarly currently each your hands are right below your shoulders make sure that your body is parallel to the bottom.
6. **Ashtanga Namaskara (Eight boughed Pose):** This is conjointly spoken as salutations victimization eight points or elements. once performing arts Chaturanga Dandasana, exhale and slowly bring your knees down toward the ground. Rest your chin on the ground and keep your hips suspended within the air. If done properly, each of your hands, knees, chin, and chest can rest on the bottom whereas your hips can stay suspended within the air.
7. **Bhujangasana (Cobra Pose):** Rest your legs and midriff flat on the bottom. Position your palms beside your chest. Inhale and apply pressure on the hands to lift your higher body. At this time, your head and body part can gibe an elapid with a raised hood.
8. **Adho Mukha Svanasana (Downward Facing Dog Pose):** Keep your palms and feet wherever they're. Exhale and gently elevate your hips, in order that the body forms associate inverted 'V'. Straighten your elbows and knees. Look toward your navel.
9. **Ashwa Sanchalanasana (High Lunge Pose):** After performing arts Adho Mukha Svanasana, return to Ashwa Sanchalanasana by conveyance your right foot forward. Keep your left leg stretched behind you and appearance forward.
10. **Hasta Padasana (Standing Forward Bend):** Inhale and produce your left foot forward, specified it's next to your right foot. Keeping the position of your hands intact, exhale, and slowly bend your body part to enter into the Hasta Padasana create.
11. **Hasta Uttanasana (Raised Arms Pose):** Inhale and elevate your higher body. be a part of the palms and lift your arms on top of your head. Then bend backward as you probably did in step a pair of.
12. **Pranamasana (Prayer Pose):** This is the last step.

take a breath and stand straight during a relaxed manner. Lower the arms and hold your palms before your chest. This marks the top of the primary set of Surya Namaskar.

Benefits of Suryanamaskar: The benefits of Surya Namaskar square measure manifold. It helps in the higher functioning of the body and mental colleges. Here square measure a number of edges of Surya Namaskar:

- The postures square measure the right mix of warm-ups and asanas
- It helps to stay you disease-free and healthy
- Regular follow promotes balance within the body
- Improves blood circulation
- Strengthens the center
- Tones the gastrointestinal tract
- Stimulates abdominal muscles, Respiratory, vascular system, spinal nerves and different internal organs
- Tones the spine, neck, shoulder, arms, hands, wrist, back and leg muscles, thereby promoting overall flexibility
- Psychologically, it regulates the link of body, breath, and mind, so creating you calmer and boosting the energy levels with a sharpened awareness

Surya Namaskar is additionally vastly helpful for losing weight, tending, and hair care.

Benefits of Surya Namaskar for weight loss:

- It is an associate intensive workout that works on each a part of the body
- You will increase the number of rounds slowly and watch the pounds begin to disappear. The bends and stretches assist you to lose adipose tissue equally

Benefits of Surya Namaskar for hair:

- Surya Namaskar improves blood circulation to the scalp, thereby preventing hair loss
- The hyperbolic blood circulation nourishes the top and permits healthy hair growth
- Different poses facilitate stop graying of hairBenefits of Surya Namaskar for glowing skin
- Surya Namaskar improves blood circulation to any or all elements of the body, so keeping the skin young
- It will increase energy and vitality, thereby creating your face glow with radiance. This helps the skin retain its firmness
- Surya Namaskar prevents the onset of wrinkles by relieving the body and mind of stress

Supplementation of Vitamin D in Diabetic Patients

Rakesh Kumar Jha[1], Ankita Kondhalkar[2], Pradip Jain[3] Mrs. Lata Kanyal Butola[4]

[1]Tutor, Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Medical College and Hospital, Nagpur, [2]Research Scholar Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Nagpur, [3]Professor and HOD Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Medical College and Hospital, Nagpur, [4]Tutor Dept. of Biochemistry Jawaharlal Nehru Medical College, AVBRH [Datta Meghe Institute of Medical Sciences] Sawangi, Wardha

Abstract

Background: Nearly 30 percent to 50 percent of people are estimated to have deficiency of vitamin D, and insufficiency and vitamin D deficiency are recognized as global health issues in the world. Although the presence of hypo-vitamin D raises the risk of rickets and fractures, higher levels of vitamin D are also associated with hypertension (HTN), cardiovascular disease (CVD) and cancer. In addition, the vitamin D levels are also associated with diabetes mellitus (DM) and chronic kidney disease (CKD). Deficiency of vitamin D was linked to DM induction and progression. While the relationship between vitamin D and insulin secretion, insulin tolerance, and β-cell dysfunction is highlighted in patients with DM, evidence of vitamin D and DM levels is inconsistent, and well-controlled studies are required.

Aim: Supplementation of vitamin D in diabetic patients.

Material and Method: The study included 50 patients were given vita D supplement and 50 subjects were not given vita D supplement in diabetic people as the control group. Directly Observed Treatment in the Department of Clinical Biochemistry, Datta Meghe Medical College, SMHRC, Nagpur in collaboration with JNMC, ABVRH (Datta Meghe Institute of Medical Sciences Deemed To Be University), Sawangi, Wardha, Maharashtra.

Conclusion: This study evaluated that vitamin D supplementation can improve HbA1c, insulin resistance, and insulin in short-term intervention in T1DM & T2DM patients, suggesting that vitamin D can be considered as a therapeutic agent along with the other T1DM & T2DM treatments. The findings show that in non-additional diabetic patients, vit D concentration was substantially lower than the additional diabetic individuals.

Keywords: *Vitamin D,HbA1c,CKD, T1DM & T2DM.*

Introduction

Diabetes mellitus [DM] is one of the most common disease around the world, and their occurrence continues to increase[1]. Type 2 diabetes is portrayed by weakened pancreatic b-cell function, insulin resistance, and systemic inflammation [2] and there is proof that vitamin D regulates these mechanisms.[3] Vitamin D may directly affect β-cell function mediated by binding of the circling dynamic structure, 1,25-dihydroxyvitamin D [1,25(OH)2D], to the vitamin D receptor, which is expressed in pancreatic β-cells [4,5].

Low vitamin D levels have been recognized globally as a major health issue. Current literature provides evidence that hypovitaminosis D is associated with different health conditions, including bone health,

Mobile: 9082126696

cardiovascular disease, hypertension, cancer risk and diabetes mellitus. In particular, higher prevalence of low serum vitamin D [25-(OH)D] levels was observed in patients with type 2 diabetes whereas higher levels of vitamin D [25-(OH)D] were associated with lower risk of type 2 diabetes (T2DM)[6,7].

The International Diabetes Federation reports that there are about 285 million people with diabetes worldwide, or 7 per cent of the world's population. This figure is projected to reach 435 million by 2030.[7] An estimated 79 million people in the United States have pre-diabetes[7,8].

The following are recommendations for vitamin D in the DRIs developed by the Food and Nutrition Board at the Institute of Medicine. DRI is the general term for a set of reference values used to plan and assess the nutrient intake of healthy people.

Table 1: Current DRI Recommendations for Vitamin D[9]

DRIs for vitamin D	
Infants	
0–6 months	AI: 400 IU [10 µg/day]
7–12 months	AI: 400 IU [5 µg/day]
Children	
12-36 Months	600 IU [15 µg/day]
48 to 96 Months	600 IU [15 µg/day]
Older Children and Adults	
9 to 70 years	600 IU [15 µg/day]
Adults > 70 years	800 IU [20 µg/day]
Pregnancy and lactation:	600 IU [15 µg/day]

Material and Method

50 diabetic patients who referred to the clinics of Department of Clinical Biochemistry, Datta Meghe Medical College, SMHRC, Nagpur in collaboration with Jawaharlal Nehru Medical College, AVBR Hospital Sawangi, Wardha were selected as case group and 50 healthy subjects [as control group] were evaluated. Inclusion criteria were patients whose diabetes was confirmed and were between 30-60 years old and agreed to participate in this study. Exclusion criteria were: use any drugs consisting of vitamin D, any disorder except diabetes such as osteomalacia, osteoporosis, inflammatory rheumatism and patients treated with corticosteroids, using drugs which interfere with vitamin D metabolisms such as carbamazepine, phenobarbital, sodium valporate, gabapentin, isoniazid, mineral oil and calcitonin. The control group was selected as the normal population subjects.

According to season changes in Vitamin D level, all samples were collected in one season. Vitamin D level was measured with quantitative ELISA. Vitamin D deficiency was defined as serum 25(OH) D concentration of less than 20ng/ml, insufficiency as 20ng/ml <25(OH) D<30 ng/ml and sufficiency was defined as 25(OH) D higher than 30 ng/ml. The data were collected and analyzed. To determine the differences in vitamin D levels, in both groups we used t-test. A p-value less than 0.05 were considered significant.

Result

25 males and 25 females were enrolled in each group. The mean concentration of vit D in diabetic patients was 15.7±9.5 ng/dl and in the non supplementary diabetic patients was 12.2±6.5 ng/dl. The mean concentration of vit D in diabetic male patients was 10.04±6.4 and in non supplementary diabetic male patients was 8.23±2.6 ng/dl (p=0.219). The mean concentration of vit D in women with diabetes was 11.3±7.3 and in non supplementary diabetic women was 9.03±2.28 ng/dl.

Table 2: Vit-D levels in the case and in the control group

	Supplementary Diabetic Patients [study group]	Non Supplementary Diabetic Patients [control group]
Male	10.04±6.4 ng/dl	8.23±2.6 ng/dl
Female	11.3±7.3 ng/dl	9.03±2.28 ng/dl
Total	**15.7±9.5 ng/dl**	**12.2±6.5 ng/dl**

In the non supplementary diabetic group [control group], 34 patients had a deficiency of Vit-D, 10 patients with insufficiency of vit D and 6 patients had sufficiency of vit D.

Discussion

The results of this study showed that there was a statistical difference between vit D concentration in supplementary diabetic patients and the non supplementary subjects. Insufficiency of vit D in two groups also had higher prevalence[7,10,11].Need et al. showed that the patients who had higher levels of vit D concentration had lower FBS in comparison with

the other groups. These results were similar to our findings[11].

Other study that was performed by Daga et al. in the North of India demonstrated that 91.1% of diabetic patients had vit D insufficiency. In their study vit-D concentration in diabetic patients was 7.88±1.2, however, in non-diabetic individuals, it was 16.64±7.83. Different diets in two groups were considered this difference. [12]

Gagnon et al. found that the mean serum concentration of vit D in diabetic patients was lower than the non-diabetic individuals[12,13]. These results were almost similar to the findings of our study.

The weakness of this study is that we did this study only in one season and because of sunshine duration difference in each season level of vitamin D may undulate during the year, so this study cannot predict the condition of hypovitaminosis in this area.

Conclusion

Our findings demonstrated that vit D concentration in non supplementary diabetic patients was significantly lower in comparison to supplementary diabetic individuals. According to the high prevalence of vit D deficiency in this group, treating with vit D supplements maybe useful and seems to be necessary.

Rasaushadhi (Herbomineral Formulations) Induced Nephrotoxicity in Children: Safety Concern Case Series

Rekha V Shinde[1], Ranjit Ambad[2], Pradip Adhav,[3] Praful Fadanvis[4], Swarupa Chakole[5]

[1]Assistant Professor, Dept. of Kaumarbhritya, Datta Meghe Ayurvedic Medical College, Hospital and Research Centre, Nagpur 440034, [2]Associate Professor, Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Medical College and Hospital, Nagpur, [3]Associate Professor, Dept. of Surgery, Bhausaheb Mulak Ayurvedic College, Butibori, Nagpur, [4]Associate Professor, Dept. of Shalyatantra, Datta Meghe Ayurvedic Medical College, Hospital and Research Centre, Nagpur, [5]Professor Dept. of Community Medicine Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Background: Use of Rasaushadhi (Herbomineral formulations) in children is sensible topic. In last decade, some articles reported in various newspapers about nephrotoxicity of Ayurvedicherbomineral medicines. These issues create negative impression regarding the use of Ayurvedicherbomineral medicines. Ayurveda itself a time tested life science and provide guidelines to stay healthy and preserve the health. Such articles have done considerable damage to the reputation of ayurveda but at same time, it has raised many questions which need to be addressed. To make system more scientific and evidence based study was conducted at Paediatric department of Government institute in 2017. Paediatric department in this institute has used Rasaushadhi in children several times and not noted any problem regarding nephrotoxicity till date.

Aim: Question: Does Rasaushadhi (Herbomineral formulations) cause Nephrotoxicity in children? To determine Rasaushadhi (Herbomineral formulations) is "safe" study was conducted.

Materials and Method: Study was conducted for recurrent and reactive respiratory illness in children and herbomineral five drugs regimen was given to children of age 4 to 14 years for 45 days at 15 days interval. To rule out Nephrotoxicity after the use of Ayurvedicherbomineral formulations kidney function test was done. Patients were clinically observed in 4 follow ups, each follow up was conducted every 15 days. Last (Fourth) telephonic follow up was taken after six months of completion of treatment course to observe any renal obstructive pathology.

Results: Total 13 patients of case series were observed normal kidney function test reports. Last (Fourth) telephonic follow up was also reported normal, no any renal complications reported.

Conclusion: This clinical case series found that use of Ayurvedicherbomineral medicines in paediatric patients is safe and there is no relation with nephrotoxicity or any obstructive renal pathology when used properly.

Introduction

Ayurveda is not a belief or faith based system. Charakasamhita defines a theory as a conclusion only once it has been established after several investigations in several ways and forms logic.[1] Rasashastra is a science of minerals aimed at intensively processing

and converting them into biomineral substances, to make them compatible for humans and to use them in an efficient and safe manner for medicinal purposes. Rasaushadhi's have 3 characteristics attributes-

1. Instant effective,
2. Requirement of very small dose,
3. Extensive therapeutic utility irrespective of constitutional variation.[2]

'Alpamatropayitwaat Arucera Apraangataha.

Kshipram Arogyadayitwat Ayushodyebhyo Adhiko Rasaha'.

(Vagbhata Rasaratnasamuchyaya.28/1, 1976a).

Rasashastra appeared as a big boon for humanity and a medicaments showed quick effectiveness even in very small doses.[3]But now a day there is big issue about the use of Rasaushadhi (Herbomineral medicine) in children regarding their safety and impurity. But there are lots of references in *Kashyapasamhita* about use of *Rasaushadihi* in children. *Acharya Kashyapa* has been mentioned herbomimeral preparations as internal use or external use in children e.g. *Lohitikagutika*in *akshiroga*a *anjana* (external application)[4], *Shilajatu* internal use in *raktagulma*. In Brihatrai and Laghutraisamhita of Ayurvedic classic has been mentioned Gold administration in newborn babies.

Nephrotoxicity is characterized as a rapid degradation in the function of the kidney due to toxic effects of medicines and chemicals.[5] Nephrotoxicity occurs when kidney-specific detoxification and excretion does not work properly due to damage or destruction of the function of the kidney by exogenous or endogenous substances. [6] In the past two years, this research study was aimed to make evidence based focus. The clinical case series of total 13 paediatric patients was conducted for 45 days exposure to rasaushadhi (Herbomineral medicines) and checked biomarkers of kidney functions to evaluate whether Rasaushadhi (Herbomineral medicines) cause any damage to kidney.

This study provides an evidence and built confidence in ayurvedic practitioners to use Rasaushadhi (Herbomineral medicines) without any hesitance.

Method

In this case series total 13 patients of 4 to 14 years age of recurrent and reactive airway disease were involved. All patients were diagnosed applying subjective and objective criteria. Patients involved in study received Rasaushadhi (Herbomineral medicines) for 45 days. Patients were clinically observed in 4 follow ups, each follow up was conducted every 15 days. Last (Fourth) telephonic follow up was taken after six months of completion of treatment course to observe any renal obstructive pathology.

Dose: As paediatric dosing system is different from adults. Appropriate dose of medicines given to the patients was calculated as per age according to Sharangdharsamhita[7] and the dose decided after consulting to experts. Five drugs regimen (Table 1) mixed well in powder form and given bid with honey after meal.

Anupana (vehicle): Honey

Consent: Well informed written consent was taken from parents.

Interventions:

Case Series:

Patient-1: 13 years male child; wt.-35.6kg, presented with the complaint of continuous dry cough; had history of Bronchial Asthma for 3yrs. Also had history of taking medications and nebulisation repeatedly and have had seasonal aggravation. Child was diagnosed Reactive Airway Disease and enrolled for study. Total 5 herbomineral Ayurvedic drug combination mentioned in table 1 was given for the period of 45 days with 15 days interval. Patient was clinically observed at follow up after every 15 days. After successfully completion of treatment course of 45 days, Kidney Function Test (KFT) was done at standard pathology lab. Last follow up was taken at 6 month of completion of treatment course to observe any renal complication or obstructive pathology.

Patient-2: 7years male child, wt. - 16.4 kg had complaint of rhinitis with h/o recurrent allergic rhinitis, specific food and seasonal aggravation, repeated medication and nebulisation for same illness. Child was enrolled for study after well informed consent. Herbomineral combination was given. After completion of treatment KFT was done. Last follow up was taken after 6 month on telephone.

Patient-3: 7 years female child; wt.-13.8kg, was presented with c/o breathlessness, cough and cold. Patient had h/o recurrent respiratory illness and allergic rhinitis and received treatment repeatedly for same illness, also had h/o bronchial asthma to grandparent. Patient was admitted in for Panchakarma (Vamana) procedure. Vamana karma was done on next day after that patient was enrolled for study. After successful treatment completion KFT was done, last f/u was taken on phone after 6 month.

Patient-4: 5years female child wt.- 13.1kg; had c/o cough and cold. Patient had h/o seasonal and specific food aggravation and h/o parental allergy. Patient had received medication repeatedly for recurrent respiratory infections (antibiotics and antihistamines). Patient was enrolled for study after well informed consent. 5 herbomineral drugs combination was given and f/u was conducted on time. after successful completion of treatment course LFT was performed at standard lab. Last f/u was taken on phone for any renal complication secondary to herbomineral drug consumption.

Patient-5: 7years female child wt.- 17.4kg had c/o cough and common cold. Patient had h/o allergic respiratory illness, seasonal aggravation and needed repeated medication for allergic respiratory illness. Patient was enrolled for study and given treatment for 45 days at 15 days interval. After course completion KFT was done. Last f/u was taken after 6 month.

Patient – 6: 5years female child wt.-14.6kg; had c/o cough and cold have had h/o specific food aggravation seasonal aggravation, allergy to parent (bronchial asthma to mother) child was diagnosed bronchial asthma by general practitioner. After well informed consent patient was enrolled for study and after completion of course KFT was done.

Patient –7: 13years male child wt. 27 kg; was diagnosed recurrent respiratory illness and enrolled for study after consent. Patient had completed treatment course after that KFT done at same institutional lab to check biomarkers.

Patient – 8: 11 years male child wt33.4kg had c/o dry cough and had h/o recurrent cough and allergic respiratory illness. Patient had h/o seasonal aggravation and parental asthma. Patient was enrolled for study and 5 herbomineral drugs combination was given for 45 days after 15 days interval. After course completion KFT was done. Last f/u was conducted after 6 month on phone for any urinary obstructive pathology.

Patient -9: 5years female child wt.-15.3 kg; had c/o cough with bouts. Patient had h/o recurrent respiratory illness and repeated medication and nebulisation for same illness. Patient was enrolled for study and 5 herbomineral drugs combination was given. After course completion KFT was done. Last f/u was taken after 6 month.

Patient -10: 4years female child wt.- 12.6kg; had c/o cough, cold, fever and nasal congestion. Patient had h/o recurrent respiratory infections and repeated medication, seasonal aggravation. After well informed consent from parent patient was enrolled for study. Total 5 herbomineral drugs combination was given to patient for 45 days at 15 days interval. After treatment course completion KFT was done at standard private pathology lab. Last f/u was taken on phone to observe any symptom of renal injury or any renal obstructive pathology.

Patient -11: 10years male child wt.-21.6kg; had c/o throat pain, cough and had h/o recurrent respiratory infections (thrice in a month).Also had h/o seasonal aggravation, parental allergy (father) and received repeated medication for same illness. On examination patient had diagnosed tonsil hypertrophy and adenoiditis. Patient was enrolled for study after informed consent. Patient had given 5 herbomineral drugs combination for 45 days. After successful completion of treatment course and on time f/u at 15 days interval KFT was done. Last f/u was done after 6 month.

Patient -12: 14 years male child wt.-50 kg; had c/o cough, common cold and fever. Patient had h/o parental allergy (Mother). Patient was enrolled for study after well informed written consent. 5 drug regimen of rasaushadhi was given to the patient for 45 days at 15 days interval. After successful completion of treatment course KFT was done. Last follow up was taken on phone after 6 months.

Patient -13: 4 year male child wt 13.5kg; had c/o

rhinitis. Patient had h/o recurrent respiratory illness and was taking antibiotics, anti allergic medicines for same illness. Patient had seasonal and specific food aggravation, parental allergy (Mother). Patient was diagnosed atopic rhinitis and enrolled for the study. 5 drug regimen of rasaushadhi was given to the patient for 45 days at 15 days interval. After successful completion of treatment course KFT was done. Last follow up was taken on phone after 6 months./

Results

Patients were observed in 4 follow ups, 3 follow ups from starting were taken at 15 days interval and at 3rd follow up KFT was done, last 4th follow up was taken on phone after 6 months to observe any obstructive pathology secondary to Ayurvedic medicines consumption. At last follow up on phone no any compliant related to renal injury was observed since at all.

Total 13 patients were involved in this case series. After completion of 45 days treatment course Kidney Function Test (KFT) was done and following value of biomarkers were observed.

Table -2 Kidney Function Test (KFT)

Sr.No.	Serum creatinine (mg/dl)	Blood Urea Nitrogen (mg/dl)	Blood urea(mg/dl)	Uric acid
Patient-1	0.9	11.29	24.17	-
Patient-2	0.46	-	40	5.01
Patient-3	0.78	-	21.16	-

Discussion

Use of metals and minerals in Ayurvedic drugs remains a most controversial issue for the followers of western medicine. These concerns not always true; mere presence of metal in a formulation will not develop adverse effects. Judicious administration considering all variants as explained in Ayurveda determines the benefit or otherwise. Pioneers of ayurveda have considered in detail about the possible ways by which untoward effects can occurred and provided all guidelines to avoid such occurrence.[8] Use of various Herbomineral medicines containing metals and minerals in therapeutics is an essential part of Ayurveda but safety and toxicity concern in the two decades creates debates in conventional community which attempted to damaging the glory of Ayurveda.[9,10]

Purpose of this study was to see the incidence of kidney injury due to Ayurvedic drug consumption. As Rasaushadhi (Herbomineral medicines) are used by Balroga department and by many of ayurvedic practitioners; and patient got relief from their illness as we expected. In spite of this adverse effect of Rasaushadhi (Herbomineral medicines) remains questionable. To answer such questions study was conducted. This study creates confidence to Ayurvedic practitioners to use herbomineral drugs in paediatric patients.

Conclusion

Proper use of Rasaushadhi (Herbomineral medicines) in paediatric patients is safe. It is clear from this case series use of herbomineral formulations that properly processed Ayurvedic medicines do not produce any toxic potential under judicious administration. Further to affirm the safety of rasaushadhi (herbomineral formulations) longitudinal study in large sample is required.

A Resistant Grave's Disease in Pregnancy: Case Report and Review of the Literature

Minal Kalambe (Akare)[1], Mugdha L. Jungari[2], Dipti Shrivastava[3]

[1]Senior Resident, [2]Associate Professor, [3]Professor and HOD, DepartmentofObst and Gyne Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur-441110

Abstract

Background: Thyroid hormones are crucial regulators of early development and play an important role in the maintenance of a normal pregnancy and in the development of the fetus, particularly the fetal brain. The effective management of Grave's Disease (GD) during pregnancy is challenging for the clinician. The most common causes of hyperthyroidism are autoimmune GD and multinodular goiter.

A 35 year old lady at 28 weeks of pregnancy, a case of Graves' disease on anti-thyroid drug with uncontrolled thyrotoxic symptoms despite regular medication didn't show clinical and biochemical normalization even with the maximum dose of antithyroid drug and antihypertensive drug permissible at pregnancy. At gestational week 28, T4 and T3 remained elevated with suppressed serum TSH and high levels of TSH receptor antibody levels. The patient had to be followed up medically with guarded prognosis. On follow up patient didn't show any clinical or biochemical remission. Despite high thyroid hormones levels and higher anti-TSH receptor antibody levels all throughout the gestation and with maximum dose of PTU the patient delivered a healthy baby with no clinical symptoms of thyrotoxicosis, goitre or any stigmata of PTU in the neonate. Mother's TFT was closed monitored and anti-thyroid medication was titred. We present a rare case of resistant GD in pregnancy, in different stages of pregnancy management encountered many challenges.

Keywords: *Graves' disease, GD, Pregnancy, Propylthiouracil (PTU), Carbimazole, PIH.*

Introduction

Hyperthyroidism in women who are of childbearing age is predominantly of autoimmune origin and caused by Graves' disease, affecting 0.2% of all pregnant women. During pregnancy due to physiological changes in the maternal immune system may influence the development other autoimmune diseases. Hyperthyroidism is defined by abnormally high levels of thyroid hormone caused by an increased synthesis and secretion of thyroid hormone from the thyroid gland.(1) 26.4% population of global adult affects due to hypertension, it was remaining the leading preventable risk factor for premature death and disability worldwide. In endocrine disorders including overt and subclinical hyperthyroidism and hypothyroidism Hypertension may be the initial clinical presentation. After thyroid dysfunction correction may normalize blood pressure (BP) in most cases, therefore checking thyroid function is essential during the workup for hypertension. Careful management and control of patients suffering from hyperthyroidism are important to prevent the possible complications related to the disease itself or to the treatment.(2,3)

Case Report: A 35-year-old pregnant woman Gravida 3 para1 live 1 abortion 1 came to the emergency department with complaints of absent foetal movements since 1 dayin her 28th weeks of pregnancy was admitted to Shalinitai Meghe Hospital and Research Centre, (DMIMS) Nagpur. The patient has never experienced bleeding or trauma before. A history of previous delivery

underwent by LSCS was with a healthy male baby in view of foetal distress followed by after 2 year (2 month) spontaneous abortion. On admission she had raised blood pressure (BP-160/100 mm of Hg) with shortness of breath. She had no prior history of hypertension, diabetics, grave`s disease. Lab investigation showed normal hemogram with renal, liver, function test, blood glucose and serum electrolytes were normal Biochemical parameters. Thyroid profile was revealed biochemically hyperthyroid state, free T4 5.49 ng/dl (0.61-1.12), free T3 31.36 pmol/L (3.8-6) and TSH 0.002 µIU/ml (0.3-5.6). She had positive anti thyroid peroxidase antibodies (2107µ/ml; Normal ≤15 µ/ml) and negative TSH receptorantibody.

She had tachycardia (pulse132/min) and a regular, high volume pulse. However, there were no postural tremors, lid retraction, exophthalmos or other features of thyroid eye disease. Pulse pressure was wide (80mm Hg),blood pressure was raised at 180/100 mm Hg; there was significant bi-pedal oedema, patient was on tablet labetolol 200mg 4 hourly, tab. Nicardia20 mg 12 hourly, tab. Phenobarbiturate 60 mg at night, propylthiouracil (PTU) 150 mg 8 hourly. USG neck diffusely enlarged thyroid gland with increased vascularity. Sonographic evaluations of the fetus had been normal at time of intialpresentation (Fetal heart rate 154/mints, gestational age corresponded to chronological age and no anomalies). Cardiac status evaluated and was within in normal limits. Every four weeks patient continued to be thyrotoxic clinically, biochemically [free T4- 4.45 ng/dl, free T3- 28.3 pmol/L, TSH- 0.001 µIU/ml]. At 30 weeks gestation patient condition remained the same and fetus sonography was normal. At 34 week gestations we repeated TRab and the antibody titer continued to be high (TRab= 33 U/L).Normal fetus, placental unit and no advancement of bone age. During the follow up period patient had no symptoms or clinical signs of cardiac failure at any point of time despite being frank thyrotoxic. At 37 weeks gestation had underwent LSCS in view of raised BP and fetal distress, delivered female baby. No perinatal or post-natal complication was noted in baby and had normal anthropometric measurement at birth (birth weight 2.8 kg, length 50 cm and head circumference 34 cm) and no anomalies detected on clinical examination. There was no goitre, symptoms or signs of neonatal thyrotoxicosis. After 2 weeks of delivery the neonate though asymptomatic showed biochemical features of thyrotoxicosis [TSH: 0.021 mIU/ml (<20), FT4- 4.33 (1.0- 1.6ng/ml) and FT3 6.77 (2.6-4.4 pg/ml)]. The infant was monitored clinically and a repeat thyroid function test after 4 weeks showed normalization. PTU dose was titrated as required.

Discussion

The incidence of hyperthyroidism is 1 in 2000 pregnancies, with virtually all cases due to the autoimmune disease. Hyperthyroidism is hyperfunction of the thyroid gland characterized by a 15-20% increase in basal metabolism, sometimes accompanied by a mild enlargement of the thyroid gland.[4] About 90% of hyperthyroidism is caused by Grave's disease, both solitary and multiple toxic nodules and toxic adenomas. Generally Grave's disease is found that at young women that is between 20 to 40 years old and more in women than men with a ratio of 5: 1. Thyrotoxicosis is defined as excess of thyroid hormone", and this due to an increased synthesis of thyroid hormone in the thyroid gland (hyperthyroidism), but can be due to in the absence of hyperthyroidism. [5]

Pregnancy is a unique condition, in which the physiology of thyroid gland is mainly affected by 3changes, 1) due to increasedestrogen levels leads to increases levelof thyroxin binding globulin (TBG) from 12th weeks of pregnancy which reaches 2 times normallevels which will increase T4 and T3 levels in serum and change in thyroid size; 2) anincrease in the secretion of thyroid-stimulating factors(TSF) from the placenta especially human chorionicgonadotropin (HCG); and 3) pregnancy is accompanied byincrease in renal clearance of iodine and iodine loss through the photo-placental complex at the end of pregnancy leads to a decrease in iodine supply in the thyroid gland it will cause a relative iodine deficiency state. [6]

Clinical symptoms of Grave's disease are presence of tremors, non-infiltrative or infiltrative eye disorders, weight loss without knowing why, local myxedema, myopathy and onycholysis. All of these conditions never occur in a normal pregnancy. In pregnancy patients can experience hyperemesis gravidarum which can only be treated with anti-thyroid medications. An uncontrolled Graves' mother can have cardiac decompensation anytime. Infections, anemia, arrhthymias and PIH are known dreaded risk factors that can lead to cardiac failure.[7] In pregnancy, there will be immunosuppressant due to increased fetal suppressor T cell. These suppressor factors cross the placental barrier leads to supressed immune system of mother. Grave's disease often

becomes more severe in the first trimester of pregnancy, so that hyperthyroidism was diagnosed in first trimester of pregnancy. After delivery, these suppressor factors will disappear. This can explain why the exacerbation of hyperthyroidism occurs in the postpartumperiod.[8]

Antithyroid drugs that are used in the group of thioamides which work to inhibit thyroid hormonesynthesis through the blockade of the tyrosine molecule iodination process. Improvement can be seen in the first week and a new euthyroid state is reached after 4-6 weeks of treatment. The maximum permissible dose of antithyroid medication during pregnancy is 30 mg of methimazole or 40 mg of carbimazole or 600 mgof PTU. Propylthiouracil (PTU) and methimazole have been widely used in pregnant women with hyperthyroidism. In pregnancy PTU has many advantages as compared to methimazole, because PTU can inhibit the change of T4 to T3 besides inhibiting thyroid hormone synthesis and crossing the placenta less than methimazole because PTU has strong protein binds and is difficult to dissolve in water.[9] The baby was asymptomatic at birth and has elevated TSH receptor antibodies in cord blood, repeated TFT after 2 weeks of birth. At 2 weeks neonate had biochemical evidence of thyrotoxicosis with increased TSH receptor. After 2 weeks as the anti-thyroid drug clears from circulation and TSH receptor antibodies have a longer half -life (2 -3 weeks) and once the antibodies disappear the neonates achieve euthyroidism .[9,10]

Conclusion

Incidence of Grave's disease in pregnancy is not uncommon but resistant Grave's in pregnancy is very rare. Resistant Grave's disease is a difficult situation to manage and fatal complications are likely. Mother as well as neonates should frequently monitored as they are likely to have Grave's or hypothyroidism which is antibody mediated. There are difficult to manage this kind of patients due to no proper guidelines, endocrinologist find difficulty to maintain an optimal balance between maternal and fotal wellbeing.

Observational Study of Patients Presenting with Bleeding in First Trimester

Sonal Nandekar[1], Mugdha Jungari[2], Deepika Dewani[3], Mrunal Nakade[4]

[1]Assistant Professor, [2]Associate Professor, Dept. of Obstetrics and Gynecology Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur, [3]Assistant Professor, [4]Junior Resident, Dept. of Obstetrics and Gynecology Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Objective: First trimester is an important period during which there is risk of bleeding and may lead to spontaneous abortion. More than 80% spontaneous abortions occur in first trimester. The aim of this study was to determine the causes of first trimester bleeding.

Method: This was a cross sectional descriptive study conducted at Shalinitai Meghe hospital and Research centre Hingana, Nagpur during January 2020 to June 2020. The patients presenting to OPD with history of bleeding or spotting per vaginum, positive urine pregnancy test and less than 12 weeks of gestation were included in this study. Clinical examination and ultrasonography was done.

Result: Most of the patients presented with moderate bleeding and associated pain. The duration of bleeding was 2 to 5 days. Majority of cases were between 4-8 weeks (69.5%). History of prior miscarriage was present in 23.7%. 61% of cases were anemic. Threatened abortion was most common in patients presenting with bleeding per vaginum (in 47.5%). 18.6% patients were with incomplete abortion and 11.8% had complete abortion. There were 2 cases of unruptured ectopic pregnancy and 1 case of ruptured ectopic pregnancy. Salpingectomy was done in all the 3. Dilatation and evacuation was done in 12 cases. Gestational sac was present in 52 cases and the appearance was normal in 53.8% cases. Yolk sac was present in 65.4% cases. Fetal pole and cardiac activity was seen in 57.7%cases.

Conclusion: Bleeding in first trimester of pregnancy is the common complaint with which the pregnant women presents to the health care worker. The commonest cause is the threatened abortion. Other causes are incomplete, complete and missed abortions. Bleeding in early pregnancy may be early presentation of a serious situation like ectopic pregnancy. Ultrasonography, especially the Trans Vaginal is very important in concluding the causes of bleeding. Pregnant women should be educated in the first visit to antenatal OPD itself for the symptoms like bleeding per vaginum and to seek help from health care worker as soon as possible.

Introduction

First trimester is an important period during which there is risk of bleeding and may lead to spontaneous abortion. More than 80% spontaneous abortions occur in first trimester[1]. The causes for bleeding in first trimester can be spontaneous abortion, induced abortion, ectopic pregnancy, molar pregnancy and local factors. Terms that are used to describe bleeding during first trimester

Corresponding Author:
Dr. Mugdha Jungari
Associate Professor Dept. of Obstetrics and Gynecology, Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Hingana, Nagpur
e-mail: ambad.sawan@gmail.com

are threatened, inevitable, incomplete, complete and missed abortion[1].

The various possible causes of spontaneous miscarriages are abnormal conceptus, immunological factors, uterine abnormalities, endocrine factors, maternal diseases, infections[2]. The factors responsible for spontaneous abortion can be advancing maternal age, medical disorders, infections, medications, uncontrolled diabetes mellitus, thyroid disorders[3,4].

Pregnancies with first trimester bleeding and subchorionic hematoma were associated with similar risk of miscarriage and antepartum haemorrhage compared to patients with first trimester bleeding without subchorionic hematoma. Pregnancies with first trimester bleeding and subchorionic hematoma were associated with similar risk of miscarriage and antepartum haemorrhage although increased risk of preeclampsia, fetal growth limits, premature pregnancy, non-reassuring fetal heart rhythm, cäsarean delivery and low birth weight.[5-7]

Material and Method

This was a cross sectional descriptive study conducted at Datta Meghe Medical College, Shalinitai Meghe hospital and Research centre Hingana, Nagpur in collaboration with Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardhaduring January 2020 to June 2020. The patients presenting to OPD with history of bleeding or spotting per vaginum, positive urine pregnancy test and less than 12 weeks of gestation were included in this study after prior informed consent. The pregnant women with history of intake of MTP pills were excluded from study. Clinical examination was done. Ultrasonography was done to note crown rump length, gestational sac, yolk sac, fetal pole and fetal cardiac activity.

Result

First trimester bleeding is a common problem during pregnancy and is a cause of major concern for the patient and family. The incidence of miscarriage is generally considered to be about 15% of all pregnancies[4]. Most of the patients presented with moderate bleeding and associated pain. The duration of bleeding was 2 to 5 days. This study included pregnant women from age 18 to 44 years. Maximum number was seen in the age group 26-30 years (59.4%)

Table 1: History of Prior Miscarriage

History of prior miscarriage	Number of cases (59)	Percentage
Present	14	23.7
Absent	45	76.3

In 23.7% women, history of previous spontaneous abortion was present. No such history was present in 76.3% cases.

Table 2: Gravida status of patients

Number of gravida	Number of cases (59)	Percentage
1	17	28.8
2	11	18.7
3	19	32.2
>/=4	12	20.3

Out of total cases, 28.8% cases were primigravida, 18.7% were second gravida, 52.5% cases were multigravida.

Table 3: Weeks since Last Menstrual period (LMP)

Weeks since LMP	Number of cases (59)	Percentage
<6	05	8.5
6-8	41	69.5
8-12	13	22

Majority of cases were between 6-8 weeks(69.5%). 8.5% cases were less than 6 weeks. 22% cases were between 8-12 weeks.

Table 4: Hemoglobin level

Hemoglobin level (gm/dl)	Number of cases (59)	Percentage
<7	08	13.5
7-11	28	47.5
>11	23	39

61% of cases were anemic. 13.5% cases were severely anemic and required blood transfusion.

Table 5: Clinical Diagnosis

Clinical Diagnosis	Number of cases (59)	Percentage
Threatened abortion	28	47.5
Incomplete abortion	11	18.6
Complete abortion	07	11.9
Missed abortion	10	16.9
Ectopic gestation	03	05.1

Threatened abortion was most common in patients presenting with bleeding per vaginum (in 47.5%). 18.6% patients were with incomplete abortion and 11.8% had complete abortion. There were 2 cases of unruptured ectopic pregnancy and 1 case of ruptured ectopic pregnancy. Salpingectomy was done in all the 3. Dilatation and evacuation was done in 12 cases.

Table 6: USG findings

Gestational sac	**Present**	**Absent**
	52	07
Gestational sac appearance (n=52)	**Normal**	**Abnormal**
	28(53.8%)	24(46.2%)
Yolk sac	**Present**	**Absent**
	34(65.4%)	18(34.6%)
Fetal pole	**Present**	**Absent**
	30(57.7%)	22(42.3%)
Cardiac activity	**Present**	**Absent**
	30(57.7%)	22(42.3%)

Gestational sac was present in 52 cases and not seen in 7 cases. The appearance of gestational sac was normal in 53.8% cases. Yolk sac was present in 65.4% cases. Fetal pole and cardiac activity was seen in 57.7%cases.

Discussion

Vaginal bleeding in early pregnancy requires prompt attention. A review of the menstrual history and prior ultrasonography can help establish gestational dating and determine whether the pregnancy location is known[8]. Bleeding equal to or heavier than a menstrual period and bleeding accompanied by pain are associated with an increased risk of early pregnancy loss[9].

A total of 59 of pregnant women who presented vaginal bleeding during the first trimester to OPD were enrolled into the study. The bleeding occurs at all gestational ages between the implantation of the embryo in the uterus and 12 weeks of gestation, mostly between 4-8 weeks in 69.5% in our study and 50.8% in that of Boco[10]. Threatened abortion (47.5%) was the commonest cause of first trimester vaginal bleeding. This similar trend was observed in other studies[11-13]. The clinical diagnosis of threatened abortion is presumed when bleeding occurs through closed cervical os before 20 weeks of gestation[1]. 18.6% women were diagnosed with incomplete abortions. This rate is comparable to that of Yang and al, who found a rate of 23.1%[12].There were 18.6% cases of stopped pregnancies (fetal demise). BelleyPriso and al found a rate of 20[13]. Bleeding from an ectopic pregnancy is the most dangerous cause of first trimester bleeding. It concerned 5.1% of the cases in our study. Belley and al found a rate of 5.2%[13]. Implantation of fertilized egg outside uterus is known as ectopic pregnancy. 11.9% were diagnosed as complete abortion[14]. This rate is similar to those of Coulibaly who found a rate of 9.1%[15]. Heavy bleeding occurred mainly in incomplete and complete abortions, while spotting and light bleeding occurred in threatened abortions, viable intra uterine pregnancy and missed abortion. Threatened abortions, incomplete abortion, missed abortion and ectopic pregnancy presented with bleeding, haemorrhage although increased risk of preeclampsia, fetal growth limits, premature pregnancy and lower abdominal pain[4,5,16]. The diagnosis was confirmed on ultrasound[17,18].

Conclusion

Bleeding in first trimester of pregnancy is the common complaint with which the pregnant women presents to the health care worker. The commonest cause is the threatened abortion. Other causes are incomplete, complete and missed abortions. Bleeding in early pregnancy may be early presentation of a serious situation like ectopic pregnancy. Ultrasonography, especially the Trans Vaginal is very important in concluding the causes of bleeding. Pregnant women should be educated in the first visit to antenatal OPD itself for the symptoms like bleeding per vaginum and to seek help from health care worker as soon as possible.

The Effect of Eye-Hand Coordination Device on Subjects with Hemiparesis

Muzahid K. Sheikh[1], Neha Chaudhary[2], Parikshit Muley[3]

[1]Asst Professor Datta Meghe College of Physiotherapy Nagpur, [2]Professor Datta Meghe College of Physiotherapy,Nagpur, [3]Associate Professor Dept. of Physiology Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical College, Sawangi, Meghe, Wardha

Abstract

"Coordination" the harmonious functioning of interrelated organs and parts, applied especially to the process of the motor apparatus of the brain which provides for the co-working of particular groups of muscles for the performance of definite adaptive useful response. In Current Clinical Practises there Less Devices Which can help in Gaining Eye-Hand Coordination. Objectives: To compare the effect of conventional training approach and eye-hand coordination along with conventional training. Materials and Method: The subjects in Datta Meghe College Of Physiotherapy were screened and 42 subjects were divided into 2 groups i.e Group A subjects were given Conventional Physiotherapy for coordination training and Group Eye-Hand Coordination Device along with given Conventional Physiotherapy for coordination training. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of NCT grading and FMA-UE.

Result: Intragroup comparison results showed that NCT grading and FMA-UE scale were statistically significant in both the groups ($p<0.0001$). Whereas the intergroup comparison results showed that Eye-Hand Coordination The device along with Conventional physiotherapy was statistically significant in improving NCT score ($p=0.0021$) and FMA-UE score ($p=0.0001$) than only Conventional Physiotherapy alone for Eye-hand In-coordination Conclusion: The Eye-Hand Coordination Device was Significantly effective when Given With Conventional Physiotherapy For treating In-coordination and improvement in coordination. Conventional Physiotherapy is also effective in treating in-coordination, but after a certain duration of treatment, the patient starts getting adapted and chances of achieving the plateau phase

Keywords: *Eye-Hand Coordination Device, Hemiparesis, NCT Grading, FMA-UE.*

Introduction

Coordinationis the even operating of interrelated vital organs and parts, applied especially to the process of the motor mechanism of the brain which provides for the co-working of particular groups of muscles for the performance of definite adaptive useful response. There are several types of coordination observed in humans namely intralimb, interlimb & visual-motor. Intralimb coordination refers to movements occurring within a single limb (eg: alternately flexing or extending the elbow). Inter-limb (bimanual coordination) refers to the integrated performance of two or more limbs working together (ex: between limb movements of the lower extremities and/or upper extremities during walking). Visual - motor coordination is the ability to integrate both visual and motor abilities with respect to the external environment in order to achieve a goal.[2]

Eye hand coordination which is a sub category of visual motor coordination hasits own merits with regards

to activities of daily living. It is also named as eye-hand-head coordination because movement of the head is typically required for the eyes to fixate on a target or object[3,4].

Incoordination isobserved in patients following a vascular insult in brain. It is suggested that the lack of coordinated voluntary movement observed in hemiparetic patients may be due to impaired regulation of spinal neurons.

The structure getting involved in the incoordination pathology is the cerebellum it receives information from the sensory systems, the spinal- cord, and other parts of the brain and then regulates motor movements. voluntary movements like posture, balance, coordination and speech leading to smooth and balanced muscular activity are all impaired if there's involvement of this structure[1]. Direct damage while not causing paralysis or intellectual impairment, might lead to lack of balance, slower movements & tremors[5]. Complex physical tasks and fine motor functions including prehension would become unsteady and halting[6]. Coordination impairments associated with dorsal column medial leminiscal (dcml) lesions are somewhat less characteristic than those produced by either the cerebellum or the basal ganglia pathology.

Biofeedback a specialized form of feedback that provides information directly to a patient about internal biological mechanisms via a somewhat sophisticated electronic device.it provides a feedback to individuals about their internal physiological events in order to state whether they are normal or abnormal and in case of abnormal to correct them respectively[7]. Biofeedback may be in the form of auditory, visual, tactile, gustatory and olfactory signals. In this research biofeedback is used to inform patient about movement and whether his activity is taking place in a coordinated manner. The instrument used in biofeedback process here is non-invasive and can be easily operated. The main goal of biofeedback here is to improve motor performance along with coordination through auditory signals and motor learning. Motor learning leading to control over the motor activities requires signalling from the external world as well as his own proprioception. hence biofeedback works best as a substitute for proprioception. Here the patient must aim in fulfilling 3 things in a progressive manner. Initially the focus should be on adapting and understanding the relationship of the electronic signal to achieve a desired task. After accomplishing this stage the individual should progress to practice controlling the feedback signals and after achieving this the task should be performed for several times until he has gained full control and coordination over it.

The learning pyramid also known as the cone of learning, experience, learning cone, the cone of retention,the pyramid of learning, or the pyramid of retention is a group of popular learning models and representations relating different degrees of retention induced from various type of learning.this pyramid of learning is a layer wise presentation represented in percentages[8]. It originated in 1954 in a book called audio-visual method in teaching. It was developed by the national training laboratories institute in the early 1960s, on its main campus in bethel, main. This model generally displays the following representation mentioned as below: out of which our feedback method provide audio-visual method, demonstration method and practice method. Therefore, the individual retention rates for audio-visual method is 20%, for demonstration is 30% & for practice is 75%. In this all the three method are combined and used in the rehabilitation process of the patient making the treatment more effective and showing better results in the prognosis of the patient.

Materials and Method

Approval for the study was obtained from the institutional Ethical Committee of the University. The subjects in Datta Meghe College of Physiotherapy and shalinitai Meghe hospital were screened and those fulfilling the inclusion and exclusion criteria were involved. Participants were informed about the study and consent was taken. Pre-test assessment was taken by using Non-Equilibrium Coordination Test, Non-Equilibrium Coordination Test Grading and FMA-UE to assess the patient. 42 subjects were divided into 2 groups, Group A and Group B based on the inclusion and exclusion criteria. The treatment was started the first day when the subject came for consultation. Group A subjects were given Conventional Physiotherapy and Group B subjects were given Eye-Hand Coordination Device Along with conventional Physiotherapy. The post-test assessment was taken by using NCT Grading and FMA-UE to assess the patient. The interpretation of the study was done on the basis of comparing pre-test and post-test assessment of Non-Equilibrium Coordination Test Grading and FMA-UE

Group A: Conventional Physiotherapy For improving Coordination

- Frenkels Exercises for upper extremities
- Ball throwing to specific target.
- Ball Juggling
- Small ball tosing
- Target practise
- Wall ball bounce
- Aiming Practise

Group B: Eye-Hand Coordination Device - Patient should be in sitting position, patient will be asked to hold the hand piece which is of diameter 5cm, 4cm, 3cm, 2cm and 1cm accordingly.

- First the therapist will demonstrate the activity.
- The patient will be handed the hand piece and ask to move the hand piece from starting position to ending position and then again reach the starting point without much shaking of hand piece and with steadiness
- If the patient touches the wire then a buzzer will be on and light will blow and that will a biofeedback that means that the patient has to go to the starting point again for
- For starting we have asked the patient to perform the procedure on a wire which will be a straight line which is the basic level.
- The levels will be made difficult by making the wire into many different shapes.
- Once the patient gains confidence that he can perform the procedure easily he can go to the next level.

Statistical Analysis: Statistical analysis was done manually and by using the statistics software's INSTAT so as to verify the results derived. The statistical analysis of non-parametric data was done by Wilcoxon matched pairs test and Man-Whitney test. Wilcoxon matched pairs test was used for statistical analysis of pre and post intervention within the group. Man-Whitney test will be used for between groups statistical analysis of Group A and Group B (pre-pre and post-post intervention).

Discussion

Eye-hand coordination is central to so many human activities–the tool used eating, sports and work, to name few as to be defining characteristics of typical human life, conversely, its disruption following the stroke, disease, injury, and developmental disorder leads to considerable degeneration in productivity and quality of life. Naturally eye-hand coordination involves the synergistic function of various systems including visual, balance system proprioception and the eye heads and arm control systems, plus aspects of awareness- like attention and, memory[9,10,11]. Eye hand coordination plays vital role in ADL activities Eg-Eating, Drinking, Doing Writing Work, Passing any object to the surrounding Cleaning, Typing in laptop or typing machine. In the patients with neurological impairment neurological impaired subjects during Rehabilitation usually, eye-hand coordination mostly gets untreated. The objectives of this study were to find the effect of eye-hand coordination device on coordination in subjects with hemiplegia. To find the effect of eye hand coordination device along with conventional physiotherapy in improving eye-hand coordination. To compare the effect of Eye-hand coordination device and conventional physiotherapy in improving eye-hand coordination[12,13]. The study was conducted with 42 subjects. Subjects were divided into two groups. Eye-Hand Coordination device along with Conventional physiotherapy (Group A) and Conventional Physiotherapy (Group B). Prior consent was taken. The treatment protocol was carried out for 6 days per week for 5 weeks. The outcome measures for this study were Non-equilibrium coordination test grading and Fugl-Meyer Assessment-Upper Extremity scoring system[14,15]. The results of this study showed that there was a significant improvement in Coordination, improving quality of life and reducing rehabilitation time after 5 weeks of intervention in both the group A and group B in Subjects with incoordination. Wilcoxon matched pairs test was used to analyzethe effect eye-hand coordination device and showed that there was extremely significant improving coordination in NCT Grading score (0.0097) and FMT-UE (p=0.0001). Researches have proved that there is improvement hand pointing accuracy. A Study Done by B. Biguer C. PrablancM. Jeannerod showed that the accuracy of pointing motion of the hand, directed at visual acuity 10° to 40° from the center, was measured in normal subjects. No visual feedback from the moving hand was available to the participants. The face could be either maintained fixed (head-fixed condition) or free to move (head-free condition) during the pointing movements. It was found that the flaw in marking was reduced for all targets in the head-free condition. This reduction was more important for the more eccentric spot. Enhancement in precision was observed without any remarkable change in either the latency or the duration of eye, head or hand movements[16]. Another Study done by Halil Ibrahim Ceylan and Ozcan Saygin conducted a study on Examining the Effects of Proprioceptive Training on Coincidence Anticipation Timing, Reaction Time and Hand-Eye Coordination The study stated that the effects of proprioceptive training on coinciding anticipation timing (CAT), reaction time and hand-eye coordination. 42 volunteer students participated in the paper. These students were randomly divided into two groups as control and experimental groups. An exercise program was applied to the experiment and control groups for approximately 3 days in 8 weeks, for about 45 to 60 minutes. Additionally, a 20-minute modified proprioceptive balance program was applied to the experimental group only. Paired sample tests were used. As a result, significant differences were found in the performance, reaction time and hand-eye coordination performances of the experiment group, pretest, and posttest ($p<0,05$). Significant differences were found in dominant hand visual reaction time and hand-eye coordination performances of the control group, pretest, and posttest ($p<0,05$). In conclusion, it is seen that proprioceptive training affect CAT performance and reaction time performances in a positive way[17,18].

Conclusion

The present study provided evidence to support the use of eye –hand coordination device along with conventional physiotherapy in improving NCT and FMA-UE scores in Subjects with Hemiparesis. In addition, results supported that among Eye-hand coordination device and conventional physiotherapy were significantly effective in improving eye-hand coordination and improving the quality of life in subjects having affected eye hand coordination in hemiparesis.

Ethical Clearance: Taken from institutional ethics committee.

Of Orthopedics Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, [5]Associate Professor, Dept. of Shalya Tantra, BMAC & RH, Butibori

Abstract

Background: The *Ksharsutra* therapy is most fascinated para surgical process for fistula–in–ano. But during the procedure hyper granulations are typically seen near the external opening of fistula which may bleed or get infected if remain untreated. Moreover it may obliterate the pus drainage and thus complicate the wound. This consequence needs to be addressed. In *Sushrut Samhita*, raised soft tissues of wound is described as *Utsanna Mrudu Vrana Maansa* and specified to be treated by "*Avasadana Dravya*" with honey.

Aim: To evaluate the effect of LA of *Kalpit Kasisadi Yoga* with *Madhu*in management of hyper granulation, found at external opening of fistula-in-ano during its treatment with *Ksharsutra*.

Material and Method: 60 operated cases of fistula-in-ano with *Ksharsutra*, presenting with hyper granulation at the external opening of fistulous tract were randomly selected and divided into two groups.

Observation: The comparison between both the group indicates that effect of the therapy was very significant on thickness while insignificant result was obtained in area of hyper granulation. However the percentage of relief in both the criteria's in experimental group was above 90%.

Result: The LA of *Kalpit Kasisadi Yoga* in the management of *Ksharasutra* induced hyper granulation at external opening of fistula-in-ano is more effective than LA of *Madhu* alone.

Keywords: *Hyper granulation, Ksharsutra, Utsanna Mrudu Vrana Maansa, Avasadana Dravya.*

Introduction

Ayurveda classics at various places have emphasized on taking care of wounds which occur either as a result of vitiated *Doshas* or due to traumatic origin. In fact a detailed protocol to address various types of wound & their complications is illustrated in *Samhitas* for the management of wound. Being prime topic of the subject *Acharya Sushruta* has described 60 measures[1] in the management of *Vrana*in addition to its indication, contra indication and limitation while *Aacharya Charaka* has described 36measures.[2] These measures deal with each and every aspects of *Vrana* according to its type, condition and stages of healing.

In modern science wound healing has been

Corresponding Author:

Associate Professor, Dept. of Shalya Tantra,
DMAMCH & RC, Wanadongri Nagpur
e-mail: prafulls26@gmail.com
Mobile No.: 9860460984

described to be completed in 4 stages viz. inflammation, wound contraction, epithelialization and granulation tissue formation followed by scar formation which comprises various pathophysiological stages in itself. In normal circumstances wound heals through these stages, however hyper granulation tissue formation is an unusual event in wound healing.

Hyper granulation is said when granulation tissue grows above the level of wound edges. The presence of this tissue results in inhibition of fibroblast proliferation and prevents wound healing. The treatment consists of destruction of tissue by cautery, shave excision, aluminium chloride, copper sulphate or curettage. But the fact is that these hyper granulation tissue still remain there as a clinical problem.[3],[4]

Fistula-in-ano is itself a complicated wound, with muco-purulent discharge from its external opening. The incidence of a fistula–in–ano developing from an anal abscess ranges from 26% to 38%.[5]According to *Aacharya Sushruta,Vranathat* discharges pus, blood and mucous etc. are referred as *Kruchhraasadhya Vrana.*[6] That is why *Bhagandara*has been incorporated in *Ashtaumahagada* i.e. diseases with poor recovery rate.

Ksharsutra is a widely accepted line of treatment in fistula-in-ano which is designated as *Bhagandara* in ayurvedic texts. During the course of treatment it has been observed that many patients presented with hyper granulation tissue at the external opening of fistula- in-ano. This hyper granulation tissue delays the healing of fistulous tract.

In *Sushrut Samhita*, raised soft tissues of wound i.e. hyper granulation tissue is described as *Utsanna Mrudu Vrana Maansa* and advised to be treated by "*Avasadana Dravya*" with honey.[7]*Avasadana* denotes suppression of the soft tissue eruptions i.e. *Utsanna MruduMaansa*. '*Avasadaneitimaansasfotane'* - Dalhan

AvasadanaKarma is described by all the three acharyas *Sushrut* (Su.Chi. 1/83)*, Charak* (Ch. Chi. 25/39-43) and *Vagbhat*(A.H. Ut. 25/48) in management of *Vrana*. Various drugs are stated for *Avasadana Karma* in *Samhitas*[8] but on the basis of availability, following drugs were selected.

1) *Kasis* 2) *Saindhav* 3) *Kukkutand Twak Bhasma* 4) *Jatikalika* 5) *Karanj*

The above drugs were identified, obtained in purified form and were grinded to fine powder. Each drug of compound was mixed homogeneously in equal proportion. The prepared compound was stored in sterilized glass bottle. As the compound is not directly mentioned in the Ayurvedic classics and the first drug being *Kasis,*the drug of trial is designated as *Kalpit Kasisadi Yoga,* to be applied with *Madhu*. In Control Group only *Madhu*was used.

Hence the present research work is designed to assess the *Avasadana Karma* of the *Kalpit Kasisadi Yoga*in the management of *Ksharasutra* induced hyper granulation at external opening of fistula-in-ano in this trial.

Aims and Objectives:

- To study the effect of local application of *Kalpit Kasisadi Yoga* with *Madhu*in management of hyper granulation found at external opening of fistula-in-ano during its treatment with *Ksharsutra*.
- To compare the effect of local application of *Kalpit Kasisadi Yoga* and *Madhu* with local application of *Madhu*alonein management of hyper granulation found at external opening of fistula-in-ano during its treatment with *Ksharsutra*.

Material and Method

In this clinical trial, 60 operated cases of fistula-in-ano with Ksharsutra, presenting with hyper granulation at the external opening of fistulous tractwere randomly selected from OPD & IPD of Shalya Tantra Department of study center. The special research proforma was prepared for diagnosis and assessment of hypergranulation at external opening of fistula- in-ano.

Informed written consent was taken from all the patients included in this study. The patients were numbered from 1 to 60. The patients with odd numbers were selected in Group A. The patients with even numbers were selected in Group B.

Group A: Experimental Group–30 patients were treated with local application of *Kalpit Kasisadi Yoga* with *Madhu* OD for 10 days.

Group B: Control Group – 30 patients were treated with local application of only *Madhu* OD for 10 days.

Follow up of the patients was taken at 3rd, 7th and 10th day.

Criteria for Selection:

- Inclusion Criteria

1. Patient presenting with signs of hyper granulation at external opening of fistula-in-ano during the *Ksharsutra* therapy, irrespective of the length of the fistula tract.
2. Age of patients: 20 – 60 years.
3. Sex:- Both male and female of caste & religion.

- **Exclusion Criteria**

1. Patients suffering from uncontrolled diabetes, uncontrolled hypertension, tuberculosis, HIV, CA-Rectum, any malignancy in other parts of body.
2. Patients who had discontinued the treatment during follow up and patients who had developed any serious complications were dropped out from the study.

Criteria for Assessment: The assessment of the hyper granulation tissue was done on the basis of their dimensions. The dimensions were recorded before, during and after the treatment. The dimensions of hyper granulation were measured every time before applying the drug on subsequent follow-up day.

1. The length & width of the hyper granulation tissue was be measured by disposable millimeter ruler. Longest axis of tissue was recorded as length and width as the longest dimension perpendicular to length in the same plane. The area of hyper granulation tissue was calculated by Kundin's equation.[9]

This equation is to calculate the area of irregular surface.

$A_{kun} = L \times W \times 0.785\ mm^2$

2. The thickness of hyper granulation was measured by millimeter ruler. Thickness of hyper granulation tissue was its growth above the skin surface. The millimeter ruler was cut at its initial marking so to record thickness accurately. (As measured in mm, more than ½ mm was counted as 1mm and less than ½ mm was counted as 0.)

The area and thickness was measured in subsequent follow up rounds and after treatment.

Statistical Analysis:

- All the calculations were calculated through 'Graph Pad Instat' Software.
- **Paired't' test-**It was used for within the group assessment.
- **Unpaired "t" test-** It was used for comparison in Group 'A' and 'B'.

Observations:

1. Maximum patients of hyper granulation in the study were of age group 40 – 60 years in both the groups-

- Gr. A – 70%
- Gr. B – 60%.

2. In experimental group out of 30 patients 80 % patients were male and 20 % were female,In control group 56.67 % were male and 43.33 % patients were female.
3. Maximum patients in both the groups were Hindu as the trial was conducted in the Hindu dominated area.
4. Maximum patients in both the groups belonged to lower middle class category.
5. In both the groups, 70% patients were having mixed dietary habits.
6. In Group A patients 36.67% were having sedentary and 63.33% patients were active type of work. In control group 43.33% patients were of sedentary work and 56.67% patients were having active type of work.
7. In this study the data shows that in group A 10% patients were habitual alcoholic, 23.33% were smokers, 16.67% Tobacco chewing and 50% were of no habits, while in group B 13.33% patients were habitual alcoholic, 6.67% smokers, 16.67% of Tobacco chewing and 63.33% were not having any habits.

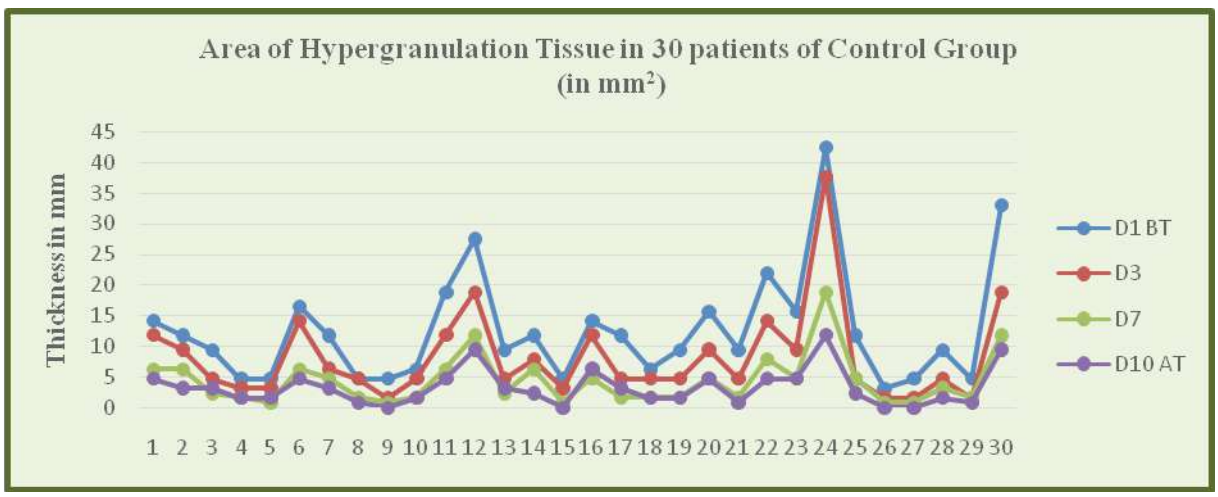
Table No. 1: Statistical Analysis of Area of Hyper Granulation Tissue In Group A & Group B (mm^2)

Area	N	Mean		% of relief	SD	SE	't' value	P value	Result
		BT	AT						
Group A	30	11.62	0.16	98.62	8.01	1.46	7.84	0.000	ES
Group B	30	12.48	3.24	74.04	6.26	1.14	8.08	0.000	ES

In Group A there was 98.62 % relief in Meanarea of hyper granulation tissue which was statistically ***extremely significant***. In Group B, there was 74.04 % relief which was also statistically ***extremely significant***.

Table No. 2. Statistical Analysis of Thickness of Hyper Granulation Tissue in Group A & Group B (mm)

Control group	N	Mean		% of relief	SD	SE	't' value	P value	Result
		BT	AT						
Group A	30	2.80	0.27	90.36	0.94	0.17	14.81	0.000	ES
Group B	30	3.30	1.40	57.57	0.62	0.11	16.26	0.000	ES

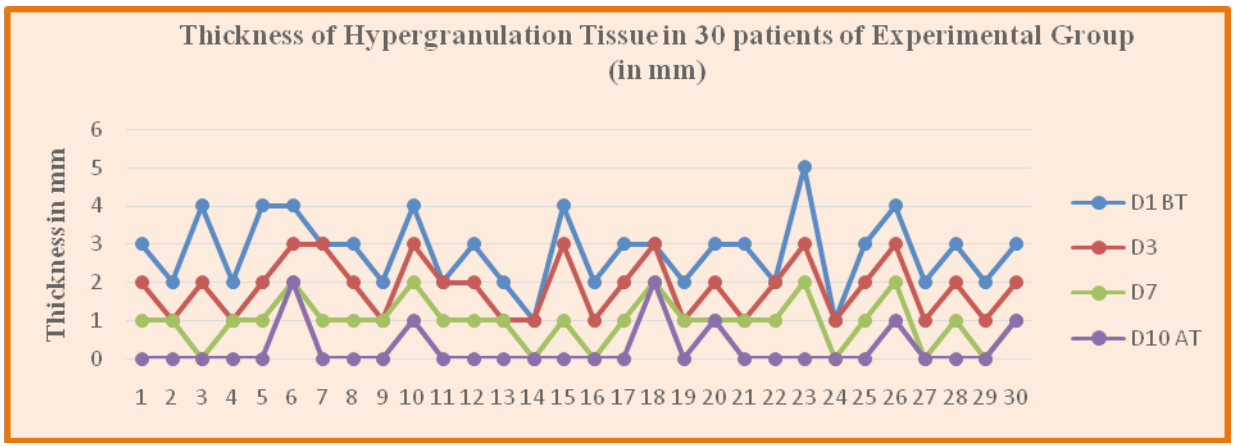


In Group A there was 90.36 % relief in Mean thickness of hyper granulation tissue which was statistically ***extremely significant***. In Group B, there was 57.57 % relief which was also statistically ***extremely significant***.

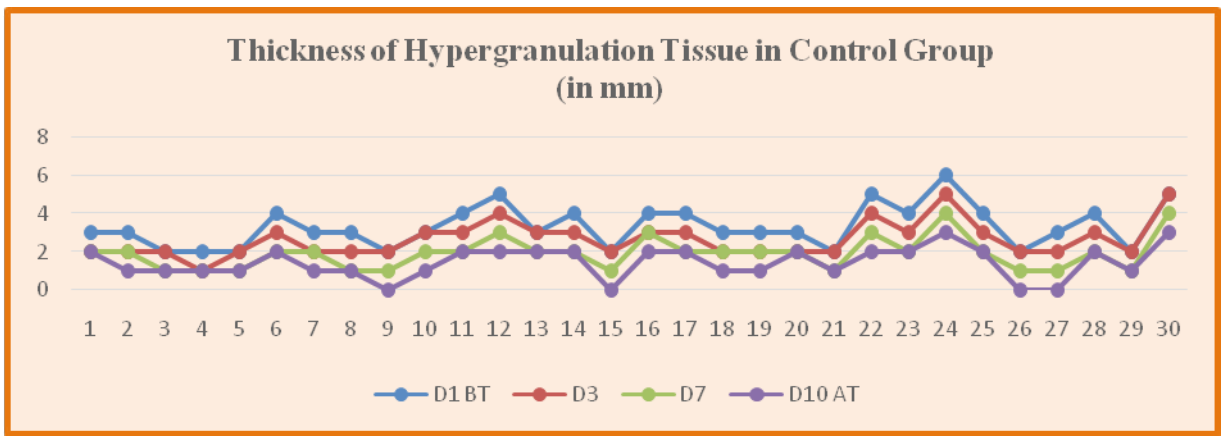
Table no. 3. Comparison between Group A and Group B

	Group	N	Mean Diff	SD	SE	't' Value	P Value	Result
Area	Group A	30	11.46	8.01	1.46	1.198	0.236	NS
	Group B	30	9.24	6.26	1.14			
Thickness	Group A	30	2.53	0.94	0.17	3.236	0.002	VS
	Group B	30	1.87	0.62	0.11			

Unpaired "t" test with Welch's correction was applied for comparison of Area and Thickness of hyper granulation tissue in Group A and Group B after treatment. It implies that



- Difference in Area of hyper granulation tissue after therapy between Group A & B is insignificant.
- Difference in Thickness of hyper granulation tissue after therapy between Group A & B is very significant.



Effect on Area of Hyper Granulation Tissue: There was highly significant decrease ($p<0.001$) in area of hyper granulation tissue after treatment in both experimental and Control Group. In both groups highly significant decrease in area was observed after 3rd day of treatment onwards. On statistical analysis,mean difference in area of hyper granulation in both groups was found insignificant ($p>0.05$). However, the percentage relief was found to be 98.62% in Experimental Group and 74.04 % in Control Group.

The line diagrams shows that diminution of area of hyper granulation tissue in course of treatment is higher in number of patients in Experimental Group than that of Control Group.

Effect on thickness of hyper granulation tissue: There was highly significant decrease ($p<0.001$) in thickness of hyper granulation tissue after treatment in both experimental and Control Group. In both groups highly significant decrease in thickness was observed after 3rd day of treatment onwards. Mean difference in thickness of hyper granulation in both groups was found more significant ($p<0.01$) on statistical analysis. The percentage relief was found to be 90.36 % in Experimental Group and 57.57 % in Control Group.

The line diagrams shows that the reduction in thickness of hyper granulation tissue in course of treatmentis higher in number of patients in Experimental Group than that of Control Group.

Thus LA of *Kalpit Kasisadi oga* with *Madhu* is more effective in decreasing area and thickness of *Ksharasutra* induced hyper granulation at external opening of fistula-in-anothan *Madhu* alone.

Discussion

The *Kalpit Kasissadi Yoga* has dominance of *Kashaya-Tikta Rasa*, *Ushna Virya*, *Laghu Ruksha Guna*, and *Katu Vipaka*. In experimental group, *Kalpit Kasisadi Yoga* along with *Madhu*was used, hence there was an additive effect. *Avasadana Dravyas* have *Ushna Virya* so as *Kasis* is. *Amla, Kashaya, Tikta Ras* of *Kasis* adds to its *Vrana Ropana* and *Avasadana* properties.

In *Ayurvedic* literature, use of *Kasis* in chronic wounds with erupted wound edges and discharge has been postulated.[10] The ferrous sulphate acts as vaso-constrictor due its astringent property thus reducing the size of hyper granulation tissue.

Karanj with its *Tikta, Katu, Kashaya rasa* and *Ushna, Ruksha Guna* acts as *Kled-Shoshan, Stroro-Akunchan*. The seeds contain alkaloids, tannin and picric acids in addition to some reducing substance. The seeds yield a type of oil which has marked fungicidal, antiseptic, cleansing and healing properties when applied locally. *Karanj* is the active principle responsible for the curative effect of the oil in the skin diseases.[11]

Jatikalika is again of *Tikta-Kashaya Rasa* and *Ushna Virya*. The flowers contain pyridine and nicotinate derivatives, alkaloid jasminine and salicylic acid. Thus having anti inflammatory activity. Flowers are astringent and mild anaesthetic hence reduces oedema of hyper granulation tissue.[12]

Saindhav and *Kukkutand Twak Bhasma*possess hygroscopic activity thus dry and up the secretions of fistulous tract. *Kukkutandtwak Bhasma*contains Ca CO_3 which is recently recognized as an accelerator for healing of wounds.[13] *Saindhav* softens the hypertrophied fibrosed tissue.

In control group only *Madhu* was used, still highly significant results were obtained. This is because of multidimensional action of *Madhu* on wound which was established since ancient time. Due to *Kashaya Anurasa* (astringent) of *Madhu* there is constriction of the micro capillaries existing in the bed of hyper granulation tissue thus checking its growth. *Ruksha* and *Sukshma Guna* of *Madhu* causes *Kleda Shoshana* thus reducing the size of hyper granulation tissue.[14] According to modern science being hygroscopic, honey speeds up the healing of wound and dry up the secretions. It has antibacterial properties due to its acidic nature and enzymatically produced hydrogen peroxide. Thus with *Lekhana*, *Vrana Shodhana* and *Ropana* properties, *Avasadana karma* of *Madhu* is established.

Thus the *Kalpit Kasisadi Yoga* becomes very effective on hyper granulation tissue as compared to use of only *Madhu* in treatment of hyper granulation tissue of fistula-in–ano which is proved from the study results.

Conclusion

Hyper granulation, one of the rare consequences of wound is observed very frequently in patients of fistula-in-ano with *Ksharsutra* in it.Excessive secretions due persistent irritation, sensitivity, mal-preparation and faulty ligation technique, all associated with *Ksharsutra*, are the probable causes of hyper granulation tissue formation in fistula-in-ano.

Kalpit Kasisadi Yoga with *Madhu* shows a very effective *AvasadanaKarma*on*Utsanna Mrudu Vrana Maansa* (Hyper Granulation) in *Bhagandara* (fistula-in-ano), during its course of treatment with *Ksharsutra*, however local application of *Kalpit Kasisadi Yoga* is more effective than merely *Madhu*.

Anesthetic Management of Patients with Sickle Cell Disease Posted for Bipolar Prosthesis

Dr. Sweety Agrawal, Dr. Pratibha Deshmukh, Dr Priyanka Deshmukh, Dr Anjali Modak,

[1]Assistant Professor, Dept. of Anaesthesiology Datta Meghe Medical College, SMRC Hospital Hingana Nagpur-441110, [2]Professor & Amp; HOD Dept. of Anaesthesiology Datta Meghe Medical College, SMRC Hospital Hingana Nagpur-441110, [3]Assistant Professor, Dept. of Anaesthesiology Datta Meghe Medical College, SMRC Hospital Hingana Nagpur-441110, [4]Professor, Dept. of Anaesthesiology Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra-442001

Abstract

In case of surgical procedures in sickle cell disease (SCD), patients are associated with high risk of perioperative complications like vaso-occlusive crisis, chest syndrome, post-operative infections, congestive heart failure, cerebrovascular accident and acute kidney injury. Preoperative assessment and stabilization like control of sepsis, blood transfusion, correction of hypoxia, hypothermia, dehydration and acidosis is needed to reduce peri-operative complications. Blood transfusion (Simple, manual exchange and automated exchange) remains an important therapeutic intervention in patients with SCD. The case study below shows the perioperative management of patients posted for bipolar prosthesis due to AVN (avascular necrosis). Adequate analgesia, incentive spirometry, early mobilisation and oxygen supplementation is the mainstay of post-operative management.

Keywords: *Sickle cell disease (SCD), Vaso-occlusive crisis (VOC), Avascular necrosis (AVN).*

Introduction

Sickle cell anemia (SCA) or sickle cell disease (SCD) is an autosomal recessive inherited hemoglobinopathy characterized by the presence of sickle hemoglobin (HbS), absent in healthy individuals. Homozygous individuals (HbSS) are characterized by chronic hemolytic anemia and repeated episodes of acute vascular occlusion leading to heart attacks, intense pain, and organ dysfunction, known as vaso-occlusive crisis (VOC).[1]

Different surgical procedures like hip replacement, obstetric surgery, gall bladder surgery, neuro surgery etc in SCD have been associated with relatively increased risks of peri-operative mortality, vaso-occlusive (painful) crisis, acute chest syndrome, post-operative infections, congestive heart failure, cerebrovascular accident and acute kidney injury.[2-3]

Hence preoperative assessment and stabilization like control of sepsis, blood transfusion, correction of hypoxia, hypothermia, dehydration and acidosis is needed to reduce peri-operative complications.

We are presenting a case of sickle cell disease with diagnosis of avascular nerosis (AVN) of femur posted for bipolar prosthesis.

Case Report: A 35 year old male, a known case of sickle cell disease HbSS pattern, was posted for bipolar prosthesis due to AVN. He was diagnosed to have sickle cell disease at the age of 12 year. He gave history of repeated hospitalization and blood transfusion since last 10 years. Last hospitalization was one month back and received 3 blood transfusions.

Mobile No.: 9545505563

On examination he was afebrile, pulse 100 beats per minute, blood pressure 130/90mmHg, SpO2 100%on room air. He had severe pallor. His respiratory, cardiac & neurological examination was within normal limits. Per abdomen exam revealed hepatomegaly. His lab investigation showed HB 5.6 gm %. Hematocrit was 16%, TLC- 17200/mm^3, platlet count, renal function, liver function, ECG and chest X-ray, were normal. USG abdomen showed mild hepatomegely and ABG showed mild metabolic acidosis. ESR and CRP were 112mm/hr and 78 mg/L. His urine culture was sterile while blood culture showed growth of methicillin senstive coagulase negative staphylococcus. 2Decho was normal and Hb electrophoresis showed HbS 65%. Airway and spine examination did not reveal any abnormality.

Patient was started on antibiotics according to culture sensitivity, warm intravenous fluid, tablets of sodium bicarbonate, folic acid, hydroxyurea. Oral paracetamol & tramadol were given for analgesia. Three blood transfusions were given. Patient was started on incentive spirometry. After one week his TLC count decreased to 10000, ESR & CRP normalized. Hemoglobin & hematocrit increased to 10.1 gm% & 31% respectively. ABG showed resolution of metabolic acidosis. So, patient was now posted for surgery.

Anaesthesia Management: Patient was kept NBM from midnight and allowed to take clear fluid up to 2 hours. Patients was given tablet alprazolam 0.5 mg and tablet pentaprozole 40 mg. Wide bore intravenous cannulation was done and warm IV fluid ringer lactate was started at the rate of 80 ml/hour to prevent dehydration in pre-operative period.

Spinal anaesthesia was planned for intraoperative management and femoral nerve block along with multimodal analgesia was planned for post operative period.

Pulse, blood pressure, oxygen saturation, temperature and ECG were monitored in intra-operative period.

Spinal anaesthesia was given with 25 G Quinkie needle at L4- L5 intervertebral space with 3 ml of 0.5% bupivacaine heavy with 75 mcg of buprenorphine.

Oxygen (5L/min) was given to the patient via facemask. Intravenous fluid 1.2 L of warm ringer lactate was infused along with one unit of blood transfusion. Urine output was maintained throughout the surgery at 40 to 50 ml/hour. Blood loss during surgery was approximately 400 ml. Patient's hemodynamic parameters remained stable in peri-operative period.

Femoral nerve block was given with 0.125% bupivacaine with 4 mg dexamethasone with the help of nerve stimulator in postoperative recovery room.

Patient was kept warm and oxygen supplementation was continued in postoperative period. Multimodal analgesia was supplemented in post-operative period with injection tramadol 100 mg and injection paracetamol 500mg thrice a day. IV fluid and antibiotics were continued in post-operative period. Early ambulation was encouraged.

Discussion

In patients with SCD undergoing surgery, peri-operative period is associated with increased risk of SCD related complications like increased risks of peri-operative mortality, vaso-occlusive (painful) crisis, acute chest syndrome (ACS), post-operative infections, congestive heart failure, cerebrovascular accident and acute kidney injury.[2-3] Careful preoperative assessment and management are important to reduce these risks. Peri-operative management requires a multidisciplinary approach, including surgeons, anesthesiologists, and hematologists.

Predictors of post-operative complications in patients with SCD include

1. Type of surgical procedure low, moderate or high risk.
2. Increased age- associated with disease progression
3. Frequency of recent complications-current activity of disease state
4. Hospitalization, marker of disease severity
5. Temporal clustering of ACS – progression of lung disease
6. Abnormal lung fields on radiograph – evidence of sickle chronic lung disease
7. Pregnancy –increased risk of maternal complications
8. Pre-existing infection – triggering agent for ACS
9. Haplotype – African haplotype have more severe disease than the Asian haplotype.[4]

Blood transfusion remains an important therapeutic intervention in patients with sickle cell disease (SCD), aiming to both increase the oxygen carrying capacity of blood and to reduce the complications of vaso-occlusion. Simple, manual exchange and automated exchange can be effective in reducing the acute and chronic complications of SCD.[5]

A randomized control trial compared conservative and aggressive preoperative blood transfusion in 604 operations in patients with sickle cell anemia. The conservative regimen (aiming for Hb 10 g/dL) was as effective as the aggressive regimen (aiming for Hb of 10 g/dL and HbS<30%) in preventing perioperative complications. Although alloimmunization was more common in the aggressive transfusion group. ACS was the most frequent clinical complication; seen in 10% of patients in both arms of the trial.[6] A subsequent RCT, the TAPS trial (Transfusion Alternatives PreOperatively in Sickle Cell Disease) compared preoperative transfusion with no preoperative transfusion in low- and moderate-risk surgical procedures in patients with HbSS or HbSb0 thalassemia. Patients randomized to transfusion were given a simple transfusion aiming for Hb>10 g/dL (if Hb<9 g/dL) or a partial exchange aiming for HbS<60% (if Hb>9 g/dL). Clinically important complications were significantly increased in the nontransfused group (39% vs 15% of patients, P = 0.023) and this difference was primarily explained by a marked increase in ACS in the un-transfused group (27% vs 3%).[7]

In our case patient was having initial hemoglobin 5.6gm% and HbS 65%. We did 3 simple blood transfusions to build hemoglobin to 10 gm% in preoperative period.

Urinary or respiratory tract infections are closely associated with the development of ACS.[8] Hence preoperative infection needs to be adequately controlledwith appropriate antibiotics. Chest radiograph, hemoglobin oxygen saturation, and lung function tests may delineate the degree of pulmonary pathology. Blood urea and serum creatinine concentrations and urine dipstick screening or proteinuria or occult urinary tract infection are useful and inexpensive screening tools. Other Investigations include screen - for antibodies, extended cross-match for E, C, K groups, arterial blood gas analysis, electrocardiogram, liver function tests, stool examination (mucosal ischaemia) and neurological imaging.[4]

During perioperative period, to avoid triggering of sickle cell crisis, factors like anxiety, emotional stress, infection, dehydration, acidosis, hypoxia, hypothermia, vascular stasis and increased blood viscosity should be addressed.[9]

Intracellular dehydration is a known trigger for HbS polymerization. Whenever possible, prolonged pre-operative fasting must be avoided.[9] The use of regional anaesthesia appears to be a useful means of pain control with effective blocking of nociceptive pathways and also prevent a vaso-occlusive crisis[10]. Use of tourniquet is safe to use provided optimum acid-base status and oxygenation are maintained throughout.[11-14]

Conclusion

SCD is a debilitating disease associated with increased risk of perioperative complications. Optimization of patient's laboratory parameters preoperatively is of utmost importance to prevent perioperative complications like VOC & ACS. Adequate control of infection, correction of anemia with simple or exchange transfusion can reduce the risk of complications. Adequate analgesia, incentive spirometry, early mobilisation and oxygen supplementation is the mainstay of post-operative management.

Triple Drug Therapy with Proton Pump Inhibitor a Better Option for Helicobacter Pylori Eradication

Lamture Y.R.[1], Thavendra Jaglal Dihare[2], Varsha Gajbhiye[3], Gode Dilip[4]

[1]Professor in Surgery, [2]Asst. Professor in Surgery, J.N. Medical College Wardha,
[3]Asso. Professor in Pharmacology, [4]Professor in Surgery, Datta Meghe Medical College, Nagpur

Abstract

Introduction: H. Pylori is a gram-negative micro organism residing in the stomach of human. It is a important cause of acid peptic disorders. Bismuth based triple therapy,triple therapy regimens(Tripple PPI) and Quadruple therapy are the available treatment options to eradicate H. pylori. Controversy still presents regarding the superiority of treatment modality and results of available studies are variable. Hence this study was undertaken to evaluate and compare the efficacy of triple PPI, Quadruple therapy, and bismuth-based triple therapy in treating acid peptic disorders and Helicobacter pylori eradication. Method: This study was a prospective interventional. After the establishment of a clinical diagnosis of the acid peptic disorder, the patient was posted for endoscopy. H. pylori status was determined by the rapid urease test and culture examination. All patients divided into three groups and offered three different medical treatments the first group received bismuth bases triple therapy, the second group got Tripple PPI therapy and the third one received quadruple therapy. efficacy and comparison of all these treatment modalities were evaluated and assessed by symptoms, endoscopic findings, and results of the rapid urease test after 6 weeks. Results: In the present study, 150 patients with upper gastrointestinal symptoms were studied It was found that the maximum number of subjects belonged to the age group 31-40 yrs. Male outnumbers than females. Maximum patients had pain in epigastric region and were having gastritis as a commonest diagnosis., Symptomatic relief by Triple therapy with PPI was maximum than other therapies. Rapid urease test (RUT) was also suggest that treatment with it gives superior eradication rates. Discussion: In our study, we have found that the treatment regime with PPI Triple therapy has given maximum symptomatic relief, there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%). the efficacy of the Rapid urease test is 66% and that of culture is 38.66% in the diagnosis of H. pylori infection in acid peptic disorder. Conclusion: PPI Triple therapy is most effective in symptomatic relief and healing of the duodenal and peptic ulcer.

Keywords: *Gastritis, rapid urease test, dyspepsia, tetracycline.*

Introduction

The acid peptic disorder is a disorder in which due to hyperacidity, there is the damage of inner lining (mucosa) of the stomach and duodenum causing various manifestations like inflammation, ulcer, etc. A major symptom of the acid peptic disorder is a pain in the abdomen typically non radiating, burning, and located at in epigastrium, Other include nausea, vomiting, dyspepsia, haemtemesis, and melena, etc. Upper gastrointestinal tract disorders are common in surgical practice. A disease of the stomach and duodenum range from a benign disease like gastritis, peptic ulcer diseases which are usually having a self-limiting although a prolonged course with a potentially dangerous complication like perforation with its attendant's peritonitis both chemical and bacterial, to malignant diseases like carcinoma of the stomach. The upper gastrointestinal disease forms

Corresponding Author:
Dr. Thavendra
Asst. Professor in Surgery, Surgery Department, J.N. Medical College Wardha

a major part of the total number of patients attending the outpatient clinic for gastrointestinal disorders. The treatment of peptic ulcers has been based on Schwartz dictum "No acid, no ulcer". Marshall and Warran in 1984 described microorganisms in the stomach of patients with gastritis and peptic ulceration first time in history. These investigators identified a spiral-shaped flagellated organism associated with peptic ulcer originally referred to as campylobacter pyloride. The organism is now known as Helicobacter Pylori[1].

H.Pylori is a gram-negative organism resides in the stomach of human and other animals,affecting half of the population of world[2].

H.Pylori is a common cause of peptic ulcer of stomach and duodenum leading to clinically present as recurrent abdominal pain. It is corelated with around 90% of duodenal ulcers and 80%of gastric ulcers, major cause of morbidity. Mortality associated however is low but can result in chronic illness leading to significant manpower loss it can also cause lymphoma and gastric carcinoma[3].

Present understanding about the aetiology of peptic ulcer disease, gastric cancer, and dyspepsia is under evolution. The invention of Helicobacter pylori as a infective aegent change our method to treat and diagnose it. Human beings are the only reservoir for Helicobacter Pylori. Direct transmission from person to person occurs via saliva and feces and infection also through contact with contaminated water[4].

The Nobel prize in physiology or medicine for the year 2005 was awarded to both J.Robin warren and Barry J Marshall. These Nobel winners made a astonishing and unbelievable invention that chronic inflammation in stomach and duodenum (Gastritis, gastic and duodenal ulcer), is due to an infection by bacterium H.Pylori. Many tried to disprove it [5]. As recent trend of decrease evidence of peptic ulcers was observed from last 40 years. The discovery of Helicobacter Pylori had a further major impact on the incidence of ulcer[6].

Bismuth based triple therapy comprising of colloidal bismuth subcitrate (120mg, q.i.d), tetracycline (500 mg, q.i.d) and metronidazole (400 mg, t.i.d) for 14 days is low cost, safe and have high success rates in metronidazole sensitive strains. Few investigators reveals upto 90 percent success rate. If tetracycline was replaced by amoxicillin then success rate decreased to 70 percent to eradicate H.pylori. Triple therapy (Tripple therapy with PPI) is a combination of a proton pump inhibitor and two antibiotics have now almost replaced the use of the classical bismuth-based triple therapy in all over world. This is due to less side effect and better eradication rate. Quadruple therapy **is** a try to get 100% removal of H. pylori by the addition of anti-secretory agents to the classic bismuth-based triple therapy. It has been noted that this quadruple treatment is more effective when a PPI is used as an anti-secretory agent rather than an H**2** receptor antagonist. Huang et al reported a promising eradication rates of 95% when omeprazole was added to the classical triple therapy.[7]

Controversy still presents regarding the superiority of treatment modality and results of available studies are variable[8]. Hence this study was undertaken to evaluate and compare the efficacy of triple PPI, Quadruple therapy, and bismuth-based triple therapy in treating acid peptic disorders and Helicobacter pylori eradication.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India. This study was a prospective interventional. The duration of this study was from September 2018 to September 2019. The numbers of patients were 150.

Sample size- 150

The sample size was calculated as per formula was around 134 Hence 150 sample size was sufficient ($N=2(Z\alpha+Z1-\beta)\ 2\ \sigma2/\Delta2$)

The present study was carried out on the patients attending surgical OPD as well as the surgical ward from September 2018 to September 2019 in a tertiary center. We selected 150 patients having gastrointestinal complaints. The complaints were a pain in the abdomen, usually, in the epigastric region, dyspepsia, nausea, vomiting, haemtemesis, melena, etc Detail history of patients was taken with regards to the symptom, their duration, and severity, other complaints, drug history. A thorough clinical examination and routine haematological examination of patients was done. After the establishment of a clinical diagnosis of the acid peptic disorder, the patient was posted for endoscopy. H. pylori status was determined by the rapid urease test and histopathological examination.

Inclusion Criteria: Patients between 15-60 years were having symptoms of the acid peptic disorder.

Exclusion Criteria:

1. Patients taking antibiotics and bismuth compounds or omeprazole 4 wks before endoscopy

2. Pregnancy.

Detail of Procedure Followed: Patients with clinical symptoms of APD were advised to attend the Gastroscopy clinic. The patients were kept nil orally at night and were advised to attend endoscopy clinic early in the morning Endoscopy was performed with Fujinon Gastroduodenoscope after obtaining informed consent. Esophagogastroduodenoscopy of each patient was done under surface local anesthesia with 4% Xylocaine viscous. Findings were noted and biopsies from the antrum and suspicious lesions were taken. Out of biopsies, one was subjected for a rapid urease test and the second biopsy specimen was used for histopathological examination. Endoscopic findings were recorded as gastritis, duodenal ulcer, gastric ulcer, gastric carcinoma, and endoscopically normal mucosa as per standard criteria.

All patients divided into three groups and offered three different medical treatments the first group received bismuth bases triple therapy, the second group got Tripple PPI therapy and the third one received quadruple therapy efficacy and comparison of all these treatment modalities were evaluated and assessed symptoms, endoscopic findings, and results of the rapid urease test after 6 weeks.

Data Collection: The data collected included the presenting complaints, clinical signs, endoscopic findings, results of rapid urease test, and histopathological examination.

Statistical Analysis: The presence of H pylori infection was correlated with symptoms, and endoscopy findings .this calculation was derived using SPSS 17.0 statistical software.

Ethical approval for the study was obtained from the ethics committee of DMIMS University.

Results

In the present study, 150 patients with upper gastrointestinal symptoms were studied It was found that the maximum number of subjects belonged to the age group 31-40 yrs. i.e. 26.66% followed by age group 21-30 yrs. ie 22.66%. It was found that of subjects male 112 and female 38.M: F 2.94:1. It was found that maximum no. subjects had pain in epigastric region 120 cases i. e. 80% followed by symptoms nausea 75 cases ie. 50%.

Table 1: endoscopic findings in patients with acid peptic disorder before treatment

Endoscopic findings	No. of Cases
Gastritis	70
Duodenitis	09
Duodenal ulcer	15
Gastric ulcer	O8
Gastric malignancy	02
Endosc. Normal mucosa but clinically symptoms of APD	46
Total	**150**

70 patients were having gastritis,15 had a duodenal ulcer,9 patients had Duodenitis, the gastric ulcer was found in 08 patients, gastric malignancy in 02 patients and 46 patients had endoscopic normal mucosa. The highest positivity of RUT was seen in patients of duodenal ulcers (86.66%), followed by gastritis (82.85%) and gastric ulcer (75%).

Table 02: Treatment regimen given in acid peptic disorder

Regimen	No. of Patients	Symptomatic relief	%
Bismuth Triple Therpy	38	24	60.52
Ppi.Triple Therpy	82	78	95.12
Quadruple Therpy	30	22	73.33

Symptomatic relief with PPI Triple therapy was 95.12%, followed by Quadruple Therapy in 73.33% and Bismuth triple therapy 60.52%.

Table 03: Gastroscopic findings after six weeks of treatment:

Endoscopic finding	No. of cases improved	%	No. of cases not improved	%
Gastritis	63	90	07	10
Duodenitis	08	88.88	01	11.11
DU	14	93.33	01	6.66
GU	06	75	02	1.25
GM	01	50	01	50
Endo. normal but clinically APD	42	91.30	04	8.69
Total	**134**	**89.34**	**16**	**10.66**

Out of a total of 150 patients who received treatment 134 patients (89.34%) improved and 16 (10.66 %) patients not improved.

Table no. 04: The result of rapid urease test and culture before treatment

Test	Positive	%	Negative	%
Rapid urease test	99	66	51	34
Culture	58	38.66	92	61.33

RUT test was positive in 66% of patients and negative in 34% of patients. Culture was positive in 38.66% patients and negative in 61.33%patients.

Table No. 05: the result of rapid urease test and culture after treatment

Test	Positive	%	Negative	%
Rapid urease test	15	10	135	90
Culture	12	8	138	92

RUT test was positive in 10% of patients and negative in 90% of patients. Culture was positive in 8% patients and negative in 92% patients 6 patients from bismuth-based treatment group 5 patients from quadruple and 4 from the Tripple PPI treatment group.

Discussion

In this study, 150 patients (112 men and 38 women), within the range of 15 to 72 years, with symptoms suggestive of acid peptic disorder, were included.

In our study, we found that acid peptic disorder was more common in the age group 31-40 years (26.66%cases). Followed by 21-30 years (22.66%cases) and 41-50 years (17.33% cases). In our study in patients with acid peptic disorder rapid urease test was positive in 99 patients (66%).

Name of the study	Year	RUT %	Culture %
Sivaprakash et al[8]	1994	38.7	43
Maimomma et al[5]	1994	65.8	47
Sharma B et al[7]	2006	59	-
In Our study	2008-09	66	38.66

In present study, the result with 3 different modalities of treatment was used as follows Bismuth triple therapy symptomatic relief in 34 patients (89.43%), PPI Triple therapy in 76 patients (92.68%) and Quadruple therapy in 28 patients (93.33%)

As per another study by Vikram kate (2005)[7]Bismuth therapy was used symptomatic relief in 30 – 90% patients, PPI triple therapy in 85-95% patients, and Quadruple therapy in 86-98% patients.

In present study, we found gastroscopic findings were improved 134 patients (88.93%) and not improved 16 patients (10.66%) after six weeks of treatment.

The cure rate of 80-85 % was achieved using combination therapy. Richard Guan et al, showed eradication of H. Pylori in 90% cases after a week with a triple regimen.

The present study was carried out on the patients attending surgical OPD as well as admitted patients in the ward who had clinical symptoms suggestive of acid peptic disease from September 2018 to September 2019 in the tertiary care center. A total of 150 patients were studied and advised to attend the Gastroscopy clinic.

1. The symptoms of acid peptic disorder were more in 31-40 years followed by 21-30 years.

2. In our study, we have found there was male predominance with male to female ratio of 2.94:1.
3. In our study, we found that there was an association of symptoms of acid peptic disease with H. Pylori infection. Pain in the epigastric region (80%) and nausea (50%) were the most frequent symptoms associated with H. pylori infection followed by dyspepsia (30.66%).
4. In our study, we have found that there is a strong association between H. Pylori in duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
5. In our study, we have found that the rapid urease test for H. Pylori was positive in 66% of patients and culture was positive in 38.66%.
6. In our study, we have found that the treatment regime with PPI Triple therapy has given maximum symptomatic relief (95.12%). The other treatment regimens and the symptomatic relief provided by them are as follows:
    a. Quadruple therapy 73.33%
    b. Bismuth triple therapy 60.52%.

Conclusion

From the study we could draw the following conclusion:

1. In our study, we have found that the incidence of Helicobacter infection in acid peptic disorder is 66%.
2. In our study, we have found that there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
3. In our study, we have found that the efficacy of the Rapid urease test is 66% and that of culture is 38.66% in the diagnosis of H. pylori infection in acid peptic disorder.
4. PPI Triple therapy is most effective in symptomatic relief and healing of the duodenal and peptic ulcer.

dangerous complication like perforation with its attendant's peritonitis both chemical and bacterial, to malignant diseases like carcinoma of the stomach. The upper gastrointestinal disease forms a major part of the total number of patients attending the outpatient clinic for gastrointestinal disorders. The treatment of peptic ulcers has been based on Schwartz dictum "No acid, no ulcer". The gastric acid has dominated the approach to the diagnosis and treatment of peptic ulcer disease. Marshall and Warran(1984) published a paper entitled unidentified curved bacilli in the stomach of patients with gastritis and peptic ulceration first time in history. These investigators identified a spiral-shaped flagellated organism associated with peptic ulcer originally referred to as campylobacter pyloride. The organism is now known as Helicobacter Pylori[1]. H.Pylori is a gram-negative organism resides in the stomach of human and other animals,affecting half of the population of world[2]. H. Pylori is a common cause of peptic ulcer of stomach and duodenum leading to clinically present as recurrent abdominal pain. It is corelated with around 90% of duodenal ulcers and 80%of gastric ulcers, major cause of morbidity. Mortality associated however is low but can result in chronic illness leading to significant manpower loss.it can also cause lymphoma and gastric carcinoma[3]. Present understanding about the aetiology of peptic ulcer disease, gastric cancer, and dyspepsia is under evolution. The invention of Helicobacter pylori as a infective aegent change our method to treat and diagnose it. Human beings are the only reservoir for Helicobacter Pylori. Direct transmission from person to person occurs via saliva and feces and infection also through contact with contaminated water[4]. The Nobel prize in physiology or medicine for the year 2005 was awarded to both J.Robin warren and Barry J Marshall. These Nobel winners made a astonishing and unbelievable invention that chronic inflammation in stomach and duodenum (Gastritis, gastic and duodenal ulcer), is due to an infection by bacterium H.Pylori. Many tried to disprove it [5]. As recent trend of decrease evidence of peptic ulcers was observed from last 40 years. The discovery of Helicobacter Pylori had a further major impact on the incidence of ulcer[6]. So This study was undertaken to evaluate the correlation of H.Pylori infection with acid peptic disorders.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India. This study was a prospective observational. The duration of this study was from September 2017 to September 2019. The numbers of patients were 150. The sample size was calculated as per formula was around 134 Hence 150 sample size was sufficient ($N=2(Z\alpha+Z1-\beta)\ 2\ \sigma2/\Delta2$). The present study was carried out on the patients attending surgical OPD as well as the surgical ward from September 2017 to September 2019 in the tertiary center. We selected 150 patients having gastrointestinal complaints. The complaints were a pain in the abdomen, usually in the epigastric region, dyspepsia, nausea, vomiting, haemtemesis, melena, etc. In personal history, the habit of tobacco chewing, cigarette smoking, alcohol consumption, and appetite were included. Detail history of patients was taken with regards to the symptom, their duration, and severity, other complaints, drug history. A thorough clinical examination and routine haematological examination of patients was done. After the establishment of a clinical diagnosis of an acid peptic disorder, the patient was posted for endoscopy. H. pylori status was determined by the rapid urease test and histopathological examination.

Inclusion Criteria: Patients between 15-60 years were having symptoms of the acid peptic disorder.

Exclusion Criteria: Patients taking antibiotics and bismuth compounds or omeprazole 4 wks before endoscopy. Pregnancy.

Detail of procedure followed. Patients with clinical symptoms of APD were advised to attend the Gastroscopy clinic. The patients were kept nil orally at night and were advised to attend endoscopy clinic early in the morning Endoscopy was performed with Fujinon Gastroduodenoscope after obtaining informed consent. Esophagogastroduodenoscopy of each patient was done under surface local anesthesia with 4% Xylocaine viscous. Findings were noted and biopsies from the antrum and suspicious lesions were taken. Out of biopsies, one was subjected for a rapid urease test and the second biopsy specimen was used for histopathological examination. Endoscopic findings were recorded as gastritis, duodenal ulcer, gastric ulcer, gastric carcinoma, and endoscopically normal mucosa as per standard criteria.

Data Collection: The data collected included

the presenting complaints, clinical signs, endoscopic findings, results of rapid urease test, and histopathological examination.

Statistical Analysis: The presence of H pylori infection was correlated with symptoms, and endoscopy findings .this calculation was derived using SPSS 17.0 statistical software.

Ethical approval for the study was obtained from the ethics committee of DMIMS University.

Results

In the present study, 150 patients with upper gastrointestinal symptoms were studied It was found that the maximum number of subjects belonged to the age group 31-40 yrs. i.e.26.66% followed by age group 21-30 yrs.ie 22.66%. It was found that of subjects male 112 and female 38.M: F 2.94:1

Table 01: Symptoms profile of patients

Symptom	No. of cases	Percentage
Pain in epigastric region	120	80
Nausea	75	50
Vomiting	42	28
Dyspepsia	46	30.66
Haemtemesis	15	10
Meleana	09	06

Table 3. shows the symptoms profile of study subjects. It was found that maximum no. subjects had pain in epigastric region 120 cases i. e. 80% followed by symptoms nausea 75 cases ie.50%.

Table 02: endoscopic findings in patients with acid peptic disorder

Endoscopic findings	No. of cases
Gastritis	70
Duodenitis	09
Duodenal ulcer	15
Gastric ulcer	O8
Gastric malignancy	02
Endosc. Normal mucosa but clinically symptoms of APD	46
Total	150

70 patients were having gastritis,15 had a duodenal ulcer,9 patients had Duodenitis, the gastric ulcer was found in 08 patients, gastric malignancy in 02 patients and 46 patients had endoscopic normal mucosa.

Table 3. Result of Rapid Urease Test in Acid Peptic Disease

Sr. No.	Diagnosis	No. of pts.	RUT positive	Percentage
1.	Gastritis	70	58	82.85
2.	Duodenitis	09	05	55.55
3.	DU	15	13	86.66
4.	GU	08	06	75
5.	GM	02	01	50
6.	Endo. Normal but clinically s/o APD	46	16	34.78

The highest positivity of RUT was seen in patients of duodenal ulcers (86.66%), followed by gastritis (82.85%) and gastric ulcer (75%).

Discussion

In this study, 150 patients (112 men and 38 women), within the range of 15 to 72 years, with symptoms suggestive of acid peptic disorder, were included. In our study, we found that acid peptic disorder was more common in the age group 31-40 years (26.66%cases). Followed by 21-30 years (22.66%cases) and 41-50 years (17.33% cases).

In similar studies following results were seen:

Table 4: comparison with previous studies:

Study	Year	Mean age of patients with APD
B Sharma[7]	2006	32.8
C. Rekha[8]	2007	40.89
GM Malik et al[9]	1999	34.80
J. Yakoob et al [10]	2005	40.89
Endale Tadesse et al[11]	2014	36
Present study	2019	38.48

Sex wise distribution: In our study, we found that Acid peptic disorder was more common in males as compared to females. M: F ratio was 2.94: 1

Table 5: Endoscopic Finding

Study	Gastritis	Duodenal ulcer	Gastric ulcer
In our study	82.85%	86.66%	75%
Yakoob et al (2005)[10]	65%	-	-
J M Pajures (2005)[12]	88%	90%	80-90%
Vandana Berry (2006)[13]	-	90%	80%
Richard G (2005)[14]	-	95%	80%

In our study, we found a maximum number of duodenal ulcer cases (86.66%) followed by gastric ulcer cases (75%) and gastritis (82.85%)

Symptom Analysis: In our study, we found epigastric pain, nausea, dyspepsia, and vomiting as the most common symptoms associated with the acid peptic disorder as detected on endoscopy (see table 3).

Vandana Berry[13] in their study found that most common symptoms are epigastric pain, nausea, vomiting, and dyspepsia

Tom Richard Okello (2006)[14,15] in their study found that the most common symptoms are a pain in the epigastric region, dyspepsia, haematemesis recurrent abdominal pain, vomiting, and miscellaneous. The findings in the present study are comparable to these studies

Table 6: comparison with previous studies for diagnosis

Name of the study	Year	RUT %
Sivaprakash et al [15]	1994	38.7
Maimomma et al [2]	1994	65.8
B Sharma [7]	2006	59
Our study	2019	66

In our study in patients with acid peptic disorder rapid urease test was positive in 99 patients (66%).

Conclusion

The present study was carried out on the patients attending surgical OPD as well as admitted patients inward who had clinical symptoms suggestive of acid peptic disease from September 20017 to September 2019 in the tertiary care center. A total of 150 patients were studied and advised to attend the Gastroscopy clinic.

1. The symptoms of acid peptic disorder were more in 31-40 years followed by 21-30 years.
2. In our study, we have found there was male predominance with male to female ratio of 2.94:1.
3. In our study, we found that there was an association of symptoms of acid peptic disease with H. Pylori infection. Pain in the epigastric region (80%) and nausea (50%) were the most frequent symptoms associated with H. pylori infection followed by dyspepsia (30.66%).
4. In our study, we have found that there is a strong association between H. Pylori in duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
5. In our study, we have found that the rapid urease test for H. Pylori was positive in 66% of patients.

From the study we could draw the following conclusion:

1. In our study, we have found that the incidence of Helicobacter infection in acid peptic disorder is 66%.
2. In our study, we have found that there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).

Increased Paediatric Screen Time During Pandemic: A Cause of Concern to Child Health

Yogita Shrivas[1], Sujata Shamkuwar[2], Radha Andhare[2], Ashish Varma[3]

[1]Professor, Dept. of Kaumarbhritya, DMAMCHRC, Nagpur, [2]Asst. Professor, Dept of Strirog and Prasuti Tantra, Govt Auto, Ayurved College, Jabalpur, [3]Professor, Deptof Kriya Sharir, DMAMCHRC, Nagpur, [4]Associate Professor Dept. of Paediatrics Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi Meghe, Wardha-442001

Abstract

COVID-19 has put the globe in an unforeseen and unexpected situation. COVID-19 has affected everyday life all over the world. Human population came face to face to this virus so gravely for the first time. During the initial days nearly all countries imposed lockdown to break the chain of viral spread. This created significant knock-on effects on the daily life of citizens. With the updates on COVID-19, the guidelines issued by medical authorities, categorized geriatric and paediatric age groups to be at high risk. In order to flatten the rising curve of exponential spread of the virus ban on gatherings resulted in enforced shut down of schools. Therefore children were bound to stay home. They were automatically exposed to the over use of electronic gadgets for recreation as well as education purpose .Hence, their screen time increased many fold. This paper describes the impact of COVID-19 and use of electronic screen on children.

Keywords: *COVID-19, Lockdown, screen time, children.*

Introduction

COVID -19 has taken a toll on every aspect of human life. Its rapid spread around the world, has posed enormous health, economic, environmental and social challenges to the global population. As a result, for the protection of their population mostly all the countries opted for lockdown. Nearly all nations are trying to slow down disease transmission by monitoring and treating patients, quarantining suspected individuals by touch surveillance, banning large gatherings, enforcing complete or partial lock-downs etc. The pandemic of corona virus is a serious disruption to the global economy. With the passage of time, to boost the sinking economy, gradually lockdowns are being lifted up. As,no records of any clinically approved antiviral drugs or vaccines that are effective against COVID-19 have been published so far. Therefore clinically vulnerable geriatric and paediatric age groups are forced to stay indoors, only. Due to schools shut all over still, over 1.*2 billion children* are out of the classroom globally. [1,2]As, the pandemic continues to exist globally, the education sector had to shift to the online method of teaching and learning.

During lockdown, children were already made to sit home. Due to lack of physical activity and social interaction, children engaged themselves with cell phones, computers, laptops, tablets and televisions. This added to many fold increase in the screen time of children. Parents also are struggling to maintain balance between work and childcare.[3] This is also one of the factors contributing to acceptance of kids engaging with gadgets.

Though, earlier there was high growth in education technology, it has been observed that there is a significant rise in usage of language apps, virtual tutoring, video

Professor, Dept of Kaumarbhritya, Datta Meghe Ayurvedic Medical College, Hospital and Research Centre, Nagpur
e-mail: yogitashrivas@gmail.com

conferencing tools, or online learning softwares, since COVID-19.[4]

The World Bank is working actively with education ministries in dozens of countries to support their efforts to use all kinds of educational technologies to provide distant learning opportunities to students while schools are closed, as a result of the COVID-19 pandemic.[5]

The Diksha, E-pathshala, Swayam, The National Repository of Open Educational Resources, are various free digital e-Learning platforms shared by the Ministry of HRD, India.

The decision of online schooling, is however, contributing to the increased screen time. During pandemic, the start of online education, urged parents to buy smart phones for schooling of kids. Not just schooling, many other online hobby classes also emerged on the web platform. Kids are being engaged in these activities, too. Thus, children are definitely spending much time on screen.

Aims: To assess the impact of pandemic on children education and health

Objectives:

1. To understand the effect of Covid-19 on education sector
2. To know the effect of online and offline screen activities on child health
3. To explore the possible solution to the problem

Materials and Method

Various Research articles, news bulletins, international reports, websites online available books, book chapters were reviewed thoroughly to understand and produce the contents.

Discussion

Many a number of researchers have done a comprehensive study on the evil effects of smart phones or cell phones on human health. Smartphones, Cordless phones emit radiofrequency radiation (RF). During the use of cell phones, brain is the easy target for radiations. Considering this fact, IARC (International Society for research on Cancer)evaluated the knowledge in case–control human studies by the Hardell group from Sweden and the IARC Inter-phone study .These studies provided supportive evidence of increased risk for brain tumors, like glioma and acoustic neuroma. (IARC Monograph, 2013). The scientific panel concluded that RF radiation in the frequency range 30 kHz–300 GHz is a Group 2B possible human carcinogen[6].

There are various possible health risks associated with overuse of mobile phones to mental and physical well-being, especially low IQ & inadequate behavioral growth in children, sleep deprivation, brain tumors and psychiatric disorders are major problems.[7]

During growing age, healthy spine is a prerequisite. When kids are slouching over a cell phone for many hours every day, their neck and back muscles are affected. So, they experience nagging pain in these parts. Pain, strain and aching neck muscles can cause a severe headache. Berolo, Wells, & Amick III in 2011 and Ning, Huang, Hu, & Nimbarte, in 2015, mentioned that hand held devices like smart phones and tablets have been associated with musculoskeletal pain and discomfort, particularly in children.[8][9]

Riadh et al., 2011 stated that as kids develop more quickly, their cell division is faster. Also their heads are more slender, hence they have bigger effect on their brain. Now, the prevalence of mobile phones use is increasing in children and possibility of children to be more sensitive than adults to potential adverse effects from exposure to RF-EMF, continuous monitoring of children's health in relation to mobile phones and tablets is needed.

Children spend 7-8 hours of time on smart phones/ computers alone, which is longer than they spend on any other activity. [10]

As children get used to personal space, it may further decrease children's social interaction. Face-to-face social interaction during childhood, is a major factor affecting the development of children's social competence [11] There is also the possibility of bidirectional associations between child social-emotional development and media use.[12]

Use of cell phones prior to sleep may affect the initial part of sleep by making changes in brain activity.[13]

Excessive screen time may lead to accelerated myopia excessive screen time.[14] Mobile phones are smaller devices that are generally held at a distance of 20–30 cm from the eyes, leading to digital eyestrain. It has been reported by Long et al that if the viewing

distances are closer, the resulting eyestrain symptoms are greater after reading for 60 min from a smartphone.[14]

Mostly digital screens are backlit and emit blue light or high-energy visible (HEV) light wavelengths. It has been found that eyes are sensitive to blue light exposure. Gradually, after a passage of time the overall damage may increase the chances and severity of eye disorders. (e.g. age-related macular degeneration and cataracts)[13]

Pediatric age group is growing up with touchscreen technology at their fingertips The speculations that the rising prevalence of asthenopia in the young may be due to over use of smart phones seems to be reasonable.[11]

An eye examination, reducing the amount of time that a child can continuously use the computer, the position of the computer, the lighting for glare on the computer screen, reduction of the amount of lighting in the room are the requirements for appropriate viewing habits in children.[14]

Similarly,the use of smart phones or tablets should also be under proper guidance by following sop of their usage.

Kesari *et al*. reported that mobile phone radiation may increase the reactive oxygen species, which plays an important role in the development of metabolic and neurodegenerative diseases. In an animal study,chronic exposure to Wi-Fi radiation appeared to cause behavioural alterations, liver enzyme impairment, pyknotic nucleus, and apoptosis in brain cortex.

With the advent of digital technology, entire population is exposed to some or the other effects of technology. Earlier generations have never been exposed during childhood and adolescence to this kind of radiation. Hence, it is going to take a long time to evaluate and conclude about the effects of radiation on younger population. Neuro-degenerative and carcinogenic changes take decades to manifest. But when earlier studies have already proved,use of smart phones as one of the possible causes of rise in cancer, education policy makers must keep in mind these established facts while designing education policy for younger population of the country.

In India, Swayam Prabha, a group of 32 Direct To Home (DTH) channels is devoted to telecasting of educational programs round the clock . The programmes are available across the country. The channels air courses for school education (class 9-12), higher education (undergraduate, postgraduate) as well as for out-of-school children, vocational education and teacher training.

A start up Think Zone" in Odisha, India has taken an initiative to reach out to children with no access to internet facility. It is broadcasting activity based learning modules with the help of a local radio channel for students aged 3 to 10.

Similarly, there is a need to explore other options of teaching and learning which are less harmful to paediatric age group. Many intellectuals assert that education system was already losing its relevance but the varying effectiveness of online learning cannot compete with the absence of classrooms.

Conclusion

To think of any long-term effects of the current online education scenario, will be a hasty step. But definitely a serious thought must be given to the future consequences of screen use by pediatric age group. Perhaps it is too necessary to educate children, but it still isn't that big problem at all. So, it is the need of the hour to think about affordability of imparting education at the cost of health. Thus, the other ways out for educating children must be explored. More the hours of use, more will be the absorption of radiations, so children must be taught to refrain from mobile phones. Landlines, Skype, and computer phone services, when connected to the internet with a cable, don't give off radiations, therefore the parents should take care that kids use those. The Wi-Fi routers in the home should be placed away from where people, particularly children, spend most of their time. To keep children healthy, overuse of cell phones and other wireless devices by kids must be restricted. We must not undermine children's mental and physical state day-by-day, caused by the excessive usage of cell phones for education as well as recreation.

Indirect Impact of COVID-19 Lockdown on Society and Environment

Radha Andhare[1], Yogita Shrivas[2], Shubhada Guru[3], Abhishek Joshi[4]

[1]Professor and HOD, Department of Kriya Sharir, [2]Professor and HOD, Department of Kaumarbhrutya, [3]Associate Professor, Department of Kriya Sharir, Datta Maghe Ayurvedic Medical College, Hospital and Research Centre, Nagpur, [4]Associate Professor Dept. of Community Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi Meghe, Wardha-442001

Abstract

In a fairly short time, the worldwide spread of COVID-19 has brought a dramatic reduction in industrial activities, road traffic and tourism. During this time of crisis restrained human interaction with nature has appeared as a blessing for nature and the environment. Reports from around the world indicate that environmental conditions, including air quality and water quality in rivers, are improving after the COVID-19 outbreak, and wildlife is blooming. India has always been a pollution hub with enormous populations. But since COVID-19 announced the lockdown, air quality has begun to improve and all other environmental parameters such as water quality in rivers have begun to offer a positive sign of restoration.

Keywords: *COVID-19, Lockdown, Impact, society, Environment, Trade, Unemployment.*

Introduction

As of 21 August 2020, Covid-19, who emerged in Wuhan somewhere back eight months in December 19, has now taken shelter in host bodies in 213 countries across the globe infecting 22,589,017 people and 792,475 deaths. India has also reported more than 2,905,823 positive cases with 54,849 death tolls on the same day[1]. The disease remains uncontrolled, and the virus has no proven cure. Locking in homes and social distances is the only preventive step the country as a whole is taking. But as the human activities in most areas are limited, the country's natural environment has begun to heal itself. Factories, trade, aircraft and aviation are all at a standstill. Social media has immerged out as platform for people to stay connected with each other. Lockdown due to COVID-19 has also affected employment status of whole world. Worldwide import and export has been reduced substantially.

Aims and Objectives:

1. Discussion about the various effects of lockdown due to COVID-19 on environment, mental health, trade, unemployment etc.
2. Try to find solutions on adverse effects.
3. Try to find out solutions to maintain positive effects of lockdown.

Materials and Method

Material and data for this article is collected from authentic official websites and news channel reports from national and international platform.

Result

Due to lockdown, environment and society is influenced as follows:

Air Quality: Thanks to the effect on travel and industry of the coronavirus outbreak many regions

Corresponding Author:

Mob No.: 9359029449, 7709046635

and the world as a whole witnessed a decrease in air pollution.[2] The Energy and Clean Air Research Centre estimated that strategies for suppressing coronavirus spread, such as quarantines and travel bans, resulted in a 25% reduction in carbon emissions.[3] NASA uses an instrument for ozone monitoring (OMI) to measure and monitor the ozone layer and contaminants such as NO2, aerosols and others. According to scientists at NASA, the decline in NO2 emissions originated in Wuhan, China and spread gradually to the rest of the planet.[4]

Water Quality: Water in the canals in Venice cleared and saw greater flow of water[5]. The increase in water clarity was attributed to the settling of sediment which is disturbed by boat traffic and the decrease in air pollution along the waterways listed.[6]

Wildlife: Some animals have been seen in towns as people remain at home due to lockdown and travel restrictions. Sea turtles were seen laying eggs on the beaches they once avoided (such as the Bay of Bengal coast), due to lower human intrusion and light pollution rates.[7]

German scientist Rainer Froese has said that fish biomass will increase due to the sharp decline in fishing, and has projected that some fish such as herring could double their biomass in European waters.[8]

Carbon Emission: A study published in May 2020 found that the daily global carbon emissions declined by 17 percent during the lockdown steps in early April and could lead to an annual decrease in carbon emissions of up to 7 percent, which according to researchers would be the largest drop since World War II. They attribute these declines largely to reducing the usage of transport and manufacturing activities.[9]

Public Mobility: Public mobility has deteriorated dramatically due to constraints, including the imposition of a lockout in several countries, a Google Study reveals. Across India, shopping and leisure places saw the steepest decline across people's presence between February 16 and March 29 relative to traffic between January 3 and February 6. There was a significant rise in phone traffic from homes, meaning more people were staying at home. Visits to restaurants, shopping malls and movie theatres plummeted by 77 per cent between Feb. 16 and Mar. 29 compared to the period from Jan. 3 to Feb. 6. Visits to stores, markets and pharmacies have dropped by 65%. Visits to national parks, beaches and public gardens have been reduced by 57%. Compared to the period between Jan. 3 and Feb. 6, the use of public transport facilities such as buses and trains fell 71 per cent between Feb. 16 and Mar. 29. Workplace visits declined 47 per cent as many people were told to work from home. People stayed 22 per cent more at home than they did between January 3 and February 6.[10]

Impact on Trade: Trade in United States has been declined which shows impact on the trade in other countries of world.

Table: Effect of lockdown on Trade

Sr.No.	Trade	Export	Import
1	Passenger cars and light trucks	Decreased by 9.8 percent	Decreased by 6.2 percent
2	Engine and parts	Decreased 28.9 percent	Decreased by 23.0 percent.
3	Crude oil	Decreased 7.9 percent	-
4	Refined petroleum products	Decreased 9.8 percent	-
5	Medical equipment	Increased 24.2 percent	-
6	Medical diagnostic equipment	Increased 34.8 percent	-
7	Medical diagnostic products	-	Increased 44.4 percent
8	Disinfectants and sterilization products	Increased by 14.4 percent	-

Impact on Unemployment: The International Labour Organization (ILO) projected that the spread of corona virus would threaten more than 25 million jobs globally. Four out of five people (81 per cent) in the 3.3 billion global work forces are currently impacted by the complete or partial closure of the workplace. The United States, the United Kingdom, Canada and most European and Asian countries have already registered huge jobs

losses leading to significant increase in unemployment. The ILO in its report '', describes COVID-19 as 'worst global crisis since World War II'[11].

Low-paid and low-skilled informal workers are particularly concerned in low- and middle-income countries, where the industries and services have a high proportion of these informal employees, who account for 61 per cent of the global workforce or 2 billion men, and lack any social security. The sudden loss of livelihood will make them horrifying.

The CMIE (Centre for Monitoring Indian Economy) report showed a major job loss and corresponding substantial unemployment rate rise in March 2020. The unemployment rate in March 2020 stands at 8.7 per cent, which is far higher than the government's estimate of unemployment in 2017-18 at a 45-year high of 6.1 per cent. This is the highest jobless rate since September 2016. Over the same time, the unemployed have also risen from32 million to 38 million. The situation got worse when we went into the lockdown time last May week and the unemployment rate rose to 23.48%.[11]

Role of Social media during lockdown: During the lockout the social media plays a significant role. During the lockdown social media always update people's current affairs. The role of social media is very important in managing the anger, tension, and fear of the people and in helping they update the current scenario. Also Study indicates that active use of social media is better for you than passive use, so consider writing a blog or sharing status updates as a way to connect. And it will help you organize virtual encounters with family and friends. These should not limit themselves to chatting; they will engage in community activities such as watching films, playing drama and online conversation through video calls and share their views on academic aspects and other aspects of cooking together. Teachers are conducting online lectures for their students so they do not skip their academics by use of social media applications during the lockdown.

Only a couple of days of isolation may cause anxiety and depression to develop. Add to it the imminent possibility of constantly hammering a terrible disease through the media, and you have a prescription for several shades of mental and physical distress.

Impact on Mental health and behavior: Human beings have evolved into social beings, and are designed to live in collaborative communities. Feeling removed from families, friends and employers can be unbalanced and stressful for most people and can lead to psychological and physical health issues in the short or even long term. Psychological consequences of isolation may include a rise in levels of anxiety, aggression, depression, forgetfulness and hallucinations. In those with inherent pre-existing susceptibilities psychiatric disorders that are precipitated and even manifest without precondition in several others. Personal relationships help us cope with tension, and if we lack this outlet for steam, a massive emotional voice will result which, for an average person, is difficult to deal with.

Solitary inmates and patients in segregated medical facilities have also had negative psychological effects including elevated anxiety, panic attacks and elevated paranoia rates. This has been found that social isolation has a correlation with greater alcoholism. Researchers who had to live in remote areas such as deserts, the Antarctica, forests and outer space have confirmed that overcoming loneliness is a tough challenge. Yossi Ghinsberg, an Israeli explorer who spent several weeks alone in the Amazon, admitted making imaginary companions to fend off the loneliness. The shutdown of Covid has put forced isolation on many.

Young people live away from their families, trapped in small apartments with abysmal cooking skills. Many senior citizens living on their own seek companionship by meeting up in community parks with age mates. We find themselves marooned, robbed of social contact and even from their children's sporadic visits. Lack of playtime with peers causes children to become irritable and edgy.

Staying in a confined space with family is not a pink picture for everyone. It may be extremely oppressive and claustrophobic for large low-income families huddled together in small single-room houses. Children are not lucky enough to have a lot of board/electronic games or books to keep them busy. Add to this the profound uncertainty of running out of food funds and basic necessities. On the other hand, there are people with dysfunctional family dynamics, such as dominant, abusive or alcoholic partners, siblings or parents, who make a period of trial stay at home. There has been a worldwide increase in the incidence of suicide and physical abuse against women. Higher anxiety and depression often impair an individual's immune system and make them more vulnerable to disease.

Discussion

The issue today is not whether the Covid-19 passage will bring similar socio-political changes; experts predict it will be a long and damaging fight. This needs to be preparing for the long term. We need to control our population's physical and psychological harm by urgently diverting full resources to improve our health-care system. We have to maintain a fair distribution of food and essential needs among the less favoured groups. Before the lockout we tripped badly by misunderstanding their worries. Even more bungling will lead to messy rioting scenarios and food theft. The Government needs to move into action quickly to prevent losing legitimacy. A higher death toll also means that many families deprive members of their earnings and put greater burden on the welfare system. Throughout India, losses are the highest in the males of the 22-40 year age group, which is also the most active.

Import and export trade has decreased all over the world due to lack of transport; but environment is seen to be recovering up to great extent.

Today, social media like Twitter, Face book and Instagram have become the main information sources. They are also platforms for misinformation and false news.

Conclusion

Stigma and blame targeted at outbreak-affected communities may hinder international trade, finance, and relationships, prompting further unrest. Care needs to be taken to erase the stigma associated with disease, racism, religious propaganda and psychosocial impact and to be implemented through regular discussions with trained and specialist healthcare staff by setting up task forces and execution teams that are directly involved in healthcare delivery systems without creating any communication gaps between policy makers and ground level.

It is desperately necessary to set up mental health organizations specific to future pandemics with branches in many nations and individual healthcare institutions for research, delivery of mental healthcare and organization of awareness programs at both personal and community levels. To relieve psychological anxiety in the general population over this continuing pandemic, standardized websites and toll-free helpline numbers can be introduced. Social media should be used in good sense to educate people about dynamics of transmission, disease symptoms, and time when precise medical consultations are required. Strict government laws and legislation regarding fake news, social media rumours, disinformation and misinformation should be implemented to protect social media from devaluations.

The COVID-19 pandemic has clearly shown us how, even in the 21st century, a "virus" can adversely impact our lives and at the same time make us aware that the greatest assets of humanity are health, goodwill, compassion, unity, creativity and awareness.

Assessment of Age in Female Population by Radiographic Examination of Carpal Bones

Pawan A. Wankhade[1], Rajesh B. Ramteke[2], B.H. Tirpude[3], Ninad Nagrale[4], Shailesh Nagpure[5]

[1]Associate Professor, Forensic Medicine Dept, GMC, Shahdol, Madhya Pradesh-484001, [2]Assistant Professor, Forensic Medicine Dept, Raipur Institute of Medical Sciences, Raipur, Chhattisgarh, [3]Prof. & Head, Forensic Medicine Dept, MGIMS,Sewagram, Wardha, MH-442102, [4]Associate Professor, Department of Forensic Medicine, Datta Meghe Medical College, Nagpur, Maharashtra, [5]Associate Professor, Department of Pharmacology, Jawaharlal Nehru Medical College, DMIMSU, Sawangi, Maharashtra

Abstract

Introduction: Assessment of the age of an individual from the appearance and the fusion of the ossification centers is a well-accepted fact in Medical and Legal professions. In the age estimation of juvenile offenders, radiological examination of bones gives valid idea of age needed in courts.

Objectives: Aim was to assess the age of the ossification of carpal bones at wrist joint in females. The objectives were to estimate the age specific difference in all subjects, also to study difference age of ossification in central part of India with other part of country and abroad.

Method: After obtaining the ethical clearance the subjects below the age of 20 years residing in central India were included in this study. As per inclusion criteria carpal bones forming wrist joint were examined radiologically with standard accepted procedures and guidelines to assess the age.

Result: The outcome of this study was very fruitful and knowledgeable as it revealed age specific difference and remarkable difference in the age of ossification as compared to the foreign countries and other parts of India.

Conclusion: Radiological examination plays very vital role in age estimation in judicial cases. It can be concluded that such studies should be conducted with good sample size and at regular intervals for academic as well as in judicial point of view.

Keywords: *Age, Asses, Ossification, Wrist joint, Radiological.*

Introduction

Age is helpful in identification of an individual which in turn is helpful in both civil and criminal cases according to Sangma William Bilkey ch. et al[1]. It has been also stated that the study of epiphyseal union of bones is considered a reasonable scientific and accepted method for age determination by the law courts all over the world[2]. **Forensic Osteology** is the branch of Forensic Medicine which deals with the study of the bones. Epiphysis of the bones unites during age periods which are remarkably constant for a particular epiphysis[3]. Epiphysis of the bones unites at the particular age and this is helpful in the age determination. In law the crime and punishment is entirely based on the criminal responsibility and this in turn depend on the age of a person[4].Reddy KSN stated that (2009) the bones of human skeleton develop from a number of ossification

Corresponding Author:
Dr. Rajesh B. Ramteke
Assistant Professor, Forensic Medicine Dept., Raipur Institute of Medical Sciences, Raipur, Chhattisgarh
e-mail: rajeshramteke558@gmail.com
Mob.: 8208761672

centers. At eleventh to twelth week of intrauterine life, there are 806 centers of ossification, at birth there are about 450. The adult human skeleton carries only 206 bones[5]. India is a vast country with diversity in social customs, multiple religions, dietary habits and variations in climatic conditions. In Modi's textbook it is quoted that owing to variation in climatic, dietetic, hereditary and other factors affecting the people of the different states of India, it cannot be reasonably expected to formulate a uniform standard for the determination of the age of the union of epiphyses for the whole of India[6]. Mehta Homi S (1963) observed that it has been approved by research in our country that the epiphysio-diaphysial union in Indian occurs about a year or two in advance of the age at which that occurs in Europeans[7]. According to Parikh CK Union of epiphysis in cartilaginous bones takes place earlier in the females by about 2 years than in males except in case of skull sutures where obliteration sets in little later and proceeds more slowly in females than in males and under tropical conditions ossification is observed earlier than in temperate areas[8]. According to Iscan M.Yasar and Loth Susan R(1984) estimation of age from the adult skeleton has been the most difficult part of Human identification studies. Human growth is continuous process which goes through first, a developmental stage and second, the maintenance of status quo. In the developmental stage, changes in skeletal and dental morphology occur in an age –age predictive sequence[9]. Jit and Balbir Singh revealed that the Precocity of epiphyseal union has been attributed to racial and climatic factors. Works in different regions of India-North (Punjab, Delhi and UP), East (Bengal) and South (Madras) have given different ages of fusion of the epiphysis. Further, workers in the same region have also given different ages of fusion of the epiphysis of the same bone and in the same sex. This difference could possibly be due to in adequate material or recording of incorrect ages of the subjects[10].

Hence, it was, decided to reestimate age radiologically in the central part of India, by including authentically examined subject, with valid age proof belonging to indigenous population.

Aims and Objectives: Radiological evaluation of carpal bones forming the Wrist joints (Scaphoid, Lunate, Triquetral, Pisiform, Trapezium, Trapezoid, Capitate, and Hamate)in female subjects was undertaken with the following aims and objectives:

1. To estimate the age from ossification of carpal bones of Wrist joint in relevant Subjects belonging to indigenous population of the central India.
2. To assess the age specific difference in ossification of bones in all the subjects.
3. To assess and evaluate the difference in the ossification in Central part of the India with other part of India on the basis of literature available.
4. To compare the deduced data with previously available data of other countries.

Material and Method

50 female subjects from age 0 to 20 years, were included in this study. The individual chosen for the study were evaluated and confirmed for the authentic proof of date of birth, physical fitness and their native place of central India. Individual involved in study were predominately right handed. A written informed consent and permission from Ethical Committee of the Institute was obtained.

Procedure of Radiography: After taking the written consent, the thorough physical examination and radiological evaluation was done. Training of Researcher was undertaken to get well acquainted with all the radiological procedures essential for X-Ray examination and developing X-Ray films. X-Rays were taken with the help of X-Ray machine in the Department. Minimum shots were taken to expose the joints involved in study and minimum and appropriate voltage settings of X-Ray machine were applied so as to avoid unnecessary radiation exposure of the subjects to get the desired qualities of X-Rays. The developed X-Ray films were studied and reporting was done with the help of by experienced Radiologist and Anatomist. All the radiological procedure was undertaken according to the present accepted standards. Skeletal maturity was evaluated according to the **Jits** and **Kulkarnis classification** as **Appeared or non appeared**[11].

The master chart was prepared and tabulated & was classified, analysed and compared with known standards. Data analysis was done in P4 computer using HPSS software. At the end conclusions were drawn which are compared with available results of various previous studies.

Table 1: Appearance of carpal bones in Female on right side.

Agein years	Scaphoid	Lunet	Triquetral	Pisiform	Trapezium	Trapezoid	Capitate	Hamet
<1-5	1(2%)	5(10%)	8(16%)	0(0%)	1(2%)	0(0%)	9(18%)	9(18%)

Discussion

Scaphoid: In the female age groups of <1-5, 6-10, 11-15,16-20 years Scaphoid had appeared in 1(2%), 13(26%), 12(24%), 15(30%)%)subjects respectively .Scaphoid appeared earliest at 5-6 year in female subjects on right side.Galstaun G. (1937) in Bengali population found appearance of Scaphoid at 6 years in female[12]. According to present study Scaphoid appeared 1 years earlier in females than in Galstaun G study. Flecker (1942) in Australians population found that the appearance of Scaphoid at 5 years in female,but in present study Scaphoid has appeared 0-1 year later[13]. Davies & Parsons (1927) in his study on Englanders found that the Scaphoid appears at 6 - 8 years, which appeared 0 - 3 year earlier in current study[14]. According to Nandy A (2000) Scaphoid appears at 6 years, which is observed 0 - 1 year earlierpresent study[15].

Lunate: In the female age groups of <1-5, 6-10, 11-15, 16-20 years the Lunate had appeared in 5(10%), 13(26%), 12(24%), 15(30%) subjects respectively. In this study Lunate was appeared earliest at 4 years in females subjects.Galstaun G. (1937) in Bengali population found appearance of Lunate at 2-3 years, but in present study Lunate appeared 1-2 years later[12].

Flecker (1942) in Australians population found that the appearance of Lunate at 4 years in males, matching to this study[13].

Triquetral: In the Female age group of <1-5, 6-10, 11-15, 16-20 years Triquetral had appeared in 8(16%), 13(26%), 12(24%), 15(30%) subjects respectively. It can be concluded that, centre for Triquetral appeared at 3 year. Galstaun G. (1937) in Bengali population found appearance of Triquetral at 2-3 years. In comparison with this study in present study Lunate appeared nearly at similar age. Flecker (1942) in Australians population found that the appearance of Triquetral at 1 ½ year. On contrary to his findings in present study it is found that Triquetral has appeared 1 ½ year later.

Pisiform: In the female age groups of 6-10, 11-15, 16-20 years, Pisiform had appeared in 6(12%), 11(22%), 15(30%) subjects respectively. In this study Pisiform was appeared earliest at 9-10 years. Galstaun G. (1937) in Bengali population found appearance of Pisiform at 9 years in female, it is matching with present study. Flecker (1942) in Australians population found that the appearance of Pisiform at 9 year in females, in present study Pisiform has appeared 0 - 1 year later.

Trapezium: In the female age group of <1-5, 6-10, 11-15, 16-20 years, Trapezium had appeared in 1(2%), 13(26%), 12(24%), 15(30%) subjects respectively. In this study Trapezium was appeared earliest at 5-6 years. Galstaun G. (1937) in Bengali population found appearance of Trapezium at 5-6 years, in present study Trapeziumappeared nearly at similar age. Flecker (1942) in Australians population found that the appearance of Trapezium at 5 year in females, but here it has appeared 0 - 1 year later.

Trapezoid: In the female age group of 6-10, 11-15, 16-20 years, Trapezoid had appeared in 13(26%), 12(24%), 15(30%) subjects respectively. In this study Trapezoid was appeared earliest at 6-7 years. Galstaun G. (1937) in Bengali population found appearance of Trapezoid at 5-6 years which appeared 1-2 years later in present study. Flecker (1942) in Australians population found that the appearance of Trapezoid at 5 year, on contrary in present study it appeared at 1-2 years late.

Capitate: In the female age groups of 6-10, 11-15, 16-20 years, Capitate had appeared in 9(18%), 13(26%), 12(24%), 15(30%) subjects respectively. In this study Capitate was appeared earliest at 1 years. Galstaun G. (1937) in Bengali population & Flecker (1942) in Australians population found appearance of Capitate at 6 months, which appeared nearly 6 months later in present study.

Hamate: In the female age group of 6-10, 11-15, 16-20 years, Hamate had appeared in 9(18%), 13(26%), 12(24%), 15(30%) subjects respectively. In this study Hamate was appeared earliest at 1 years. Galstaun G. (1937) in Bengali population found appearance of Hamate at 1-14 months in present study Hamateappeared 2 months later[12]. Flecker(1942) in Australians population found that the appearance of Hamate at 6 – 10 months, on contrary to his findings in present study it is found that Hamate has appeared 2 – 6 months later[13].

Summary and Conclusions

1. This study was conducted exclusively on the young indigenous male population of Central India keeping in mind that very less literature about the age estimation from ossification of Wrist joint on both the right and left side is available involving this particular region of India.
2. The ossification of carpals at the Wrist joint in females on right is completed in all instances at the age 9-10 year respectively.
3. By comparing the available literature, the age of skeletal maturity in females in this region is nearly similar to those in state ofWest Bengal.
4. By comparing the available literature ossification center appeared one to two years earlier in this study with population of Central India than those in Australia and England.
5. As this study is done in Central India region the application of standards of this study can be considered ideal for application in the region of Central India.
6. As the sample size is limited further studies are necessary. Region wise studies should be conducted for better correlation and comparison.
7. Due to changing life style pattern, dietary, climatic,

behavioral factors age of ossification is changing as mentioned in the available literature. So as to evaluate these changes, studies are recommended in every region of India at regular time period for academic and judicial interest.

8. Along with the clinical and dental examination, radiological study plays an import role to arrive at the opinion about the age in medicolegal cases.

9. The opinion about age should be given always in the range. From this study range of 1-2 years of margin of error can be concluded.

Conflict of Interest: No conflict of interest was reported during conduction of study and preparation of this research article

Source of Funding: No fund was taken to carry out this study and preparing this article

Ethical Clearance: Due ethical clearance from institutional ethics committee was taken to undertake this study.

Professor in Pharmacology, Datta Meghe medical college. Nagpur, [4]Associate Professor in Biochemistry, Datta Meghe medical college. Nagpur

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This study has been undertaken to evaluate the efficacy of the newer Yash scoring system which has been found more effective for the Indian population in diagnosing acute appendicitis.

Method and Material: A prospective study of the Yash scoring system was done on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Yash scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated.

Results: The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 87.50%, and 94% respectively.

Conclusion: The Yash scoring system was a good tool to diagnose acute appendicitis.

Keywords: *Negative appendicectomy, C-reative protein, Hyperaesthesia in sherrens triangle, Blumberg sign.*

Introduction

Acute appendicitis is amongst the many encountered emergencies seen in casualties requiring intervention. There is a 6% chance of appendicitis in the general population[1]. Though the mortality has declined from 26% to 1% with the dawn of broad-spectrum antibiotics and timely surgery, it remains 5 to 15% in the elderly [2]. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity, the frequency being more in women of reproductive age group (till 45%) due to the commonness of inflammatorytubo-ovarian diseases, ectopic pregnancy, and other gynecological pathology[3]. The delay in diagnosis may lead to rupture of the appendix in 17% to 40% of cases mostly in extremes of age. In the adolescents and elderly, it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death [4]. Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

The regular laboratory investigations of blood and urine are necessary. Leukocytosis is a convenient finding but is non-specific and may be missing in the elderly [5]. C – Reactive protein is elevated in almost all acute inflammatory conditions, hence is considered as a non-specific marker but its estimation guides a surgeon in reducing negative appendicectomies[6,7].

Magnetic resonance imaging (MRI) as an investigation is only taken typically in the pregnant population where radiation exposure is not warranted. It provides outstanding resolution and is highly efficient in diagnosing acute appendicitis. MRI has high sensitivity and specificity of 100% and 98% respectively. The PPV and NPV of MRI are 98% and 100% respectively. It is also operator-independent. The only issue is its higher cost, motion artifact, and complexity in reading MRI by non-radiologists with limited experience [6].

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearby to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation[7,8,9].

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR)[10,11].

The study done by Lamture YR et al[12] in India on the Yash scoring system reveals a sensitivity of 99.48%, a specificity of 92.86%, PPV of 99.48%, and NPV of 92.86%.Though the validity of the Yash scoring system is promising for the Indian population, its only disadvantage was in the mode of a single study.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients.[13]

This non-randomized prospective study has been undertaken to evaluate the effectiveness of the newer Yash score which has been found more effective for the Indian population in diagnosing acute appendicitis.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

Study Design: Prospective non-randomized study.

Study Population: All patients of acute appendicitis with age >15 years and <60 years.

Study Duration: July 2018-July 2020.

Sample Size: 50 patients

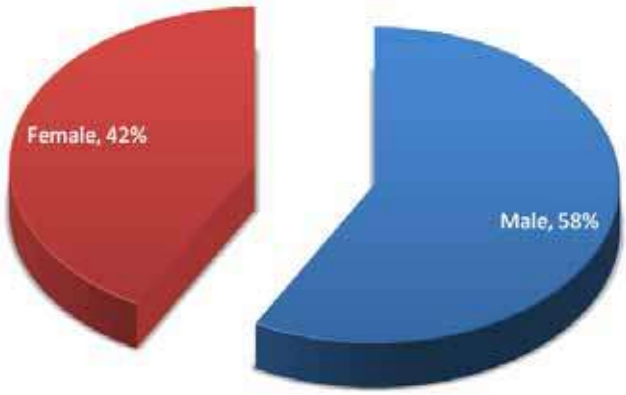
Inclusion Criteria: All patients with right lower quadrant pain and clinically diagnosed as acute appendicitis of age >15 years and <60 years.

Exclusion Criteria:

1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

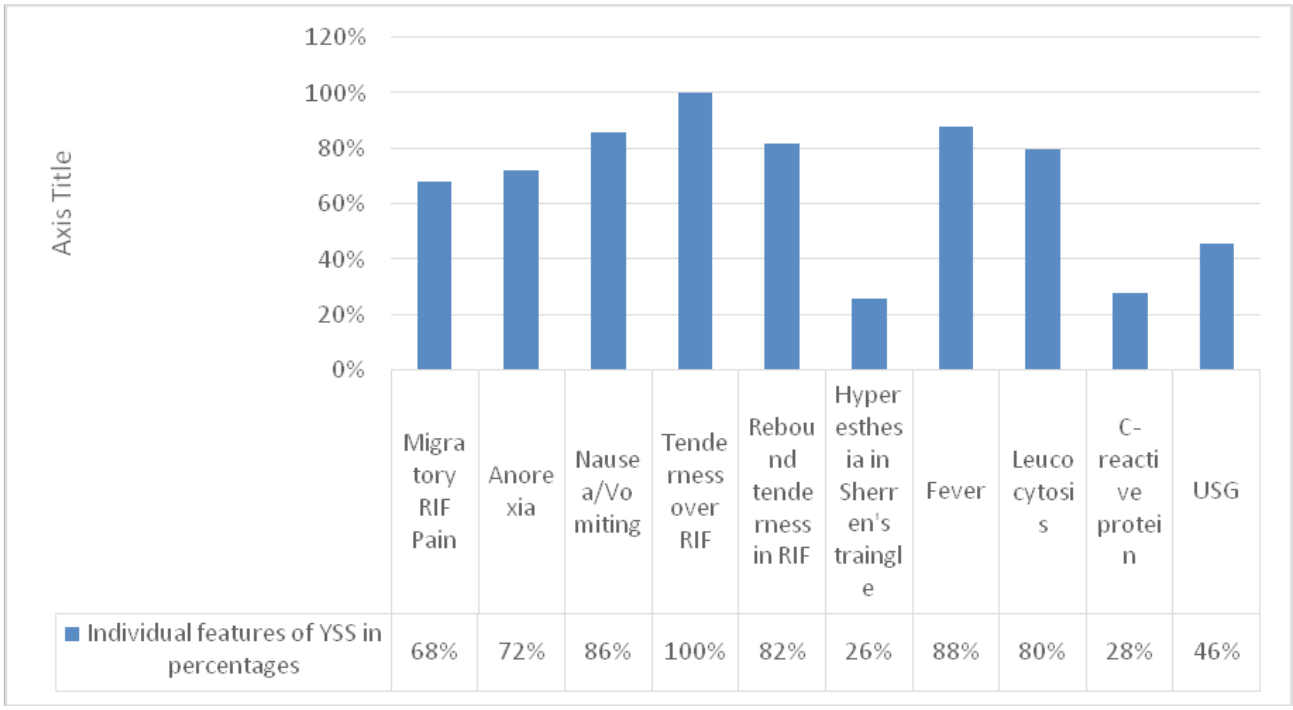
Ethical clearance was obtained from the Ethics committee of Datta Meghe Institute of Medical Sciences (Deemed to be University) [Ref. No. DMIMS(DU)/ IEC/2018-19/7426].This prospective non-randomized study was conducted in Acharya Vinoba Bhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, C-reactive protein, USG, and were scored based on the Yash scoring system.

The components of the Yash scoring system are as follows:



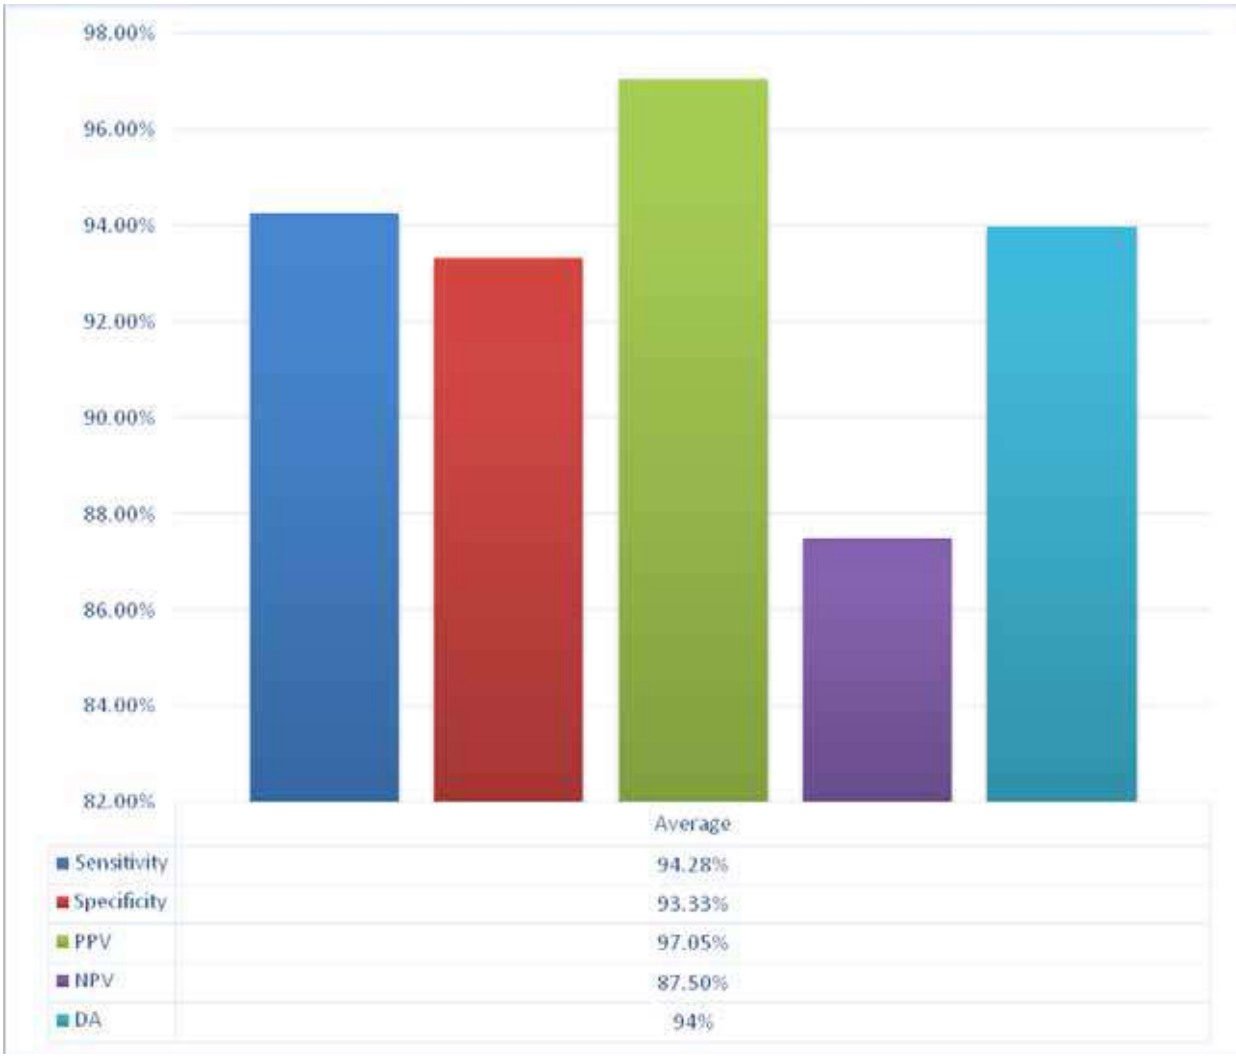
- Migration of pain to the right iliac fossa = 1 point
- Nausea and vomiting = 1 point
- Anorexia = 1 point
- Right iliac fossa tenderness = 2points
- Rebound tenderness = 1 point
- Hyperesthesia in Sherren's triangle = 1 point
- Fever = 1 point

- White blood cell count > 10,000 mg/dl =2 points
- C-reactive protein (> 15mg/dl) = 3 points
- Ultrasonography = 4 points



A score of 7 or more is suggestive of acute appendicitis requiring surgery[12].

The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examination for confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria[1]. The result of the Tzanakis score and Yash score was reported independently. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.



Observations and Results

NPV	96.50%	33.30%	31.25%	33.33%	15.15%	91%	87.50%

Graph 5: Comparison with various studies

Discussion

Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Furthermore, negative appendicectomy also accounts for the loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demand more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations.

The current study will deal with the evaluation of the Yash scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females (see graph 01).

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, C-reactive protein, USG and were scored based on the Yash scoring system. The decision to operate the patient including patients with scores less than the cut-off value was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our study, 82% of the patients were operated by open method whereas 18% of patients were operated by laparoscopy. The study done by Malla BR et al[14] consisted of 200 patients in which 128 patients (64%) underwent appendectomy by an open method and 72 patients (36%) underwent appendectomy by laparoscopy.

The most common incision used in open appendectomy was Mc Burney's in about 83% of cases followed by the right Para median which was used in 17% of cases. Similarly, in the study done by Lamture YR et al[12] the most common incision used was Mc Burney's in 94.74% of patients followed by right Para median in 5.26% of cases. In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis, three patients had Meckel's diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al[9] in her study had five out of 50 patients with the alternative diagnosis; out of which one patient had enterocolitis and four patients had the pelvic inflammatory disease. Another study was done by Kumar SLA et al[13] his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel's diverticulitis. The new Yash score described by Lamture YR et al [12] in 2017 has a significant role in identifying acute appendicitis. It differs from earlier scoring systems by including various parameters such as C-reactive protein, leukocyte counts, USG, and clinical data. A score of seven or more in patients was considered as acute appendicitis and such patients were subjected to operative intervention.

In our study, out of ten parameters, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients. The other two signs i.e. rebound tenderness and hyperesthesia in Sherren's triangle was seen in 82% and 26% of patients respectively. The most common symptom was fever which was present in 88% of cases followed by nausea or vomiting which was found in 86% of the cases. Anorexia was seen in 72% of patients, whereas 68% of patients gave a history of migratory right iliac fossa pain. Out of the three investigations included in the scoring system, leucocytosis defined as WBC count more than 10000/mm^3 was present in 80% of cases. C-reactive protein with a value of more than 15mg/dl was present in 28% of cases with USG showing features of appendicitis in only 46% of cases (see graph 02).

In the present study, 34 patients had a score of seven or more, and16 patients who had a score of less than seven according to the Yash score. Out of the 34 patients who scored seven or more, there were 33 patients with features of appendicitis on histopathological examination whereas only one patient hada histologically normal appendix with no features of inflammation.Similarly, out of 16 patients who scored less than seven, there were 14 patients with a histologically normal appendix with no features of inflammation and only two patients with features of appendicitis on histopathology.

The sensitivity and specificity of the Yash scoring system in the present study were found to be 94.28% and 93.33% respectively. It had PPV and NPV of 97.05% and 88.50% respectively. The overall diagnostic accuracy of the Yash scoring system in our study was found to be 94% (see graph 03). The following results are comparable to the single original study done by Lamture YR et al in which the sensitivity, specificity, PPV, and NPV was 99.48%, 92.86%, 99.48%, and 92.85% respectively. The diagnostic accuracy of the Yash score reported by Lamture YR et al was 98.56%.

The negative appendicectomy rate (NAR) of the Yash scoring system in the present study was found to be zero percent in males and 4.76% in females. This discrepancy in NAR was due to the high probability of another possible diagnosis in females of reproductive age group such as pelvic inflammatory diseases and ovarian cyst. The overall NAR observed for the Yash scoring system was 2% (see graph 04) which is way lower than the accepted rate of 15 to 25%. In the study done by Lamture YR et al[12], the NAR was found to be 6.69% which is comparable to our study[14].

The negative appendectomy rate of the Yash scoring system was dramatically lower than other studiesand the diagnostic accuracy of this scoring system is better when compared with other studies (see graph no 5).

Conclusion

The study also shows that the Yash scoring system is a better tool to avoid unnecessary operations due to its exceptionally low negative appendectomy rate thus lowering morbidity in patients of acute appendicitis and thereby lowering the cost of treatment and prevention of misuse of valuable resources and manpower.

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This study has been undertaken to evaluate the efficacy of the Tzanakis scoring system for the Indian population in diagnosing acute appendicitis.

Method and Material: A prospective study to evaluate Tzanakis scoring system on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Tzanakis scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated.

Results: The Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA of 71.42%, 66.67%, 83.33%, 50%, and 70% respectively.

Conclusion: Tzanakis scoring system in diagnosing acute appendicitis has a lower value in Indian populations.

Keywords: *Inflammation of the appendix,gangrene of appendix,perforation peritonitis.*

Introduction

Acute appendicitis is amongst the many encountered emergencies seen in casualties requiring intervention. There is a 6% chance of appendicitis in the general population[1]. Though the mortality has declined from 26% to 1% with the dawn of broad-spectrum antibiotics and timely surgery, it remains 5 to 15% in the elderly [2]. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity, the frequency being more in women of reproductive age group (till 45%) due to the commonness of inflammatorytubo-ovarian diseases, ectopic pregnancy, and other gynecological pathology[3]. The delay in diagnosis may lead to rupture of the appendix in 17% to 40% of cases mostly in extremes of age. In the adolescents and elderly, it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death [4].Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

Ultrasonography (USG) with graded compressions has immense capacity in diagnosing appendicitis in its

acute stage[5]. Various studies have been conducted on the utilization of these imaging systems. These studies reported a sensitivity of 75% to 94%, a specificity of 86% to 100%, and gross precision up to 96% [6]. Its superiority over computed tomography is the absence of exposure to ionizing radiation thus helpful in pregnant and pediatric patients. The major disadvantage is that it is operator dependent leading to inter-observer bias and failure to see the appendix during the scan does not rule out the possibility of having an inflamed appendix[5].

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearby to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation [7].

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR).

The original study done by Tzanakis et al[8] in Greece reported sensitivity and specificity of 95.4% and 97.4% respectively. The diagnostic effectiveness of the score was 96.5% in his study. But in India, this scoring system was found inferior. For example, a comparative study between Tzanakis score and Alvarado score done by Shashikala V[9] in India revealed that Tzanakis scoring system had a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which was found better than Alvarado scoring system but still posing difficulties in diagnosis with a NAR of 12%. Another study was done by Iqbal MM et al[10] in Postgraduate medical center, Karachi, Pakistan revealed that the Tzanakis score had a sensitivity of 99%, the specificity of 91%, PPV of 99%, and NPV of 91% with a diagnostic accuracy of 95%. Similarly,A study done in Kathmandu Model Hospital, Nepal did by Sigdel GS et al [11] reveals that Tzanakis has a sensitivity of 91.48%, a specificity of 66.66%, and diagnostic accuracy of 90%.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients.

This non-randomized prospective study has been undertaken to evaluate the effectiveness of the Tzanakis score in diagnosing acute appendicitis.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

Study Design: Prospective non-randomized study.

Study Population: All patients of acute appendicitis with age >15 years and <60 years.

Study Duration: July 2019-July 2020.

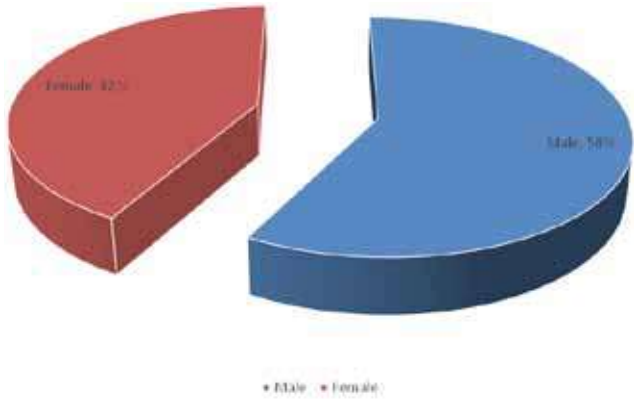
Sample Size: 50 patients

Inclusion Criteria: All patients with right lower quadrant pain and clinically diagnosed as acute appendicitis of age >15 years and <60 years.

Exclusion Criteria:

1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

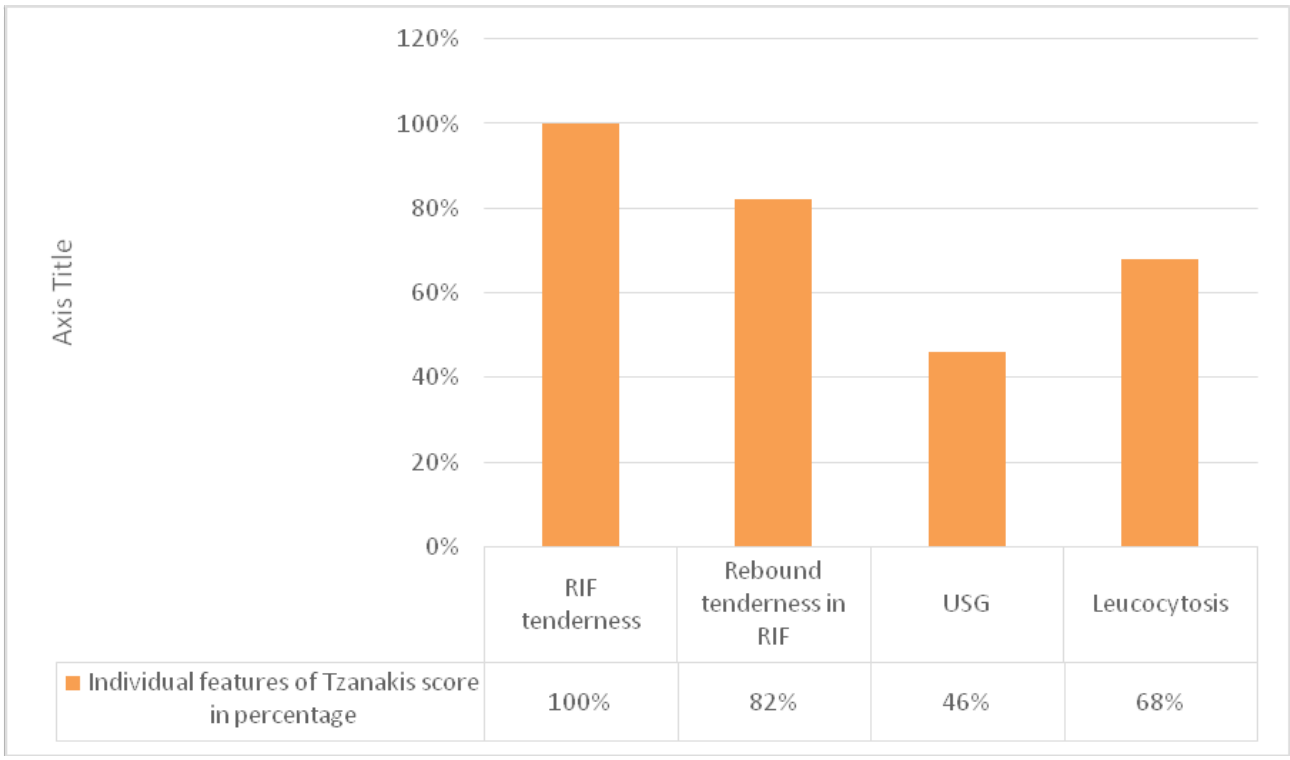
Ethical clearance was obtained from the Ethics committee of Datta Meghe Institute of Medical Sciences (Deemed to be University).This prospective non-randomized study was conducted in Acharya Vinoba Bhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, USG, and were scored based on Tzanakis scoring system.



Tzanakis scoring system combines 4 variables as follows:

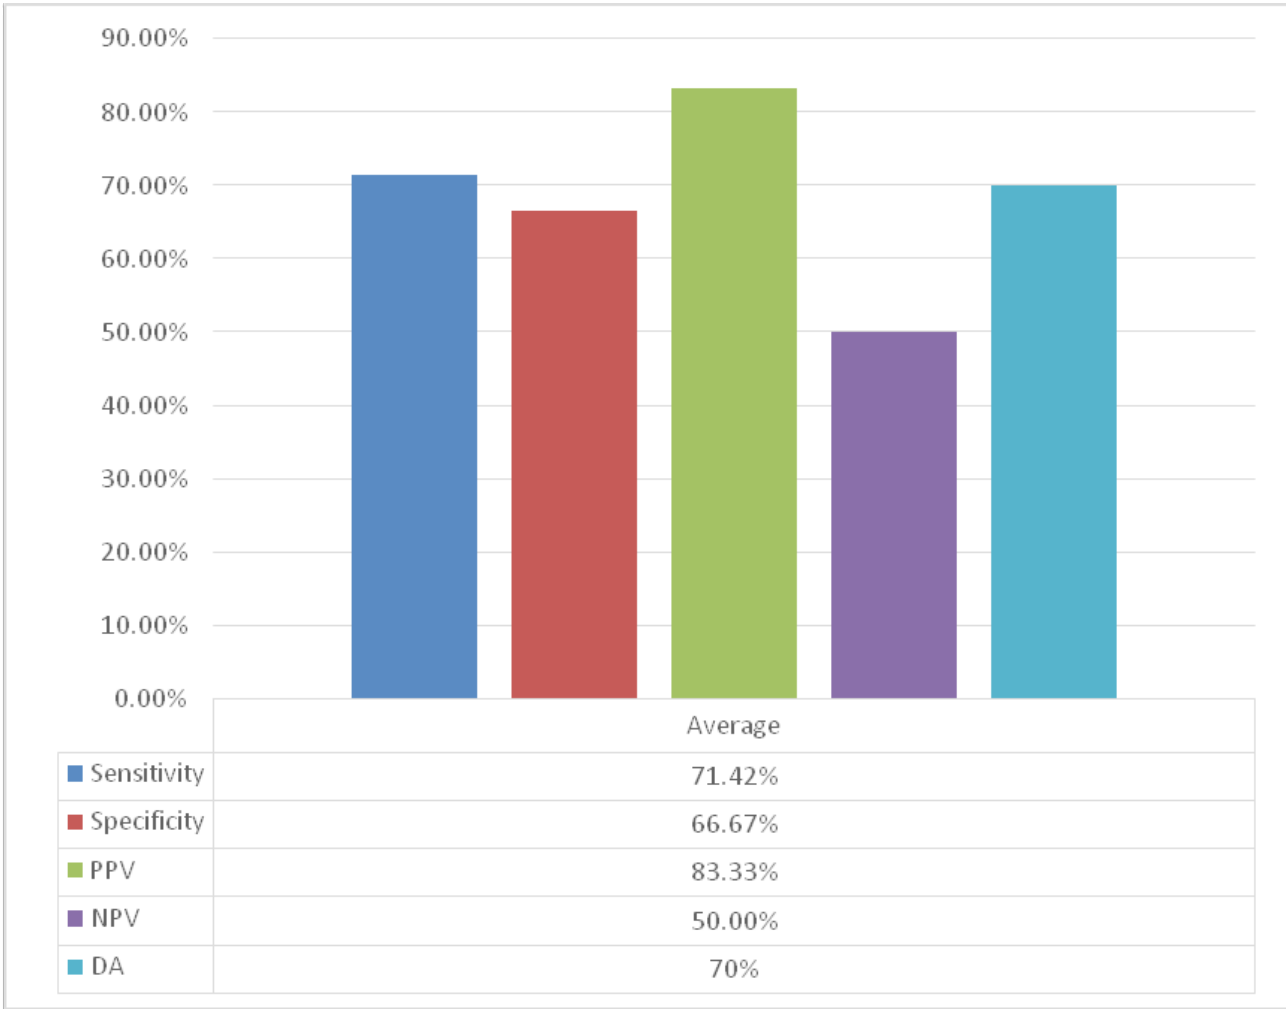
- Presence of right lower abdominal tenderness= 4 points
- Rebound tenderness(Bloomberg sign)= 3 points
- Laboratory findings: the presence of white blood cells greater than 12,000 in the blood= 2 points
- Ultrasound findings: the presence of positive ultrasound scan findings= 6 points

A score of 8 or more is suggestive of acute appendicitis requiring surgery [8].

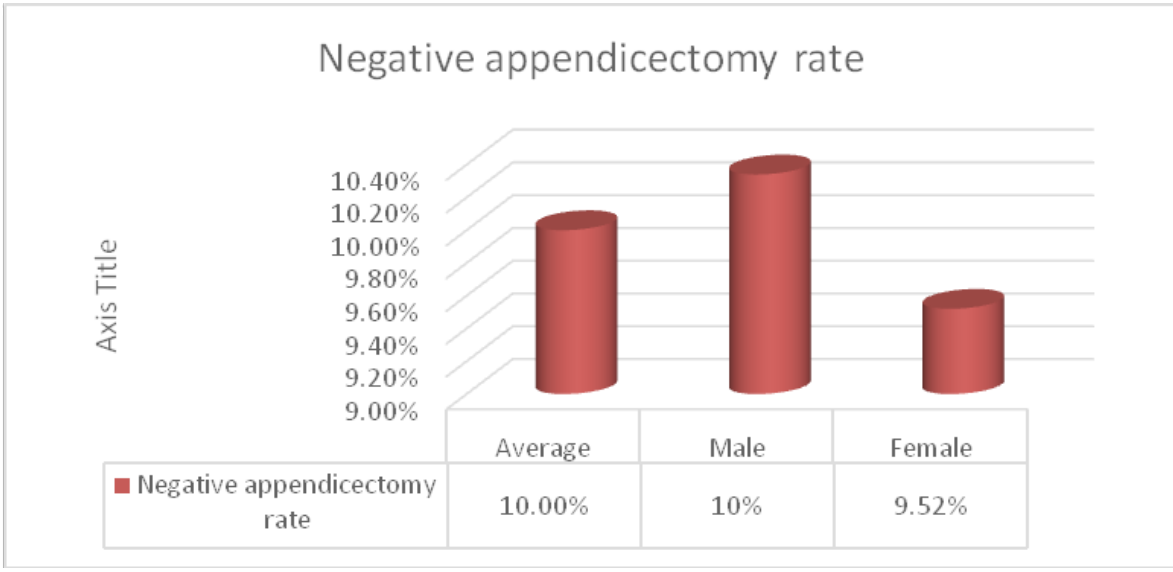


The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examinationfor confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria[1]. The result of the Tzanakis score was calculated. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.

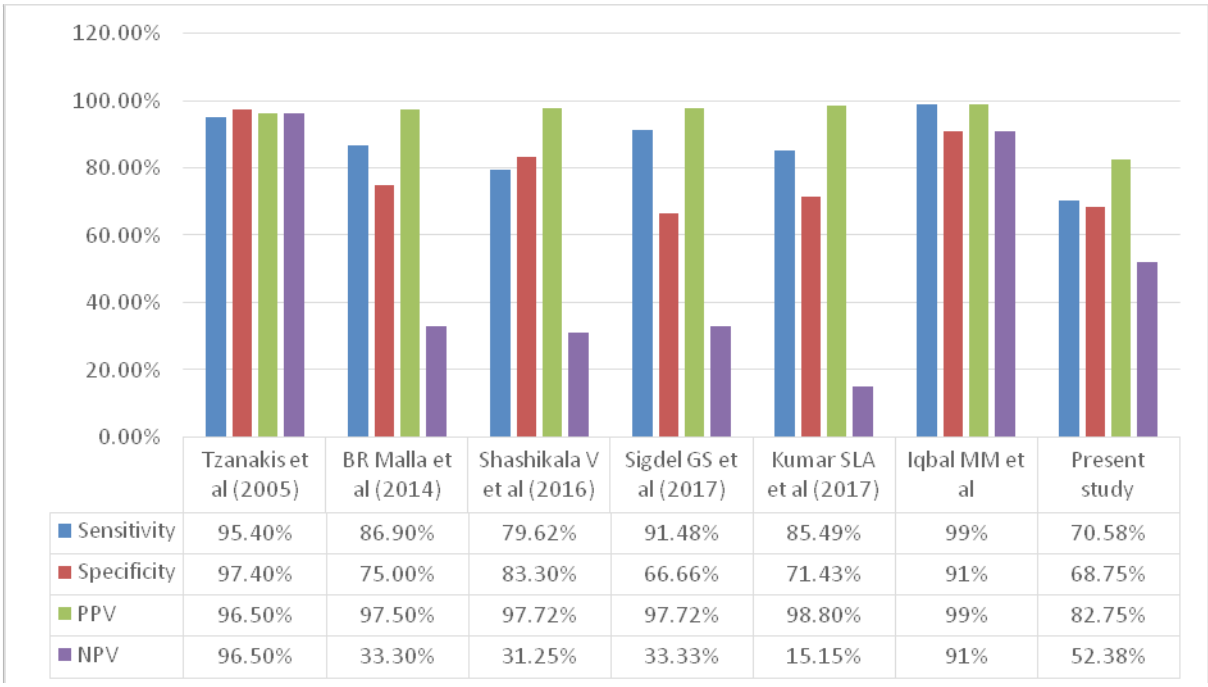
Observations and Results:



Graph No. 01: Gender



Graph 02: Individual characteristics of Tzanakis score :



Graph 03: Outcome of Tzanakis Scoring system

Graph 04: Negative appendicectomy rate of Tzanakis scoring system:

Graph 5: Comparison of final results of Tzanakis scoring system of various studies with our present study:

	Tzanakis et al (2005)	BR Malla et al (2014)	Shashikala V et al (2016)	Sigdel GS et al (2017)	Kumar SLA et al (2017)	Iqbal MM et al	Present study
Sensitivity	95.40%	86.90%	79.62%	91.48%	85.49%	99%	70.58%
Specificity	97.40%	75.00%	83.30%	66.66%	71.43%	91%	68.75%
PPV	96.50%	97.50%	97.72%	97.72%	98.80%	99%	82.75%
NPV	96.50%	33.30%	31.25%	33.33%	15.15%	91%	52.38%

Discussion

Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Furthermore, negative appendicectomy also accounts for the loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demand more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations[12,13].

The current study will deal with the evaluation of the Tzanakis scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females (see graph 01). The male to female ratio in our study was found to be 1.4:1 which is comparable to the study done by Kumar SLA et al[14] in which the male to female ratio was 1.6:1.

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, USG, and were scored based onthe Tzanakis scoring system. The decision to operate the patient including patients with a score less than the cut-off value was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis, three patients had Meckel's diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al[9] in

her study had five out of 50 patients with an alternative diagnoses; out of which one patient had enterocolitis and four patients had a pelvic inflammatory disease. Another study was done by Kumar SLA et al[14]his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel's diverticulitis.

Tzanakis et al [8], in 2005 revealed a more comprehensible system to help in making the diagnosis of appendicitis. It includes four parameters comprising of specific signs, laboratory and radiological investigations such as right iliac fossa tenderness, rebound tenderness over the right iliac fossa, leucocytosis (WBC count>12,000/mm^3), and USG. A score of 8 or more is considered as acute appendicitis.

In our study, out of the four parameters present in the scoring system, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients whereas rebound tenderness and leucocytosis was found in 82% and 68% of the patients respectively. USG showed features of appendicitis in only 46% of cases (see graph 02).

In the present study, 30 patients had a score of eight or more, and 20 patients who had a score of less than eightaccording to the Tzanakis score.

The 30 patients who scored eight or more had 25 patients with features of appendicitis on histopathology whereas 5 patients had a histologically normal appendix with no features of inflammation.

Similarly,20 patients scored less than eight out of which there were 10 patients with a histologically normal appendix with no features of inflammation and 10 patients with features of appendicitis on histopathology.

The sensitivity, specificity, PPV, NPV, and diagnostic accuracy of the Tzanakis scoring system in our study was found to be 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively (see graph 03). The low sensitivity and specificity rate was due to the presence of high false-negative and false-positive results. The study done by Tzanakis et al [8] in 2005 had a sensitivity of 95.4%, the specificity of 97.4%, PPV of 96.5%, NPV of 96.5%, and diagnostic accuracy of 96.5% which is much higher as compared to our present study. This difference may occur due to low sample size, ethnic variation, and other demographic factors such as diet (see graph 5).

The study done by Shashikala V et al[9] in 2016 reported a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25%which were comparable to our present study. The study done by Iqbal MM et al[10] in 2018 had results similar to that of Tzanakis et al [8] with a sensitivity of 99%, a specificity of 91%, PPV of 99%, NPV of 91%, and diagnostic accuracy of 95% (see graph 5).

The study was done by Sigdel GS et al [11] and Kumar SLA et al [14] in 2017 had a specificity of 66.66% and 71.43% respectively which was comparable to our study whereas the NPV of both the studies was lower than our present study. Both studies had a sensitivity and PPV higher than our present study but the difference is not significant (see graph 5).

Similarly, the study done by BR Malla et al[15] in 2014 had sensitivity, specificity, PPV, and NPV of 86.9%, 75%, 97.5%, and 33.3% respectively. The outcome of the Tzanakis scoring system in the study conducted by Malla BR et al was comparable to our present study (see graph 5).

The negative appendicectomy rate (NAR) of the Tzanakis scoring system in the present study was found to be 10.34% percent in the males and 9.52% in females. The overall NAR observed for the Tzanakis scoring system was 10% (see graph no 04).

The negative appendicectomy rate in our present study for the Tzanakis Scoring system was comparable to NAR obtained in the studies done by Shashikala V et al [9](12%) and Iqbal MM et al [10](10.30%).

The disadvantage of the Tzanakis scoring system is that it does not include more clinical symptoms such as fever, nausea and vomiting, anorexia, migratory right iliac fossa pain, and supportive investigations such as CRP which augments the accuracy of the scoring system. Another factor for the low specificity of the Tzanakis score is that it gives the highest weightage to ultrasonography in its scoring system which has variable sensitivity and specificity due to inter-observer bias.

Conclusion

- Similarly, the Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively.
- The overall negative appendicectomy rate of the Tzanakis scoring system was 10%.

Comparison between the Tzanakis Scoring System and Yash Scoring System in the Diagnosis of Acute Appendicitis

Aditya Mundada[1], Yeshwant Lamture[2], Varsha Gajbhiye[3], Ranjeet Ambad[4]

[1]Junior Resident, Dept. of General Surgery, J.N.M.C. Sawangi (Meghe) Wardha, [2]Professor, Dept. of General Surgery, J.N.M.C. Sawangi (Meghe) Wardha, [3]Asso. Professor in Pharmacology, [4]Associate Professor in Biochemistry, Datta Meghe Medical College, Nagpur

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This comparative study has been undertaken to evaluate and compare the efficacy of the Tzanakis scoring system with the relatively newer Yash scoring system which has been found more effective for the Indian population in diagnosing acute appendicitis.

Aim: To compare the efficacy of the Yash scoring system with the Tzanakis scoring system in diagnosing acute appendicitis.

Method and Material: A prospective comparison of the Tzanakis scoring system and Yash scoring system was done on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Tzanakis scoring system and Yash scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated and compared.

Results: The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 87.50%, and 94% respectively. The Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA of 71.42%, 66.67%, 83.33%, 50%, and 70% respectively.

Conclusion: The Yash scoring system was significantly better than the Tzanakis scoring system in diagnosing acute appendicitis.

dryrlamture@yahoo.co.in

it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death [4]. Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

Conventional history and clinical examination continue to exist as the potent and actual diagnostic modalities in pinpointing acute appendicitis[5]. The chronology is the commencement of periumbilical pain shifting to the right iliac fossa with subsequent development of anorexia and nausea or vomiting. The clinical examination may disclose signs resembling peritonitis such as local rebound tenderness (Blumberg's sign), guarding, rigidity, cutaneous hyperesthesia, and tenderness on rectal examination. Thirty-three percent of all cases with inflamed appendix present with unusual symptoms such as blunting of pain by the presence of overlying bowel in cases of retrocecal or retro iliac position of the appendix, increased urinary frequency, and tenesmus. Several conditions mimic appendicitis such as enterocolitis, terminal ileitis, pelvic inflammatory diseases, ureteric colic, peptic ulcer, diverticulitis, etc, and hence should be considered in the list of differential diagnosis[6].

The regular laboratory investigations of blood and urine are necessary. Leukocytosis is a convenient finding but is non-specific and may be missing in the elderly [2]. C – Reactive protein is elevated in almost all acute inflammatory conditions, hence is considered as a non-specific marker but its estimation guides a surgeon in reducing negative appendicectomies[7].

Plain x rays have validity in diagnosing appendicitis in only 8% of cases showing non-specific findings with low sensitivity and specificity [8]. The reliability of barium enema examination is 50% to 84%, but it has a major complication of caecal perforation when done in acute inflammatory conditions [9].Computed tomography (CT) is another imaging modality used to confirm appendicitis and is exceedingly efficacious and precise. It is operator independent and has shown a sensitivity of 90% to 100% and specificity of 91% to 99%.CT has a positive predictive value (PPV) of 92% to 98% and a negative predictive value (NPV) of 95% to 100%[10].

Ultrasonography (USG) with graded compressions has immense capacity in diagnosing appendicitis in its acute stage[10]. Various studies have been conducted on the utilization of these imaging systems. These studies reported sensitivity of 75% to 94%, a specificity of 86% to 100% and gross precision up to 96%[10,11]. Its superiority over computed tomography is the absence of exposure to ionizing radiation thus helpful in pregnant and paediatric patients. The major disadvantage is that it is operator dependent leading to inter-observer bias and failure to see the appendix during the scan does not rule out the possibility of having an inflamed appendix[10].

Magnetic resonance imaging (MRI) as an investigation is only taken typically in the pregnant population where radiation exposure is not warranted. It provides outstanding resolution and is highly efficient in diagnosing acute appendicitis. MRI has high sensitivity and specificity of 100% and 98% respectively. The PPV and NPV of MRI are 98% and 100% respectively. It is also operator-independent. The only issue is its higher cost, motion artifact, and complexity in reading MRI by non-radiologists with limited experience [11].

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearby to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation [12].

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR).

The original study done by Tzanakis et al[13] in Greece reported sensitivity and specificity of 95.4% and 97.4% respectively. The diagnostic effectiveness of the score was 96.5% in his study. But in India, this scoring system was found inferior. For example, a comparative study between Tzanakis score and Alvarado score done by Shashikala V[14] in India revealed that Tzanakis scoring system had a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which was found better than Alvarado scoring system but still posing difficulties in diagnosis with a NAR of 12%. Another study was done by Iqbal MM et al[15] in

Postgraduate medical center, Karachi, Pakistan revealed that the Tzanakis score had a sensitivity of 99%, a specificity of 91%, PPV of 99%, and NPV of 91% with a diagnostic accuracy of 95%. Similarly,A study done in Kathmandu Model Hospital, Nepal did by Sigdel GS et al [16] reveals that Tzanakis has a sensitivity of 91.48%, a specificity of 66.66%, and diagnostic accuracy of 90%.

The study done by Lamture YR et al[17] in India on the Yash scoring system reveals a sensitivity of 99.48%, a specificity of 92.86%, PPV of 99.48%, and NPV of 92.86%.Though the validity of the Yash scoring system is promising for the Indian population, its only disadvantage was in the mode of a single study.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients.

This comparative non-randomized prospective study has been undertaken to evaluate and compare the effectiveness of the Tzanakis score with the relatively newer Yash score which has been found more effective for the Indian population in diagnosing acute appendicitis.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

Aim: To compare the efficacy of the Yash scoring system with the Tzanakis scoring system in the diagnosis of acute appendicitis.

Objectives:

1. To study the outcome of the Yash scoring system regarding its sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy.
2. To study the outcome of the Tzanakis scoring system about its sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy.
3. To compare the outcome of Yash and Tzanakis scoring system.

Study Design: Prospective non-randomized study.

Study Population: All patients of acute appendicitis with age >15 years and <60 years.

Study Duration: July 2018-July 2020.

Sample Size: 50 patients

The sample size was calculated by the modified Fischer's formula. The prevalence rate of appendicitis was taken as 6% from the study done by Yogesh Pralhad Chaudhari, Prasanna Gambhir Jawale[18] in 2015.

- Where $N \geq \{Z^2 1\text{-}\alpha/2 \times P \times (1\text{-}P)\}/d2$
- Z1-a/2 = is standard normal variate (at 5% type 1 error (P<0.05) it is 1.96 and at 1% type 1 error (P<0.01) it is 2.58). In most of the studies,P values below 0.05 are considered significant. Therefore, value of 1.96 is employed in formula**.**
- p = prevalence of appendicitis in community anticipated on the basis of past studies.
- d = Absolute error or precision – decided by researcher.
- p= 6%
- d= 0.07 (7% error of margin).

The minimum sample size would be 44.12 patients, thus 50 patients included in the study.

Inclusion Criteria: All patients with right lower quadrant pain and clinically diagnosed as acute appendicitis of age >15 years and <60 years.

Exclusion Criteria:

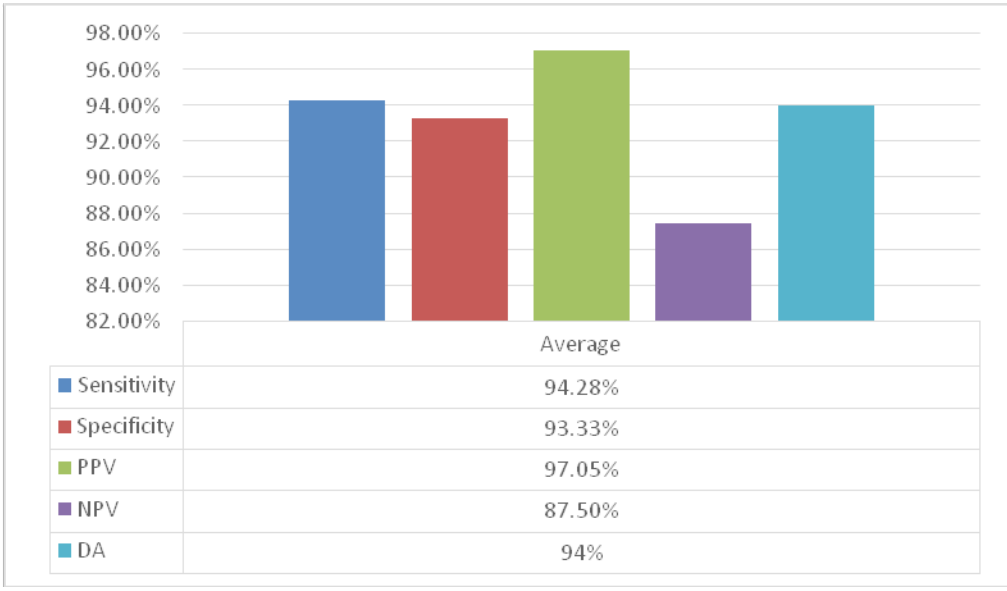
1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

Ethical clearance was obtained from the Ethics committee of Datta Meghe Institute of Medical Sciences (Deemed to be University) [Ref.No. DMIMS(DU)/

IEC/2018-19/7426].This prospective non-randomized study was conducted in Acharya Vinoba Bhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, C-reactive protein, USG, and were scored based on Yash and Tzanakis scoring system.

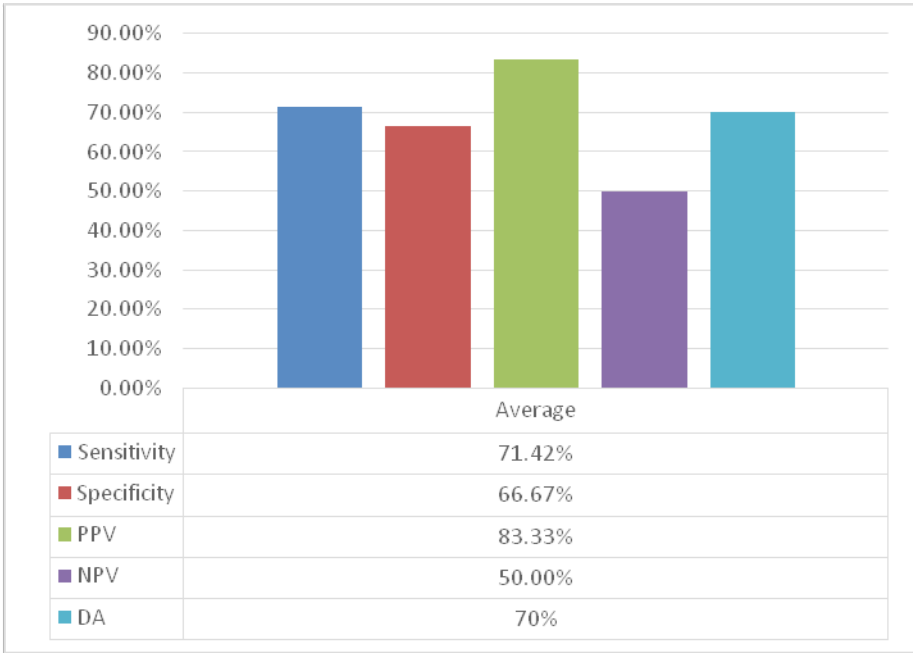
Tzanakis scoring system combines 4 variables as follows:

- Presence of right lower abdominal tenderness= 4 points
- Rebound tenderness(Bloomberg sign)= 3 points
- Laboratory findings: the presence of white blood cells greater than 12,000 in the blood= 2 points
- Ultrasound findings: the presence of positive ultrasound scan findings= 6 points



A score of 8 or more is suggestive of acute appendicitis requiring surgery [13]. Similarly, the components of the Yash scoring system are as follows:

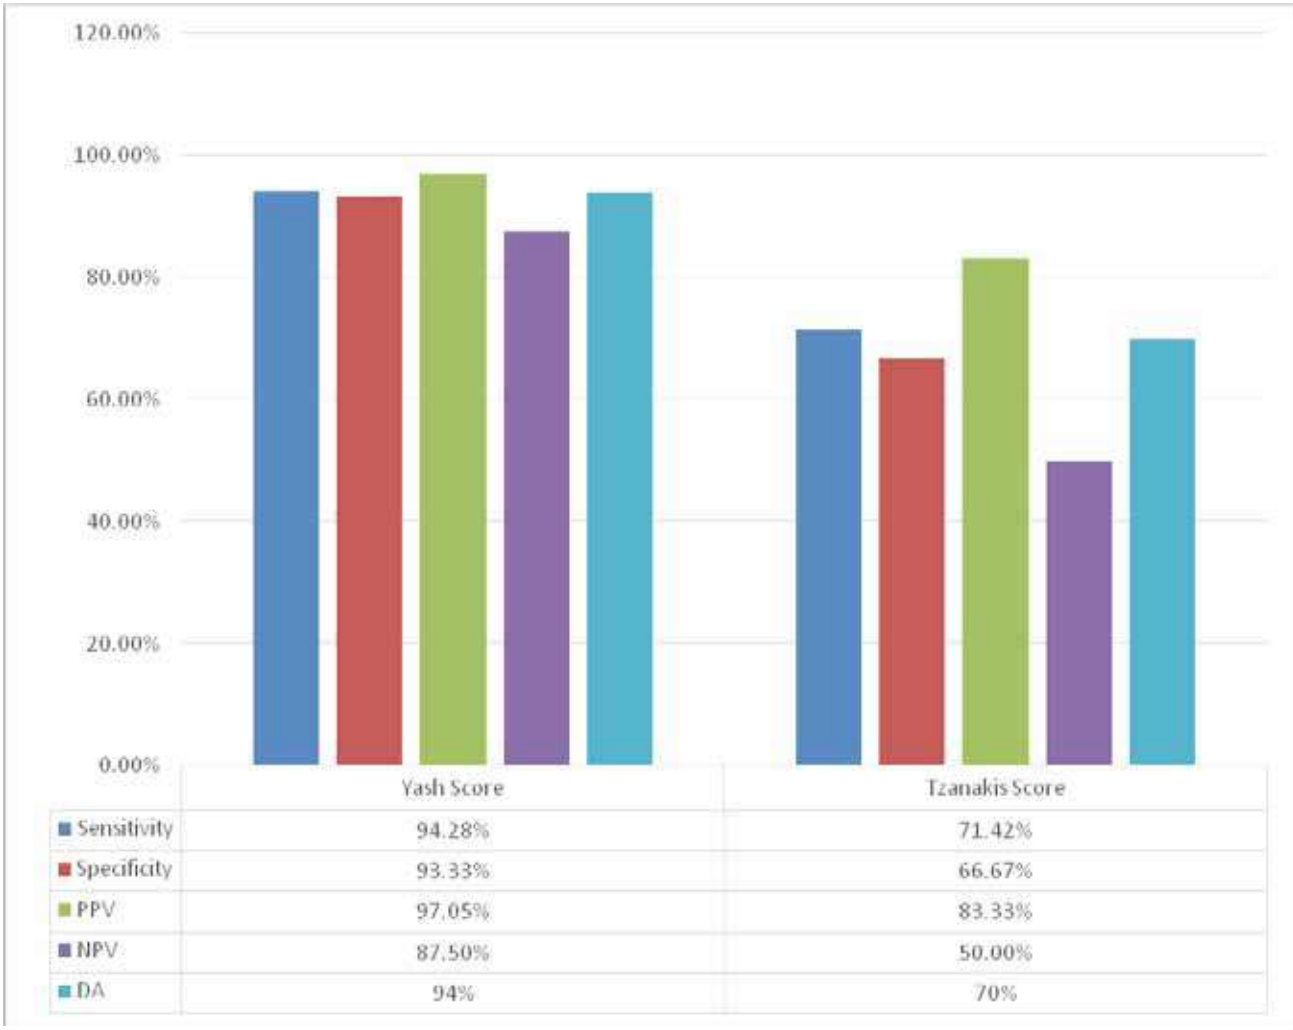
- Migration of pain to the right iliac fossa = 1 point
- Nausea and vomiting = 1 point
- Anorexia = 1 point
- Right iliac fossa tenderness = 2points
- Rebound tenderness = 1 point
- Hyperesthesia in Sherren's triangle = 1 point
- Fever = 1 point
- White blood cell count > 10,000 mg/dl =2 points
- C-reactive protein (> 15mg/dl) = 3 points
- Ultrasonography = 4 points



A score of 7 or more is suggestive of acute appendicitis requiring surgery[17].

The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examination for confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria[1]. The result of the Tzanakis score and Yash score was reported independently. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.

Observations and Results



Graph 01: Outcome of YASH scoring system

	Average
Sensitivity	71.42%
Specificity	66.67%

Discussion

Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Furthermore, negative appendicectomy also accounts for a loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demand more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations.

The current study will deal with the evaluation of the Yash scoring system with the Tzanakis scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females. The male to female ratio in our study was found to be 1.4:1 which is comparable to the study done by Kumar SLA et al[19] in which the male to female ratio was 1.6:1. A larger part of the study population (50%) was present in the age group of 15 to 29 years. The age group of 30 to 44 years had 26% of patients followed by 24% in the age group of 45 to 60 years. This is comparable to the study done by Kumar SLA et al[19] in which 40% of patients were in the 2nd to 3rd decade of life, 27% of patients in 3rd to 4th decade of life, and only 3% of patients in 5th to 6th decade of life.

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, C-reactive protein, USG and were scored based on Yash and Tzanakis scoring system. The decision to operate the patient including patients with scores less than the cut-off value

was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our study, 82% of the patients were operated by open method whereas 18% of patients were operated by laparoscopy. The study done by Malla BR et al[20] consisted of 200 patients in which 128 patients (64%) underwent appendectomy by an open method and 72 patients (36%) underwent appendectomy by laparoscopy. The most common incision used in open appendectomy was Mc Burney's in about 83% of cases followed by the right Para median which was used in 17% of cases. Similarly, in the study done by Lamture YR et al[17] the most common incision used was Mc Burney's in 94.74% of patients followed by right Para median in 5.26% of cases. In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis, three patients had Meckel's diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al[14] in her study had five out of 50 patients with an alternative diagnosis; out of which one patient had enterocolitis and four patients had a pelvic inflammatory disease. Another study was done by Kumar SLA et al[19] his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel's diverticulitis.

The new Yash score described by Lamture YR et al [17] in 2017 has a significant role in identifying acute appendicitis. It differs from earlier scoring systems by including various parameters such as C-reactive protein, leukocyte counts, USG, and clinical data. A score of seven or more in patients was considered as acute appendicitis and such patients were subjected to operative intervention.

In our study, out of ten parameters, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients. The other two signs i.e. rebound tenderness and hyperesthesia in Sherren's triangle was seen in 82% and 26% of patients respectively. The most common symptom was fever which was present in 88% of cases followed by nausea or vomiting which was found in 86% of the cases. Anorexia was seen in 72% of patients, whereas 68% of patients gave a history of migratory right iliac fossa pain. Out of the three investigations included in the scoring system, leucocytosis defined as WBC count more than 10000/mm^3 was present in 80% of cases. C-reactive protein with a value of more than 15mg/dl was present in 28% of cases with USG showing features of appendicitis in only 46% of cases.

In the present study, 34 patients had a score of seven or more, and16 patients who had a score of less than seven according to the Yash score.

Out of the 34 patients who scored seven or more, there were 33 patients with features of appendicitis on histopathological examination whereas only one patient hada histologically normal appendix with no features of inflammation.

Similarly, out of 16 patients who scored less than seven, there were 14 patients with a histologically normal appendix with no features of inflammation and only two patients with features of appendicitis on histopathology.

The sensitivity and specificity of the Yash scoring system in the present study were found to be 94.28% and 93.33% respectively. It had PPV and NPV of 97.05% and 88.50% respectively. The overall diagnostic accuracy of the Yash scoring system in our study was found to be 94%. The following results are comparable to the single original study done by Lamture YR et al[17] in which the sensitivity, specificity, PPV, and NPV was 99.48%, 92.86%, 99.48%, and 92.85% respectively. The diagnostic accuracy of the Yash score reported by Lamture YR et al was 98.56%.

The negative appendicectomy rate (NAR) of the Yash scoring system in the present study was found to be zero percent in males and 4.76% in females. This discrepancy in NAR was due to the high probability of other possible diagnoses in females of reproductive age group such as pelvic inflammatory diseases and ovarian cyst. The overall NAR observed for the Yash scoring system was 2% which is way lower than the accepted rate of 15 to 25%. In the study done by Lamture YR et al[17], the NAR was found to be 6.69% which is comparable to our study.

Tzanakis et al [13], in 2005 revealed a more comprehensible system to help in making the diagnosis of appendicitis. It includes four parameters comprising of specific signs, laboratory and radiological investigations such as right iliac fossa tenderness, rebound tenderness

over the right iliac fossa, leucocytosis (WBC count>12,000/mm^3), and USG. A score of 8 or more is considered as acute appendicitis.

In our study, out of the four parameters present in the scoring system, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients whereas rebound tenderness and leucocytosis was found in 82% and 68% of the patients respectively. USG showed features of appendicitis in only 46% of cases.

In the present study, 30 patients had a score of eight or more, and 20 patients who had a score of less than eightaccording to the Tzanakis score.

The 30 patients who scored eight or more had 25 patients with features of appendicitis on histopathology whereas 5 patients had a histologically normal appendix with no features of inflammation.

Similarly,20 patients scored less than eight out of which there were 10 patients with a histologically normal appendix with no features of inflammation and 10 patients with features of appendicitis on histopathology.

The sensitivity, specificity, PPV, NPV, and diagnostic accuracy of the Tzanakis scoring system in our study was found to be 71.42%, 66.67%, 83.33%, 50.00%, and 70%respectively. The low sensitivity and specificity rate was due to the presence of high false-negative and false-positive results.

The study done by Tzanakis et al [13] in 2005 had a sensitivity of 95.4%, a specificity of 97.4%, PPV of 96.5%, NPV of 96.5%, and diagnostic accuracy of 96.5% which is much higher as compared to our present study. This difference may occur due to low sample size, ethnic variation, and other demographic factors such as diet.

The study done by Shashikala V et al[14] in 2016 reported a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25%which were comparable to our present study. The study done by Iqbal MM et al[15] in 2018 had results similar to that of Tzanakis et al [13] with the sensitivity of 99%, a specificity of 91%, PPV of 99%, NPV of 91%,and diagnostic accuracy of 95%.

The study was done by Sigdel GS et al [16] and Kumar SLA et al [19] in 2017 had a specificity of 66.66% and 71.43% respectively which was comparable to our study whereas the NPV of both the studies was lower than our present study. Both studies had a sensitivity and PPV higher than our present study but the difference is not significant.

Similarly, the study done by BR Malla et al[20] in 2014 had sensitivity, specificity, PPV, and NPV of 86.9%, 75%, 97.5%, and 33.3% respectively. The outcome of the Tzanakis scoring system in the study conducted by Malla BR et al was comparable to our present study.

The negative appendicectomy rate (NAR) of the Tzanakis scoring system in the present study was found to be 10.34% percent in the males and 9.52% in females. The overall NAR observed for the Tzanakis scoring system was 10%.

The negative appendicectomy rate in our present study for the Tzanakis Scoring system was comparable to NAR obtained in the studies done by Shashikala V et al [14](12%) and Iqbal MM et al [15](10.30%).

The result of the Yash scoring system as compared to the result of the Tzanakis scoring system in our present study reveals that the Yash scoring system had a better outcome than the Tzanakis scoring system and was more efficacious than Tzanakis scoring system in diagnosing acute appendicitis. The disadvantage of the Tzanakis scoring system is that it does not include clinical symptoms such as fever, nausea and vomiting, anorexia, migratory right iliac fossa pain, and supportive investigations such as CRP which augments the accuracy of the scoring system. Another factor for the low specificity of the Tzanakis score is that it gives the highest weightage to ultrasonography in its scoring system which has variable sensitivity and specificity due to inter-observer bias.

The negative appendectomy rate of the Yash scoring system was dramatically lower than that of the Tzanakis scoring system.

Conclusion

- The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 88.50%, and 94% respectively.
- The overall negative appendicectomy rate of the Yash scoring system was 2%.
- Similarly, the Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively.

- The overall negative appendicectomy rate of the Tzanakis scoring system was 10%.
- Thus, our study reveals that the Yash scoring system is a valuable and plausible modality in detecting acute appendicitis and reducing NAR due to its outstanding outcome regarding its sensitivity, specificity, PPV, NPV, and diagnostic accuracy when compared to Tzanakis scoring system.
- The study also shows that the Yash scoring system is a better tool to avoid unnecessary operations due to its exceptionally low negative appendectomy rate thus lowering morbidity in patients of acute appendicitis and thereby lowering the cost of treatment and prevention of misuse of valuable resources and manpower.

Abstract

Thyroid gland has multiple effects on the neuromuscular system and brain, its dysfunction is associated with characteristic symptoms and signs with functional alterations in many organs and systems. Thyroid disease may cause signs and symptoms of neuromuscular dysfunction. Hypothyroidism has been associated with the clinical features of proximal muscle weakness, mononeuropathy and sensorimotor polyneuropathy.Nerve conduction studies (NCS) are useful adjunct to the clinical examination of the peripheral nervous system as it is helpful to test speed of signals through a nerve. They help to delineate the extent and distribution of the neural lesion and distinguish two major categories of peripheral nerve disease demyelination and axonal degeneration. Present cross sectional studywas conducted at Central Neurophysiology Laboratory in tertiary care teaching hospital, J.N.M.C, Sawangi (M), Wardha catering to rural population of central India to assess the nerve conduction in early diagnosed hypothyroid patients. Total twenty seven patients; 20-50yrs of age were screened for nerve conduction.In our study we got mixed type of peripheral neuropathy. Out of 27 patients with age 18-30 yrs- 1(16.67%), 31-40 yrs- 13(61.90%) and 41-50 yrs -7 (33.3 %) had abnormal NCS. Occurrence of neuropathy was more common in female patients 80.95% as compared to male patients 19.05%.Sensory nerve action potential (SNAP) amplitudes and conduction velocity were significantly reduced ($p<0.05$) in cases diagnosed as hypothyroidism in median (77%), sural (70%) and ulnar nerves (33%)as compared to controls.

Keywords: *Nerve conduction study, hypothyroidism, central India.*

Introduction

Thyroid gland has modulatory effect on the neuromuscular system and brain through its secretions, thyroxin (T4) and triiodothyronine (T3) which are essential to maintain metabolism in the tissues that is optimal for their normal growth,function and maturation[1].

Thyroid dysfunction is associated with characteristic symptoms and signs and functional alterations in many organs and systems. Central and peripheral nervous systems affection may provide the major presenting symptoms[2]. Prevalence of neuromuscular disorders related to thyroid dysfunction is 20-80 % [3].

Thyroid disease may cause signs and symptoms of neuromuscular dysfunction. Hypothyroidism has been associated with the clinical features of proximal muscle weakness; mononeuropathy and sensorimotor polyneuropathy [4]. Most of the patients of thyroid disorders with neuropathy are asymptomatic. The severity of the neuromuscular signs and symptoms are known to be related to the duration and degree of

hormonal deficiency[5]. Sometimes the nerve damage in untreated patients can lead to carpal tunnel syndrome and these patients end up getting hand surgery when they may have reversed that just by early screening with nerve conduction studies and getting treated for thyroid disorder[6].

The nerve conduction study (NCS) consists of Motor NCS, sensory NCS study. Motor nerve conduction studies assess motor axons by selectively recording muscle responses to nerve stimulation. In sensory nerve conduction studies SNAP is obtained by directly stimulating a sensory nerve and recording directly from it or its branches[7]. With a brief electrical pulse applied to the overlying skin, peripheral nerves can be easily stimulated and brought to an action potential [5]. Nerve conduction studies (NCV) are useful adjunct to the clinical examination of the peripheral nervous system. It is a test of the speed of signals through a nerve. They help to delineate the extent and distribution of the neural lesion and distinguish two major categories of peripheral nerve disease demyelination and axonal degeneration[6,8].

Complications occurring due to hypothyroidism are responsive to thyroid treatment or thyroid replacement therapy, but if are related to neuropathy then there could be a life long struggle with neuropathy pain if not treated promptly. Understanding neuropathy and hypothyroidism is crucial for all thyroid disease patients. Few studies are there who compare nerve conduction in early diagnosed hypothyroid disease with age and sex matched control group in rural population of central India. Electrophysiological studies are non invasive and helpful in early detection of neuropathy as they are most sensitive, specific and repeatable[9]. Neurological manifestations which may be noted in conjunction with systemic features of disease can be detected with nerve conduction studies[10,11]. Hence present study was conducted to assess the alterations of some selected variables of nerve conduction in early diagnosed hypothyroid patients and also to find out which type of neuropathy is more prevalent in those populations of rural area.

Aim: To assess the nerve conduction studies in the cases diagnosed as hypothyroidism.

Objectives:

1. To study the motor and sensory nerve conduction in the cases diagnosed as hypothyroidism.
2. To compare the motor and sensory nerve conduction of cases diagnosed as hypothyroidism with euthyroid subjects.
3. To evaluate type of neuropathy present in the cases diagnosed as hypothyroidism.

Method and Materials

Study Setting: Study was conducted at Central Neurophysiology laboratory in tertiary care teaching hospital, J.N.M.C, Sawangi (M), Wardha catering to rural population of central India.

Study Design: Cross-sectional comparative study.

Study Duration: Nine months

Sample Size:

Formula: $N = X^2.N.P\ (1-P)/C^2\ (N-1) + X^2.P\ (1-P)$

N = Total newly diagnosed patients

= 27

X^2 = Chi-square value for 1 degrees of freedom at some desired probability level is 3.84 at 5% level of significance.

P = 50% proportion

C = Confidence interval of one choice (95%)

= 0.05

$N = 3.84\times25\times0.5(0.5)/0.05^2\times49+3.84\times0.5\times0.5$

= 27

Study group -27 patient diagnosed as cases of hypothyroidism and

Control group -16 euthyroid subjects.

Inclusion Criteria:

- Study group included hypothyroid patients who were untreated of age 18-50 years[12] and both genders attending medicine outpatient department of AVBRH, Sawangi (M), Wardha.
- The diagnostic criteria for hypothyroidism were based on T_3, T_4 and TSH levels [4].
- Among the controls age and sex matched euthyroid subjects who had no past/present or family history of thyroid disorders and apparently healthy were included in the study.

Exclusion Criteria:

- Patients who were less than 18 years old to limit our study sample to the adult population.
- Patients suffering from secondary hypothyroidism or with other possible cause of neuropathy like diabetes mellitus, neuromuscular disorder, leprosy, drug induced neuropathy.
- Patients with family history of neuropathy, malignancy, HIV, liver and kidney diseases, myopathy, alcoholics, smokers and drug abuser were excluded from the study.

Methodology

After IEC clearance study was conducted in central physiology lab of AVBRH hospital, Sawangi (M) Wardha. Adult patients attending the outpatient department who were advised thyroid function tests were isolated and only those patients with biochemical evidence of hypothyroidism i.e. low tri – iodothyronine,thyroxine levels and thyroid stimulating hormone levels were enrolled for the study after getting their consent. Thyroid function tests were done in AVBRH hospital central lab by ADIVIA Centaur CP Immunoassay system of company Siemens (Photo-1). Normal values of lab were T3-0.60-1.81 ng/ml, T4-3.2-12.6 ug/ dl and TSH-0.25-5 µIU/ml. Patients were diagnosed cases of hypothyroidism who were not on any treatment, willing to participate in the study, were included in the study. Demographic parameters like height, weight and BMI were taken. Detailed history regarding neuromuscular symptoms with their duration based on questionnaire was asked. Age and gender matched healthy subjects with normal thyroid function tests were chosen as the control group for comparison.

Nerve conduction study was performed using the Neuron Spectrum 5 machine. The motor nerves tested were median, ulnar and peroneal. The sensory nerves studied were median,ulnar and sural. Parameters for motor nerve conduction study taken were latency (ms), amplitude (mv), conduction velocity (m/s) and for sensory nerve conduction study were amplitude (µv) and conduction velocity (m/s) [6]. Motor nerve conduction study involved stimulation of a motor nerve at two different sites with maximum stimulus, the distance was measured and automatically divided by conduction time between the two points (difference between proximal and distal motor latencies) which gave conduction velocity. Sensory conduction study (antidromic) involved stimulation of sensory nerves proximally and recording SNAPs with electrodes placed distally over the dermatomal distribution.

Result

Quantitative data analysis was done by using students unpaired' test and qualitative data by chi-square. All the values were expressed as mean and standard deviation (±SD) and p- value was considered statistically significant if found to be less than 0.05. GRAPHPAD PRISM 5.0 and SPSS 22.0 version was used.

Table 1: Distribution of patients according to demographic characteristics

Demographic Characteristics	Control (n = 16)	Hypothyroidism (n=27)	X^2 - Value	p-value
Mean Age	36.12±4.16	36.76±3.31	2.67	0.26,NS
18-30 yrs	0(0%)	2(7.41%)		
31-40 yrs	13(81.25%)	16(59.26%)		
41-50 yrs	3(18.75%)	9(33.33%)		
Gender				
Male	5(31.25%)	6(22.22%)	0.43	0.51,NS
Female	11(68.75%)	21(77.78%)		
M:F Ratio	1:2.2	1:2.5		
Wt (kg)	59.75±2.38	61.76±3.81	1.84	0.07,NS
Ht (cm)	155.50±5.54	154±5.75	0.79	0.43,NS

Demographic Characteristics	Control (n = 16)	Hypothyroidism (n=27)	X^2 - Value	p-value
BMI (kg/m2)	24.79±1.90	26.07±1.55	24.32	0.0001,S
Normal	16(100%)	6(22.22%)		
Overweight	0(0%)	9(33.33%)		
Obese	0(0%)	12(44.44%)		

Maximum 81.25% of the subjects in control group and 59.26% in hypothyroid group were in the age group of 31-40 years followed by 18.75% in control group and 33.33% in hypothyroid group were in the age group of 41-50 years which is statistically not significant using Chi-square test(א2-value=2.67,p-value=0.26).

Most of the subjects in control group (68.75%) and 77.78% in hypothyroid group were females which is statistically not significant (א2-value=0.43, p-value=0.51).

Mean weight of the subjects in control group was 59.75±2.38 and in hypothyroid group it was 61.76±3.81 and the difference was not significant using student's unpaired t test (t=1.84,p-value=0.07)

Mean height of the subjects in control group was 155.50±5.54 and in hypothyroid group it was 154±5.75and the difference was not significant using student's unpaired t test (t=0.79,p-value=0.43).

All(100%) of the subjects in control group had normal BMI, where as in hypothyroid group 44.44% of the patients were obese and 33.33% were overweight which is statistically significant א (א2-value=24.32, p-value=0.0001).

Table 2: Significant correlates of neuropathy

Demographic Characteristics	Abnormal Nerve Conduction(n=21)	Normal Nerve Conduction(n=6)	X^2- Value	p-value
18-30 yrs	1(4.76%)	1(16.67%)	1.00	0.60,NS
31-40 yrs	13(61.90%)	3(50%)		
41-50 yrs	7(33.33%)	2(33.33%)		
Gender				
Male	4(19.05%)	2(33.33%)	0.55	0.45,NS
Female	17(80.95%)	4(66.67%)		
Duration of disease				
<1 yr	6(28.57%)	3(50%)	0.96	0.61,NS
1-5 yrs	10(47.62%)	2(33.33%)		
>5 yrs	5(23.81%)	1(16.67%)		
BMI (kg/m^2)				
Normal	4(19.05%)	2(33.33%)	2.41	0.29,NS
Overweight	6(28.57%)	3(50%)		
Obese	11(52.38%)	1(16.67%)		
Signs and symptoms of neuropathy				
Absent	2(9.52%)	4(66.67%)	8.81	0.008,S
Present	19(90.48%)	2(33.33%)		

Maximum 61.90% of abnormal nerve conduction and 50% of normal nerve conduction was found in the age group of 31-40 years followed by 33.33% abnormal and 33.3% normal nerve conduction in the age group of 41-50 years,4.76% abnormal and 16.67 % normal nerve conduction in 18-20 years of age group in hypothyroid patients was observed which was statistically not significant (א2-value=1.00,p-value=0.60).

Most of the females 80.95% had abnormal nerve conduction while 66.67% had normal nerve conduction in hypothyroid group. Where as in males 19.05% had abnormal nerve conduction and 33.3% had normal nerve conduction which was statistically non significant (א2-value=0.55, p-value=0.45).

Maximum 47.62% of abnormal nerve conduction and 33.3% of normal nerve conduction was observed in 1-5 yrs duration, followed by 28.57% abnormal and 50% normal nerve conduction in less than one year,28.81% abnormal and 16.67 % normal nerve conduction in more than 5 years of duration of diseases in hypothyroid patients which was statistically not significant (א2-value=0.96,p-value=0.61).

Abnormal nerve conduction was observed maximum in obese hypothyroid patients 52.38% followed by 28.57% in overweight and 19.05% in normal weight hypothyroid group. Normal nerve conduction was found in 50% of overweight, 33.3% normal weight and 16.67% in obese hypothyroid patients which was not significant (א2-value=2.41, p-value=0.29).

Abnormal nerve conduction was present in 90.48% while 33.3% had normal nerve conduction in patients of hypothyroidism who showed signs and symptoms of neuropathy. Abnormal nerve conduction was present in 9.52% while 66.67% had normal nerve conduction in patients of hypothyroidism who didn't had signs and symptoms of neuropathy which was statistically significant (א2-value=8.81, p-value=0.008)

Discussion

Hypothyroidism is an endocrine disease and peripheral nervous system involvement is a well-documented. 20-80% of researchers have observed prevalence of neuromuscular disorders related to thyroid dysfunction, the severity of which correlates with the degree and duration of hormonal deficiency[3]. In fact neurological complications in hypothyroidism are a well-established finding. Peripheral nerve abnormalities known to be associated with hypothyroidism are entrapment neuropathy or sensorimotor polyneuropathy[13].

In hypothyroidism polyneuropathy is mild and rarely it could be a subclinical entity and hence most of these cases would have gone unnoticed if only clinical examination has been done as it alone may be insufficient to make a conclusive diagnosis specially to make a distinction between axonal and demyelinating disorders. At such times nerve conduction studies are particularly useful. They assess the functional integrity of sensorimotor conduction and give a reliable evidence of peripheral nerve dysfunction. In fact, the estimated prevalence of polyneuropathy diagnosed by electro physiologic tests is 718/1000 [(1).]

In our study on neurological examination two cases of hypothyroidism showed decreased reflexes. Out of 27 cases of diagnosed hypothyroidism 21 (77.78%) had at least one type of nerve conduction abnormality, most commonly in median and sural sensory nerves which was also observed in the studies done by Asia and Ettore et .al [(1,14)]. None of cases of hypothyroidism had signs of muscle atrophy or hypotonia. The commonly reported subjective complaints of tiredness, myalgias and weight gain were encountered in our study too. Tiredness, myalgias in 77.78%, weight gain in 59.26%, constipation in 37%, it correlates with other studies where it was 64% and 68% respectively [(14)]. Paresthesia were found in 33% and menstrual irregularities 22.2% was the next predominant symptoms. Similar results were also observed by Karne and Shetty et.al. [(8, 15)] The increased weight in cases of hypothyroidism would be due to accumulation of mucopolysaccharides, hyaluronic acid and chondroitin sulphate in the interstitial spaces. Those spaces being hydrophilic nature, retain water along with them resulting in weight gain. Also, hormonal imbalance leading to menstrual irregularities [(9)]. Neurological dysfunction associated with disorders of thyroid gland could be the result of hormonal imbalance or immune mechanism accompanying thyroid disease [(1)].

There are studies which reported primary axonal degeneration while some reported demyelination as the predominant feature of neuropathy in hypothyroidism[(8,15)]. In our study we got mixed type of peripheral neuropathy. SNAP amplitudes and Conduction velocity were significantly reduced($p<0.05$) in cases diagnosed as hypothyroidism as compared to controls in median (77%), sural (70%) and ulnar nerves (33%). Similar results were also observed by other studies [(14,15)].

Disturbed myelin synthesis during acute hypothyroidism may be the cause for demyelinating peripheral neuropathy in hypothyroid patients. Hormonal and metabolic changes associated with hypothyroidism are responsible for the nerve conduction changes in the form decreased nerve conduction velocity also thyroid hormones are involved in gene expression, neurotransmitter system and axonal transport , the plausible mechanism of axonal neuropathy is a hypothyroidism induced ATP deficiency with reduced activity of ATP ase enzyme may result in reduced SNAP amplitudes.

Similar to other researchers[9,13] distal latency and conduction velocity in our study was prolonged, amplitude was decreased in median motor nervesin early diagnosed hypothyroid patients as compared to that of control. This could be attributed to hypothyroidism leading to energy deficit due to decreased oxidation of nutrients also decreased degradation of glycogen leads to formation of glycogen deposits around the nerves. These metabolic alterations induced by hypothyroidism may initially damage the functions and later on induce structural changes in the nerves [16].The motor neural dysfunction seen in the present study may be linked to the various functional and structural changes in peripheral nerves associated with deficiency of thyroid hormones.

Presence of neuropathy correlated independently with advanced age and female gender. Out of 27 patients with age 18-30 years 1 patient (16.67%), 31-40 years 13 patients (61.90%) and 41-50 years 7 patients (33.3%) showed abnormal nerve conduction. Occurrence of neuropathy was more common in female patients 80.95% as compared to male patients 19.05%. Similar results were also seen in studies conducted by other researchers[1,8,15]. Neuropathy was more common with duration of disease 1-5 years (47.62%) and obesity (52.38%) but these findings were not statistically significant (P = 0.60,0.45,0.61 and 0.29) respectively. Signs and symptoms of neuropathy was present in 19 patients (90.48%) of early diagnosed hypothyroid patients which was statistically significant (P = 0.008) as shown in Table 2.

Conclusion

This study concluded that the polyneuropathy which is associated with early diagnosed hypothyroidism was largely of mixed type (axonal as well as demyelinating type). There was a predominant involvement of sensory nerves, especially the median nerve and sural nerve on nerve conduction study. In adults, as the hypothyroidism has insidious onset, diagnosis can be delayed by months or years and the neuropathic manifestations can go unrecognized for longer period. Clinical symptoms and laboratory assessment of thyroid function must be performed concurrently to determine the presence of thyroid dysfunction. Nerve conduction studies in cases of hypothyroidism are suggested, early in the course of the disease in order to detect nervous system involvement.

Limitations: Major shortcomings of this study are the small sample size. Furthermore, we could not perform EMG in patients.

Risk Factor: As it is non- invasive study there was no harm to the study subjects.

Ethical Clearance: Taken from institutional ethics committee.

Source of Funding: Self.

Conflict of Interest: Nil.

Work Related Musculoskeletal Disorders Assessment in Cab Drivers

Samreen Fatima[1], Ambreen Fatima[2], Utsav Raj[3], Mangalam Kumari[4], Akshay Anand[5], Neha Chauhan[6], Sakshi Arora[6]

[1]Ph.D. Scholar AMU, [2]Assistant Professor, Galgotias University Greater Noida, [3]Student Researcher, BPT Galgotias University, [4]Assistant Professor, Galgotias University Greater Noida, [5]Assistant Professor Manav Rachna University, [6]Assistant Professor, Galgotias University

Abstract

Background: The cab drivers have to be in a particular posture for driving. They have to be in a prolonged sitting position till the time they are driving the car, this affects their back, neck, ankle &foot. it was found in the previous studies that these people develop work related musculoskeletal disorders & pain due to their wrong posture. This study focuses on assessment of musculoskeletal disorder in professional cab drivers.

Methodology: It is a one-time observational study,30 cab drivers were involved in the study of the age group 18-55 years. They were screened for the inclusion & exclusion criteria,then they were asked to fill the questionnaire for assessment, analysis of the result will be done finally.

Result: The result shows that the 70% of cab drivers were suffering from lower back pain

Conclusion: In this study we found that most of the car drivers suffers from back pain. They were advised for the posture correction.

Keywords: *WRMSD, posture, pain, musculoskeletal disorder.*

Introduction

Work-related musculoskeletal disorders (WMSD) are the category of musculoskeletal disorders that will include problem related to tendons, tendon sheaths, and synovial lubrication of tendon sheaths, and related to bones, muscles, and nerves of hands, wrists, elbows, shoulders, neck, and back.[1] Many factors make cab drivers different from other occupations in terms of exposure to the risk of work-related disorders. Previous studies said that cab drivers takes longer time in driving than other professions. The design of the seat can affect the posture of drivers and posture in turn also can effect both the comfort and physical conditions of a driver. Work-related musculoskeletal disorders (WRMD) and other postural harm may result in physiological illness that may grow over a long period due to prolonged mechanical stresses levied on the musculoskeletal system. Musculoskeletal pain includes a major health problem for the general population, distressing their quality of life, demanding increased need of health care and organization. A number of previous studies assessed the occurrence of musculoskeletal disorders amongst Iranian workers [2-4] and many other country. It has been suggested that people have changing perceptions about their musculoskeletal problem and insights about illness may influence health outcomes such as pain and disability directly or indirectly by their resultof coping. If a person reflects that musculoskeletal problem is a serious disease that medical care or health services can do little about, this belief may have an effect on the level

Student (BPT), Noida
e-mail: utsavraj5433@gmail.com

of interference in daily life from that disease that the person reports and on their decision to consult or seek treatment for it. This discloses that perceptions may be an vitalissue to address as part of dropping the impact of disease and reassuring appropriate management.

After headaches and tiredness, back pain is the third most common health problem described by individuals. The exact cause of the augmented occurrence of low back pain (LBP) in populations of professional cab drivers is often uncertain. The most often reported risk factor for LBP is heavy physical workload such as lifting, awkward posture, and whole-body vibration. The prevalence and risk factors of WRMSDs among drivers would vary between countries due to differences in racial background, geographical location, ethnicity, and socio-demographics.. An earlier report found a 70.5% prevalence rate of WRMSDs among taxi drivers.

Bureau of Labour Statistics 2006 data on injury and illness show that the drivers of heavy trucks and tractor-trailers in the US are associated with the second-highest number of occupational illnesses and injuries for the past three years. It has been estimated that the indirect costs of one workday lost due to sickness absence amount to over than five hundred dollars [5]

A study in Japan inspected the risk factors of back pain reports that the prevalence of back pain among 285 taxi drivers was 45.8% which is consistent with other studies [6]. Some investigation showed risks of WMSDs in drivers are very high in Iran [7]. The evidence illustrated that people are driving at least half of working hours each day to endure three times more than other workers [8]. High prevalence of spinal disorders observed among the official worker, truck and bus drivers, particularly back and neck pain, frequently leads to invariable suffering and disease and possibly pre-retirement [9,10]. The aim of this study was to assess the musculoskeletal disorders among cab drivers of Delhi. This study will help us to determine the presence of WRMSD in drivers & to guide them for posture correction to help them in relieving their pain.

Methodology

In the methodology we use Nordic questionnaire. It is used to evaluate musculoskeletal symptoms, and the reliability has been checked out by test re-test system ,tells us that answers ,that are non-distinguishable fluctuate from zero to twenty-three percent, validity test tells us that answers that are non-distinguishable, changed between zero to twenty percent. The validity and reliability of the questionnaire were investigated and approved in different studies and several languages, including the Persian language[11,12] . This study design was one time observational.

Data Collection: The data collection procedures have been done recruiting the cab drivers of the age group 18-55 years & by using a "standardized general Nordic questionnaire". we collect data after taken an informed consent from subject they were explained about the study and they were asked to fill questionnaire. As this questionnaire is used to assess musculoskeletal symptoms& pain specifically back pain we have collected data from cab drivers of Delhi, India about musculoskeletal symptoms. The Inclusion criteria was drivers who drive cab only, drive cab, daily for at least 10 hours&cab drivers who have experience of at least one year of driving a cab&the Exclusion criteria was cab drivers, who were experiencing any kind of systemic or chronic musculoskeletal disease,Drivers who are involved in regular physical activity , Drivers with cardiovascular diseases

Result Analysis: Result was analysed by using SPSS 21 version. Study variables were measured using frequencies and discrete variables were measured by using mean and standard deviation, and as this is descriptive study, we use descriptive index test or frequency test or histogram test or box plot test.

On the analysis of the data we found 70% of cab drivers were suffering from lower back pain. Back pain was found to be most common problem for drivers in their daily activity. Back pain is affecting the daily works of the drivers so they are suggested exercise for their posture correction.

	No	9	30.0	30.0	100.0
	Total	**30**	**100.0**	**100.0**	

Discussion

In the current study found that most of the drivers were suffering from back pain. This affects their activity of daily living and stopping them from doing many works. This is a matter of serious concern because it affects their health & they must be guided for the posture correction & counselling will be done so that they must go for the regular visit to the physician & physiotherapist for the consultation & the treatment of their problem. In ROBB study on professional truck drivers, the most common reported disorders were low back, knee and neck pain.[13] The difference of spine pain between truck drivers and taxi drivers could be connected with the difference of vehicle vibration. Studies show that the vibration dose of taxi is lower than pain is more truck.[1415]

The vibration exposure level for taxi drivers is much lower than that for other professional drivers . Thirdly, direct back injury during motor vehicle accidents (MVAs) is another physical hazard associated with low back disorders of professional drivers.[16] The association between bending/twisting movements while behind the wheel and higher prevalence of LBP is also supported by recent reports from biomechanical experiments .[17,18] The observed association between long duration of car driving and LBP conforms to previous studies on other occupational groups often operating small automobiles.[11] Our cross-sectional analyses of the TDHS baseline data suggested that urban taxi drivers were a high-risk group for work-related LBP. The significantly higher prevalence of LBP (51%) in Taipei taxi drivers than other professional drivers (33%) in Taiwan is consistent with a previous study[18] High prevalence of musculoskeletal disease particular low back pain is possible due to prolong sitting position and absence of enough exercise among truck drivers[19]. Another point is a form of seats. Patterson et al., found that musculoskeletal disorders were the most prevalent health problem in bus drivers[20]. This study showed that low back prevalent in cab drivers.

In a study of Backman, about 70% of the drivers had suffered from musculoskeletal pain during the last month. In all, 40% of the drivers had often had back problem.[21]

Conclusion

The result of the current study showed the significance of frequent musculoskeletal disorders in cab drivers in different body regions, Among these, a lumbar area in drivers is more common .Present study concludes that there is high frequency of musculoskeletal disorders common in cab drivers in Delhi. Most commonly effected regions were upper back and lower back least common was wrist/hands region. This affects their activity of daily living & and stopping them from doing many works of day to day life as well this affects their job also.

Immediate Effect of Buteyko Breathing and Bhramari Pranayama on Blood Pressure, Heart Rate and Oxygen Saturation in Hypertensive Patients: A Comparative Study

Samiksha Sanjiv Sathe[1], Tejal Rajandekar[2], Kirti Thodge[3], Amol Bhawane[4], Utkarsh Thatere[5]

[1]Assistant Professor, Datta Meghe College of Physiotherapy, Nagpur, [2]Lecturer, Narayana Hrudayalaya College of Physiotherapy, Bangalore, [3]MPT Cardiovascular and Respiratory Physiotherapist, [4]Assistant Professor, [5]Junior Resident Dept. of General Medicine Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Aim: There are studies showing the use of Buteyko breathing technique & Bhramari Pranayama in reducing cardiorespiratory parameters in normal healthy individuals but to the best of our knowledge there is hardly any study that has reported comparative immediate effect of these two techniques. Thus the aim of our study was to evaluate the immediate effect of these two techniques on Blood pressure, heart rate and SpO2 in Hypertensive patients.

Method: The research design used was Comparative Experimental study design. Total 52 participants were screened and those meeting the inclusion criteria (n=42) were included in the study. The participants were randomly divided into two groups- Buteyko breathing and Bhramari pranayama Group of 21 each. Pre and immediate post intervention scores were measured in terms of systolic BP, Diastolic BP, heart rate and SpO2.

Findings: Inter group comparison (student's unpaired t test) showed that there was no statistically significant difference between the two groups in terms of Systolic and Diastolic BP, Heart rate and SpO2. The comparison of pre and post intervention valuesof the outcome measures in Buteyko group showed a significant difference in Systolic BP, Heart rate and SpO2 values whereas in Bhramari group there was statistically significant difference only the in Systolic BP values.

Conclusion: It can be concluded from the present study that Buteyko breathing and Bhramari pranayama are equally effective in immediately reducing the systolic blood pressure in hypertensive patients.

Keywords: *Buteyko breathing, Bhramari pranayama, Immediate effect, Hypertension.*

Introduction

Hypertension is defined as the persistent high blood pressure.[1] Systemic hypertension is one of the commonest non-communicable diseases in our country and also a prominent hazard to health[2] Around the world, hypertension is the foremost cause of premature mortality, with a rate of one in four men and one in five women.[3] Even though there is remarkable advancement in disease management, 30% of the global mortality are due to CVD.[2] It is considered as a silent invisible killer as the symptoms are usually invisible in early stagesupto occurrence of severe results. The international guidelines (2020) of Hypertension or elevated blood pressure diagnoses a patient with Hypertensionif systolic blood pressure (SBP) in the office or clinic is ≥140 mm Hg and/or diastolic bloodpressure (DBP) is ≥90 mm Hg. Further classification- Grade 1 Hypertension if SBP is

Corresponding Author:
Dr. Samiksha Sanjiv Sathe
Assistant Professor, Datta Meghe College of Physiotherapy, Nagpur

140–159mmHg and/or DBP is 90–99 mmHg and Grade 2 Hypertension if SBP is≥160 mmHg and/or DBP is ≥100mmHg.[4]

Out of many treatment alternatives, the non-pharmacological interventions comprise a range of measures like reduction of weight, increasing physical activity, diet modification, tobacco and alcohol consumption restriction, yoga & meditationetc[6,7] Main aim of yoga is to makethe individual attain and maintain the "sukhasthanam" that is a dynamic sense of physical, mental and spiritual wellbeing. Pranayama - the science of well-ordered, conscious expansion of Prana (the life force) has many useful effects. A type of Pranayama, Bhramariis originated from the Sanskrit word 'Bhramar' meaning Wasp. The name Bhramari pranayama has come from the humming noise impersonating the flying wasp.[8] There are studies showing the immediate positive effect of Bhramari pranayama on resting cardiorespiratory parameters in normal healthy individuals.[10]

Yet another breathing technique was devised in 1950's by Dr. K P Buteyko.[9] It was basically developed to treat the asthmatics for hyperventilation. It is a unique breathing technique that utilises the breath holding and breath control exercises. Easy to understand and easy to perform are the merits of this technique. There are several studies claiming positive immediate effect of Buteyko breathing technique on cardiorespiratory para metes in healthy adults[12].

Aim: There is hardly any study that has reported comparative immediate effect of these two techniques. Thus the aim of our study was to evaluate the immediate effect of these two techniques on Blood pressure, heart rate and SpO2 in Hypertensive patients.

Materials and Methodology

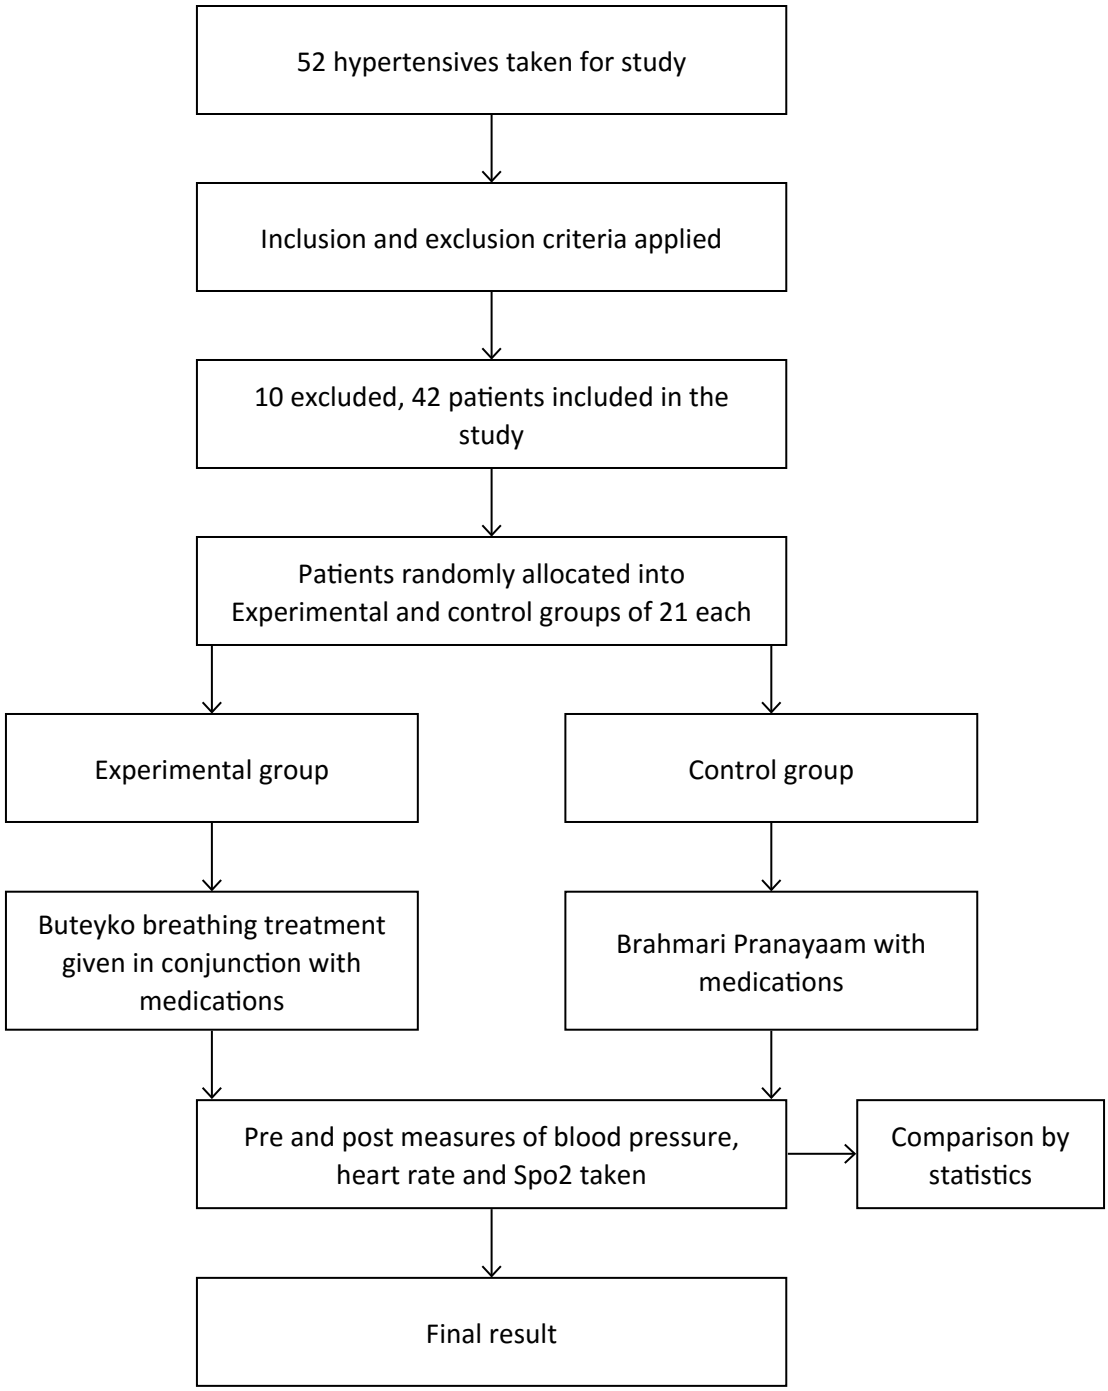
Our study was a Comparative study. Total 52 Hypertensive (above 40 years of age) subjects residing in Nagpur region and outskirts were considered in the study. Study continued over a period of one month.

Inclusion Criteria:

1. Participants clinically diagnosed with hypertension in the past 20 years[13]
2. Age group -above 40 years
3. Participants with history of Coronary artery bypass grafting or angioplasty in the past 20 years.
4. Participants with addictions like alcohol, tobacco.
5. Participants having history of diabetes and thyroid.
6. Participants engaging in mild physical activity on daily basis.
7. Participants who have taken or are taking medications for hypertension.
8. Participants with a history of respiratory disorders but currently stable.

Exclusion Criteria:

1. Participants with active respiratory infection or kidney problems[21]
2. Cognitively unstable hypertensive patients.
3. Participants unwilling to cooperate in the study.
4. Participants with a history of organ transplant.
5. Participants undergoing any cardiac or respiratory rehabilitation program.



Materials: Digital B.P. apparatus, Pulse oximeter

Outcome Measures: Blood pressure, Pulse rate, Oxygen saturation

Methodology: 52 patients with hypertension were screened for the study. Ethical approval was obtained from Institutional Ethical Committee & an informed consent was obtained from the participants.Inclusion and exclusion criteria was applied and 10 patients were excluded from the study.

The study was conducted on 42 hypertensives fulfilling the inclusion criteria. The participants were randomly divided into two groups Buteyko and Bhramariof 21 each. One group performed the Buteyko breathing exercises and the other performed Bhramari pranayama.

The blood pressure, heart rate and Spo2 of the patients were taken pre Buteyko and Bhramari technique. The techniques were explained through video and audio to the patients and the patients were made to perform it. Immediately after the technique, the post readings of the blood pressure, heart rate and Spo2 were measured.

Buteyko technique:

Step 1: Control pause phase:

The patient was asked to sit in an upright chair, close the mouth and breath in normally through the nose for 30 seconds.

The patients were further instructed to:

- Breathe in a small breath and breathe out
- Then close both the nostrils with empty lungs, taking care lungs are not too void of air
- Keep a count for how much time one is comfortable before feeling urgency to breathe in again and hold on until then
- Breathe in byreleasing the nostrils
- Patients were asked to keep a watch on first breath after CP, to avoid taking a breath deeper than the one taken before CP. Patients were instructed to not

hold the breath for a longer duration as this may lead to deep breathing after measuring the CP.

Step 2: Shallow breathing

The patient was asked to:

- Sit up straight.
- Monitor the amount of air flowing through nostrils by placing the finger under the nose in a horizontal position.
- The patients' finger should lie close enough to nostrils so that the airflow can be felt, but not so close that the airflow is blocked[16]

Patients were asked to repeat Step 1 and 2 for 5 mins (or approximately 6 cycles)

Bhramari pranayama: In an ambient atmosphere patients were made to perform the Bhramari pranayama. The breathing technique was explained and demonstrated in the following manner

To start with, one has to be atease in a relaxed position (Sukhasana) with eyes closed, and maintainan erect and steady posture.

Placing the thumbs on the external auditory meatus, index and ring finger on the closed eyes and ring finger near the nostrils one should breath in slowly through both the nostrils for maximum of 5sec and exhale out completely again through both the nostrils for about 15sec. While exhaling one has to chant the word "AUMmmmmm" with a simultaneous nasal humming sound impersonating the sound of humming wasp. This leads to vibration of the inner nostril and laryngeal walls. With the completion of these steps one completes a cylcle of Bhramari pranayama. (RR 3/min).After 5 minutes of practicing Bhramari pranayama, the outcome measures were reassessed.

Once the pre and post measures of Blood pressure, heart rate and Spo2 were obtained, the statistics of the respective outcome parameters were calculated on the basis of MYSTAT 12 software.

Results

MYSTAT 12 software was used to calculate the results in this study. The outcome measures used were Systolic and diastolic blood pressure, heart rate and oxygen saturation.Mean and standard deviations were calculated to describe all the variables. The paired t-test and the unpaired t-test were used to verify differences between pre- and post-intervention

The gender ratio was 10:11 (10 females and 11 males) in Buteykogroup and 11:10 (11 females and 10 males) in Bhramari group. The difference in the mean age of both the groups was statistically not significant (Table 1).

Table 1. Baseline demographic data of both the groups

Group	Buteyko group	Bhramari group	t value	p value	Inference
Age (years)	60.57 ± 8.96	59.71 ± 8.95	2.17	0.86	Not significant
Gender ratio(M:F)	10:11	11:10			

Table 2: Mean and SD scores of Buteyko group and Bhramari groups, Pre intervention and Post intervention

	Buteyko Group				Bhramari Group				Between groups	
			Paired t test				Paired t test		Unpaired t test	
	Pre intervention Mean ± SD	Post intervention Mean ± SD	Mean Difference	p value	Pre intervention Mean ± SD	Post intervention Mean ± SD	Mean Difference	p value	p value	Inference
Systolic BP	140.75±21.27	125.55±26.42	15.2	0.003	139.61±6.04	129.95±8.25	9.66	0.004	0.56	Not Significant
Diastolic BP	83.15±10.75	84.56±6.56	1.41	0.56	81.28±5.22	82.77±4.98	1.49	0.31	0.31	Not Significant
Heart rate	78.31±12.55	75±8.21	3.31	0.001	75.06±9.07	74±9.65	1.06	0.86	0.62	Not Significant
SpO2	95.91 ± 2.23	97.89 ± 1.36	1.98	0.002	96.35 ± 2.65	97± 1.44	0.65	0.49	0.42	Not Significant

Inter group comparison (student's unpaired t test) showed that there was no statistically significant difference between the two groups in terms of Systolic and Diastolic BP, Heart rate and SpO2 (Table 2). The comparison of pre and post intervention values of the outcome measures in Buteyko group showed a significant difference in Systolic BP, Heart rate and SpO2 values whereas in Bhramari group there was statistically significant difference only the in Systolic BP values.

Discussion

The readings for pre and post values of Heart rate,SpO2 and blood pressure were taken for both Buteyko patients and Bhramari patients. Both the groups were compared for the effects using an unpaired t test. The results showed that there was no significant difference in systolic blood pressure, diastolic blood pressure, heart rate and SpO2 when the two groups were compared (p value - systolic B.P - 0.56,diastolic B.P - 0.31,heart rate - 0.62,SPO2 - 0.42)

However,individually Buteyko technique was helpful in improving systolic blood pressure (p value 0.003) and SpO_2 (p value 0.002), heart rate (p value -0.001)and bhramari was effective in improving systolic blood pressure. (p value 0.004)

The following could be the mechanism of action for Bhramari Pranayaam. Bhramari pranayama being a type of slow speed breathing exercise, it stimulates the parasympathetic nervous system. More they described that while exhaling, vibration effect on the nasal/ laryngeal mucous membrane together with the humming of "AUMmmm" lead to reflex apnoea by turning off inspiratory centre. It causes bradycardia through chemoreceptor sinu-aortic mechanism[14]

Further the neural respiratory elements may be responsible for a mechanism that clarifies how slow deep breathing affects the autonomic nervous system. During extended voluntary expiration, there is an increase in intrathoracic pressure causing more blood flow to the heart from lung and thus increasing the stroke volume. This leads to increased blood pressure causing stimulation of the carotid sinus baroreceptors. The increase in baroreceptor discharge leads to inhibitory action on the vasoconstrictor nerves and excites the vagus innervations of the heart. These may be the possible reasons for reduction in blood pressure in the present study. Another study by Jerath et al. explained that there is decreased oxygen consumption, heart rate and blood pressure resulting from slow deep breathing in pranayama, thus adding more strength to our study[15]

The Buteyko method is based on the concept that hyperventilation is the underlying cause of numerous medical conditions (Rosalba Courtney,2008)[16,17] One possible biochemical mechanism of Buteyko may be through its influence on nitric oxide (NO). NO is involved in a large number of physiological responses including bronchodilation and vasodilatation.[18] Ritu et al (2013) state that Buteyko breathing exercise is useful in management of respiratory rate and heart rate in chronic obstructive pulmonary disease patients.[19]Apart from this, it is also mentioned in studies that holding the breath can cause accumulation of carbon dioxide, that will lower blood pressure, as also breath holding will also improve the collateral ventilation which can be effective reasons for reduction of blood pressure, heart rate and improvement in SPO_2 in some patients. These can be the reasons that individually Buteyko and Bhramari have a significant effect on vital parameters.

The reason for no significant difference in both these two techniques can be that it was an immediate effect study. If the study was for a longer time, then maybe there would have been a significant difference noticed. There are several studies showing the effectiveness of Buteyko in cardiac and respiratory disorders over a long term.[9,10] There are also studies which show the effectiveness of Bhramari in long term on cardiac and respiratory disorders.[8] There are also studies that have shown that there is immediate effect on cardiorespiratory parameters by Buteyko technique.[12] So the study here proves thatButeyko and Bhramari techniques are both effective in hypertensive patients individually, but have no significant difference when compared for immediate effect.

Conclusion

It can be concluded from the present study that Buteyko breathing and Bhramari pranayama are equally effective in immediately reducing the systolic blood pressure in hypertensive patients.

Limitation: The present research was to study the immediate effect, thus the effect of long term treatment was not studied. Also the sample size was less.

Ethical Clearance: Taken from institutional ethics committee.

The Normal Response to Slump and Straight Leg Raising Test (SLR) in an Asymptomatic Subjects

Shweta A. Panchbudhe[1], Kiran Janbandhu[2], Shilpa Hatewar[3], Vasant Gawande[4]

[1]Assistant Professor, Dept. of Cardio Respiratory Sciences Datta Meghe College of Physiotherapy, Nagpur, [2]Associate Professor, [3]Professor, Dept. of Musculoskeletal Sciences, VSPM'S College of Physiotherapy, Nagpur, [4]Associate Professor Dept. of Orthopedics, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha.

Abstract

Background: Neurodynamics is a test which check the mechanical movement of neurological tissue. It is used in an assessment to gain an impression of neural tissue mobility & sensitivity to mechanical stress. Slump and straight leg raising test are said to be the standard neurodynamics test for the lower limb.

Objectives: The aim of the study is to investigate the effect of neck and ankle position on knee and hip flexion movement during slump and straight leg raising (SLR) test and to know the neural tissue response to the neurodynamic test by addition of sensitizing manoeuver

Material and Method: It is an cross sectional study where 30 male & 30 female asymptomatic subjects in the age group of 18-39 years were taken

Results: It is concluded that there is a change in the range of movement in a normal asymptomatic subjection during Slump and SLR test. Therefore structural differentiating manouver has a significant effect on the body movement

Keywords: *Normal asymptomatic subjects, Neurodynamic test (slump & SLR test), Goniometer*

Introduction

Neurodynamic tests such as the straight leg raising (SLR) and slump test are frequently used for assessment of mechanosensitivity of neural tissue Sensitizing manoeuvres are limb or spinal movements added to neurodynamic tests, which aim to identify the origin of the symptoms by preferentially loading or unloading neural structures. A prerequisite for the use of sensitizing manoeuvres to identify neural involvement is that the addition of sensitizing manoeuvres has no impact on pain perception when the origin of the pain is non-neural.[1]

Comprehensive evaluation of patients with low back pain must include a method of testing the integrity of related neural tissues. The straight leg raise test is recognized as the first neural tissue tension test to appear. During straight leg raise testing, the leg is elevated with the knee extended and the patient in a supine position. This places a tensile stress on the sciatic nerve and exerts a caudal traction on the lumbosacral nerve roots from L, to S,the straight leg raise test, nonneural structures, such as lumbar zygapophyseal joints, muscles, and connective tissue, can limit leg elevation and provoke patient discomfort during testing Flexing the cervical spine, dorsiflexing the ankle, and medially rotating the hip during the straight leg raise test increases tension exerted on the spinal cord, spinal dura, and lumbosacral nerve roots. In Maitland's slumptest, the patient is seated in full flexion of the thoracic and lumbar regions of the spine. Sensitizing manoeuvres are then systematically applied and released to the cervical

spine and lower extremities, while the tester maintains the patient's trunk position. The slump test evaluates the excursion of neural tissues within the vertebral canal and intervertebral foramen, detecting impairments to neural tissue mobility .They found that full spinal flexion, or flexion of the cervical, thoracic, and lumbar regions of the spine, produces lengthening of the vertebral canal. When the vertebral canal is elongated, the spinal dura is stretched, transmitting tension to the spinal cord, lumbosacral nerve root sleeves, and nerve roots. During full spinal flexion, the cauda equina becomes taut and the lumbosacral nerve roots and root sleeves are pulled into contact with the pedicle of the superior vertebra. When extension of the cervical spine is introduced, the dura and the nerve roots slacken as the vertebral canal begins to shorten. Extending the thoracic and lumbar spine increases the slack in the neural tissues as the vertebral canal continues to shorten.[2]

The straight leg raise (SLR) is a common neurodynamic test used to examine the mechanosensitivity of the lower extremity nervous system in individuals with low back or lower extremity pain. The SLR consisted of placing the knee in end range extension, determined by the examiner as end range resistance, followed by bringing the limb into hip flexion Pre-positioning in ankle dorsiflexion compared to plantar flexion is commonly utilized for purposes of structural differentiation during SLR testing. The movement was stopped at the first moment any sensory response was indicated, including but not limited to the sensation of stretch, pulling, tension, pain, numbness, or tingling.[3]

Methodology

1. **Study design:** Cross sectional study
2. **Study set up:** Physiotherapy department
3. **Selection criteria:**

Inclusion Criteria:

- Asymptomatic subjects were taken
- Age group 18-39 yrs

Exclusion Criteria:

- H/O of low back pain
- Joint injury
- Neurological or vascular impairment

Materials Used: Goniometer

Procedure: Permission to carry out the research were taken from the ethical committee of the Datta Meghe college of Physiotherapy, Nagpur. Subjects who were volunteered to participate in the study were selected keeping in view of inclusion and exclusion criteria. Structural differentiation or sensitizing manoeuvre have a significant effect on test response in terms of range of movement during neurodynamic tests.

The Slump & SLR tests are standard neurodynamics tests for the lower limb, it is demonstrated as follows:

Slump Test Procedure: The subject should be sat on table with the pelvis fixed and thigh fully supported with knees together. The patient is asked to slump the back into thoracic and lumbar flexion. A strap is positioned across the shoulder to maintain thoracic and lumbar flexion so that patient maintain the chin in neutral position. A universal goniometer was placed i.e stationary arm between lateral condyle of knee and greater trochanter and moving arm of goniometer should be placed between lateral condyle of knee and lateral malleolus of ankle. The zero was taken as the point of full extension.

For cervical flexion, the subject was asked to put their chin to chest & the examiner applied ankle dorsiflexion and passively extend the knee until the onset of resistance, then the range of knee flexion should be measured relative to zero. All time, the subject was monitored for the presence of adverse symptoms during testing.

Straight Leg Raising Test Procedure: The subject should be in a supine lying position with the trunk,shoulder and hip in a neutral position. A goniometer was positioned with the stationary arm aligned between the greater trochanter and midline of trunk and moving arm aligned between greater trochanter and lateral condyle of femur. The examined leg should be kept in full extension by placing the examined hand on thigh proximal to knee and other hand under the heel. Subjects were asked to dorsiflex the foot and elevates the leg in a sagittal plane about the hip joint until the onset of resistance. Then the range of hip flexion should be measured relative to zero.

All time, the subject was monitored for the adverse symptoms during testing.

Outcome Measures:

Knee flexion ROM during Slump test

Hip flexion ROM during straight leg raising test

Results

Table No. 1: Distribution of subjects according to age

Age Group	No of Subject	%
19-28	48	80
29-38	12	20
Total	**60**	**100**

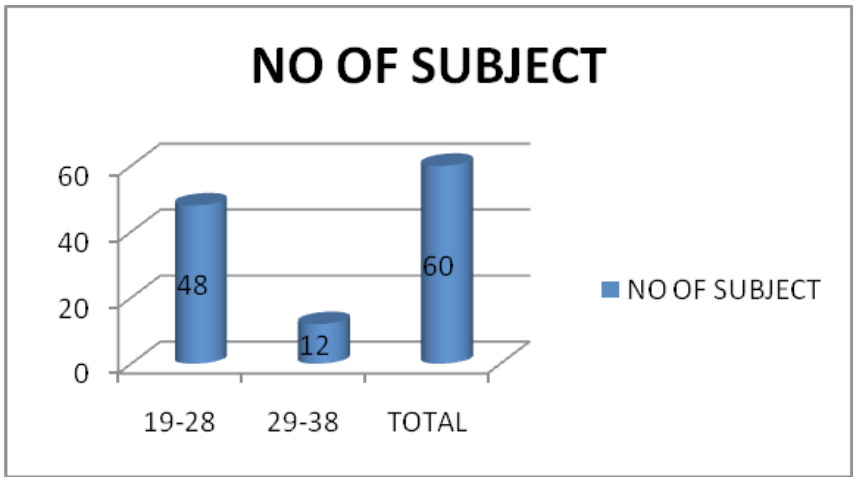

Figure 1

Table no 1 shows that, total 60 subjects were taken out of which 48 were participated in the age group of 19-28 years whereas 12 subjects in the age group of 29-38 years

Table No 2: Distribution of subjects according to Gender

Gender	No of Subject	%
Male	30	50
Female	30	50
Total	**60**	**100**

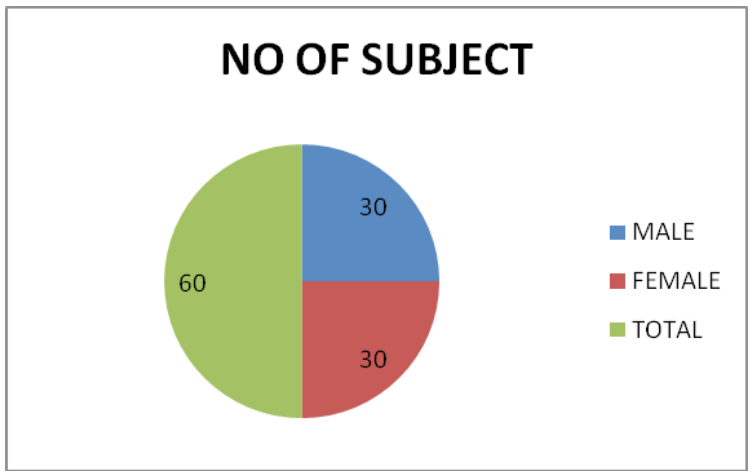

Figure 2

Table no 2 shows that total 60 subjects were taken out of which 30 male & 30 female who were volunteered to participate in the study in the age group of 19-38 years.

Table No 3: Mean and S.D of Flexion

	Male	Female
Knee flexion at slump neck flexed	42.7	37.77
Knee flexion at slump neck extended	48.6	47.6
SLR hip flexion at ankle dorsiflexion	73.9	73.3
SLR hip flexion at ankle neutral	82.23	81.23

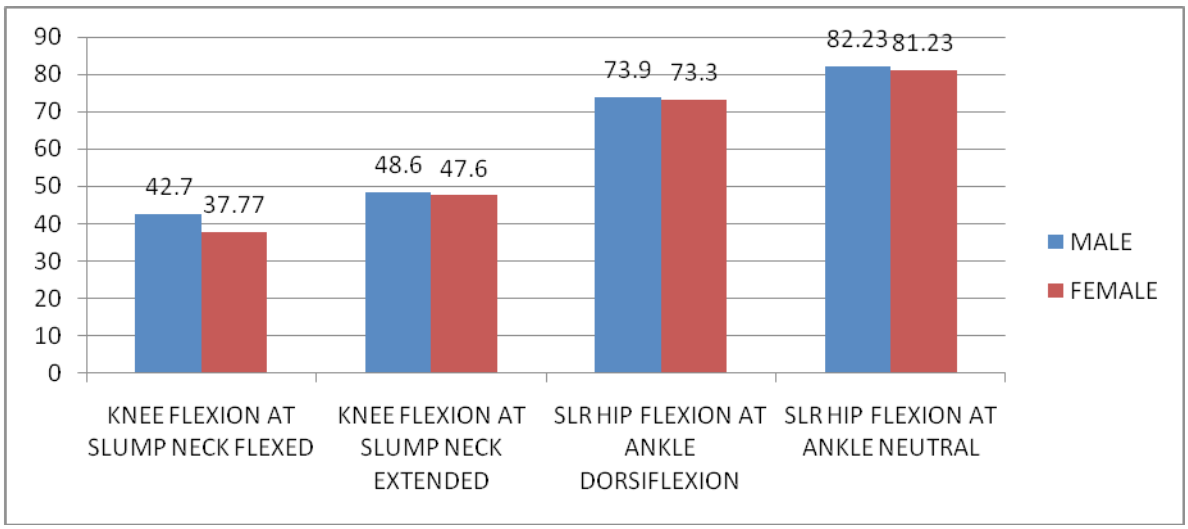

Figure 3

Table no 3 shows that range of knee and hip flexion angle during slump test and straight leg raising (SLR) test .It is found that there is an significant difference in knee & hip flexion angle in both male and female subjects.

Discussion

All data were analysed using statistical package, 60 subjects were taken (30 male and 30 female) who were volunteered to participate in the study between the age groups of 19-38 years. Structural differentiation or sensitizing manoeuvre have a significant effect on test response in terms of range of movement during neurodynamic tests. Cervical flexion & cervical extension during slump test whereas ankle dorsiflexion & ankle neutral during straight leg raising test act as a sensitizing manoeuvre. During slump test it is observed that knee flexion angle decreases when cervical flexion component wasadded, on the other hand knee flexion angle increases when cervical extension component was added both in male and female subjects.

This is supported by the study of P.C Lew, CA. briggs et al who conducted a study on asymptomatic patients between the age groups of 18-30 years he found that whether changing the cervical position during slump test altered posterior thigh pain/or tension in hamstring muscles,and there is an averaged over the group there was a 40% decrease in posterior thigh pain with cervical extension,it indicates that cervical movement did not change hamstring muscle tension the change in experimentally induced pain during cervical flexion was not due to change in hamstring muscle,it is concluded that posterior thigh pain caused by slump test and relieved by cervical extension arises from neural structures rather than hamstring muscle.[4]

This is also supported by Ketakijoshi, charu. Eapen et al who determine normal sensory and ROM responses during the movement components of thoracic slump test in an asymptomatic subjects,he conducted slump test in two sequences,proximal initiation which was proximal to distal and distal initiation which was distal to proximal its results shows the prevalence of sensory responses, its nature area and intensity,it concluded that the intensity of symptoms of proximal initiation

sequences was significant (p>0.05) when compared to distal initiation sequences and there is a change in ROM was significant for distal initiation when compared to proximal initiation,these normal responses is used as a reference when using thoracic slump test.[5]

During straight leg raising test it was found that there was a diminished range of hip flexion due to addition of ankle dorsiflexion, and increase in hip flexion due to addition of ankle in neutral position .Ankle dorsiflexion and neutral act as a sensitizing manoeuvre. The study was based on a sample of asymptomatic subjects in response to standard Neurodynamic test during slump and SLR test following the addition of structural differentiating manoeuvre.This study is supported by Benjamin s Boyd et al who conducted a cross sectional observational study on 20healthy subjects without low back pain,he measured hip flexion angle and surface electromyographic measures were taken and compared at the onset od symptoms P1 and at the point of maximally tolerated symptoms during SLR with ankle dorsiflexion and ankleplanter flexion, he concluded that addition of ankle dorsiflexion during SLR testing induces earlier distal muscle activation and reduces hip flexion motion.[6-8]

Forensic Age Estimation from Proximal End of Femur: A Radiological Study in Living Individuals

Ninad Nagrale[1], Swapnil Patond[2], Ranjit Ambad[3], Nandkishor Bankar[4], Karan Jain[5]

[1]Associate Professor, Department of Forensic Medicine, Datta Meghe Medical College, Nagpur (MS), [2]Associate Professor, Department of Forensic Medicine, Jawaharlal Nehru Medical College, DMIMS, Wardha (MS), [3]Associate Professor, Department of Biochemistry, Datta Meghe Medical College, Nagpur (MS), [4]Associate Professor, Department of Microbiology, Datta Meghe Medical College, Nagpur (MS), [5]Tutor, Department of Community Medicine, Datta Meghe Medical College, Nagpur (MS)

Abstract

Age determination is a very essential work in the field of forensic anthropology, which is a scientific study of human skeleton to determine age, sex and time of death to identify an individual. The identification is nothing but the recognition of an individual through various physical features or biological parameters. This study aims to examine the relationship between the stage of epiphyseal union of ossification centres at proximal end of femur & biological age in Chhattisgarh population. The study was carried out in 140 healthy subjects (70 girls and 70 boys) aging from 13 to 20 years. The obtained results revealed that the complete fusion of epiphysis of proximal end of femur is seen at 17-19 years. Females were consistently developing epiphysealunion at a younger age than their male counterparts with one year of difference. Results also suggest that the age of epiphyseal fusion at proximal end of femur is found to vary greatly all over the India, indicating the need for separate standards for separate regions.

Keywords: *Epiphyseal Union, Head of femur, Greater trochanter, Lesser trochanter.*

Introduction

Age determination by the epiphyseal fusion of bones is an intrinsic part of the biological characteristics by a forensic anthropologist to assist in achieving the identification of an individual. There are many well-known variables for identification of an individual like birthmarks, mal-formations, tattoo marks, scar marks etc. These types of identification are done by the forensic anthropologist. Several decomposed, burned, mutilated bodies are difficult to recognise & hence the identification of an individual becomes difficult[1,2]. Forensic anthropologist plays a crucial role in age determination & is one of the stringent problems in the medical justice system in both civil & criminal matters. As age advances, it becomes a wide problem in view of factors like nutrition, heredity, race, endocrinal etc. By taking into account the radiological analysis, this study will be of great help in further understanding the details of accurate assessment of age in Central Indian population[3,4,5].

Aims and Objectives:

1. To evaluate age specific difference in epiphyseal union at proximal end of femur.
2. To estimate age from epiphyseal union at proximal end of femur.
3. To compare bisexual difference in epiphyseal union at proximal end of femur.
4. To compare the findings of epiphyseal union at proximal end of femur in Central Indian population with other parts of India on the basis of previous studies.

Material and Method

The present study was carried out in the Department of Forensic Medicine & Department of Radiology, SSIMS, Bhilai, Chhattisgarh. A total of 150 individuals participated in this study. The subjects included were students of 13-20 years of age from schools & colleges from Bhilai & Durg city. They are born to parents domicile from Central India & have lived here since birth. The subjects do not have any disease/deformity related to bones or chronic disease affecting the general health. An informed consent was taken from all subjects prior to each procedure. Skeletal maturity was evaluated according to the Jit & Kulkarni's classification[1] of four stages: Appearance, Non fusion, Partial fusion & Complete fusion. X-Rays showing clear gap between the epiphyseal and diaphysial ends & showing saw tooth like appearance end were designated as "Non-fusion" (NF) X-rays. X-Rays showing a line replacing the hiatus between the epiphyseal & diaphysial ends & not showing saw tooth like appearance were designated as "Partial Fusion" (PF) X-rays. X-Rays showing the same bony architecture in the diaphysis and epiphysis & showing scar of the previous stage were designated as "Complete Fusion" (CF). It was classified, analysed and compared with known standards. At the end conclusions were drawn, which were compared with available results of various previous studies.

Results

In males, Head of femur shows: non fusion in 4 (5.71%) cases in age group of 13-15 years, partial fusion in 38(54.28%) cases in age group of 13-18 years & complete fusion in 28 (40%) cases in age group of 16-20 years. Complete fusion is seen in all the subjects in age group of 18-20 years. In females, Head of femur

shows: partial fusion in 28 (40%) cases in age group of 13-17 years & complete fusion in 42 (60%) cases in age group of 14-20 years. Complete fusion is seen in all the subjects in age group of 17-20 years.

In males, Greater trochanter shows: non fusion in 7 (10%) cases in age group of 13-16 years, partial fusion in 34 (48.57%) cases in age group of 13-18 years & complete fusion in 29 (41.43%) cases in age group of 16-20 years. Complete fusion is seen in all the subjects in age group of 18-20 years. In females,Greater trochanter shows: partial fusion in 26 (37.14%) cases in age group of 13-17 years & complete fusion in 44(62.85%) cases in age group of 14-20 years. Complete fusion is seen in all the subjects in age group of 17-20 years.

In males, Lesser trochanter shows: non fusion in 5 (7.14%) cases in age group of 13-16 years, partial fusion in 37 (52.86%) cases in age group of 13-18 years & complete fusion in 28 (40%) cases in age group of 16-20 years. Complete fusion is seen in all the subjects in age group of 18-20 years. In females, Lesser trochanter shows: partial fusion in 28 (40%) cases in age group of 13-17 years & complete fusion in 42 (60%) cases in age group of 14-20 years. Complete fusion is seen in all the subjects in age group of 17-20 years.

Discussion

Table 3: Comparison of Age of union (years)

Sr. No	Researcher	Region/population	Union of head, greater trochanter & lesser trochanter with shaft of femur (years)	
			Male	Female
1	Davies & Parson[2]	England	19-20	19-20
2	Hepworth[3]	Punjabi	15.5 - 17	15.5 - 17
3	Flecker[4]	Australians	17	14
4	Galstaun[5]	Bengalis	16-19	14-15
5	Chaurasia[6]	Indian	17-18	17-18
6	Parikh[7]	Indian	16 - 18	16 - 18
7	Nandy[8]	Indian	16 - 17	14 - 15
8	Vij[9]	Indian	17 - 18	17 - 18
9	Bhise S et al[10]	Mumbai	16 - 18	14 - 16
10	Sharma Y et al[11]	Udaipur	18-19	18-19
11	Devraj N et al[12]	Dhule	-	17-18
12	Present Study	Central India	18-19	17-18

When we compare our study with the previous studies for female population we found that our study is in agreement with studies conducted by Chaurasia[6], Parikh[7], Vij[9], Sharma Y et al[11] & Devraj N et al[12]. Whereas for male population we found that our study is in agreement with studies conducted by Galstaun[5], Chaurasia[6], Parikh[7], Vij[9], Bhise S et al[10] & Sharma Y et al[11]. If we carefully go through the above chart and analyse the overall age range for the Union of head, greater trochanter & lesser trochanter with shaft of femur, we found out that there is a lot of regional variation. So address this problem there is immense need of such studies in different regions of our country & these studies must include larger sample size.

Summary and Conclusion

1. This study was conducted exclusively on the young indigenous population of Central India.
2. The epiphyseal union at proximal end of femur in males is completed in all instances (100%)at the age of 18-19 years.
3. The epiphyseal union at proximal end of femur in females is completed in all instances (100%) at the age of 17-18 years.

4. Females were consistently developing epiphysealunion at a younger age than their male counterparts, with one year of difference.
5. Central Indian population is of mixed type comprising of various religions and castes. The opinion about age should always be given in the range.
6. From this study, range of 1-2 years of margin of error can be concluded.
7. For age estimation, relevant joints should be radiologically examined for different centres and opinion should be arrived considering the status of multiple centres.

A Prospective Observational Case Series of Liver Injury in Paediatric Patients Secondary to Consumption of Ayurvedic Herbomineral Formulations

Rekha V. Shinde[1], Ranjit Ambad[2], Sunanda C. Patil[3], Parag Aradhey[4]

[1]Assistant Professor, Dept. of Kaumarbhritya, Datta Meghe Ayurvedic Medical College, Hospital and Research Centre, Nagpur 440034, [2]Associate Professor, Dept. of Biochemistry, Datta Meghe Medical College, Shalinitai Meghe Medical College and Hospital, Nagpur, [3]Assistant Professor, Dept. of Agadatantra, N.K. Jabshettey Ayurvedic Medical College and P.G. Centre, Bidar, Karnataka, [4]Senior Resident General Medicine Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Background: Ayurvedic medicines especially herbomineral formulations are combinations of metals and herbs but not in a raw form. There are very good positive things in society about these herbomineral medicines and lots of misconceptions in modern world and modern scientist. They are much confused that how ayurvedic doctors can use metals in medicines; because they feel that metals are toxic to human body, metal can cause hepatotoxicity and nephrotoxicity. This is on scientific level totally confusion and misunderstanding in the mind of allopathy people. Why this confusion arises…? Actually they must little bit understand about ayurvedic science. This science never suggests to use these metals in the raw form. They are converting these metals totally nano particle level so original metal has been lost its molecular structure and it is completely new ayurvedic bhasmas are only oxides of metal. First purify the metal and after purification with lots of complicated biochemical processing, converting them into such molecule that molecule does not have a single raw metal molecule. This must be understood that final product is completely different than raw metal used. If try to study this things then nobody will challenge to ayurvedic science.

Aim: Observe the incidence of hepatic injury in paediatric patients due to herbomineral drug consumption.

Material and Method: In this prospective case series 5 drugs regimen of herbomineral medicine was given to 14 paediatric patients of age group 4 years to 14 years who were diagnosed as reactive and recurrent respiratory disease. The total duration of drug delivery was 90 days. After successful completion of treatment course Liver Function Test (LFT) of each patient was done and conclusion was drawn.

Outcomes: Total 14 patients, biomarkers of Liver Function Test were observed normal and at last follow up every patient was clinically fine.

Conclusion: Use of herbomineral medicines in paediatric patients is safe and it does not cause hepatotoxicity.

Introduction

Ayurveda believes in eradicating the disease right from its root and propound drugs that cause no complications. The metabolism of drugs depends upon the Bhautikagni's (enzymes) in liver and the Dhatvagni's in the cells or tissues.[1,2] In order to produce main desired

effect a drug must be present in appropriate concentration at the site of action. The optimum concentration of the drug depend upon the dose administered and the extent and rate of its digestion, absorption, localisation or bioinformation and excretion.[3] Despite rapid advancing theories in modern pharmacology; much a remains to be said about drug versus disease, pharmacokinetics, biotransformation, selective affinity of drugs to a particular cell or system.[4] Ayurveda believes in treatment without complications and therefore the Ayurvedic drugs as remain administered show s no encouraging pharmacodynamic or chemicotherapetic actions, they show only the pharmacotherapeutic actions well.[5]

The use of herbomineral Ayurvedic formulations is sensible and objectionable topic from the site of western science followers but at the same time the use of these medicines is interesting in Ayurvedic practitioners as they get desired effects among the patients. Various articles regarding the nephrotoxicity and hepatotoxicity secondary to consumption of Ayurvedic herbomineral and metallic medicines are found at internet. To address such issues the study was conducted to make evidence based knowledge and to claim the safe use of herbomineral medicines in paediatric population.

This prospective clinical trial was done with well informed consent in paediatric patients under the age group of 4 to 14 years which were diagnosed as Reactive and recurrent respiratory diseases and herbomineral five drug regimen was given for 3 months. Study was conducted at government Ayurvedic college osmanabad, Maharashtra in 2017-2018. Patients were observed for Hepatic pathological changes by applying biomarkers of Liver Functions.

This study provides evidence to use of Ayurvedic herbomineral medicines in children without causing harm to liver and also build confidence regarding the use of Ayurvedic herbomineral medicines among Ayurvedic practitioners and society also.

Material and Method

Study design

Study type: Observational, Prospective Clinical Trial.

0.- 14 participants of age group 4 years to 14 years.

Study duration: 1 year.

Group and cohorts: Single group/cohort diagnosed reactive and recurrent respiratory disease.

Sampling Method: Non-probability sample.

Study population- Children's in the age group of 4 to 14 years suffering from Reactive and recurrent respiratory diseases was involved in study and given 5 herbomineral drugs regimen for same illness.

Criteria: Inclusion criteria – children in the age group of 4 to 14 years presenting with complaints of recurrent respiratory illness episodes wheeze associated respiratory illness, reactive airway disease. Exclusion criteria - children suffering from tuberculosis, congenital heart disease and malformations, child suffering from any hepatic disease and any life threatening conditions.

Intervention: 5 herbomineral drugs regimen from standard and GMP certified Pharma Company.

1. Swaskaschintamani rasa[6]
2. Swaskuthar rasa[7]
3. Laxmivilas rasa[8]
4. Abraka bhasma (shataputi)[9]
5. Sitopaladi churna.[10]

Dose: Dose was decided as per age according to Sharangadhara samhita[11] and after discussed with higher authority of concerned subjects (Rasashastra department and paediatric department of institute). Above mentioned 5 drug regimens in powder form, 500 mg up to 7 years and 1 gm to above 7 years children BID after meal.

Anupana (vehicle): Honey

Duration of drug delivery: 5 drug combination was given for 3 months at one month interval.

Consent: Child was enrolled in study after taking well informed written consent from parents.

Follow up- total 4 follow ups were conducted at one month interval. At last follow up Liver Function test of each patient was done at authentic pathology laboratory.

Case Series:

Table 1: Case series/case details

Case	Age in years	Sex	Weight in Kg	Present complaints	History	Diagnosis	Treatment	Written Consent
Pt -1	14	M	35.6	Dry cough, cold, chest pain	Specific food and seasonal aggravation, repeated medication and nebulisation.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -2	7	M	16.4	Rhinitis	Repeatedly received medication and nebulisation.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt-3	7	M	13.8	Breathlessness, cough, cold	Asthama in grandparents, repeated medication and nebulisation.	Reactive airway disease	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt-4	5	F	13.1	Cough, cold	Seasonal and specific food aggravation, parental allergy, repeated medication and nebulization	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt-5	7	F	15	Rhinitis	Specific food aggravation, repeated use of nebulisation.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -6	5	F	14.6	Cough and cold	Parental allergy, specific food and .seasonal agrravation	Reactive airway disease	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt-7	13	M	27	Continuous rhinitis	Specific food and seasonal aggravation, repeated medication for same illness.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -8	11	M	33.4	Continuous dry cough	Grand Parental allergy, specific food and seasonal aggravation	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -9	5	F	15.3	Cough with bouts	Seasonal and specific food aggravation, parental allergy, repeated medication and nebulisation	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -10	4	F	12.6	Tonsillitis, fever, cough, cold.	Specific food and seasonal aggravation, repeated medications for same illness.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -11	10	M	21.6	Running nose	Seasonal and specific food aggravation, parental allergy, repeated medication and nebulisation.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -12	14	M	50.2	Cough, cold, fever	Seasonal aggravation, repeated medication, parental allergic rhinitis.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -13	4	M	13.5	Rhinitis	Seasonal and specific food aggravation, parental allerg.	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes
Pt -14	5	M	12.5	Cough, cold	Seasonal and specific food aggravation, parental allergy, repeated medication and nebulisation	Recurrent respiratory disease/illness	Swaskaschintamani rasa, swaskuthar rasa, lsxmivilas rasa, abhraka bhasma, sitopaladi churna.	Yes

Results

The present observational clinical trial was carried out to observe the liver injury after giving Ayurvedic herbomineral medicines to paediatric patients had same diagnosis. After successful completion of 3 months treatment course Liver Function Test was done and following results were obtained.

Table 2: Liver Function Test (LFT) Patient's Value

Sr.No.	Bilirubin Total (mg/dl)	Direct (mg/dl	Indirect (mg/dl	S.G.O.T. (U/L)	S.G.P.T. (U/L)	Total Proteins (g/dl)	Albumin	Globulin	Alkaline Phosphate (U/L)

Discussion

Generally speaking, Ayurvedic drugs possess no toxicity nor do they cause any complication and therefore, the Ayurvedic treatment never causes iatrogenic diseases (diseases caused by misguided treatment). But if the disease has not been properly diagnosed and only symptomatic treatment is given the duration of treatment is unnecessarily increased and obviously, this has socio-economic repercussions. Even though drugs have got active principles which with they work, they have some other fractions which counteract their bad effects, if any. Therefore Ayurveda advocates that drug should be used as a whole so that the desired effects may be had without any side effects.[12]

In Ayurvedic medicines the calculated proportion of ingredients in different formulations has a scientific meaning behind it. Disturbance in that proportion causes incompatibility. Once these explanations are accepted, it should be admitted that Ayurveda treats the patient while other systems of medicine treat the disease. To a lay and ignorant man, it is difficult to understand a disease without patient and a patient without disease.

There are some Ayurvedic metallic preparations, but they are fully and perfectly purified before administration. The finished product of Ayurvedic formularies does not cause any toxic or side effects. In some of the formulations antidotes are addedto avoid any possibility of toxic effects. Majority of Ayurvedic drugs show only the pharmacotherapeutic actions and do not cause any complication.[13]

Some articles published in journal regarding hepatic toxicity[14] and nephrotoxicity secondary to consumption of Ayurvedic medicines are observed and to address such articles the study was conducted. Paediatric department of this institute several times used Herbomineral medicines in children and does not noted any adverse effect of such medicines till date. Actual study was conducted over the paediatric patients suffered from recurrent respiratory illness and reactive airway disease[15], and herbomineral medicines (5 drug regimen)for 3 months. Along with this, to observe hepatotoxicity secondary to these combinations Liver Function Test was carried out after successful completion of treatment. And results was found no any pathological changes in the biomarkers

of liver function after given the herbomineral 5 drugs combination for 3 months in appropriate dose.

Conclusions

The present study,In this 14 patients observational clinical trial it was observed that use of Ayurvedic herbomineral medicines is safe and there is no relation to hepatotoxicity secondary to consumption of Ayurvedic herbomineral formulations.

Concluded as:

1. The aim of treatment is to cure the disease and to restore the health. Proper selection of drugs brings desired effects. Keeping all the pharmacological aspects in view, a drug should be chosen and employed to cure a disease.
2. Drug administration should be preceded by perfect diagnosis of disease and followed by expected results only.
3. the social implication of medicine is to see that man remains healthy and happy, and also useful to society. except in case where life itself is in danger, any drug causing iatrogenic disease should be socially and ethically contrabanded.

The Ayurvedic drugs fulfil all above requirements and therefore, satisfy the social obligation of medicine.

Study of Non-Stress Test as a Screening Tool in Low Risk Pregnancies at Term Gestation

Snehal Deshmukh[1], Amruta Choudhary[2], Mugdha Jungari[3], Arpita Jaiswal[4]

[1]Senior Resident, [2]Assistant Professor, [3]Associate Professor, 4Professor, Department Obstetrics and Gynaecology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Introduction: Various antepartum surveillance method aim at early detection of fetal distress preventing intrauterine fetal death. Non Stress Test is one such tool used for screening antenatal patients. In this study non stress test is used to screen and monitor fetus of low risk mothers, to detect fetal distress take necessary intervention and correlate fetal outcome with test results.

Materials and Method: This was a prospective longitudinal study conducted in Shalini Tai Meghe hospital and Research Centre, Wanadongiri, Nagpur from august 2019 till August 2020. 180 Antenatal patients with 37 completed weeks in labour and with no high risk factors were included in the study. Non Stress Test was performed on the patients and according to NICE guidelines, the result was interpreted as normal or abnormal.

Results: Out of 180, 130 patients had normal Non-Stress Test and 46 patients had abnormal Non Stress Test. The percentage of normal delivery was 60.4% in normal non stress test group and 23.91% in abnormal non stress test group, where as the percentage of caesarean section was 33.58% in normal non stress test group and 63.04% in abnormal non stress test group. The most common indication for caesarean section in abnormal non stress test group was fetal distress with 68.96%. Meconium stained liquor was present in 73.91% patients with abnormal non stress test, with negative predictive value 72.34%, sensitivity 73.91% and specificity 72.34%. APGAR score < 7 at 5 minutes was present in 34.78% patients with abnormal non stress test group, with negative predictive value 81.36%, sensitivity 34.78% and specificity 97.76%. 18 babies from abnormal non stress test group were admitted in NICU with no perinatal mortality.

Conclusion: Non stress test is a reliable screening tool for detecting high risk fetus in low risk mothers. The probability of adverse outcome like meconium stained liquor, low APGAR score, NISU admission increases with abnormal non stress test.

Keywords: *APGAR score, NISU, stress test, liquor and risk fetus.*

Introduction

Maternal mortality has been drastically reduced in developing countries and now modern obstetricians are more focused on maternal as well as fetal wellbeing. Originally, fetus was still deemed a conception result, but today the fetus is deemed another patient, and it often needs as much supervision as mother's well being. Intra partum monitoring of fetal health is one of the main component of contemporary obstetrics education. Approximately 50 % of fetal mortality happens in low risk mothers without obvious cause.(1)

Prof E. H. Hon and Prof. Caldeyro Barcia invented cardiotocogram (CTG) for fetal monitoring (2). In the

Corresponding Author:
Dr. Snehal Deshmukh,
Senior Resident, Department Obstetrics and Gynaecology, Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Nagpur

western countries,continuous fetal monitoring is being used extensively but due to economic constraints, itis not feasible in most of the developing countries like ours for practicing it. Ingemarsson et al.[3] has described analternative, in the form of Admission Test(AT) or Non stress test (NST) which is a short recording of FHR by cardiotocogramanduterine contractions of 15-20 minutes, at the time of admission in labour ward.

Non Stress Test is a non invasive, patient friendly, highly simple to perform and results are easily interpreted. The test detects transient FHR acceleration associated with fetal movements affecting the cerebral cortex and is caused by physiological and pathological effects on the brain of the fetus.

NST could be used as a screening technique to diagnose preexisting fetal hypoxia, and to schedule early intervention to avoid perinatal adverse outcome. The preset research was performed to forecast the perinatal result by conducting NSTas an admission test to minimize fetal morbidity and mortality by early diagnosis and intervention

Nice (2007) Classification of FHR trace feature[4]:

Feature	Baseline	Variability	Deceleration	Acceleration
Reassuring	**110-160**	**_>5**	**None**	**Present**
Non–reassuring	100-109 161-180	<5for 40-90min	Typical variable deceleration with over 50%of contraction, occurring for over 90min Single prolonged deceleration for up to 3min	The absence of acceleration with otherwise normal trace is of uncertain significance
Abnormal	<100 >180	<5 for 90min	Either atypical variable decelerations with over 50% of contractions or late decelerations, both for over 30 minutes Single prolonged deceleration for more than 3 minutes	The absence of acceleration with otherwise normal trace is of uncertain significance

Categorise cardiotocography traces as follows:

- **Normal:** All features are reassuring
- **Suspicious:** 1 non-reassuring feature and 2 reassuring features
- **Pathological/abnormal:** –1 abnormal feature or 2 non-reassuring features(4)

Aim of the Study: To study the role of Non Stress Test as a screening tool in management of low risk pregnancies in labor.

Materials and Method

Antenatal patients with 37 completed weeks in labour and with no high risk factors were included in the study. High risk pregnant patients like pre eclampsia, severe anaemia, heart disease, gestational diabetes mellitus, antepartum eclampsia, twins, previous lscs, intrauterine growth restriction were excluded from the study.

Informed written consent were taken from the patients. Detail history, general examination, systemic examination and obstetric examination was done. Routine blood investigations were done.

Non stress test was performed on the patient with patient in supine position. The Doppler transducer was strapped to the abdomen at the location where fetal heart sound was distinctly heard. The tocodynamometer was strapped at the fundus of the uterus. The fetal movement probe was given to the patient to press at the the time of fetal movement. Record was taken for full 20 minutes. Tracings were categorized according to NICE guidelines(4) as normal, suspicious and abnormal or pathological.

If NST was normal, monitoring was carried out with intermittent auscultation of fetal heart sounds. Repeat NST was done after 3 hours. If NST was suspicious, further extended NST was done for the patient for 40 minutes after following corrective measures like - patient

given left lateral position, oxygen was given, patient was hydrated with I.V fluids. If extended NST was found to be still suspicious continous monitoring with NST carried out till NST turns out to be normal. If NST turns abnormal, artificial rupture of membranes was attempted and decision for termination of pregnancy by LSCS, or instrumental delivery was taken dependingon amount and color of liquor and stage of labour.

Results

Total 180 antenatal patients in first stage of labour were included in the study. Maximum patients were in the age group of 21- 30 years i.e 82.22%. 11.11% patients were more than 35 years of age and 6.66 % patients were 18-20 years of age .51.66 % patients were primigravida and 48.33% were multigravida. Out of 180, 134 (74.4%) patients had normal NST recordings. 46 patients (25.55%) had abnormal NST out of which 26 had suspicious NST and 20 had pathological NST.

Table 1: Correlation of mode of delivery with admission NST

	Normal NST	**Abnormal NST**	
Ftnd	81(60.4%)	11 (23.91%)	92
Instrumental Delivery	8 (5.9%)	6 (13.04%)	14
Lscs	45 (33.58%)	29 (63.04%)	74
Total	134	46	180

As seen in the table, out of 134 patients with normal NST, 81 patients (60.4%) had full term normal delivery, 8 patients (5.9%) had instrumental delivery and 45 patients (33.58%) had caesarean section. Out of 46 patients with abnormal Non Stress Test, 11 patients (23.91%) had full term normal delivery, 6 patients (13.04%) had instrumental delivery and 29 patients (63.04%) had caesarean section.

Table 2: Indication of LSCS in all types of NST

Indication of LSCS	**Normal NST (n=134)**	**Abnormal NST (n=46)**
Fetal Distress	3(6.66%)	20 (68.96%)
Others	42 (93.33%)	9 (31.03%)
Total	**45**	**29**

In normal Non Stress Test Group, out of total 45 caesarean sections, 3 patients (6.66%) had caesrean section due to fetal distress. In patients with abnormal Non Stress Test, out of 29 caesarean sections, 20 patients (68.96%) had caesarean sections for fetal distress.

Table 3: Correlation of NST with Meconium stained liquor

Status of Liquor	**Normal NST (n= 134)**	**Abnormal NST (n=46)**	**Total (n= 180)**
Liquor Clear	121(90.29%)	12 (26.08%)	133(73.88%)
Meconium Stained Liquor	13 (9.70%)	34 (73.91%)	47(26.11%)

As seen from above table, liquor was clear in 121 patient (90.29%) with normal Non Stress Test, where as 13 patients (9.70%) with normal Non Stress Test had meconium stained liquor. Out of 46 patients with abnormal Non Stress Test, clear liquor was present in 13 patients (9.70%) while meconium stained liquor was present in 34 patients (73.91%). Out of total 180 patients 73 .88 % patients had clear liquor while 26.11% patients had meconium stained liquor.

Table 4: Correlation of NST with APGAR Score

APGAR Score	Normal NST	Abnormal NST
APGAR>7 AT 1 MIN	128(95.5%)	21(45.65%)
APGAR<7 AT 1 MIN	6(4.47%)	25(54.34%)
APGAR>7 AT 5 MIN	131(97.76%)	30(65.2%)
APGAR<7 AT 5 MIN	3(2.23%)	16(34.78%)

The table depicts the correlation between NST and APGAR score. At 1 minute, APGAR score was equal to or more than 7 in 128 babies (95.5%) and APGAR was less than 7 in 6 babies (4.47%) among patients with normal Non Stress Test. In babies of patients with abnormal Non Stress Test, 21 babies (45.65%) had APGAR at 1 minute,equal to or more than 7 and 25 babies (54.34%) had 1 minute APGAR less than 7. At 5 minutes, 3 babies showed improved APGAR more than 7, in normal NST group. So finally at end of 5 minutes, only 3 babies with low APGAR less than 7 were admitted in neonatal intensive care unit.

In abnormal Non Stress Group, 25 babies (54.34%) had APGAR score less than 7 at 1 minute. After 5 minutes, 9 babies showed improved APGAR of more than 7 . So at the end of 5 minutes 16 (34.78%) babies had APGAR less than 7 and were admitted to neonatal intensive care unit.

Table 5: Correlation of NST with fetal outcome

	Normal NST	Abnormal NST
Admission in NICU	4(2.98%)	18(39.13%)
Neonatal Death	0	0

4 babies (2.98%) were admiited to neonatal intensive care unit from normal Non Stress Test group, out of which 3 babies had low APGAR and 1 baby had good APGAR more than 7. 18 babies (39.13%) from abnormal Non Stress Test group were admitted to neonatal intensive care unit, out of which 16 babies had low APGAR, 2 babies had good APGAR with congenital anomalies. There was no neonatal death.

Performance Characteristics of Non Stress Test:

	Sensitiivity	Specificity	Positive Predictive Value	Negative Predictive Value
APGAR < 7 AT 1MIN	54.34%	95.52%	80.64%	85.90%
APGAR < 7 AT 5MIN	34.78%	97.76%	84.21%	81.36%
MSL	73.91%	90.29%	72.34%	90.97%
NICU Admission	39.13%	97.01%	81.81%	82.27%

Discussion

In our study,total 180 patients were studied. Out 180, 134 patients (74.44%) had normal Non Stress Test while 46 patients (25.55%) had abnormal Non Stress Test. In study conducted on similar subject, by Phelan et al [5], 85.4% had reactive Non Stress Test and 14% had nonreactive and 0.6% had unsatisfactory Non Stress Test. In Studies by Shrestha et al[6] and Panda et al[7] 10% and 14% had abnormal Non Stress Test respectively.

In this study, 60.4% patients had full term normal

delivery in normal NST group while 23. 91% patients had normal delivery in abnormal NST group. 33.58% patients had caesarean section in normal NST group and 63.04 % patients had caesarean section in abnormal NST group. This is comparable to study by Eden et al[8] where, caesarean section rate in reactive group was 23.2%, however in non reactive group caesarean section rate was lower as compared to our study i.e 37.7%.

Meconium stained liquor was found in 9.7% patients with normal Non Stress Test and 73.91% patients with abnormal Non Stress Test. In study done by Lohana et al[9], in reactive Non Stress Test Group, meconium stained liquor was present in 8.24% of reactive NST group which is comparable to our study while, in non reactive NST group the percentage of meconium stained liquor was 33.33% which is less compared to our study. The variation in gestational age of patients and number of post dated pregnancies can be accountable to the difference. The sensitivity and negative predictive value of the test for meconium stained liquor was 73.91% and 90.97 % respectively, which is comparable to study by Bano et al ([10]which showed negative predictive value to be 90.9%, and study by Khooshideh et al[11] which showed sensitivity of 62%.

APGAR score < 7 at 1 min was present in 4.47 % babies of normal Non Stress Group patients and 54.34% babies of abnormal Non Stress group patients. APGAR score < 7 at 5 min was present in 2.23 % babies of normal Non stress test group patients and 34.78% babies of abnormal Non Stress Test group patients. This was comparable to study done by Bano et al[10] which had APGAR<7 at 5min to be 3.4% in reactive group and 42.8 % in non reactive group.

For APGAR<7 at 5 minutes, the negative predictive value was 81.36% and specificity was 97.76% comparable to study done by Bano et al [10], with 98.8.% negative predictive value and 90.6% specificity respectively. The negative predictive value and specificity of APGAR<7 at 5 minutes is also comparable with the values of 95.23% and 83.33% respectively in study by Bhide et al[12]

4 babies (2.98%) were admitted to neonatal intensive care unit from normal Non Stress Test group and 18 babies (39.13%) from abnormal Non Stress test group. This is comparable to study by Bano et al[10], where, 3.6% babies were admitted from reactive nst group and 28.5% babies from non reactive Non Stress Group test.

Conclusion

Non stress test is a simple, noninvasive screening test which can be used to detect at risk babies in low pregnancies. It is easy to perform and the results are simple to interpret. It aids in early diagnosis of fetus with risk or hypoxia and helps in planning timely intervention. It is of great help in detecting meconium stained liquor with good precision. Non Stress Test is also a good predictor for babies with low APGAR score needing nicu facility so timely termination of pregnancies can be planned. Thus Non Stress Test is auseful tool to avoid obstetric litigation as parental expectation of a good outcome is extremely high.

Abstract

Introduction: Vitiligo is a long-term skin condition that is characterized by skin patches which lose their pigment. The affected skin patches are becoming white and typically have narrow margins. The skin hair can also turn white. Mouth and nose inside might also be involved. Occasionally, the vitiligo "comes in families," implying a genetic origin. It ensures that the risk of other family members contracting vitiligo is not predictable. Approximately 25 to 50 per cent of people with vitiligo have a parent with vitiligo, and around 6 per cent have vitiligo siblings. Low serum levels of vitamin D have been associated with many autoimmune disorders and a number of other skin conditions. Vitiligo is an autoimmune disease which is characterized by immune processes that kill melanocytes. Melanocytes express vitamin D receptors, and vitamin D status can affect their function.

Objective: To assess serum Vit-D levels of vitiligo patients and contrast the outcomes and controls.

Material and Method: In all out, 50 vitiligo patients and 50 controls were taken on the examination. Vit-D levels were estimated from blood tests. Gathering correlations were performed utilizing fitting factual strategies.

Observation and Results: The patients had lower serum Vit-D levels than the controls, yet this distinction was not noteworthy ($p = 0.570$).

Conclusion: It stays obscure whether Vit-D inadequacy causes vitiligo. Bigger controlled investigations are required to demonstrate whether low flowing VIT-D is a causative factor in vitiligo.

Keywords: *Vitiligo, Vit-D, immune system illnesses, Etiopathogenesis.*

Introduction

Vitiligo affects approximately 2 percent of the world's population regardless of skin type, age and sex[1]. The malady may influence the two sexual orientations and all skin types[2] and may likewise be related with fundamental immune system sicknesses, for example, lupus erythematous, scleroderma, immune system thyroiditis and alopecia areata[3]. Diminished serum Vit-D levels are found in numerous immune system illnesses including foundational lupus erythematosus, diabetes mellitus, rheumatoid joint inflammation,

different sclerosis and alopecia areata[4].Genetic factors play an important pathogenic factor. Multiple studies have included multiple genes in the pathogenesis of vitiligo, including studies on Jordanian population [5, 6].

Vitiligo has a significant psychological and social effect on individuals especially affected by women, or on exposed sites and more so in people of colour (POC) [7]. Vitamin D3 is a vitamin essential to humans. The majority of its active form is obtained by activating the pre-vitamin D3 formed in the skin following exposure to sunlight, in particular UVB (290–320 nm).Diet is only a minor vitamin source. This vitamin plays an important role in immunity (innate and adaptive), calcium control, and melanin synthesis; in addition, several diseases have been associated with decreased vitamin D levels. Melanocytes express vitamin D receptors which may indicate a possible role for vitamin D in melanocyte function regulation.[8].

Vit-D is a basic hormone that is orchestrated in the skin[9]. The dynamic type of Vit-D, 1, 25-dihydroxyvitamin D3, is a hormone that manages calcium and bone digestion, controls cell multiplication and separation and furthermore displays certain immunoregulatory capacities [10].Vit-D may influence both natural and versatile resistant reactions through receptors in T and B lymphocytes, macrophages and dendritic cells[11]. What's more, Vit-D3 increments tyrosinase action and melanogenesis by means of an atomic hormone receptor – the Vit-D receptor (VDR) in melanocytes[12]. Vit-D and its analogy are utilized to treat skin issue, including psoriasis and vitiligo[13]. Patients with vitiligo have been treated with topical calcipotriene [13]. Hardly any reports have examined the relationship among vitiligo and decreased Vit-D levels, yet these examinations give clashing outcomes [14,15]. Point: This examination expected to decide if patients with vitiligo have lower serum Vit-D levels contrasted with controls.

Material and Method

In all out, 50 patients determined to have vitiligo, in our outpatient division from 1 December 2013 to 31 March 2014, were taken a crack at the examination; 47 age-, sex and skin phototype-coordinated sound controls additionally took part. The patients were analyzed by a similar dermatologist and the analysis of vitiligo was made by clinical discoveries and a Wood's light assessment. Punch biopsy was performed on dubious cases, with the conclusion at that point checked. Point by point sickness and family ancestries were gotten from all patients. Different segment and way of life factors were recorded, including age, sexual orientation,skin model and sunscreen utilization. Members with liver or kidney issue, hyperparathyroidism, hypo-parathyroidism, any metabolic bone issue (for example osteoporosis or osteopenia) or fiery ailments were rejected from the investigation, similar to those taking Vit-D-or calcium-including drugs, or any fundamental or topical treatment for vitiligo inside the earlier month. Controls were selected from the accomplices or family members of patients, if not influenced by vitiligo, to limit contrasts because of dietary admission of Vit-D. Educated assent was acquired from all members and the neighbourhood Ethics Committee affirmed the examination, which was led as per the fundamentals of the Declaration of Helsinki. Blood tests were taken in the first part of the day after a base fasting time of 8 hour. Serum free T3, free T4, thyroid animating hormone, fasting glucose, against thyroid peroxidase antibodies, hostile to thyroglobulin antibodies, Vit-B12 and Vit-D levels were estimated.

Observation and Results

In complete, 26 (52%) guys and 24(48%) females were remembered for the investigation gathering. The benchmark group comprised of 30 (60%) guys and 20 (40%) females. The mean periods of the patient and control bunches were 31.96 ±10.68 and 32.45 ±9.52 years, separately. There was no huge distinction between the patient and controls as far as age ($p = 0.809$). All patients had summed up vitiligo as controlled by the nearness of reciprocal evenly circulated depigmented macules in trademark areas. The mean age at vitiligo macules beginning was 17.48 ±9.81 years. The term of the injuries extended up to 25 years. A family ancestry of vitiligo was accounted for in one patient. No patients had diabetes mellitus or Vit-B12 lack. Immune system thyroid ailments were accounted for in 14 (28%) patients. Vit-D levels were tried throughout months, from December 2019 to May 2020. The patients' serum Vit-D levels ran from 6 to 42 ng/ml (mean: 12.54 ±9.29 ng/ml); in the benchmark group they ran from 8 to 39 ng/ml (mean: 13.07 ±5.98 ng/ml). The patients had lower coursing Vit-D levels than controls, however this distinction was not critical ($p = 0.7352$).

Discussion

In the current investigation, we discovered lower

serum Vit-D levels in patients with vitiligo comparative with controls; be that as it may, this distinction was not huge. Both the patients and controls had exceptionally low circling Vit-D levels. This might be on the grounds that the blood tests were gathered during winter months. There are not very many examinations assessing serum Vit-D levels in vitiligo patients [14, 15]. Ustun et al. examined 25 vitiligo patients and 41 controls: deficient (< 30 ng/ml) or low (< 15 ng/ml) levels of Vit-D were seen in most of patients, yet the distinctions were not huge contrasted with controls [14]. These examiners expressed that countless examinations had announced low degrees of flowing Vit-D in immune system sicknesses; however it stays muddled whether this is a reason or consequence of immune system maladies [14]. Another examination researched 40 vitiligo patients and 40 age-and sexual orientation coordinated controls. Altogether lower serum Vit-D levels were found in the patient comparative with controls. The creators estimated on the chance of Vit-D supplementation for the treatment of vitiligo patients later on [15]. The pathogenesis of vitiligo remains to a great extent obscure. There are various hypotheses clarifying the pathogenesis of vitiligo, with all hereditary, immune system, autocytotoxic and neurogenic causes hypothesized. The immune system hypothesis is the best-bolstered one, since vitiligo might be related with other immune system sicknesses including malignant sickliness, hyperthyroidism, Hashimoto's thyroiditis, alopecia areata and adrenocortical disappointment. Besides, histological investigations have exhibited a high recurrence of cytotoxic T lymphocytes explicit to melanocytic antigens in vitiligo injuries, proposing an immediate, melanocyte-explicit T cell assault [16, 17]. Vit-D, which is a fat-dissolvable vitamin acquired by people through eating routine, is specifically compelling to dermatologists since it is combined in the skin by bright light. It has been utilized to treat psoriasis, vitiligo and other skin ailments for a long time [17]. The dynamic type of Vit-D, 1, 25-dihydroxyvitamin D3, directs calcium and bone digestion, yet in addition controls cell multiplication and separation and applies immunoregulatory exercises [13]. In a past report, it was accounted for those patients with comorbid immune system diseases are bound to have low serum Vit-D levels [16].Vit-D has anuclear receptor called Vit-D receptor (VDR). Vit-D receptors are available in the cells engaged with calcium and bone digestion, and furthermore in keratinocytes, melanocytes, fibroblasts and resistant framework cells of the skin. Polymorphisms in VDR are corresponded with expanded helplessness to numerous sclerosis, provocative entrail malady, rheumatoid joint pain and type 1 diabetes mellitus [19]. Vit-D applies a noteworthy impact on melanocytes and keratinocytes by means of different instruments. In vitro investigations have demonstrated that Vit-D3 is related with an expansion in tyrosinase action and melanogenesis [11], which may add to re-pigmentation in vitiligo macules. Vit-D analogs, including calcipotriol and tacalcitol, are known to improve re-pigmentation in vitiligo patients [20-22]. Another investigation announced that Vit-D applies immune-modulatory impacts by hindering the declaration of interleukin (IL)- 6, IL-8, tumor rot factor (TNF)- α, and TNF-γ [23]. Besides, it has likewise been indicated that the dynamic type of Vit-D lessens the apoptotic action prompted by UVB in melanocytes[13].

Conclusion

More investigation is required to outline the connection between VITAMIN D and vitiligo, to assess whether a low degree of serum Vit-D is a causative factor in vitiligo, and to learn whether Vit-D supplements are helpful for both the anticipation and treatment of vitiligo. Irreconcilable circumstance the creators proclaim no irreconcilable situation.

Immediate Effect of Buteyko Breathing in Hypertensive Patients: An Experimental Prospective Study

Samiksha Sanjiv Sathe[1], Tejal Rajandekar[2], Saurabh Hadake[3], Vinayak Shegaonkar[4]

[1]Assistant Professor, Datta Meghe College of Physiotherapy, Department of Musculoskeletal Physiotherapy, [2]Lecturer, Narayana Hrudayalaya College of Physiotherapy, Bangalore, [3]Assistant Professor Dept. of Medicine Datta Meghe Medical College, Shalinitai Meghe Hospital and Research Centre, Nagpur, [4]Professor Dept. of General Medicine Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Background: There are ample studies showing effect of Buteyko breathing technique on cardiovascular parameters in asthmatics but very few studies have been done to see its immediate effect on hypertensive patients.

Aims: The aim of this study was to assess the immediate effectiveness of Buteyko breathing technique on hypertensive patients in terms of Systolic and Diastolic Blood pressure, Heart rate and Oxygen saturation (SpO2)

Method: The research design used was Experimental prospective study design. Total 50 participants were screened and those meeting the inclusion criteria (42) were included in the study. The participants were randomly divided into two groups-experimental and control Group, by computer generated randomised table into groups of 21 each. The experimental group performed the Buteyko breathing exercises. The control group did not receive any treatment. Pre and immediate post intervention scores were measured in terms of systolic BP, Diastolic BP, heart rate and SpO2.

Findings: On comparing the pre and post intervention values of the outcome measures, it was observed that there was statistically significant difference in Systolic BP, Heart rate and SpO2 values in Buteyko breathing group. No significant difference was seen in Pre and Post values of Systolic and Diastolic BP, Heart rate and SpO2 values in Control group. On comparing between the groups, it was observed that there was statistically significant difference between the two groups in terms of SpO2

Conclusion: Thus it can be concluded from the present study that Buteyko breathing technique has an immediate positive response on oxygen saturation level in hypertensives.

Keywords: *Hypertension, Buteyko breathing technique, SpO2, BP*

Introduction

Hypertension is defined as the persistent high blood pressure.[1] More than a billion people all over the world are affected with Hypertension[2] and it is anticipated that the number will increase to 1.56 billion in 2025[3,4] Globally, hypertension is the leading cause of premature deaths, with a rate of one in four men and one in five women.[5] For cardiovascular diseases, hypertension is one of the eminent risk factor. It is considered as a silent invisible killer as the symptoms are usually invisible in early stages until it takes a severe face later as of stroke, heart attack or chronic kidney disease.[2]

The Buteyko breathing technique named after its creator Dr. K P Buteyko was devised in 1950's.[6] It was basically developed to treat the asthmatics for hyperventilation. The beauty of Buteyko breathing technique is that it is easy to understand and patients can perform the exercise comfortably. It is a distinctive

breathing technique that utilises the breath holding and breath control exercises. This technique weighs more on shallow breathing pattern, correcting the hyperventilation. Thus basically it aims its attention on nasal breathing and holding the breath along with relaxation. The technique stresses on the optimum retention of CO2 which in succession has vasodialatory effect, resulting in the reduction in heart rate and blood pressure.[7]

There are several studies claiming successful effect of Buteyko breathing technique on Bronchial Asthma. A randomised control trial on Buteyko breathing technique as an addition to conventional treatment showed 39% increase in asthma control.[8] A similar study showing effects of Buteyko breathing technique on asthmatics revealed positive results.[9]Aslo there are a few studies showing immediate effect Buteyko breathing technique on Cardiorespiratory parameters in healthy adults[7], but to the best of our knowledge no study has been done to see the immediate effect of Buteyko breathing technique on cardiorespiratory parameters in Hypertensive patients. Thus the aim of our study was to evaluate the effect of Buteyko breathing technique on Blood pressure, heart rate and SpO2 in Hypertensive patients.

Methodology

The aim of the study was to assess the effect of Buteyko breathing technique on hypertensive patients.

Study Design:

Research Design: Experimental prospective study.

Sample Population: Hypertensive subjects residing in Nagpur region above 40 years of age.

Sample size: 50

Type of sample: Convenience sampling

Source of sampling: Nagpur district and outskirts

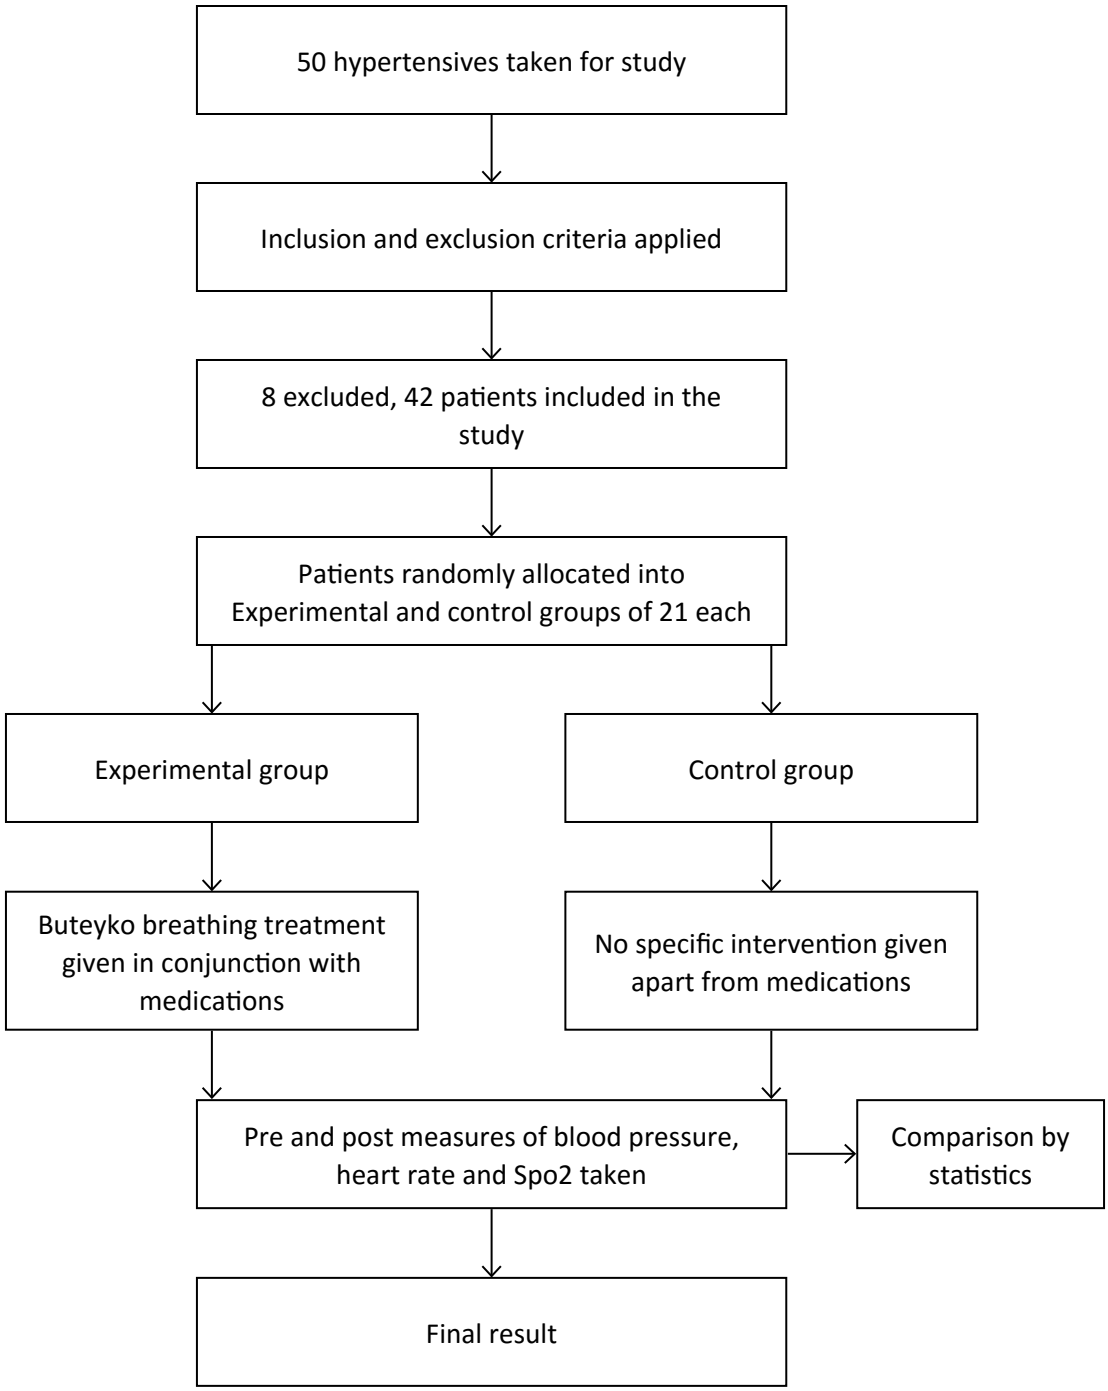
Place of study: Datta Meghe College of Physiotherapy

Duration of study: 1 month

Inclusion criteria:

1. Males and females clinically diagnosed with hypertension.
2. Age group -above 40 years
3. Patients with history of Coronary artery bypass grafting or angioplasty in the past 20 years.
4. Patients with addictions like alcohol, tobacco.
5. Patients having history of diabetes and thyroid.
6. Patients engaging in mild physical activity on daily basis.
7. Patients who have taken or are taking medications for hypertension.
8. Patients with a history of respiratory disorders but currently stable.

Exclusion Criteria:



1. Patients with active respiratory infection or kidney problems.
2. Cognitively unstable hypertensive patients.
3. Patients unwilling to cooperate in the study.
4. Patients with a history of organ transplant.
5. Patients undergoing any cardiac or respiratory rehabilitation program.

Materials used: Digital B.P. apparatus, Pulse oximeter

Outcome measures: Blood pressure, Pulse rate, Oxygen saturation

The study was carried out at the Datta Meghe College of Physiotherapy, Wanadongri Nagpur. Ethical approval was obtained from Institutional Ethical Committee & an informed consent was obtained from the participants. 50 patients with hypertension residing in Nagpurregion were included in the study. The study was conductedfor a month. Inclusion and exclusion criteria were applied and 8 patients were excluded from the study. The study was conducted on 42 hypertensives fulfilling the inclusion criteria. The participants were randomly divided into two groups-experimental and control Group, by computer generated randomised table into groups of 21 each.

The Experimental group was given Buteyko Breathing technique.

A Digital B.P. apparatus and Pulse Oximeter were used in the study to measure Systolic and Diastolic Blood pressure, Heart rate and oxygen saturation. The blood pressure, heart rate and SpO2 of the patients were measured before the Buteyko technique. The technique was explained through video and audio to the patients and the patients were made to perform it. Immediately after the technique, the post reading were taken. The control group did not receive any treatment . The pre and the immediate post reading of the blood pressure, heart rate and Spo2 was taken in this group aswell after a 5 min interval.

Buteyko technique:

Step 1: Control pause phase:

The patient was asked to sit upright in a chair and breathe normally through the nose for 30 seconds (keeping mouth closed)

Subsequently instructions were given to the patient:

- Do not change your breathing pattern before taking control pause.
- Take a small breath in and a small breath out.
- Hold the nose on the "out" breath, with empty lungs but not too empty. (In order to prevent the air to enter the airways)
- Count for how many seconds you can last comfortably before need to breathe in again.
- Hold breath until feeling the first urgency to breathe in.
- Release nose and breathe in through it.
- First intake of breath after the CP should not be greater than the breath prior to taking measurement; patients were advised not to hold breath for too long as this may leadto taking a deep breath after measuring the CP.

Step 2: Shallow breathing

The patient were asked to:

- Sit up straight.
- Observe the air flow through the nostrils by placing a finger under the nose in a horizontally
- The patients' finger should lie just below the nostrils so that the airflow can be felt, but at the same time not blocking the airflow.[10]

Step 1 and 2 were repeated for 5 mins or 6 cycles approximately.

Once the pre and post measures of Blood pressure, heart rate and Spo2 were obtained, the statistics of the respective outcome parameters were calculated on the basis of SPSS software.

Result

The software MYSTAT 12 was used in this study. Outcome measures used were systolic and diastolic blood pressure, heart rate and oxygen saturation. Descriptive statistics such as mean and standard deviations were calculated to describe all the variables. The paired t-test and the unpaired t-test were used to verify differences between pre- and post-intervention. The statistical analysis was conducted at 95% confidence level, and $p<0.05$ was considered statistically significant.

The gender ratio was 12:9 (12 females and 9 males) in Group A and 11:10 (11 females and 10 males) in Group B. The difference in the mean age of both the groups was statistically not significant. (Table 1).

Table 1. Baseline demographic data of both the groups

Group	Group A Buteyko	Group B Conventional	t value	p value	Inference
Age (Years)	60.57 ± 8.50	60.71 ± 10.54	2.02	0.96	Not significant
Gender ratio (M:F)	12:9	11:10			

On comparing the pre and post intervention values of the outcome measures, it was observed that there was statistically significant difference in Systolic BP, Heart rate and SpO2 values in Buteyko breathing group. No significant difference was seen in Pre and Post values of Systolic and Diastolic BP, Heart rate and SpO2 values in Control group. On comparing between the groups, it was observed that there was statistically significant difference between the two groups in terms of SpO2 whereas no statistically significant difference was found between Systolic and Diastolic BP and Heart rate. (Table 2).

Table 2: Mean and SD scores of Buteyko and Control groups, Pre intervention and Post intervention

	Buteyko Group A				Conventional Group B				Between groups	
			Paired t test				Paired t test		Unpaired t test	
	Pre intervention Mean ± SD	Post intervention Mean ± SD	Mean Difference	p value	Pre intervention Mean ± SD	Post intervention Mean ± SD	Mean Difference	p value	p value	Inference
Systolic BP	139.57±23.48	126.00±28.44	13.57	0.002	139.57±22.82	19.42±20.83	0.14	0.79	0.08	Not Significant
Diastolic BP	83±12.51	84.42±6.86	-1.42	0.59	82.85±12.95	82.71±12.75	0.14	0.32	0.59	Not Significant
Heart rate	79.28±13.81	75±11.21	4.28	0.001	79.28±13.81	79.14±13.52	0.14	0.08	0.28	Not Significant
SpO2	97±1.22	98±1.44	-1	0.0001	97±0.94	97±1.09	0.00	1	0.01	Significant

Discussion

Table 2 shows the Pre-Post immediate effect comparison of Experimental and Control group. In data analysis, paired t test was applied for intra group comparison and unpaired t test was applied for intergroup comparison. On the basis of intra group comparison it can be said that there are positive changes of Buteyko breathing technique on Systolic blood pressure, heart rate and oxygen saturation in hypertensives. The results for the inter group comparison, showed a significant difference with Buteyko on SPO_2 (p value 0.01) as compared to the control group and thus it is seen that Buteyko technique has an immediate effect on increasing the SPO_2 level in hypertensive subjects.

Following could be the some of the reasons for the above results. According to the study by Yosreah et al(2019) titled "The effect of Buteyko breathing technique among patients with bronchial asthma: Comparative study" the major component of the Buteyko 'package' is to reduce hyperventilation through bouts of controlled reduction in breathing, known as 'slow breathing' and 'reduced breathing', combined with bouts of breath holding, known as 'control pauses' and 'extended pauses.'[10]

The Buteyko method is based on the concept that hyperventilation is the underlying cause of variety of medical conditions (Rosalba Courtney, 2008.) One possible biochemical mechanism of Buteyko may be through its influence on nitric oxide (NO). NO is involved in avarious of physiological responses including bronchodilation and vasodilatation[12]

According to Richa et al, Buteyko performed for 5 min at rest showed a significant increase in heart rate and reduction in systolic blood pressure, which is a normal physiological response. But however,they have notnoted any immediate changes in cardio respiratory parameters in the instances 'sub maximal exercise with Buteyko' and 'sub maximal exercise without Buteyko'.As also seen Review of the 'Australian government rebate on natural therapies' for private health insurance is is stated that there is no evidence about Buteyko Breathing Technique improving pulmonary function in adults. The reason for this can be that deep inspiration that is required to perform a lung function test might lead to bronchoconstriction and override any beneficial effect from the Buteyko breathing technique. This can explain the no significant change in diastolic Blood pressure and heart rate[7]Ritu et al(2013) stated that Buteyko breathing exercise is useful in management of respiratory rate and heart rate in chronic obstructive pulmonary disease patients[13,14]

Apart from this, it is also mentioned in studies that holding the breath can cause accumulation of carbon dioxide[15,16,17] that will lower blood pressure, as also breath holding will also improve the collateral ventilation which can be effective reasons for reduction of blood pressure, heart rate and improvement in SPO_2 in some patients. Thus these can be the reasons of the improvement in SPO_2 and reduction in systolic blood pressure in hypertensive patients in the study[18,19]. Also, since the immediate effect only was seen in the study, that can also justify why the diastolic blood pressure and heart rate was not significantly affected. The limitation of this study can be that it was a single intervention based study. Also it is recommended to use a larger sample size in further studies.

Conclusion

It can be concluded from the present study that Buteyko breathing technique has an immediate positive response on oxygen saturation level in hypertension.

Abstract

Background: Sex determination from analysis of bony remains is one of the most important arduous job for medicolegal experts, especially in cases where identity of the deceased person is in question. Aims & objectives: Our study focuses on evaluation of different osteometric parameters of skull which will be helpful for sex determination.Material and Method: Current study was conducted on 60 human skull bones & they were studied by using calipers for various osteometric measurements. Results: In our study we observed that, skull length, interorbital breadth, biorbital breadth, maxillo-alveolar breadth, maxillo-alveolar length, bizygomatic breadth & nasion-prosthion length are the statistically significant variables & are good determinants for sex than rest of the parameters. As compared to them, cranial breadth & orbital height are poor parameters for sex determination. Conclusion: Human Skull bone as a whole & it's different measurements taken from anatomical landmarks & their osteometric analysis is a good determinant for sex of an individual.

Keywords: *Human skull, cranial osteometry, human identification, bony remains.*

Introduction

There are many challenges, a medicolegal expert faces during his work & sex determination from bony remains is one of such a crucial task to establish an identity of the individual. Such condition arises in many cases like homicidal investigation, archeological interest, mass disaster (both natural & manmade), cases where there is violation of human rights etc. Current global sex ratio is 1.018, which implies that if we are well versed with the aspects of sexual dimorphism then we can reduce our search result to nearly half of the population[1,2]. If whole skeleton is available for analysis then, sex determination is extremely authentic. But in most of the cases, part of the skeletal remains or some bones or even in extreme cases parts of the bony fragments are available for examination. Now in such cases, there arises a need of studies of various skeletal elements of individual bone for determination of sex of that individual. From the past studies it has been well established that sex determination from examination of skull bone & its components has precision rate of almost 85-95%[3]. There is a long list of factors that determine & influence the characteristics of bony prominences which are useful for sex determination, especially during the adolescence. Generally boys have exceptionally vigorous growth surge as compared to girls in their adolescent age group[4]. Roughly there are two techniques for determination of gender from bones & their characteristics. They are: visual evaluation & osteometric method. Visual method is comparatively very easy to asses, does not require any instrument to asses but is highly individual specific & depends on the skill of the forensic expert (which is variable). While the osteometric method is more objective, reliable, depends on indices & is less dependent of investigator's

subjective evaluation. It in turn reduces the bias between two individual experts which means the results obtained from this method are highly reproducible. Our investigation is done to evaluate the dimorphic features of male and female crania of Central Indian origin based on osteometric analysis.

Material and Method

Current study was performed on dry skull bones at Datta Meghe Medical College, Nagpur which is a part of Datta Meghe Institute of Medical Sciences University. Institutional Ethics committee gave approval for the same. Intact skull bones which are showing well defined sexually dimorphic characteristics on visual examination were involved in our research. Skull bones were taken from departments of Anatomy & Forensic Medicine of Datta Meghe Medical College, Nagpur & Jawaharlal Nehru Medical College, Sawangi. Skull bones which are showing inconclusive dimorphic characteristics on direct visual examination/incomplete skull bones or skulls having any bony deformity were excluded from our study. On the basis of our inclusion & exclusion criteria, we finalized a total of 60adult skull bones out of which 35 were of males & 25 were of females.After reviewing the past researches regarding skull osteometry, we took ten measurements into our consideration. All the measurements were taken using Vernier calipers & sliding calipers. Following anatomical landmarks were included: ecto-conchion, dacryon, nasion, eurion, zygion, prosthion, opisthocranion, glabella, basion, alveolon, opisthion, ectomolare.

Table 1: Following measurements were taken into consideration for our study:

Variable	Abbreviation	Distance between
Maximum Cranial Length	MCL	Opisthocranion & glabella
Maximum Cranial Breadth	MCB	both the eurions
Inter-Orbital Breadth	IOB	both the dacryons
BiorbitalBreadth	BOB	outer & lateral margins of orbital rims
Orbital Breadth	OB	lateral & medial border of the orbit
Orbital Height	OH	superior & inferior border of the orbit
NasionProsthionLength	NPL	Nasion & prosthion
BizygomaticBreadth	BZB	two zygions
Maxillo Alveolar Breadth	MAB	two ectomolares
Maxillo Alveolar Length	MAL	Alveolon & prosthion

Our obtained data was analyzed using statistical package for social sciences (SPSS) software. Student's t- test was applied to study the mean differences in various cranial parameters. P- value< 0.05 was considered as significant.

$$\text{Index of sexual dimorphism} = \frac{\text{Meanvalueinmales}}{\text{Meanvalueinfemales}} \times 100$$

Results

Table 2: Descriptive statistics for cranial parameters

Variable	Male (N=35)		Female (N=25)		p – value
	Mean	SD	Mean	SD	
BZB	10.08	0.49	9.44	0.51	<0.0001
BOB	9.86	0.57	8.88	0.5	<0.0001
OB	3.87	0.25	3.55	0.33	0.0001
IOB	2.31	0.24	2.52	0.31	0.0477
OH	3.21	0.28	3.2	0.31	0.2174
NPL	4.81	0.42	4.19	0.57	<0.0001
MCL	13.46	0.6	12.41	0.65	<0.0001
MCB	10.39	0.63	10.21	0.28	0.3257
MAL	6.46	0.36	6.06	0.45	<0.0001
MAB	5.28	0.39	4.96	0.31	0.0012

In present study mean Bizygomatic Breadth was found to be significantly higher in males. Both Biorbital breadth and Orbital breadth were higher in males but no significant difference was observed between males and females in Orbital breadth whereas Biorbital breadth in males was significantly higher compared to females. Similarly inter-orbital breadth in males was observed to be significantly higher in this study. Orbital height was found have insignificant difference and was much similar in males and females. Nasion-Prosthion length and Maximum Cranial length were noted to be significantly higher in males while maximum cranial breadth was insignificant although it was higher in males compared to females. Both MaxillOo-Alveolar Length and Maxillo-Alveolar Breadth were found to be larger in males significantly.

Calculation of sexual dimorphism indices revealed that Nasion-Prosthion Length was strongest determinant of sex followed by Biorbital breadth, Orbital breadth, Maximum Cranial length. Inter-orbital breadth, Bizygomatic breadth, Maximum alveolar length and maximum alveolar breadth also showed good degree of sexual dimorphism. Maximum crania breadth and orbital height are observed to be poor determinants of sex in our study.

Table 3: Sexual dimorphism indices.

Variable	Index of sexual dimorphism
BZB	106.78%
BOB	111.04%
OB	109.01%
IOB	91.67%
OH	100.31%
NPL	114.80%
MCL	108.46%
MCB	101.76%
MAL	106.60%
MAB	106.45%

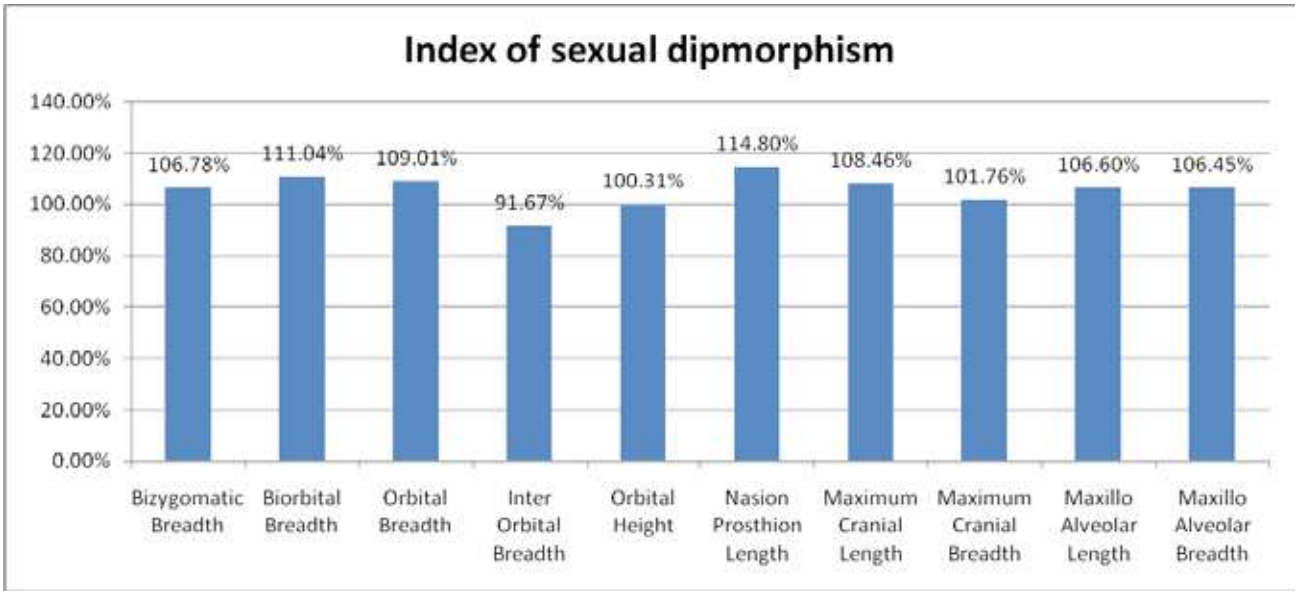

Figure 1: Graphical depiction of Sexual dimorphism indices

Discussion

In this study BB, BOB, IOB, OB, NPL, MCL, MAB and MAL were significantly higher in males compared to females. OB and MCB were found to be insignificant although they were comparative higher in males. The findings in our study are in agreement with study done by Gupta A et al.[5] The sexual dimorphism indices indicate that NPL is the strongest index followed by BOB, OB, IOB, and MCL. Also MAL, MAB, BZB are good at determination of sex while OH and MCB are poor determinants of sex from crania. These findings are similar reported to indices calculated by Gupta

A et al. When BZB, MCL, NPL were compared with study conducted bySteyn M et al[6] findings reported were similar and the parameters differed significantly among males and females. Steyn M et al. also reported that accuracy of prediction of sex from human skull was found to be 85.7%, which was highest among rest of the bony parameters which were analyzed in the same study. Thuangthong T et al[7] conducted a study on sex determination using computer aided software and compared those results with the findings obtained by conventional caliper method. In that study it was reported that OH and BZB differed significantly among both sexes. Also use of computer aided technique determined sex with greater accuracy as compared with use of conventional caliper method. A study done by Saini V et al[8]assessed various parameters for determination of sex among which BZB and BOB differed significantly similar to our study but in contradiction IOB was insignificant between both sexes. OH was insignificant in agreement to present study. Indices such as BZB(105.5), OB(103.295), BOB(103.251) in that study were not in agreement with indices found in our study BZB(106.78), OB(109.01) and BOB(113.04). Ramamoorthy B et al[9] conducted a similar study by using CT head scans of adult live subjects using various craniometric parameters (few of them are included in our study). They found out that accuracy for sex determination approximately ranged from 91.4% to 97.1% in multivariate analysis. Accuracy was highest when all variables were taken into consideration. The parameters which were similar in our study are in agreement with results obtained by Ramamoorthy B et al. Dayal M.R. et al[10] in their study reported that MCL, BZB, OB are significant while OH is not significant which matches to the results of present study. In the same study Dayal M. R. et al. reported that the accuracy of determination for sex is greater with mandible(85%) compared to that with cranium(80.8%). The findings in present study are in agreement with those in a study done by IscanM et al[11]in modern Japanese crania.

Conclusion: India is a diversified country with respect to climatic conditions, food habits, occupations, etc. With such a wide geographical variations, skeletal assortment to represent whole country is difficult. This study indicates the index for sexual dimorphism for various cranial parameters. In this study Nasion-Prosthion Length is observed to be strongest index for sexual dimorphism followed by Biorbital breadth, Orbital breadth, Interorbital Breadth and Maximum cranial length. These indices are useful for the population with similar groups. It is necessary to conduct more & more studies in geographically diversified population especially in different regions of our country on a larger scale so as to represent whole population as the results may not fully reveal true nature of sexual variation in parameters in a small sample size.

Abstract

There are hundreds of formulations in the market, which are mostly prescribed by the physicians depending upon their knowledge about the general context of reference. Analysis of the ingredients and the phalshruti of each formulation give a clear picture about them and also help to make a better application in clinical practice. Nowadays, most of the diseases are caused due to unconventional etiology. When a disease is caused by unconventional etiology, it can be managed effectively by using principles of Agadtantra. Currently most of the diseases require Nirvishikarana (Detoxification), for this reason Antitoxic formulations mentioned under Ayurveda which contains singleantitoxicherb, combinationofanti-toxicherbs, herbs-minerals combinations etc can be very effective insuch unknown etiology diseasedconditions. Antitoxic preparations with Vishaharatwa(Antitoxic) property, as one of the action have a better effect in general diseases than other formulation. This review article places of interest in the significant role of antitoxic formulations mentioned in Agadtantra (Ayurvedic perspective of toxicology) to overcome diseases which are produced due to unknown etiology.

Keywords: *Antitoxic preparations, Agadtantra, Non poisonous conditions, Vishaharatwa, Nirvishikarana.*

Introduction

Ayurveda an ancientIndianSystemofMedicine has principal scopethataretomaintain the good health and to cure the diseases or pathological conditions. In Ayurveda, Health is defined as the state of equilibrium of Doshas (Bio energetic humors), equilibrium in Agni (The governing processofdigestivesystem), equilibriuminDhatus(bod ytissues) and normal expulsion of Malas (wastes like feces, urine, sweat etc.)withstateofpeaceinAtma(soul), Indriya(senses)andMana (mind)[1] According to Modern Science, basically it is the phytochemical constituent in the herbs which leads to desired healing effect, such as saponins, tannins, alkaloids, alkenyl phenols, flavonoids, terpenoids, phorbol esters and sesquiterpenes lactones. In the management of general diseases or poisoning, Ayurveda focus on Equilibrium of Dhatu by maintaining equilibrium in Dosha and Agni with the help of various single herb or combination of herbs (Poly herbal formulation) or combination of herbs-minerals. The principle behind any formulation of Ayurveda in any disease or poisoning condition is to correct Agniandvitiation of Doshasviz. vata, pitta and kapha which may be seen in that specific disease or poisoning condition. In the management of visha, the primary focus is to remove visha before it has chance to harm Dhatu and ojus. In case of sthavara, we have an opportunity to eliminate by vamana or virechana. As jangamavisha is directly entered into rakta, it spreads quickly and damage the Dhatu much faster .Here we want to hurry to make sure quick paka of visha before this happens

and for that ushna, teekshnadravyas are essential to be introduced though they are similar to visha in properties. In the detoxification of visha and containment of vata, ushnapradhan agada has a significant role. At this stage, we should remember the other side of the truth. As the properties of pitta and visha have common characteristics significantly, the pakaof ofvisha in pittapradhanvisha is enabled only with shita and tiktapradhandravya. Like sariva and chandana. Thus it is natural finding that some pittaharaaushadhis are also having vishahara property.

Many diseases are characterized by a component of something that refuses to undergo paka or digestion. This apaki component gives such diseases resemblance of vishajanyavyadhi . Normally a disease is managed with drugs that have qualities opposite to those that caused the disease. In diseased condition with higher visha component, we make use of another visha instead of employing the viparitguna. This exception becomes inevitable because the vyavayi and vikasigunas of the vyadhikarakvishdravya can be matched only by another vishadravya. The notable point here is that the vishadravyaemployed as a drug, even if ushna, doesn't aggrevate the potency of vishadravya that caused the disease. Even in the formulation of vishaharayogas. Teekshna and ushnagunas are dominant. With this understanding of the dynamics of visha and vishachikitsa, we can try to analyse the application of this management of diseases not caused by the visha.

The word Agada is derivative from Gada. Gada has two meanings one is Roga (Disease) and the other is Visha (poison). Agadaisadrug that conquers disease or poison. In Ayurvedic Samhitas various single herb, poly herbal formulation or herb-mineral formulation are mentionedasAntitoxic. Accordingly, single herbs or poly herbal formulation or herb-mineral formulations are used in that disease or poisoning condition. Physician can also change combinations, forms, vehicle of these formulations as per vitiation of Doshas in the patient ordisease. Charakacharya mentioned Vishghnamahakashaya which includes ten Vishghnadrugs[2] Drugs which act against these qualities of toxic substances are called as Vishghna (Antitoxic). Drugs mentioned under, work due to their Raspanchak antagonist to Visha (poison) and helps in the management of diseases.

Vishghna Mahakashaya contains:

1. Haridra (Curcuma longa)
2. Manjishtha (Rubiacordifolia
3. Suvahaa (Pluchealanceolata)
4. Sookshamaelaa (Elettariacardamomum)
5. Paalindee (Operculinaturpethum)
6. Chandan (Santalum album)
7. Kataka (Strychnospotatorum)
8. Shireesh (Albizzia lebbeck)
9. Sinduvaara (Vitex negundo)
10. Shleshmaataka (Cordia dichotoma).

Drugs which act against toxic substances are called as Vishaghna (Antitoxic). Some Vishaghna drugs act by Dravyaprabhava (virtue of their own nature), some drugs act by Gunaprabhava (by virtue of their properties) and some drugs act by Dravya Gunaprabhava (virtue of their nature as well as properties. These Vishaghna Dravya (Antitoxic herbs) and Vishaghna Yogas/Agadas (Antitoxic formulations) are used in various poisoning and diseased condition. Most of these antitoxic formulations acts as Raktashodhaka (Blood purifier), Tridoshaghna (causes equilibrium in body humors), Hridya (Cardio protective) and Ojavardhaka (Rejuvenate). Sushrutacharya has mentioned 95 antitoxic drugs in different Gana (Group) like Aaragwadhadi Gana (20), RodhradiGana (13), Arkadi Gana (14), Shyamadi Gana (19), Patoladigana (07), AnjanadiGana (8), Utpaladigana (7), Trapvadi Gana (7) in the chapter 38 Dravyasamgrahaniya of Sootrasthana[3]. Twenty antitoxic drugs are also mentioned in EkasaraGana in SushrutaSamhita[4]. AshtangHridaya describes 104 antitoxic drugs which are listed in Gana like AnjanadiGana (9), Patoladi Gana (6), Aaragwadhadi Gana (20), Rodhradi Gana (13), ArkadiGana (14), EladiGana (24) and ShamadiGana (18)[5]. These antitoxic drugs can be used singular or in combination with other drugs mentioned in that specific Gana. VishaghnaYogas (Antitoxic formulations) like Kshara agada[6], Dooshivishari Agada[7], BilwadiGulika[8], Maha agada[9], Ajita Agada[10], Sanjeevana Agada[11] etc. are described in Ayurvedainparticular poisoning as well as in diseased conditions with unknown etiology.

Some Antitoxic Formulations and their Mechanism of action:

1. **Bilwadi Gutika:** Most ingredients of Bilwadigutikahave ushna and teekshnaguna and pachana karma . The phalshruti includes almost all

jangamavisha, jwara, garavisha, ajeerna, visuchika .One safe interpretation is that this yoga corrects apakwa in rasa Dhatu and regulates vata. Clinically it has an extended efficacy in conditions like atisara, chardi and jwarawhrere ama is predominant.In psychiatric illness as well as somatic illness that affect the mind, with an appropriate anupana, this gutika stabilizes the mind.

2. **Kalyanaka Ghrita:** In the kalyanakaghrita described in Ashtanghridaya, Visha is an indication. Its specific utility is to produce hridayavarana in jangamavisha . Now most physicians use this yoga in manovyadhichikitsa. In comparision to Bilwadigutika, ushna and teekshnadravyas are less in Kalyanakaghrita and Tiktakaghrita. These two yogas execute their pachana karma more due to the vayu and aakash in the tikta rasa dravya and less due to the tejbhuta in the katu rasa dravyas.

3. **Aargwadhadikashay:** Aargwadadikashaya is generally employed kaphapittajanyavikaras. We all know its efficacy to reduce the dushtamedas . Its antitoxic property is one reason why it is particularly effective in dushtavrana and kaphajaprameha.

4. **Dhanwantaraghrita:** Even though this drug is mentioned in pramehaadhikara, the indications also include visha, gara, kushtha The majority of ingredients have ushna and teekshna property which makes it useful in pachana karma in the above mentioned diseases.

5. **Sanjeevani Vati:** The indication of this drug is mentioned according to its dose. It is indicated in minimum dose for ajeerna whereas an increased dosage for sanyasa and visha. This means the action of this drug is according to the pachana karma.

6. **Patolkaturohinyadikashayam:** This is mainly indicated inkaphapittapradhan diseases. It can be used in lutha Visha, Pittapradhan Visha and visarpa. It is used in this condition because of its rechana property.

Discussion

The current circumstances of world facing many health issues and occurrence of communicable diseases (Sankramaka Roga) are predominantly causing health problems. Acharya Charak mainly described the concept of Janpadodhwans as Sankramakroga, Aupasargikrogas which multiply from person to person, which resembles population demolition in an area. In current scenario, such types of diseases creating great health trouble since large number of global population affected with pathogens. The toxins; endotoxins or exotoxins releasedby microbial agents initiate pathogenesis of diseases.[12, 13, 14] The modern science has also mentioned some diseases which spread from person to person and occurs due to the microbial infections. These are huge challenges & creating a trouble over health care system, it is advised to include the use of Ayurvedatreatment.

Physical fitness of the people is deteriorating day by day duet ode forestation, globalwarming, indiscriminate use of pesticides-fertilizers in the farming, food adulteration, incompatible food, food additives-preservatives- sweeteners, increasing pollution levels, industrial emission, hormonal administrations in poultry-dairy, indiscriminate use of various synthetic drugs etc. In present circumstances, most of the diseases are caused due to unconventional etiology. For this unconventional etiology due to toxicants/chemicals Agadtantra focuses on ViruddhaAhar (Incompatible diet), GaraVisha (Artificial poison) and Dushivisha (polluting poison). All these toxicants/chemicals in the form of Viruddhaahara or Garavisha or Dushivisha enters into the human body by different routes and responsible for various. According to Ayurveda, diseases are produced due to imbalance of Dosha (Body Humors) and Dushya/Dhatu (Body tissues)[15]. Poison first vitiates the blood, then vitiates the humors Kapha, Pittaand Vatainsequencealong with their substrata, proceed to heart and then become fatal[16]. Vitiation of Doshas is very important factor in the production of both diseased and poisoning condition. Only difference is in the case of poisoning it vitiates blood first then body humors. Diseases caused by Viruddha Ahar, Garavisha and Dushivisha have same principle of management that is Shodhana Chikitsa (Eliminationoftoxins)by induction of emesis or purgation before using antitoxic formulations. As antitoxic formulation act as bloodpurifier, causes balance in body humors viz. vata-pitta- kapha, helps in rejuvenation, it reverses the action of poison and helps to become free from poison. These antitoxic formulations are useful in diseases caused by incompatible diet, artificial poison and pollutant poison. Therefore antitoxic preparations help to get better health status and longevity of the humanbeing. Ayurveda explains good health by using wholesome diet, lifestyle and natural remedies prepared from medicinal plants and minerals. Modern science generates the theory of balance between free radicals and antioxidants to maintain the goodhealth.

The diet which provokes bio energetic humors without eliminating them is considered as Viruddha Ahara[17]. Drugs and food materials incompatible with the normal body tissue elements are Viruddha[18]. Viruddhaahara generally do not have any effect on those who are habituated to it or consume it in a small quantity, their Agni (Digestive power) is strong and who are young and practicing exercise regularly[19]. Incompatible food like Garavisha (Artificial or synthetic poison) may beone of the reasons of several diseases anddeath[20]. For prophylaxis of these diseases, Ayurveda emphasizes on prohibition of incompatible food. Diseases caused by incompatible food may be treated with emesis, purgation, by using the drugs which act opposite to that particular disease and wholesome diet[21].

In current era, knowingly or unknowingly we the people are exposed to various types of poisons which may be of natural or artificial origin. Gara is the combination of substances, non poisonous or poisonous which exerts toxic effect after interval of sometime and as such does not kill the patient instantly. Low potency this poisons of artificial origin called as Garavisha after sometime it act as Dushivisha. Dushivisha becomes symptomatic when storage of chemicals/toxins get the rate of exposure is greater than rate of metabolism or excretion. Ayurveda explains this concept of accumulation of toxin in the body under the concept of Dushivisha. As Dushivisha is less dangerous it does not cause any immediate clinical features and lies inactive in the body for some years. . In current era diseases with unknown etiology are increased due to incompatible food, unhealthy lifestyle, exposure to toxic substances, pollutants, chemicals and drugs. In this condition, Dietetic foods and traditional herbal medicines work effectively. In the case of any formulation, it goes without saying that the clinical conditions indicated in the phalshruti will have atleast one common component of samprapti that threads through them. Apakwavastha is the key factor in all vishajanyavikaras. Similarly, the clinical success of the antitoxic preparations in jwara, pandu, ajeerna and visuchika points towards the common factor namely apakwavastha in rasa Dhatu.

Conclusion

Though Vishahraaushadhis (Antitoxic preparations) have many advantage to cure diseases, should not, need not and cannot be used in the management of common diseases. Only when the nidana, samprapti and lakshana is indicative of visha or vishasamancomponents, should we suggest the superior clinical contribution a vishaharaaushadhi is likely to make. In any common disease, we may identify a component or stage of the samprapti to be vishasaman. That would be the right time to employ Vishaharaaushadhis.

Nowadays, Agadtantra is the branch of Ayurveda is unnoticed due to less use in clinical practice by expert Ayurvedaphysicians . Most of the diseases caused in present scenario are due to unconventional etiology such as indiscriminate use of pesticides-fertilizers in the farming, food adulteration, food additives-preservatives-sweeteners, indiscriminate use of various synthetic drugs etc. For this unconventional etiology, In Ayurveda Agadtantra insist on Virudha Ahar (Incompatible diet/ food), GaraVisha (Artificial poison) and Dushivisha (Polluting poison). Oxidative stress can be correlated with the concept of Virudhaahar, Garavisha and Dushivisha. This unknown etiology causes diseases like cancer, cardiovascular disorders, neurological disorders, liver disorders, renal disorders, psychological disorders, skin diseases etc. For the management of such diseases of unknown etiology, routine drugs/treatment may not behelpful. Now it's time to explore and use the principles of Agadtantra with Antitoxic formulations not only to poisoning conditions but also in various diseases and pathological conditions to improve health status and longevity of human being. According tot he ideology of management in Agadtantra, in current era most of the disorders require, Detoxification, Elimination of Toxins, Blood purification, Equilibrium in body humors, Rejuvenation therapy. Anti- toxic formulations help in detoxifications. Thus, these anti toxic formulations mentioned in Agadtantra will be useful for society in the disorders of present scenario. Additional Preclinical and Clinical study have scope in this regard.

Perception of Medical Professionals and Pharmacists towards Generic and Branded Drugs

Shrikrishna Dhale[1], Ankit Singh[1]

[1]Assistant Professor, Symbiosis Institute of Health Sciences, A Constituent of Symbiosis International (Deemed University)

Abstract

Background: Doctors and pharmacist are in a state of dilemma at the time of prescribing and dispensing medicines. The Government of India is pushing the adoption of generic medicines to lower down the cost of treatment and the perception of the medical practitioners and the pharmacists can play a crucial role in the implementation of this initiative.

Aim and Objective: To understand the factors affecting the prescription of drugs among medical professionals. To understand the factors affecting the dispensing of drugs, To study determinants of prescription of generic drugs.

Methodology: A study is been conducted on doctors and pharmacist were the sample size was taken as 100, it is a purposive study where the data is been collected through questionnaires. Out of 100 participants, 50 were Doctors and 50 were pharmacist. The analysis of the data is performed in SPSS V20.

Result: Out of 100, About 59% of participants perceived that generic drugs are as effective as original drugs. However, interestingly, when they were asked if they ever experienced the difference in quality between the two, 23% participants believed that the generic drugs were not as efficacious Only 64% of the participants agreed that generic drugs are as safe as original drugs. About 46% of participants agreed that most of the generic drugs lack the quality of their branded counterparts. About 70% felt that more confidence should be built among patients about generic medicines. A majority of physicians and pharmacist 61% considered the socioeconomic status of the patient while prescribing medicines. About 24% of the doctors and pharmacist think that generic drug hasa high side effect compare to branded drug, whereas 64% says that the generic drug does not have much side effect. About 47% of the doctors and pharmacist think that they have high efficacy were as 47% thinks that the efficacy level of the drug is low compare to the branded drug."

Conclusion: This study found a gap between knowledge score and generic prescription practices. This can be improved by the combined approach of Information, Education and Communication (IEC).

Keywords: *Generic Medicine, Branded Medicine, Pharmacist, Doctor.*

Introduction

Prescription cost of medicines has increased drastically in the last decade and pharmacy outlets are looking for means for cost minimization by adopting generic fill rate[(1)]. Even in India also generic medicines have been considered as a tool to improve access to medicines for poor population[(2)]. A generic drug is a drug that is made and distributed without a patent. Formulation of the generic drug may be patented but its active ingredient is not patented. Generic medicines are not inferior in quality to any branded medicines and are as effective[(3)] as branded medicines. Even their

Corresponding Author:
Dr. Shrikrishna Dhale
Assistant Professor, Symbiosis Institute of Health Sciences,
A Constituent of Symbiosis International (Deemed University)

dosage, side-effects, active ingredients etc. are similar to all branded medicines[4]. Generic medicines have to go through all strict procedures of quality standards before they are licensed to market.

For the treatment of a particular disease, it is recommended to give a chemical element/compound as a special medicine after all the research. Different companies sell different names to this element. The name of generic medicines is determined by an expert committee based on the name of the active ingredient present in that medicine. The generic name of the medicine is the same all over the world.

Benefits of generic medicines:

- Generic medicines are cheaper than branded medicines. With this, you can save a significant price every month.
- Generic medicines reach the buyer directly.
- Nothing is spent on the publicity of these drugs. So they are cheap.
- The government decides the price of these medicines themselves.

Generic medicines have the same effect, dosage and effects as branded drugs.

Difference between branded generic and generic drugs: The difference between the two is just the name. One is sold with a brand name and the other is sold with a generic name. But the reality is that both these are generic medicines, which are being made after the patent expires. Generic medicines are sold without any trademark or generic name instead of a brand name. The International Nonproprietary Name (INN) is a unique name given to identify pharmaceutical substances or active pharmaceutical ingredients.

National Drug Pricing Authority: The establishment of the National Drug Pricing Authority (NPPA) was conceived in 1994, based on the discussion in Parliament, in the order of the liberal procedure as prescribed in the amendments to the Drug Policy 1986. Approving the resources in the Drug Policy, 1986, the Cabinet-Committee on Economic Affairs approved the establishment of an independent body of subjects called the National Drug Pricing Authority in September 1994 and the NPPA in its light. Approved the establishment of the authority and the Government Resolution on the handing over of specialized works was notified on 29 August 1997. Thus the N.P.P.A. The date became fully functional from August 29, 1997.

Methodology

The study was undertaken to understand the perception of medical professionals and pharmacists about generic drug and branded drug. The study also aims at identifying determinants of prescription.

Study setting: The study was carried out at Nagpur city in Maharashtra State during the period November 2019 – February 2020.

Sampling: Purposive Sampling was performed to access a particular subset of people.

Inclusion criteria: Should have a minimum of 1 year of experience as a clinical practitioner or should be working in a pharmaceutical shop for more than 1 year.

Exclusion criteria: Students who are pursuing there a career for becoming Doctor or pharmacist, should not have any experience and not be an intern.

Sampling: A total of 100 samples were taken out of which 50 were Doctors and 50 were Pharmacist.

Doctors who are working in their clinic or are working in a government or private hospitals data is collected from them.

A pharmacist who is having their shops or are working in another shop and are registered under the pharmacy council of India, the questionnaire is circulated among them

The need for study:

1. To understand the factors affecting the prescription of drugs among medical professionals.
2. To understand the factors affecting the dispensing of drugs
3. To study determinants of prescription of generic drugs

Statistical Tools: The tools that were used in SPSS V20, MS Excel.

Study tool: The study tools that are been used are Questionnaires, literature review, observation and in-depth interview of the pharmacist as well as the doctors.

Primary data: Data has been collected through questionnaires. A Google form is prepared and is been circulated between doctors and pharmacist who are having experience minimum of 1 year.

Secondary: The secondary data was collected through journals and magazines which are verified.

Analysis: The analysis of the data is done by representations of charts and graphs.

Analysis and Interpretation:

Discussion

This study was undertaken in 100 participants to evaluate the perception of prescribers and dispensers toward generic and original drugs. The study participants were the Doctors and pharmacist. At 100in number, Doctors and pharmacist were the highest participants with a clinical experience of 1–5 years. The reason for this could be that they were readily willing to participate in the study and present in the hospital premises at most times. About 59% of participants perceived that generic drugs are as effective as original drugs. However, interestingly, when they were asked if they ever experienced the difference in quality between the two, 23% of participants believed that the generic drugs were not as efficacious. We can, thus, conclude that there is a clear gap identified between the knowledge and perception of generic versus original drugs.

When asked about how many patients specifically ask for a generic drug it is been observed that only 4% of patient specifically ask for the generic drug whereas only 11% patient specifically asks for the branded drug. Whereas 40% never ask for a generic drug. Only 11% of the doctor and pharmacist explain the generic drug to the patient were like 35% of the doctors and pharmacist never giver explanation about the generic drug to the patient."

Only 64% of the participants agreed that generic drugs are as safe as original drugs. About 46% of participants agreed that most of the generic drugs lack the quality of their branded counterparts. About 70% felt that more confidence should be built among patients about generic medicines. A majority of physicians and pharmacist 61% considered the socioeconomic status of the patient while prescribing medicines. If the patient could afford, then the majority of participants preferred to prescribe original brand drug against those who referred to prescribe the generic drug. About 24% of the doctors and pharmacist think that the generic drug has a high side effect compare to branded drug, whereas 64% says that a generic drug does not have much side effect. About 47% of the doctors and pharmacist think that they have high efficacy were as 47% thinks that the efficacy level of the drug is low compare to the branded drug."

A majority of participants perceived that there was a significant difference between the price of generic and original brand drugs. Nearly similar findings were reported by studies done in different countries such as Australia, Iraq, and Malaysia. In one article, authors classify industry to innovating pharmaceutical companies and generics producers. It was interesting to note that a majority of healthcare providers were willing to substitute generic drugs but not for all the cases they treated, thus reinforcing the clear difference in the perception of the efficacy of two classes of the drugs. Physicians were doubtful about the efficacy of the generic drugs, which in turn shows the lack of confidence for the use of such drugs and lack of knowledge regarding generic drugs. This finding also corresponds to the earlier work where physicians were found to prescribe most of the medicines with their brand names[5]. "The overall results also corresponds to a study done in Bangladesh

where it was found that the medical practitioners [6] and pharmacy students were knowledge deficit about the various aspects of generic medicines [7]. Moreover the instances of patients switching back to branded drugs after opting for generic medicines are also noticed in the earlier studies [8].

We suggest that this could be overcome by training medical professionals at the undergraduate level by making curricular innovations. Basic information on health policy, pharmaceutical policy, essential drug list, innovators and generic medicines, and their availability and affordability should be provided. Health-care providers also doubted the efficacy of the quality of generic drugs although they thought it was cheaper. This could probably be owing to poor quality control of some generics. More number of medical representative visits resulting in more promotion of drugs by noncommercial sources could be the reason. We have also tried to understand the difference in the perspectives of various specialties toward prescription of generic and original drugs. As medical representatives visited doctors more frequently, they were the most common sources of drug information."

Conclusion

"Although a good percentage of doctors and pharmacist had good knowledge and attitude about generic medicines and the majority of them said that they prescribe/Dispense generic drugs but there was a meaningful proportion who expressed concerns about them. These beliefs could represent a significant hurdle to larger generic use and could lead to increased health-care expenses. Above all, it was observed in this study that the efficacy, safety, and quality profile of the medicine was the most important factor considered by physicians and pharmacist when they prescribe/ Dispense drugs. A sustainable generic pharmaceutical market requires active regulatory measures to build confidence among the physicians to prescribe them without any doubt. We would recommend conducting similar studies among health-care providers from private practice to understand their prescribing practices and find ways to improve them to reduce drug expenditures in a no medical reimbursement situation."

Drivers of Home Health Nursing Profession

Ankit Singh[1], Vivek Chaudhari[1]

[1]Assistant Professor, Symbiosis Institute of Health Sciences, A Constituent of Symbiosis International Deemed University

Abstract

Introduction: It is important to determine the perceived factors of home health nursing professionals which are the drivers of home health nursing as a profession in developing countries.

Objectives: To identify the variables driving the growth of the home care nursing profession.

Methodology: Responses of 150 home health nursing professionals is processed with factor analysis.

Result: Analysis reveals that the three factors together explained 45.6 percent variation in the data.

Conclusion: The identified factors are "Comparative benefits over hospital care", "Exclusive benefits of home healthcare", and "Holistic view linking hospital care and home healthcare."

Keywords: *Home Healthcare, Holistic linkage between home healthcare and Hospital care, Home Health Nursing.*

Introduction

People tend to use healthcare services when it becomes urgent, as the behaviour of seeking healthcare is at the end of help-seeking behaviour[(1)]. These results in an increased number of chronic diseases and home healthcare are considered as one of the preferred modes of healthcare delivery for patients suffering from chronic diseases. Home Health Care is clinical medical care provided by Doctors, registered nurses, occupational therapists, physical therapists, and other healthcare and allied healthcare professionals at the patient's home. It is often prescribed as a part of a care plan following a hospitalization. The goal of home health care is to help an individual improve functions and lives with greater independence, promote the clients an optimal level of well-being, and assist the patient to remain at home, avoiding admission to a long term care institution. Home Healthcare is a relatively newer addition in the assortment of healthcare services in India[(2)]. As a matter of fact, in the United States alone home healthcare sector had employed around 1, 10, 000 registered nurses in the year 2008 and this sector was expected to grow by 66 per cent for the next ten years[(3).] However, home healthcare is characterised with many benefits of its own in comparison to institutional care such as lower cost, lower risk of healthcare-associated infection, and increased patient autonomy in terms of allowing the patients to stay with their family in times of sickness[(2)]. Considering the benefits of home healthcare, its acceptance in India is also on the rise. However, to meet the healthcare requirements of the home healthcare consumers, there should be an adequate supply of healthcare professionals and especially nurses who were willing to visit the patient's home to render medical care. Furthermore, there is a huge contrast between hospitals and patient's home in terms of work settings and this widens the range of risks and hazards which are peculiar to home settings of the patients. An earlier study has identified that hazards associated with slippery floors, and exposure to blood were rated by the Indian home health nurses as the high priority hazards, which required the management attention for risk reduction[(4).] Despite these challenges, the number of home health

Assistant Professor, Symbiosis Institute of Health Sciences, A Constituent of Symbiosis International Deemed University.

care providers are increasing, whereas the number of nurses and midwives ratio was 1.7 per 1000 populations, which is far less than the world average of 3.28 nurses per 1000 populations[5]. Moreover, in the year 2020, the world health organization has suggested that India alone requires 2.4 million nurses. However, with a new job avenue in terms of home healthcare nursing in India, it becomes pertinent to ponder upon what could be the driving factors for increasing adoption of the home health nursing role.

Objectives: The home healthcare sector has started to attract nursing professionals in India. However, the nursing professionals opting for home health nursing profession is still lesser in comparison to nurses opting for the hospitals. This put forwards a major challenge in front of the home health agencies in recruiting and retaining qualified, trained, and committed home health nurses in the organization. However, the numbers are slowly but steadily increasing and hence this raises the research question of what are the factors which drive the home health nursing profession as an option for the nursing graduates. Hence, this exploratory study is conceptualized to capture the perception of working home healthcare nurses towards the home health profession and to summarize these perceptions into the factors. The identified factors will be useful to the home health care providers and the recruitment agencies to attract and hire competent home health nurses.

Methodology

This cross-sectional study is carried out in the city of Bangalore of Southern India. The home care nurses working in three agencies were contacted. The nursing staff were selected based on systematic random sampling after getting the manpower list from the agency. The selection criteria were home healthcare nurses who have completed one month tenure in the home healthcare profession, as anyone lesser than that duration might not be getting an opportunity to experience the various facets of home health nursing profession. Furthermore, based on the analysis of related literature from the healthcare sector and the opinions of fifteen home health nurses, who were asked a two-part question, which was, what are the good things and the bad things you like in the home health profession and why home health is growing in India? A self-administered questionnaire was prepared, and the content validity of the questionnaire was checked by getting it reviewed from five subject experts with rich experience in the domain of home health nursing. The questionnaire consisted of ten demographic questions together with 15 items to identify the drivers associated with the growth of the home health nursing profession in India from the working home health nursing professional's perspective. Furthermore, and it was pilot tested on around 15 individuals, to assess the suitability of the questionnaire. However, the three items were removed due to low communality value, thus making the final questionnaire consisted of final 12 items. The internal consistency of the questionnaire was checked with the help of Cronbach alpha which came as 0.78, which is higher than the cut-off value of 0.73[6], See Table 1.

Table 1: Questionnaire

Sr.No.	Items	Cronbach Alpha
1	Facilitates access to preventive health services	0.73
2	Home care is a demanding job and only dedicated personnel must join this	
3	Allows terminal ill patient to pass away in the home environment	
4	Provides psychological support to the family	
5	It provides exclusive care that one will get anywhere else	
6	It is cost-effective than hospital care	
7	Offers a holistic assessment of the patient in the environment	
8	Risk of infection is less than hospital	
9	It should be preferred for a terminal ill patient	
10	Decreases rehospitalisation	
11	Home health care has new job avenues for nursing professionals	
12	It is important thus hospital and home care service providers must work closely	

The data were captured by a survey method where a total of 197 home health nursing professionals, working in the selected three home healthcare agencies of Bangalore City were contacted out of which only 165 nurses have responded and filled the questionnaire, thus making the response rate 79%. However, fifteen responses were discarded for incomplete information, thus at the end, 150 numbers of questionnaires were finally used for analysis and interpretation. The demographic details of the respondent are mentioned in Table 1, see below.

Table 2: Demographic details of the respondents

Gender (Percentage)	**Male**	**Female**		
	48.7	51.3		
Age (Percentage)	**20-30**	**31-40**	**41-50**	**51-60**
	28.8	41	29.5	.6
Years of experience in home healthcare (years)	**0-1**	**1-3**	**3-5**	**More than 5**
	24.4	37.2	34.6	3.8
Education (Percentage)	**Diploma**	**Bachelors**	**Masters**	**PhD and Above**
	29.5	67.9	2.6	Nil
Tenure of work with the current employer (Percentage)	**Less than 1**	**2-5**	**6-9**	**9 and above**
	45.5	51.9	2.6	Nil

The demographic data reveal that the females were slightly more than males with 51.3 % in the home health nursing profession. Additionally, the largest age group segment belonged to the age group 31-40 years with 41 % and very few were having experience in the home health nursing profession for more than 5 years i.e. 3.8 %. The largest section of the respondents was having a bachelor's degree in the educational qualification with 67.9 % and almost half of the respondents had an association with the current employer in 2-5 years of work experience.

Data reduction technique factor analysis[7] is used with extraction method principal axis factoring and rotation method Varimax with Kaiser Normalization. Kaiser Mayer Olkin (KMO) test is done for sampling adequacy and it was found to be .729, higher than the cutoff level 0.6[8], similarly, Bartlett's test of sphericity also found to be statistically significant $p<0.01$, implying that the correlation matrix is an identity matrix.

The factors were derived based on the criteria of having eigenvalues greater than 1, the identified three factors explained 45.6 percent of the variance. See Table.

Table 3: Total Variance Explained

Factor	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	3.883	32.356	32.356	3.329	27.744	27.744	2.698	22.486	22.486
2	1.641	13.675	46.031	1.155	9.626	37.371	1.697	14.138	36.624
3	1.516	12.636	58.668	.995	8.290	45.661	1.084	9.037	45.661
4	1.017	8.474	67.142						
5	.878	7.320	74.462						
6	.691	5.755	80.217						
7	.540	4.497	84.714						
8	.534	4.449	89.163						

Factor	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
9	.401	3.339	92.502						
10	.328	2.731	95.234						
11	.309	2.577	97.811						
12	.263	2.189	100.000						
Extraction Method: PAF.									

All the items loaded well on the factors with factor loadings higher than 0.5. Hence, it becomes evident that three factors are important contributors for the growth of home health nursing profession in India as perceived by working home health nurses, which are exclusive benefits of home healthcare, comparative benefits over the hospital, Holistic views linking hospitals and home health providers.

Table 4: Rotated Factor Matrix

	Factor		
	1	2	3
Facilitates access to preventive health services	.710		
Home care is a demanding job and only dedicated personnel must join this	.705		
Allows terminal ill patient to pass away in the home environment	.694		
Provides psychological support to the family	.527		
It provides exclusive care that one will get anywhere else	.525		
It is cost-effective than hospital care	.509		
Offers a holistic assessment of the patient in the environment	.458		
Risk of infection is less than hospital		.753	
It should be preferred for a terminal ill patient		.675	
Decreases rehospitalisation		.488	
Home health care has new job avenues for nursing professionals			.708
It is important thus hospital and home care service providers must work closely			.642
Extraction Method: Principal Axis Factoring. Rotation Method: Varimax with Kaiser Normalization.			

Based on the identified factors, the authors propose to depict the relationship between the three factors in figure 1.

Figure 1: Relationship between the identified Factors

Discussion

This study establishes that home health nursing profession in the organized sector in India is comparatively very new as ninety-six per cent of the home health nurses were having less than five years of work experience in home health nursing profession, this finding supports the postulation of an earlier study which has postulated that home health care is a new service segment in India[2]. Moreover, this finding also throws light on the attrition problem in the home health nursing profession as the work tenure of less than one-year duration with the current employer is around forty-five per cent, this is on the higher side, however, there is no earlier study to measure the attrition rate of home health nurses in India but this finding is relatable to another third-world country "Kenya" where the attrition rate for community health workers was found to be 33 per cent[9]. Another interesting finding of the study was that around 69% of the home health professionals were lesser than forty years of age. Moreover, only 3-4 % of the home health nurses had a master's degree in educational qualification, this finding was commensurate with an earlier study[4] also. Furthermore, the analysis of data reveals that there are majorly three factors which are promoting the growth of home health nursing services and the profession in India, these three factors are exclusive benefits of home healthcare, comparative benefits over the hospital, Holistic views linking hospitals and home health provider. The first-factor exclusive benefits of home healthcare highlight that some aspects of home healthcareare exclusively available with home health services only. This includes aspects such as enabling preventive healthcare in a better way than hospitals[10], home healthcare provides a unique opportunity which allows the terminally ill patients to spend their last times at home peacefully being around the family members, home healthcare also helps to reduce the caregiver burden by providing psychological support to the family members[11][12], home healthcare are more cost-effective than hospital care for chronic disease care[13] and lastly, home healthcare can provide holistic care to the patient i.e. all the levels of care such as preventive, promotive, restorative care can be provided with home health services. Similarly, nursing professionals also makes a direct comparison between the home health services and hospital care and finds that in some aspects home health is superior to hospital care for example with home healthcare services there is lesser risk of infection[14], it reduces the hospitalization[15] and it should be always preferred for terminally ill patients. Lastly, the third factor reveals that nursing professional also perceive that home health and hospital services are complementary to each other as this factor covers that home health service opens new job avenues for nursing professionals and both home health nursing professionals and hospital nursing professionals must work in close association in the interest of the patients. Which as a concept is also largely promoted in the earlier studies done in Germany, and these studies have insisted upon the home care integration with other healthcare services at all the levels (primary, secondary and tertiary) levels of healthcare delivery[16].

Conclusion

This study concludes that there is a positive perception of home health nursing professionals towards home health nursing profession and there are majorly three factors driving the growth of home health nursing profession in India, namely exclusive benefits of home healthcare, comparative benefits over the hospital, Holistic views linking hospitals and home health providers. Home healthcare is superior to hospital care in matters related to decreased infection, reduced res-hospitalization, and care for terminally ill patient care. Lastly, Home Health nursing professionals perceive that the home health nursing profession has started a new job avenue for them and it's important that hospital nursing professional and home health nursing professionals work in close collaboration to get the desired patient outcomes. In cognizance with the identified factors, it can be expected that in the comping years the numbers of nursing professionals opting for home health nursing profession is going to increase.

Effectiveness of an Educational Program on Critical Care Nurses' Practices Regarding Endotracheal Suctioning of Adult Patients Who are Mechanically Ventilated in Hospitals at AL-Najaf, Iraq

Jihad Jawad Kadhim[1], Fakhria Gaber Mhabes[2]

[1]MSN-NEd, Lecturer at University of Kufa-College of Nursing-Adult Health Nursing, Ph.D. Student at University of Babylon-College of Nursing-Adult Health Nursing, [2]Ph.D. Prof. at University of Babylon-College of Nursing-Adult Health Nursing

Abstract

Background: Nurses need to participate in many different educational activities that enhance and promote lifelong learning, professional and personal growth. Structured endotracheal educational program is developed to articulate new scientific approach by using researches in the clinical setting and apply research findings in clinical practice.

Objective: The study is aimed to evaluate the effectiveness of an educational program on critical care nurses' practices regarding endotracheal suctioning of adult patients who are mechanically ventilated in hospitals at AL-Najaf, Iraq.

Methodology: This study is carried out by using quasi-experimental of pre-test and post-test one group design. The study conducted over the period of time that started from December 10, 2019 and ended on February 20, 2020, by using observational schedule that concentrated on critical-care nurses' practices related to endotracheal suctioning. The study involved observation of critical-care nurses' practices prior to educational intervention and post-test evaluation of participants' practices after four weeks from implementing ETS educational program.

Results: The preliminary assessment of participants' practices related to endotracheal suctioning indicated that most of the nurses were not be committed to the best evidence-based recommended practice guidelines. Dramatically improvement in participants' practices occurred after implementing educational intervention with statistical highly significant indicators.

Conclusion: In-service educational program is a cornerstone in clinical care settings in terms of promoting healthcare providers' knowledge and practices that can lead to quality care and achieve desired outcomes of critically ill patient.

Recommendations: emphasizing on providing in-service educational program is an imperative aspect to enhance practicum skills for novice nurses. Incorporating most recent scientific approaches plays vitally important role in tracking recommended clinical evidence that reflects on embracing change to daily practice standards.

Keywords: *Critical-care Nurses; Educational program; endotracheal suctioning; Evidence-based practice guidelines.*

Introduction

Patients who are critically ill generally hospitalized in critical care units. Most of these patients commonly having critical diseases such as respiratory failure and require mechanical ventilation (MV). Therefore, an artificial airway like endotracheal tube is commonly placed through the mouth to connect patients with MV in order to maintain breathing and aspirate airway secretions. Endotracheal suctioning (ETS) is one of the most frequent and important practiced procedures in critical care units. This procedure is often performed by critical care nurses in terms of removing accumulated secretions from the respiratory airway. The ETS includes threatening complications if it is performed incorrectly and may expose patient to risky deterioration.

Therefore, critical-care nurses need to be well trained, educated and competent in providing this procedure. In spite of published scientific practice modalities, many researchers addressed that nurses are having lack of commitment in terms of following evidence-based recommended practice guidelines[1-3]. A study carried out in Australia by Gilder, Parke, and Jull (2018) indicated that nurses were not adhering to follow international recommended guidelines related to ETS.[4] Moreover, a study in Turkey (2017) aimed to assess ICU nurses' knowledge and practices regarding ETS demonstrated that most of the nurses are relying solely on their individual experience rather than incorporating scientific approaches in performing suctioning.[5] Therefore, providing educational program based on clinical evidence is necessary to enhance nurses' practices and to guarantee excellent nursing care to patients who are mechanically ventilated.

Nurses should keep practicum skills, knowledge, and providing effective nursing care update. These aspects can be accomplished by attending continuous education. Schweitzer and Krassa (2010) asserted that "One way to keep current on nursing advances is to attend continuous opportunities." (p. 447).[6] Thus, developing structured educational program concerning ETS based on scientific clinical trials can prompt nurses' practice and achieve desired patient outcomes. Hence, the current study is aimed to evaluate the effectiveness of evidence-based practice educational program on critical-care nurses' clinical skills regarding endotracheal suctioning of adult patients who are mechanically ventilated in Hospitals at AL-Najaf AL-Ashraf City, Iraq. Accordingly, the evidence-based practice PICOT research question posed for this study is "Do critical-care nurses (P) who attend ETS educational program (I) improve their practice level (O) as compared to their pre-intervention practices (C) after four weeks from implementing educational program (T)". Moreover, the researchers hypothesized that there will be a statistical significant enhancement on the level of participants' practices about ETS after applying educational program as compared to their pre-test practices. General System Theory (GST) has been utilized to provide theoretical framework to guide this study.

Materials and Method

Research Design: This study is carried out by using quasi-experimental of pre-test and post-test one group design. The study involved evaluation of critical-care nurses' practices prior to educational intervention and post-test evaluation of participants' practices after four weeks from implementing ETS educational program.

Study Setting and Population: The population for the present study is nurses who are working in hospitals at AL-Najaf AL-Ashraf City, Iraq. The target population is nurses who are working in critical care units in selected hospitals. The accessible population is nurses who are met inclusion and exclusion criteria and who are working in AL-Sadder Medical City, AL-Hakeem General Hospital, and Middle Euphrates Hospital. The sampling technique was a non-probability, convenience sample of 87 out of 172 critical-care nurses who were interested in participating in this study.

The inclusion criteria for sample selection include:

1. Both male and female critical-care nurses at selected hospitals.
2. Critical-care nurses who were interested in participating in this study.
3. Critical-care nurses who were available at the period of data collection.

The exclusion criteria were as follow:

1. Nurses who were holding administrative position.
2. Nurses who were not available during the period of data collection.
3. Nurses who were not working in the critical care units.
4. Nurses who were not attending the ETS educational program.

5. Critical-care nurses who were selected for Pilot Study

Educational Program and Observational Checklist: The educational program has been developed based on extensive review of published studies from 2010 to 2020 and according to recent evidence-based recommended practice guidelines. The structured program is focused on improvement of participants' psychomotor skills by demonstrating and re-demonstrating essential steps in performing ETS. The objectives of the structured educational program are: to provide nurses the most recent scientific clinical evidence related to ETS, to articulate the significance of the suctioning procedure in terms of preventing ETS associated complications and enhancing patient outcomes, and to ameliorate collaboration between nurse educator (researcher) and critical-care nurses by identifying their areas where improvement can be made in order to meet the educational session goals. The researcher used various teaching-learning strategies to meet each individual nurse needs such as facilitate guided group discussion, role playing, concept map, problem solving approaches, and debriefing. However, the program concentrated on practices before suctioning, aseptic technique practices, practices during suctioning event, and post suctioning practices.

The observational checklist developed by Kelleher and Andrews (2008) was utilized and authors' permission was secured as well. The authors developed the clinical performance checklists based on comprehensive systematic reviews and recommended practice guidelines. The researchers took permission to adopt the final version of the tool. The observational schedule is peer reviewed to critical care nursing experts with experience in practice development. The authors did a pilot study to ensure validity and reliability.[7]

The tool contains 20 items that specified the most essential ETS practices: Prior to ETS practices includes nine items, and five items represents infection control practices, the suctioning episode incorporates five items, and post suctioning practices includes six items. These items can be found in the following tables. Moreover, after getting permission to use this observational checklist in the current study, we further requested opinion from ten experts from faculty members in adult nursing and anaesthesiologists with subspecialties in intensive care. The tool was valid and no major modifications were made. In addition, a pilot study was carried out for the reliability of the instrument and was analysed by using test retest method, which measured the coefficient of internal consistency. The obtained value for the instrument score was r = 0.81.

Method of Data Collection/Procedure: After getting the ethical approval from institutional review board, the researchers provided a brief description about the study purpose and informed consent was obtained to ensure confidentiality and privacy. We explained to nurses that observations would be occurred to investigate nursing-care practices related to infection control strategies in order to avoid bias during actual suctioning performances. The study began from December 10, 2019 and ended on February 20, 2020.

The participants were observed in their actual critical care units during morning and evening shifts by using observational checklist to document their actual practices against best evidence-based recommended practice. It took about 20 minutes for each observational checklist. The observation was done through three consecutive periods before implementing the educational program. Moreover, after providing an ETS educational intervention, the researcher used the same observational checklist three times in order to compare pre and post practices. The first observation checklist was done one day after presenting ETS educational program, while the second observation was carried out two weeks later and the third observation was done after one month from educational intervention to evaluate the effectiveness of educational program on nurses' practices.

Results

Eighty seven critical-care nurses are participated in this study. Demographic data for the study sample is shown in table 1. The results indicate that all nurses (100%) did not follow ETS guidelines. The vast majority (97.7) have not been attended previous educational or training program related to ETS. The majority of nurses (70.1%) had nursing diploma. Most of the participants (64.4%) had more than 5 years total experience in nursing, while only (12.6%) of them had more than 5 years experiences in critical care units (Table 1).

Table 1: Demographic Characteristics of the Critical-Care Nurses (N = 87).

Characteristics	Rating & Intervals	*n*(%)
Age/Years Mean 7.30 Standard Deviation 31.77	20–24	10(11.5)
	25–29	33(37.9)
	30–34	21(24.1)
	35–39	9(10.3)
	40+	14(16.1)
Gender	Male	64(73.6)
	Female	23(26.4)
Level of Education	Nursing Secondary School	5(5.7)
	Nursing Diploma	61(70.1)
	B.Sc. in Nursing	21(24.1)
Participation in Training/Educational Program	Yes	2(2.3)
	No	85(97.7)
If the answer is (Yes)	One Attendant	2(2.3)
Follow ETS Guideline	No	87(100)
Self-education	Yes	8(9.2)
	No	79(90.8)
If answer is (Yes)	Internet	6(6.9)
	Journal	2(2.3)
Total Experience as a Nurse	1–3 years	20(23.0)
	3–5 years	11(12.6)
	5 years and more	56(64.4)
Total Experience in Critical Care Units	Less than one year	29(33.3)
	1-3 years	24(27.6)
	3–5 years	23(26.4)
	5 years and more	11(12.6)

N = total study sample; *n* = sample number; (%) percentage.

Table 2: Evaluation of Nurses' Practices *Prior to Suctioning* at the Pre-test and Post-test.

Item	Observation	Pre-test	Post-test
		n(%)	*n*(%)
1. Patient Assessment: Did the nurse auscultate the patient's chest before ETS?	Done	29 (33.3)	73 (83.9)
	Not done	58 (66.6)	14 (16.1)
2. Patient preparation: Did the nurse explain to/communicate with the patient about the procedure?	Done	9 (10.3)	33 (37.9)
	Not done	78 (89.7)	54 (62.0)
3. Pre-suctioning hyper-oxygenation/hyperinflation	Done	71 (81.6)	73 (83.9)
	Not done	16 (18.3)	14 (16.1)
4. Sodium Chloride instillation	Done	79 (90.8)	7 (8.0)
	Not done	8 (9.2)	80 (92.0)

n = sample number; (%) = Percentage.

The results in table (2) indicate that the frequency and percentage of the correct performance in aspect "*Practices Prior to Suctioning*" is increased at the post-test as compared with pre-test. This gives an indication that there is an enhancement in the nurses' practices after the application of the ETS educational program.

Table 3: Evaluation of Nurses' Performances Regarding *Infection Control Practices*.

Item	Observation	Pre-test	Post-test
		n (%)	*n* (%)
5. Hands are washed prior to suctioning	Done	47 (54.0)	79 (90.8)
	Not done	40 (46.0)	8 (9.2)
6. Gloves are worn	Done	85 (97.7)	87 (100%)
	Not done	2 (2.3)	0 (0.0)
7. Apron is worn	Done	35 (40.2)	67 (77.0)
	Not done	52 (59.8)	20 (23.0)
8. Goggles/face mask worn	Done	30 (34.5)	70 (80.5)
	Not done	57 (65.5)	17 (19.5)
9. Sterility of suction catheter maintained until inserted into airway	Done	39 (44.8)	63 (72.4)
	Not done	48 (55.2)	24 (27.6)

n = sample number; (%) = Percentage.

Table (3) indicates that there is an improvement in frequency and percentage scores of participants' practices regarding infection control measures after implementing ETS educational program at post-test period.

Table 4: Evaluation of Nurses' Practices during "*Suctioning Event*"

Item	Observation	Pre-test	Post-test
		n (%)	*n* (%)
10. Size of suction catheter & Size of ET Tube: Done = Less than half internal diameter of ETS. Not done = More than half internal diameter of ETS.	Done	57 (65.5)	78 (89.7)
	Not done	30 (34.5)	9 (10.3)
11. Number of suction passes: *Done = two or less, Not done = more than two*	Done	60 (69.0)	82 (94.3)
	Not done	27 (31.0)	5 (5.7)
12. Length of time suction applied to airway: *Done = less than 15 seconds, Not done = more than 15 seconds*	Done	47 (54.0)	71 (81.6)
	Not done	40 (46.0)	16 (18.4)
13. Level of suction pressure: Done = 80 – 120 mmHg, Not done = more than 150 mmHg	Done	11 (12.6)	82 (94.3)
	Not done	76 (87.4)	5 (5.7)
14. Position of catheter when suction applied: *Done = withdrawal, Not done = insertion*	Done	49 (56.3)	82 (94.3)
	Not done	38 (43.7)	5 (5.7)

n = sample number; (%) = Percentage.

The results in the above table demonstrate that there is an enhancement in nurses' practices at post-test in regard to use suctioning catheter less than half internal diameter of ET tube. Similarly, items number 11, 12, and 14 indicate improvement in participants' practices at post-test. Concerning item number 13, the majority of nurses (87.4%) were exceeding the suctioning pressure limit in most of the time to more than 150 mmHg at the pre educational intervention. While after education, the participants adhered to recommended guidelines presented during the implanting ETS educational program.

Table 5: Evaluation of Nurses' Performance Regarding *Post Suctioning Practices*.

Item	Observation	Pre-test	Post-test
		***n* (%)**	***n* (%)**
15. Patient reconnected to Oxygen: *Done = less than 10 seconds, Not done = more than 10 seconds*	Done	56 (64.4)	65 (74.7)
	Not done	31 (35.6)	22 (25.3)
16. Post suctioning hyper-oxygenation/hyperinflation	Done	80 (92.0)	87 (100.0)
	Not done	7 (8.0)	0 (0.0)
17. Post ETS assessment: Did the nurse auscultate the patient's chest?	Done	32 (37.0)	65 (75.0)
	Not done	55 (63.0)	22 (25.0)
18. Patient reassured	Done	16 (18.4)	50 (57.5)
	Not done	71 (81.6)	37 (42.5)
19. Used catheter and gloves are disposed of in a manner that prevents contamination from secretions	Done	81 (93.1)	87 (100.0)
	Not done	6 (6.9)	0 (0.0)
20. Hands washed post suctioning	Done	41 (47.1)	72 (82.8)
	Not done	46 (52.9)	15 (17.2)

n = sample number; (%) = Percentage.

The finding in table (5) shows that prior to implementing ETS educational intervention, most of the critical-care nurses did not auscultate patient chest after suctioning procedure, whereas after education, most of nurses did auscultation examination. This table illustrates enhancement in the level of nurses' practices after providing the educational program.

Table 6: Mean Difference among Overall Nurses' Practices in Two Periods of Measurements (Pre-Test and Post-Test).

Phases of ETS	Pre-test	Post-test	Enhancement	Paired t-test	p- value S
	Mean (SD)	Mean (SD)	Mean (SD)		
Practices Prior to Suctioning	0.72 (0.43)	1.38 (0.42)	0.66 (0.11)	9.57	0.0001 HS
Infection Control Practices	0.88 (0.27)	1.19 (0.40)	0.31 (0.16)	6.01	0.0001 HS
The Suctioning Event	1.06 (0.33)	1.61 (0.28)	0.55 (0.9)	11.61	0.0001 HS
Post Suctioning Practices	1.11 (0.26)	1.43 (0.26)	0.32 (0.12)	8.14	0.0001 HS
Overall Practices	0.94 (21)	1.40 (0.22)	0.46 (0.7)	12.79	0.0001 HS

SD = Standard Deviation; S = Significance; HS = Highly Significance;

Paired t-test analysis is conducted to determine the difference in the mean of the nurses' practices at two points of measurements (pre-test and post-test). The study results presented in table (6) show that there are statistically highly significant differences in the nurses' practices at p-value less than 0.01. Based on the statistical mean, the results indicate that there is a highly significant improvement in the statistical mean in the post-test as compared with pre-test (i.e. there is an enhancement in the nurses practices after application the education program).

Discussion of the Study Finding

Regarding critical-care nurses' practices, the researchers observed participants during three times in each period of measurement (pre-test and post-test) in order to ensure the accuracy of recorded performances. The three recorded observations were statistically

analysed and calculated to compare overall mean scores for pre and post intervention. However, during pre-educational intervention period, the result of item no 1 regarding patient assessment shows that most of the participants did not perform auscultation technique before suctioning procedure (Table 2). This is consistent with what has been found in previous study in Finland that conducted by Jansson et al., (2013a) who stated that "the majority of suctions were carried out without clinical indicators (related to chest auscultation) being identified". (p.103).[3] A similar pattern of results was obtained from study in Iran that conducted by Haghighat and Yazdannik (2015) who reported that (90%) of nurses did not perform auscultation technique in terms of finding indications to ETS.[2]

On the other hand, after applying ETS educational program, the vast majority of participants performed auscultation in order to examine suctioning indications. This is evident that our educational intervention was an effective approach in terms of enhancing participants' practices. Our finding was directly in line with Azizian, Azadi, Veisani and Bastami (2020) who concluded that different educational method regarding ETS can be effective and significantly improving nurses' practices.[8] Özden and Görgülü, (2012) mentioned that nurses' practices about ETS improved after training program and reflected on enhancement of patient safety and excellent quality of nursing care.[9] The nurse must be aware that chest auscultation is a mandatory technique to determine clinical indicators for ETS. Performing chest auscultation is one of the most important assessment techniques that nurses should master to detect respiratory indicators to ETS.

In the same domain "*Practices Prior to Suctioning*" item number 4 "Sodium Chloride Instillation" the result indicates that most of participants had been doing normal saline instillation (NSI) before suctioning episode (Table 2). This was revealed in the study by Haghighat and Yazdannik (2015), where most of the nurses implemented NSI before suctioning event.[10] Similar study results that carried out in Baghdad Teaching hospital and Surgical Specialties Hospital/ Medical City Directorate by Majeed (2017) has also demonstrated that the majority of ICU nurses performed NSI.[11] AARC (2010) does not recommend using NSI because there is no enough evidence that articulated its benefits.[12] In spite of evidences that do not support using normal saline (NS), nurses still practicing this procedure. The reason for that could be lack of nurses' knowledge about recent evidence-based recommended practice guidelines. Oppositely, after implementing ETS educational program, the vast majority of participants did not use NSI prior suctioning (Table 2). Moreover, the statistical finding regarding participants' practices "*prior to suctioning"* revealed highly significant improvement in nurses' practices (p = 0.0001) after educational intervention as indicated in table (6). This is proved that our structured educational program has a positive impact on nurses' practices in terms of adhering to the best recommended practices.

In relation to the second aspect "*Infection Control Practices*" the result of pre-test shows that nurses were not fully adhere to infectious preventive measurements. For example, apron was not be worn in most of the participants (59.8%), many participants (65.5%) did not wear face mask and (55.2%) of nurses were not maintain sterility of suction catheter when inserted into airway (Table 3). Our finding is in line with Haghighat & Yazdannik (2015) who found that most of nurses in their study did not adhere to infection control practice guidelines such as (82.5%) of nurses did not wash their hands and goggles were not be worn in (90%).[2] Infection control practices are an essential aspect in terms of preventing hospital acquired infection specifically in ICU. The most common nosocomial infection in critical care units is ventilator-associated pneumonia (VAP) with the occurrence rates ranging up to 70%.[12] Jansson et al., (2013b) stated that despite current available guidelines regarding VAP prevention, nurses still have discrepancies between evidence-based best practices and their performances.[13] Another research study in Jordan conducted by Aloush (2017) indicated that nurses' commitment to infection control strategies regarding VAP were low. The researcher emphasized that poor adherence toward infection control principles could be due to the lack of in-service education for ICU nurses.[14]

Consequently, after providing in-service educational program, the result in table (3) indicates that most of the participants adhered to the best recommended practice guidelines related to infection control practices. Our results demonstrated that there is an improvement in nurses' practices occurred after applying ETS educational program. According to overall statistical analysis for the aspect "*Infection Control Practices*" the result appeared to be very highly significant (p = 0.0001) as indicated in table (6).

Concerning the next domain (table 4) "*The Suctioning Event*", our finding shows that there is a statistically highly significant improvement in participants' practices after implementing ETS educational intervention as illustrated in table (6). In addition, the last section (Table 5) namely "*Post Suctioning Practices"*, our finding revealed that the participants' performances enhanced significantly after educational intervention as delineated in table (6). These findings are in accordance with findings reported by Fernandes, Dasila, and Banerjee, (2018) who mentioned that "Regular in-service education programme at every hospital is required to keep the nurses updated with evidence-based guidelines to achieve positive patient outcomes" (p. 147).[15]

After application the ETS educational program, our finding shows that the overall evaluation of participants' practices in all domains was statistically very highly significant. This could be due to our structured educational program was focusing on the main aspects related to ETS. The second reason can be the study was guided by GST which provided a conceptual framework as a roadmap to delineate crucial steps in demonstrating and re-demonstrating practicum skills through input, output, and feedback process. Thus, our hypothesis is accepted at high level of significance ($p = 0.0001$) and null hypothesis is rejected as shown in table (6).

Conclusion and Recommendation

Directed by general system theory, evidence-based practice recommended guidelines, most recent studies, and standards of nursing care were used to develop an effective ETS educational program to improve practices of critical-care nurses in performing suctioning to patients who are mechanically ventilated. The structured educational intervention is provided in one session. For future researchers, different didactic approaches should be considered, for example using simulation training modalities and implementing several sessions over period of times to include more sample size are highly recommended. Studies recommended conducting continuous educational intervention to maximize the benefit in gaining knowledge and refining practical skills. Bridging the gap between knowledge and practices is the key to enhance the quality of nursing care and improve outcomes for patients who are under mechanical ventilation. In-service educational program based on evidence-based recommended practice guidelines is strongly advised to embrace change with updated scientific approach. Finally, ETS must be performed by well trained, educated and competent nurse to avoid potential adverse event of suctioning procedure.

Nurse Educators Examine the Applicability of Health as Expanding Consciousness Theory: A Qualitative Review Study

Jihad Jawad Kadhim[1], Mansour Abdullah Falah[2], Iman Qasim Kteo Al-hussein[3]

[1]MSN-NEd, Lecturer at University of Kufa-College of Nursing-Adult Health Nursing, [2]Assist. Prof. at University of Kufa, College of Nursing-Community Health Nursing, [3]MSN, Lecturer at University of Kufa, College of Nursing-Adult Health Nursing

Abstract

Background: Health as expanding consciousness (HEC) is a grand theory by Margaret Newman, and it is one of those key tools to be used in order to understand a patient as a whole. The theory is based on identifying the pattern of an individual. The HEC focuses on all aspects of the individual as a social, cultural, physical, emotional, and spiritual. It works for understanding the disease as well as other factors pertaining to the pattern of the individual.

Objective: The present review study is aimed to provide inside comprehension on the applicability and feasibility of HEC from nurse educator perspectives based on review of qualitative studies.

Results: This study shows how successfully the theory was applied to coronary heart disease patients, women with multiple sclerosis or rheumatoid arthritis, and pain during perioperative period. Thus, the theory is effective in all scenarios and provides the nurse ways to understand patients from varied backgrounds. The authors of reviewed studies used the hermeneutic-dialectic approaches as a tool for the research study. The nurses played an important role by help the patients to recognize their pattern and move to a higher level of consciousness. The nurse-patient relationship built on mutual trust and respect, which helped both nurses and clients to interact effectively in order to identify their pattern.

Conclusion: Newman's theory can be applied in every nursing setting in both short and long-term interaction with the patient.

Keywords: *Health as Expanding Consciousness; Nursing Theory; Qualitative Review.*

Introduction

Nursing theory is one of the most important subjects that every nurse should know and gain knowledge about. Understanding the nursing theory is a crucial point, and it guides the nurses to apply their knowledge and experience in appropriate ways. Nursing theory is like a roadmap that helps the nurses to move forward and reach the desired outcome. However, nurses must know the main concepts about how to select a specific nursing theory to draw a broad framework that encompasses all nursing responsibilities. Additionally, it is essential that advance professional nurses use theoretical frameworks in nursing clinical settings, education, and research. In fact, nursing is a comprehensive field that deals with not only health and disease issues, but also with every single phenomenon that somewhat is related and incorporated with environment, individual, family, community, society, as well as global population.

As the patient seeks help and comes to the healthcare provider with not only health issues, but also with other problems. Hence, the Newman's theory focuses on

e-mail: jihadj.alsudani@uokufa.edu.iq

health as expanding consciousness in which the person is viewed as a whole. Therefore, this approach is the best way to consider with the patient. This paper is focused on expanding consciousness of the patient and nurse through partnerships in order to find a new way of person-environment interaction in spite of the disease deterrent. Disease is not an enemy to fight against, but is a meaningful point that allows people to find new ways to interact with their environment.

Purpose: The purpose of this research article is to illustrate the importance of Newman's theory, which is supported by a research study done on patients with coronary heart disease, a woman with multiple sclerosis (MS) or rheumatoid arthritis (RA), and pain expression in the perioperative period of Somali Women. Newman's theory is based not only on the treatment of the disease, but also on the overall pattern of an individual in different cultures. This theory helps the nurse to expand the consciousness of the patient, simultaneously expanding the nurse's consciousness as well. This in turn supports nurses to improve their knowledge and experience in providing holistic care to an individual. Additionally, Newman's theory can be applied in multi-cultures as well.

Significance: People who live with acute or chronic diseases are facing so many difficulties, such as isolation, frustration, hopeless.[1] They feel unable to do something that they would like to do or have done before. Hence, they have lack in interest in life. However, Newman's theory is helping both nurse and client to expand their consciousness. Newman's theory helps patients to find new meaning of life and to interact with the environment by their remaining energy. Patients with multiple sclerosis or rheumatoid arthritis have restricted mobility and have difficulties to interact with their environment. The Newman's theory is a best approach to assist those patients in order to improve their interaction with the environment and implant the hope in their life.

Overview of the Theory: Newman's theory Health as Expanding Consciousness (HEC) is one of the most recent nursing theories. This theory focused on the health of all persons regardless of the presence or absence of disease. Health is a major concept of Newman's theory of health as expanding consciousness.[2] Newman (1994) provides a new perspective of health, which is opposite from the old definition of health as the absence of disease, and she explained health is a process encompasses that both disease and non-disease, and disease as a meaningful manifestation of the pattern of the whole, which is not the separate entity of the whole.[3] In addition, she believes that health and illness are the same entity and manifested in the pattern of the person. Disease and non-disease are each reflections of the larger whole, health is the pattern of the whole, and the wholeness is cannot be gained or lost.[4] Accordingly, when the person becomes ill, illness does not diminish wholeness, but wholeness takes on a different form. For example, when a person has certain disease, he or she can get to a healthy place even though that person has a particular disease, because disease is a reorganizing state and part of the wholeness, so the person can find a new situation (pattern) to live and interact with the environment. At the same time, that person is expanding his or her consciousness by changing his or her mind (consciousness) and becoming more aware about how to live and interact with new situation. According to Newman (2008), pattern is seen as information that depicts the whole, and understanding of the meaning of all of the relationships at once.[5]

Therefore, health can be identified by the pattern in which one interacts with the larger pattern of the environment and it is manifested in the way one moves, works, speaks, and relates with others. Moreover, when the person gains more information about his or her current situation, the person's pattern develops and the person begins to organize his or her life in high level, by which it becomes more congruent with environment interaction.

Based on Newman's theory, every person exhibits a unique pattern, which is constantly unfolding or open system that interacts with the environment.[6] In addition, Newman describes the nature of the pattern and she states that anything explicate (that which we can hear, see, taste, smell, touch), is a manifestation of the implicate (the unseen underlying pattern). In other words, there is information about the underlying pattern of each individual which we can sense about them, such as their movement, tone of voice, interactions with others, activity level, genetic pattern, vital signs. For example, we can recognize the patient's condition when he or she complains of pain by seeing the patient's facial expression or body posture. There is also information about the patient's underlying pattern in all that the patient tells us about his or her experiences and perceptions of pain. When the patient is providing us the necessary information by describing the pain such as aching, sharp, stabbing, throbbing, or on scale the pain from 1 to 10, or the patient tells us there are

contributing factors that increase pain, such as before or after eating, so all of these are subjective data. Hence, the pattern is just like objective and subjective data. The HEC perspective sees illness, disorder, disruption, and disequilibrium as an explication of the underlying implicate pattern of the person, family, and community.[6] These conditions need reorganization in order to keep balance between individual and environment interaction. Finding a new situation to adapt with is a part of the process of expanding consciousness.

Pattern recognition is one of the essence concepts of Newman's theory. Understanding the pattern is essential. The expanding consciousness is the pattern recognition. When persons face a disruptive situation such as during an illness, they are in a period of chaos. They may be unable to recognize their own pattern. A partnership with a nurse during this period can create an opportunity for reflection on a pattern and a shift in perspective. Nurse-client relationship often begins during a period of disruption, uncertainty, and unpredictability in patient's life. Becoming aware of the pattern of the other person is by becoming "in touch with one's own pattern" nurse should focus on the pattern of other person, acting as the reference beam in a hologram.[4] The nurse needs to be in touch with the patient and focusing on every single detail that interferes with the patient's condition in order to help the patient recognizes his or her own pattern and to clarify that the old rules of pattern are not working anymore, and need to shift into a new way of interaction with the environment. Dr. Newman (1999) referred to this period as a choice point in which the patient most needs nurses during this period, and by a partnership, the patient can recognize his or her pattern and make a decision to shift to a new pattern.[7] This transformation occurs by partnership with the nurse who provides all necessary information and helps the patient to adapt a new pattern, which more coincides with the patient's new condition. The client-nurse relationship becomes more in harmony during this period, both of them is growing by sharing information, experience, and perception, which reflects on expanding consciousness for both of them. We need to remind ourselves as nurses that when we get in touch with the patient it is to focus not only on treating symptoms, but also on identifying the patient's pattern and treating the patient as a whole rather than a part, as Dr. Newman mentioned and called a paradigm shift.[7]

Newman also mentioned the interrelatedness of time, space, and movement. Time and space are the temporal pattern of the patient, and they have a complementary relationship. People are constantly changing through time and space, and it shows a unique pattern of reality.[4] She also explained that time and space have a complementary relationship. Furthermore, Newman (1986) stated, "Individuals come into being from a state of consciousness, they were bound in time, found their identity in space, and through movement they learned the "law" of the way that things worked and then made choices that ultimately took them beyond space and time to a state of Absolut consciousness".[4] On the other hand, the person with limited mobility has limited space-time. However, transcendence occurs when the patient moves and finds a new meaning for life, which reflects that the patient reaches the higher level of awareness to interact with the environment.

Consciousness and expanding consciousness are also the major concepts of the theory of HEC. Consciousness is defined as both the informational capacity of the system (human being) and the ability of the system to interact with its environment.[4] Also, Dr. Newman (1986) asserts that consciousness not only includes the cognitive and affective awareness, but also the inter connectedness of the entire living system which includes physicochemical maintenance and growth process as well as the immune system. Each system in the human body has specific information and has an ability to interact with environmental system. The environment includes ourselves, our bodies, and the world around us. During the life span, people interact with environment, this interaction between complex information of systems reflecting by gaining experience and knowledge, which in turn these are contributing to expanding consciousness.[4] Life is a process of progression toward a higher level of consciousness. The process of expanding consciousness is defined by Newman (2008) as "a process of becoming more of oneself, of finding greater meaning in life, and reaching new heights of connectedness with other people and the world."[5] Nurses and their clients are gaining knowledge and experience from each other during interaction, and when there is a meaningful quality to their relationships. Nurses and their clients must be open and flexible in order to build mutual respectful and trustful relationships.

Moreover, relationships that are more open, loving, caring, connected, and peaceful are a manifestation of expanding consciousness. Unconditional acceptance is one of the most important issues for the nurse in order to build trustful and respectful relationship with clients.

Nurses must accept the client as he or she is, and whatever his or her health problem. Again, nurses must exhibit professional behavior such as paying attention to every single detail that may be very valuable to the patient. When the nurses are putting themselves in the patient's condition, they can understand and feel the patient's overall situation. Nurses must recognize what are the most important issues to the patient, and why the patient is concerning about these issues. Dealing with patient as a whole is a better approach to treat the patient. By doing so, the patient can realize that the nurse is caring about him or her and will be more open and cooperative to interact with the nurse.

Relevant Literature to the Theory: The following research article presented information on life patterns of persons with coronary heart disease by using Newman's theory HEC. The study included eleven clients (7 men and 4 women) in a cardiac rehabilitation program, a cardiovascular nursing specialist, and the investigators.[8] The most important part in this study is pattern, because the main concept of Newman's theory is that the disease is a manifestation of the individual's pattern, and the pattern can be seen in behavior and inner experience of the individual's pattern. The authors conducted this study by interviewing the clients and asked them to describe the most meaningful persons and events in their life. The interviews were audio-taped in order to organize them into chronological order. The nurses were considered as co-researchers and co-interviewers. The nature and purpose of the interview as collaboration between researchers and clients to understand the individual's overall life pattern was explained. The authors found similarities of patterns among these clients who have coronary heart disease (CHD) and classified them under three main themes, which are (a) the need to excel, (b) the need to please others, and (c) the feeling of being alone.[8] All of participants had these themes, but they expressed their thought in different manners. All clients tend to be successful people or they wish to be the best. These feelings were very important to them because their pleasure arose from recognizing of their accomplishments and from being the center of activity and in control. In addition, all of the clients had strong need to please others, but they were in difficult situations to express their feeling at that time. Moreover, they were experiencing loneliness. The feeling of being alone and lack of connectedness to others was the main cause for alcoholism and isolation. These are theoretical similarities of pattern, which reflect the pattern of the disease. However, the authors described these clients as having poor coping behaviors during the period of disruption (disease), and when the clients reached the choice point they realized that the old ways are not working with new situation (disease) and they need to change their life style.[8] They figured out that the disease crisis was the critical time of re-evaluation of the meaning and direction of their lives. Finally, most of them found things that made their life much easier and have meaningful aspects, such as closer relationships with their families and significant others, quit drinking, and find much more time for entertainment.[8] The role of the nurses was helping the clients to recognize their patterns, and then move forward to the state of absolute consciousness. Our opinion, this is a good research and precisely fits with Newman's theory HEC. The nurses cooperate or deal with the wholeness of the clients rather than treating the symptoms of the disease, and help patients to find new tracks to interact with their environments. The nurses assist the clients, as they are able to do interesting things and interact positively with their environment, rather than they are unable to interact with their environment because of their health problems. The nurses helped the patients to accept that the diseases are only parts of their health.

Neill in 2005 conducted research that supported Newman's theory about seven women living with multiple sclerosis or rheumatoid arthritis, both of which is considered as chronic and autoimmune diseases.[9] In this study, the author used hermeneutic-dialectic process of Newman's theory, which means the communication based on mutual respect and interpretation of content, focusing on meaningful experiences, surrendering control over responses provided, and sharing meanings and insights that evolved[9], in order to understand patterns of person-environment interaction. The author interviewed clients by using dialogue to pursue the communication with the patients' narratives. The study was conducted through partnerships over 2-year a period. The study allowed the clients to narrate their life-stories, in which the most important people and events they remembered were featured along with their patterns of person-environment interaction[9]. The synopsis of the seven women's stories that there was no movement or change in their patterns of person-environment interaction until they reached the choice point when the women developed new awareness of their situations and progressed to the transcendent stages of expanding consciousness. When the women reached the choice

point, they realized that the old ways of interaction with the environment were not working anymore, and during this time, they need new ways to interact with the environment by changing or re-modeling their life activities. However, the researcher assisted those women by helping them to recognizing their patterns. Then, they worked together and found meaning in living with MS or RA, even though their illnesses were not cured medically. Meaning was evident as new ways of living that restored harmony to their lives. All the seven women spoke of finding simple pleasure, being positive and gaining self-control.[9] New ways of living occurred during the transcendent stage of expanding consciousness, and represented a profound personal change and transformation. All the seven women started to think positively after reaching the choice point, and they began to reconnect with their families, practice simple hobbies, and manage their energy expenditure to avoid fatigue, identifying their limitations, and caring for themselves better than in the past.[9]

Neill (2005) declared that for nurses who interested to use HEC theory to guide their practice, these findings (finding simple pleasure etc.) suggest how best to interact with people who manifest health at different levels of expanding consciousness. Neill (2005) also asserted that nurses could become aware of identifying choice points in illness stories or life stories and might be able to move the patients toward higher level of awareness.[9]

The other research study that supported Newman's theory HEC was about pain expression in the perioperative period: insights from a focus group of Somali women. This study was conducted by Ness in 2009, about Somali women who live in Minnesota. Somali women have different pain expression than other cultures.[10] Nowadays, many nurses understand the importance of the variety of cultures and the impact of these cultures on nursing care process. Hence, caring of individuals from different culture needs more attention and it is a critical situation.[11] Ness (2009) used focus group design in the research study. The group was four Somali women who participated in this study. The researcher explained that pain expression is varying from culture to culture, and nurses need to understand those variations in order to recognize the patient needs. Delivering appropriate nursing care for patients from different culture needs a special attention on the way they express pain. The author used the Newman's theory as a theoretical framework and was focused on pattern recognition, interconnectedness, and wholeness, which offered an excellent integration for this project. The Newman's theory designates the major role of the nurse as helping others in identifying the power within them to progress to a healthy state.[12] The author used open-ended questions as a way to gain knowledge about their pain experience during perioperative surgery, and to identify patient patterns. Callister (2003) stated that the pain experience should be understood within the context of the beliefs, values, coping mechanisms, and life experiences of each patient.[13] However, the results of the study indicated that Somali women have unique perspectives on the pain experience. The references to Allah and the importance of expression in their native language during the pain experience are very helpful to know when caring for Somali women.[10] The results also showed that the Somali women have pain expressions and behaviors that are universal, which are the similar expressions of most people from different cultures. For example they expressed and described the pain as screaming, moaning, sighing, making a face, eye movements, guarding by holding the site of pain, holding the head in the hands, and movement of the head back and forth.[10] Additionally, those women spoke about their concern after surgery that they were worried about family because they were not able to do daily activities as they were before the surgery. Hence, the researcher provided some resources like social and community support that took care of their children, which were helping them to get better health and eliminate the hardship at that time. These finding will serve to strengthen culturally sensitive nursing practice and provide a positive impact on Somali women experiencing pain within the health care setting.[10] Finally, the women gained more awareness about pain experience while sharing their experience with each other as well as the researcher. The nurses can use the Newman's theory in multi-cultures in order to improve their interaction with patients from different cultures to reach the desired outcome.[10]

Synthesis of the Theory: The theory of health as expanding consciousness is a holistic nursing theory, and can be applied in both long and short-term nursing clinical settings. We believe that Newman's theory can be used in every interaction that nurses have with the patient. The following example exhibits how the Newman's theory can be applied in short-term setting in emergency room (ER). The female patient is 42 year old, comes to the ER for treatment of severe dehydration related to nausea and vomiting secondary to her AIDS infection. Based on this case, the nurse would apply the

Newman's theory, while the nurse is introducing her/ himself to the patient, the nurse will show the patient that she is highly respected, and she/he will do her/ his best to provide a good holistic health care. This is a good approach to show the patient in order to get a mutual respectful relationship. Then, the nurse would say according to the medical record it found that you are dehydrated, and we are going to help you for that, just in order to begin the conversation and discuss how the nurse is going to give her the IV fluid. Moreover, while the nurse is discussing the administration of treatment to her, the nurse would also ask her some other questions, such as how is everything going with you? Alternatively, do you have any other concerns or anything else I can do for you today?

Obviously, the questions will lead to open conversation, and then the nurse can identify or recognize the patient's pattern. During conversation, the nurse realized that the patient is a single mother for three kids and she feels isolated because there is no one around her who can offer a help. In addition, she has a full time job. She is worried about her kids and about her job as well. These are examples about this case, and the patient may demonstrate different situations. However, the key point is that the nurse must know what are the most important people or events to the patient and why. After knowing that, the nurse can work as partnership with the patient in order to assist the patient to recognize his or her pattern. Then, the nurse and patient can move forward to find a new way that would be much better and congruent with the patient's current situation. The nurse would give the patient some resources such as, social support or community support to help her by taking care of her kids and she can return to her job, and spend more time to take care of her health as well.

To sum up, the nurse focused not only on treating the symptoms of the patient, but also tried to recognize her pattern, and identify the most important issues that she was worried about. The nurse treated her as a whole. The nurse helped her to identify her pattern, and both of them are growing and gaining more awareness by finding new way of person-environment interaction.

Conclusion

In the final analysis, nursing theories have a great emphasis on nursing practice, education, and research. Nursing theories address the most valuable phenomena that improve nurses' knowledge, practice, and experience. Equally important, nursing theories are useful for individual, family, community, and society. This paper discussed one of the most important nursing theories, which is health as expanding consciousness by Margret A. Newman. This theory focuses on the health as a whole, and the disease as a part of the wholeness. Disease and non-disease manifests individual's pattern. Consciousness includes all the entire living systems in the human body. People during the life span are moving forward to the higher level of consciousness. The environment encompasses human beings and the world around them. Furthermore, the nurse-client relationship is very important part of the Newman's theory. Hence, both of them are gaining knowledge, expanding their consciousness in partnership, and exchanging their information by interacting with each other. Patients with acute or chronic diseases are seeking help and Newman's theory is an idealistic approach to assist these patients. This has been justified by the instances provided in this paper. It shows that this theory is dynamic in practice and can serve a variety of communities.

Recommendation: HEC is an excellent theory that can provide a roadmap and be applied in nursing research, clinical settings, and education. It is feasible and we strongly recommend applying this theory in short and long term clinical practice to achieve desired outcomes.

Assessment of Satisfaction Levels of Health Insurance Policy Holders with Claims Settlement Process in Pune, Maharashtra

Neha Ahire[1], Parag Rishipathak[2]

[1]Assistant Professor, Symbiosis Institute of Health Sciences, Symbiosis International (Deemed) University, Pune-411004, India, [2]Professor & Director, Symbiosis Centre for Health Skills, Symbiosis International (Deemed) University, Pune- 411004, India

Abstract

Introduction: Customer satisfaction is an important determinant of health insurance penetration. It is not only indicative of customer loyalty but is also helpful in identifying the needs of the customer and further necessity of product innovation. As compared to other verticals of insurance, health insurance is more complex as for the administration and implementation of the policy various stakeholders are involved. Theses take holders are namely hospitals, Third Party Administrators and health insurance agents and advisors. Equally important is the satisfaction with the claim settlement process, which significantly impact overall satisfaction with health insurance policies.

Aim and Objectives: To assess of customer satisfaction levels with the claim settlement process amongst health insurance policyholders in Pune, Maharashtra. Further, the study is aimed to identify the potential areas of dissatisfaction and weaknesses in the claim management system.

Materials and Method: The study design is and exploratory and descriptive. Sequential random sampling used to select participants from the data of health insurance policyholders who have availed the benefit of health insurance through hospitalisation. 5-point Likert scale was used to assess the responses on claim settlement process.

Results: Health insurance claims administration involves coordinated efforts of stakeholders viz insurance companies, TPA services, Hospitals and agents and advisors. The study shows scope of improvement in the claims settlement process. The policyholders experience depends on the coordination, timeliness and transparency in the process.

Keywords: *Health insurance policies, customer satisfaction, claim settlement.*

Introduction

India has conventionally been the country with low health insurance penetration. The out of pocket expenditure is still the most common source of healthcare expenditure.[1]

There has been considerable improvement the penetration health insurance in this decade. The sales of the insurance industry has almost doubled in the last 5 years. Oxford Economics projects revenue from health insurance premiums to reach US$3.5 by 2021, depicting growth of more than 12% annually.[2]

Effective functioning of the health insurance mechanism requires coordinated efforts amongst multiple stake holders. These are hospitalization, healthcare service, third party administration and agents. Equally important is the satisfaction with the claim administration process, which significantly impact overall satisfaction with health insurance policies. Likewise, it

e-mail: nehaahire@sihspne.org

is important to focus on the existing customers along with new customers as it suggests satisfaction with the products offered. Also, it is seen that the efforts in retaining customers are less as compared to the targeting new customers as they are aware of the benefits of the policy. Further, with the increased competition among the insurance companies, the assessment of satisfaction levels is of utmost importance as policyholders have various choices available.

Satisfaction is the degree of fulfilment of the expectations from the product between perceived performance and expected performance for an individual. If the performance fails to meet the customers' needs they will become dissatisfied. Customer satisfaction has a lead role to play in renewal of health insurance policies as the policy are to be renewed annually. Researchers have considered health insurance as a most complex type of insurance as the service administration requires coordinated efforts from hospitals, TPAs and agents. Also, it is seen that there exists a constant struggle between the insured expectations and the insurers performance. Health insurance sector in India has much scope for improvement.[3]

The role of agents is also very influential in communication along with the personal and social demographic factors influencing the awareness about the health insurance policies. Awareness and opinion about health insurance and health insurance practice is strongly affected by communication and transparency[4]

According to a study, which examined the customer expectation and satisfaction of insurance policyholders towards the services provided by 11 life insurance companies in India, the companies were offering different products, though they were providing similar kinds of service. This shows the need of targeted approach. [5]

Studies focused on the factors influencing the customer satisfaction of policyholders in insurance industry have strongly advocated the need of evaluating service quality factors along with the socio economic factors.[6]

In the assessment of health insurance satisfaction three factors namely personal, marketing and social needs to be focused upon separately to understand the needs and preferences of the customers. It is also recommended that understanding the pattern of subscription of health insurance in different demographic groups and their awareness of health insurance plays a crucial role.[7]

Insurance companies need to focus on customer satisfaction strategies in insurance industry for a successful implementation of business. This is of strategic importance as customer satisfaction directly correlated to a firm's growth.[8]

Health insurance policies are usually for one year and are typically renewed every year. Customer satisfaction with the existing policies and the claims settlement transparency was found to be an important determinant of renewal of health insurance.[9]

Considering the recent innovations in health insurance sector, customer satisfaction is the one of the identified future areas for and associated challenges and enhancing reachability to complex issues involving health insurance. [10]

IRDAI report of 2019 states the claim settlement ratios of most companies. The report also states that there not all health insurance companies are showing positive claim settlement ratios. This means that there much scope of improvement and thus satisfaction.[11]

Studies also show variation in satisfaction levels of Policyholders who have availed policies from private sector and those purchased insurance from the public sector companies. Group policyholders are more satisfied with health insurance compared with family floater policies and individual policies.[13]

In such case the study of customer satisfaction becomes more important to identify potential areas of improvements which will ensure trust in insurance sector and improve the penetration of the same.

The evaluation of the satisfaction levels of these users will help in identifying whether the expectations are being met or not and it will highlight the problems faced and issues identified. This will also help to understand whether the present health insurance policy addresses the need of the respondents. It is important to know how satisfied the policyholders with the Hospitalization and claim settlement process. Health insurance policy administration involves stakeholders like insurance companies, TPA services, Hospitals stay, facilities and the overall treatment. Thus the experience depends on the whether the needs and preferences are being met or not.

Aim and Objectives: The objective of the study is to assess customer satisfaction with the claim settlement

process amongst health insurance policyholders in Pune, Maharashtra. Also, the study aims to identify the potential areas of dissatisfaction and weaknesses in the claim management system.

Research Methodology

The study is based on exploratory and descriptive research. Sequential random sampling was used to select participants from the data of health insurance policyholders. The study period was April – August 2019. The data was collected from 152 health insurance policyholders who had availed the benefit of hospitalisation through either cashless treatment or reimbursement from Pune, Maharashtra.

The respondents belonged to various demographic profiles. 5-point Likert scale was used to assess the responses of the policyholders. The parameters studied were communication transparency and timeliness, role of TPA and documentation and the overall coordination between various stakeholders.

Findings and Discussion

The findings of the study are presented below. Table 1 represents socio-economic characteristics of the respondents having availed benefits of health insurance. It shows that the sample taken adequately represents population in terms of age, gender occupation, education, marital status, income and healthcare expenditure.

Table 1 Demographic profiles of the respondents: The satisfaction levels of the respondents on various parameters of hospitalization and claim settlement have been discussed. The responses show significant scope for improvement. Most of the respondents were not satisfied with the communication and coordination between hospitals, TPA and insurance companies.

Table 1: Demographic profiles of the respondents

Characteristics	Pune N (%)
Area of residence	
Rural	1.3
Urban	98.7
Sex	
Male	56.5
Female	43.5
Age	
Below 25	5.9
25-40	52.7
40 - 60	35.9
Above 60	5.9
Occupation	
Business	14.8
Govt sector employee	12.2
Private sector employee	43.0
Retired and others	53.4
Education	
School Level	23.2
Graduate	33.8
Post graduate & Above	43.0
Marital status	
Married	89.0
Unmarried	11.0
Gross monthly income	
Less than Rs.20, 000	17.3
Rs.20, 001-Rs.30, 000	17.3
Rs.30, 001-Rs.50, 000	36.3
More than Rs.50, 000	29.1
Monthly percentage income spend on health	
Less than 5%	44.3
5-10%	37.6
10-20%	15.6
More than 20%	2.6

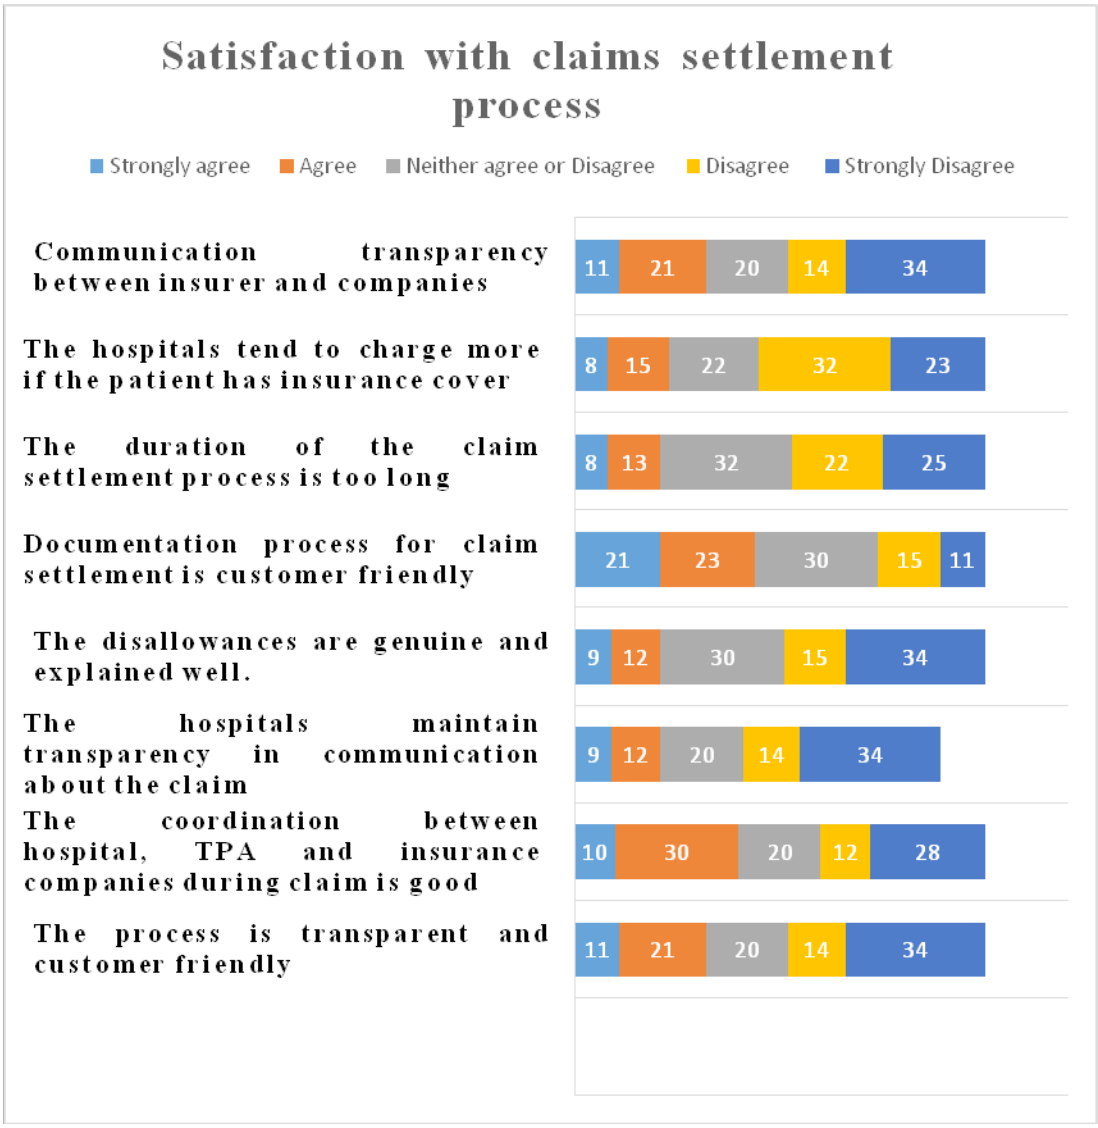

Fig 1 Satisfaction with claim settlement process

Fig 1 depicts the satisfaction levels of the respondents with respect to claim settlement process. Respondents stated that at the time of discharge the documentation process is very lengthy and the disallowances and other parameters are not well explained. This shows that process improvement is needed and communication and coordination needs to be improved to achieve maximum satisfaction level.

When enquired about the transparency and customer friendliness of process of hospitalization and claim settlement only 11 % respondents strongly agreed to the point. The results shows that there is much scope for improvement as the expectation of the policyholders is not being met. Efforts needs to be taken in this regard to make the process more customer friendly.

It is often seen that the communication transparency between insured and the company is not up to the mark. Only 21 % of the respondents agreed that communication was clear enough to understand the deductibles and co-payments.

There is a preconceived notion that the hospitals tend to charge more if the patient is having health insurance. The hospitalisation expenses exceeds than that of the self-paying patients. When enquired regarding the same. 22% respondents were neutral and 32% disagreed to the same.

It is see that the duration of claim settlement is long and exceeds up to 45 days. Often the disallowances in the health insurance policy are exceeding the expectation of

the policyholder and communication and understanding regarding the same is lacking. The respondents were questioned whether the disallowances were genuine or not to which 34% strongly disagreed and 15 % disagreed. This is of importance and ultimately affects satisfaction and further renewal of the policy in the subsequent years.

Hospitals are also one of the important stakeholder in the health insurance administration as the care providers. The role of hospitals in maintaining transparency in communication is important. 22% of the respondents agreed that the communication transparencies maintained.

It is often seen that the coordination between all stakeholders is important determinant of the satisfaction of the policyholders. In the study, it was found to be lacking. This shows that all the stakeholders be it hospitals, insurance companies or TPAs need to improve overall communication and coordination.

Conclusion

Health insurance claims administration involves stakeholders like insurance companies, TPA services, Hospitals stay, facilities and the overall treatment and involvement of agents and advisors. The study shows scope of improvement in the claims administration process. The policyholders experience depends on the coordination, timeliness and transparency in the process.

Recommendations: The claims settlement process needs to be made more customer centric and transparent. At the time of purchase of health insurance policy the policyholders should be explained about the disallowances, co-payments and deductibles. The hospitals and TPAs need to show more coordinated and targeted efforts towards documentation and communication in claims administration.

Relevance of the Study: Health insurance has become a dire necessity of the hour because of increase in the cost of medical care the medical expenses. The customers will purchase and renew policies if their needs are addressed. Results of the study will be helpful for insurance companies and TPAs operating in health insurance sector for improving their claims administration process and overall service quality.

A Study to Assess the Knowledge, Attitude and Practice about Management of Acute Exacerbation of Chronic Obstructive Pulmonary Disease amongst EMS Professionals in Pune, India

Parag Rishipathak[1], Anand Hinduja[2], Shrimathy V.[3], Navnita Sengupta[4]

[1]Professor & Director, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India, [2]Adjunct Faculty, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India, [3]Medical Officer, Academics, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India, [4]Medical Officer, Academics, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India

Abstract

Background: Chronic Obstructive Pulmonary Disease (COPD) is one of the common, slow progressive disorder the respiratory system, considered an important cause of morbidity and mortality across the globe. Although being a chronic disability, COPD presents with acute exacerbations in the form of breathlessness and cough. Knowledge regarding about diagnosis of COPD, appropriate titration of Oxygen and effective management are essential to prevent mortality and morbidity due to COPD.

Objective: To assess the Knowledge, Attitude and Practice level about management of Acute Exacerbation of COPD among EMS Professionals.

Methodology: The study was conducted amongst 100 Emergency Medical Professionals in Pune, India. A previously tested and validated KAP questionnaire prepared by Sylvia Saade et al[2] was utilized for the study. The questionnaire was administered through online mode after obtaining informed consent from the respondents.

Discussion: The analysis of data shows EMS professionals are aware of the aetiology, pathophysiology and clinical features but require more training in management aspects of COPD. In terms of attitude towards COPD, broad agreement was found amongst respondents that COPD patients must quit smoking and passive smoking contributed to COPD. However, opinion amongst respondents with respect to recommendations regarding exercise was divided. In terms of Practices in COPD, broad consensus was found amongst the respondents on the usage and precautions regarding metered dose inhalers (MDI).

Conclusion: The study finding point towards a healthy degree of knowledge, attitude, and practice with regards to COPD amongst EMS professionals. Although the finding do red flag areas of improvement which can be focused upon in future training session. The study is limited by number of respondents yet attempts to provide a broad view on Knowledge, attitude and Practices in COPD.

Introduction

Chronic Obstructive Pulmonary Disease (COPD) is one of the common, slow progressive disorder of the respiratory system, considered an important cause of morbidity and mortality across the globe[1,2]. COPD is projected to be the third leading cause of death by the

year 2030 globally and the second leading cause of death after Road Traffic Accidents in India[3].

Although being a chronic disability, COPD presents with acute exacerbations in the form of breathlessness and cough. This can present as medical emergencies requiring hospitalizations and pose an increased risk of mortality[4].

In early phases of management of acute exacerbation of COPD, sufficient Oxygen must be administered to prevent hypoxemia, but if given in excess it can cause hypoventilation or dangerous hypercarbia. This can lead to fatality. A study by Michael. A. Austin *et al*[5] suggested that routine use of titrated Oxygen in prehospital setup for acute exacerbation of COPD significantly reduce mortality rate compared to high flow Oxygen therapy.

Emergency Medical Professionals are trained to administer Oxygen preemptively in Cardiovascular or Respiratory emergencies to ward off cardiacor respiratory failure, respectively. A study by Goktalay *T et al*[1] emphasized importance of training to the primary care providers for early detection, effective treatment and prevention of complications in case of COPD.

Hence, Knowledge regarding about diagnosis of COPD, appropriate titration of Oxygen and effective management are essential to prevent mortality and morbidity due to COPD.

Objective: To assess the Knowledge, Attitude and Practice about management of Acute Exacerbation of COPD amongst EMS Professionals.

Methodology

The study was conducted amongst 100 Emergency Medical Professionals in Pune, India. A previously tested and validated KAP questionnaire prepared by Sylvia Saade et al[2] was utilized for the study. The original 37 item questionnaire was meant for pharmacists. Only 23 items relevant to the Emergency Medical Professional were retained.

The twenty-three-item questionnaire comprised of three parameters –nine items testing Knowledge of which 4 items were open-ended questions and had to be answered within 25 to 30 words while the remaining 5 items were close ended requiring yes/no answers. Six items measuring Attitude and Eight items measuring Practice related to management of Acute Exacerbation of COPD required response in Likert scale method. All items were required to be mandatorily filled. The questionnaire was administered through online mode after obtaining informed consent from the respondents. The respondents were given two days to fill the questionnaire and revert. Any queries pertaining to questionnaire was clarified during data collection.

All 100 respondents reverted with completely filled questionnaire. The data was tabulated and statistically analyzed with the help of SPSS version 23.

Results

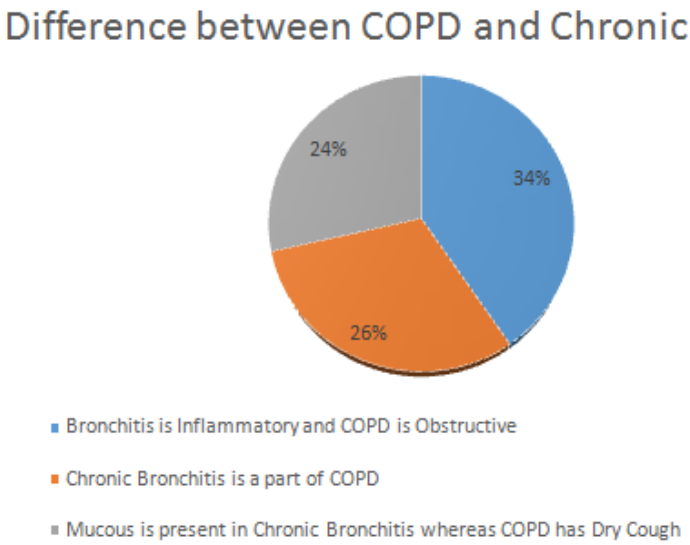

Figure 1

As shown in figure 1. and indicated about difference between COPD and Chronic Bronchitis, 34% of the respondents were of the opinion thatchronic bronchitis was inflammatory while COPD was of Obstructive Pathology.

26% respondents considered Chronic Bronchitis to be a subtype of COPD .

24% stated that COPD presented with dry cough while chronic bronchitis presented with mucoid cough.

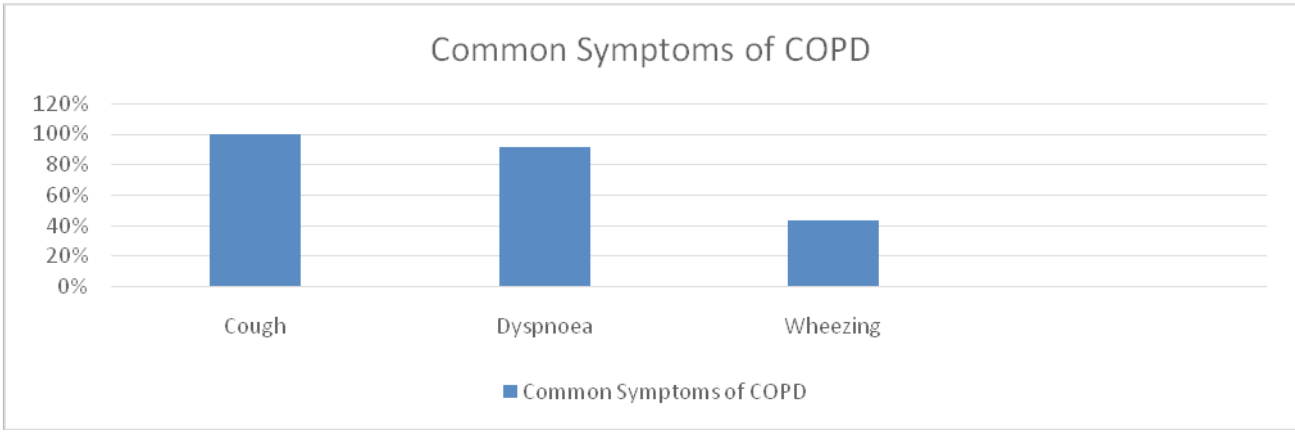

Figure 2.

As seen in figure 2. respondents stated cough, Dyspnea and Wheezing as common symptoms of COPD.

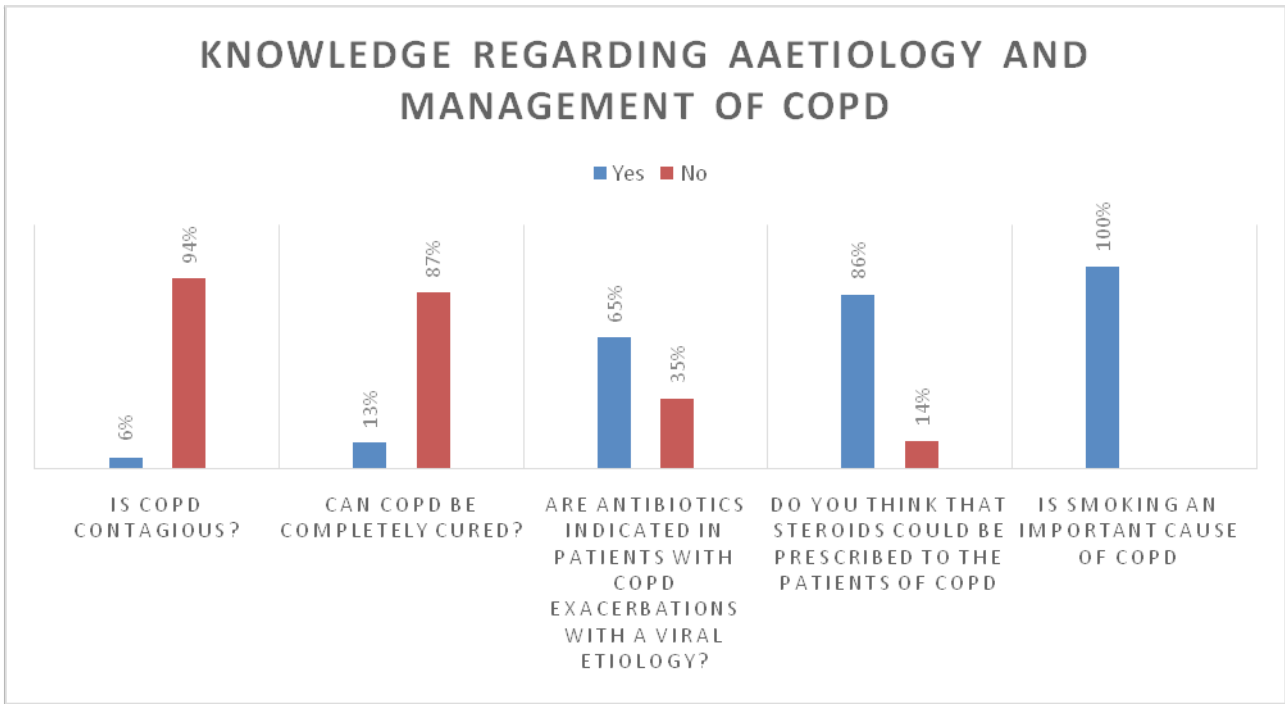

Figure 3.

As shown in figure 3. On the items pertaining to Knowledge regarding aaetiology and management of COPD, as many as 94% respondents felt COPD is not contagious while 87% respondents were of the opinion that COPD cannot be completely cured.

65% believed antibiotics are recommended in acute exacerbation of COPD due to viral aetiology while 86% felt that steroids could be prescribed to COPD patients.

All the respondents attributed smoking to be an important cause of COPD.

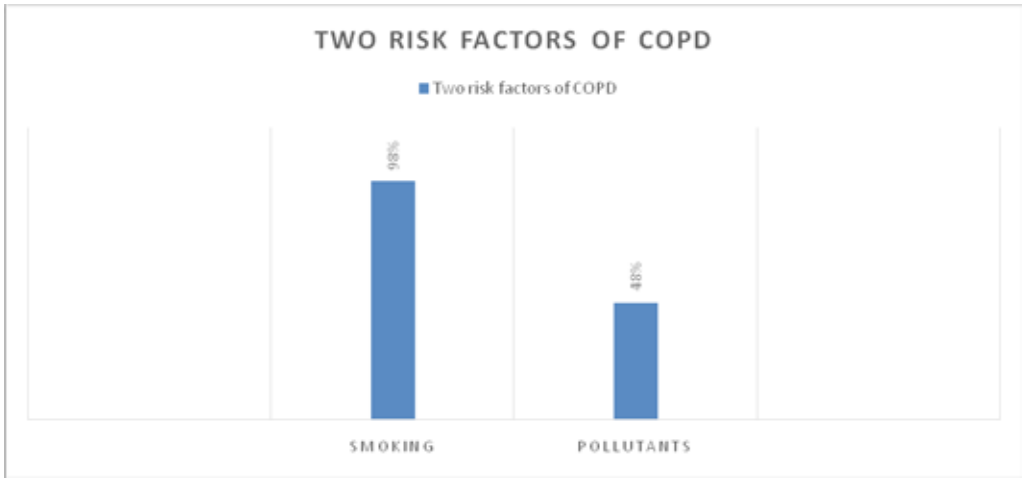

Figure 4.

As seen in figure 4, respondents stated smoking and pollutants as risk factors of COPD.

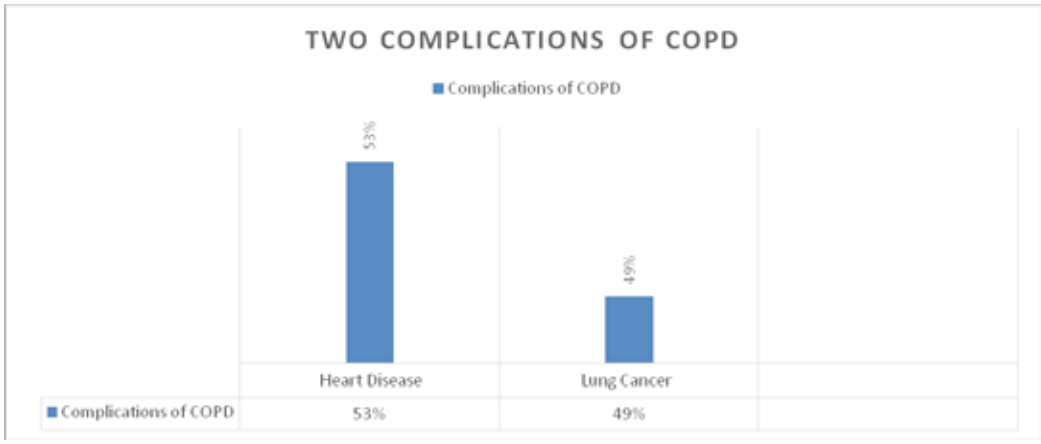

Figure 5.

As seen in figure 5, respondents stated the Heart disease and Lung cancer were common complications of COPD.

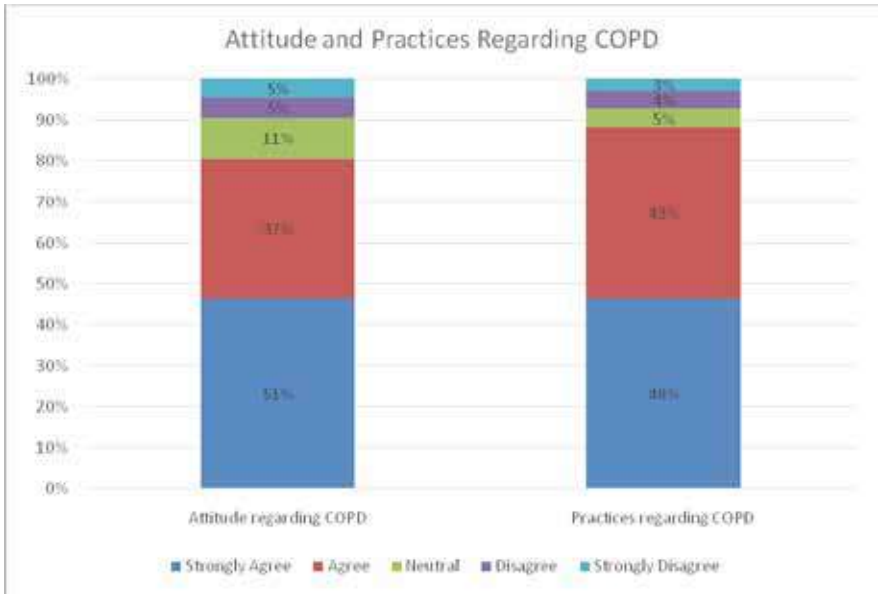

Figure 6.

As seen in figure 6. Broad agreement was found amongst respondents in parameters pertaining to attitude and practices regarding COPD.

Discussion

Most of the respondents were able to correctly differentiate between COPD and Chronic Bronchitis based on clinical picture. They were aware of the common symptoms of COPD. More than half of the respondents stated correctly that COPD is a non-communicable disease and has no permanent cure. All the respondents considered smoking to be an important cause and risk factor contributing to COPD. This shows that the respondents had a clear idea and in-depth knowledge regarding the aaetiology of COPD. In terms of Knowledge regarding management of COPD, most of the respondents correctly stated that steroids could be prescribed to COPD patients. However, more than half of the respondents incorrectly recommended antibiotics for acute exacerbation of COPD due to viral aaetiology. The analysis of data shows EMS professionals are aware of the aaetiology, pathophysiology and clinical features but require more training in management aspects of COPD.

In terms of attitude towards COPD, broad agreement was found amongst respondents that COPD patients must quit smoking and passive smoking contributed to COPD. Majority of the respondents agreed that inhalers and humidifiers are useful in acute exacerbation of COPD and there is requirement of long-term treatment in COPD patients. However, opinion amongst respondents with respect to recommendations regarding exercise was divided.

In terms of Practices in COPD, broad consensus was found amongst the respondents on the usage and precautions regarding metered dose inhalers (MDI). Majority of respondents believed that counselling the patient about worsening of situation and admission to tertiary care hospital during an exacerbation was essential.

Conclusion

The study finding point towards a healthy degree of knowledge, attitude, and practice with regards to COPD amongst EMS professionals. Although the finding do red flag areas of improvement which can be focused upon in future training session. The study is limited by number of respondents yet attempts to provide a broad view on Knowledge, Attitude and Practices in COPD.

Effect of Facilitated Tucking on Physiological and Behavioural Responses to Pain among Infants Receiving Vaccination

Mercy Joseph[1], Reshma K. Sasi[1], Alphonsa Michael[2], Amrutha C.[2]

[1]Lecturer, Department of Child Health Nursing, Amrita Vishwa Vidyapeetham,, Kochi, Kerala, India,
[2]Vth Year B.Sc. Nursing, Amrita Vishwa Vidyapeetham,, Kochi, Kerala, India

Abstract

Objective: To evaluate the effect of facilitated tucking on physiological and behavioural responses to pain among infants between experimental and control group before and after the IM vaccination

Method: A quantitative approach with true experimental design and consecutive sampling technique was used in this study. Researcher selected 100 infants up to the age of 6 month receiving IM vaccination in the immunization clinic, AIMS, Kochi, and they are randomly assigned to control and experimental group. Demographic and clinical data was collected using structured interview schedule. Heart rate and SPO2 was monitored 2 minutes prior to the vaccination and facilitated tucking was given to the experimental group before and during the immunization and routine position was given to the control group, after that behavioural response was assessed by using neonatal infant pain scale and physiological response such as heart rate and SPO2 was assessed after 5 minutes.

Result: The result showed that all the subjects in the control group had severe pain 100 %, whereas in the experimental group 50 % of the subjects had moderate pain and 50% of them had mild pain**.** Also there was a significant difference in the mean score of the physiological and behavioural response between the control and experimental group after the intervention

Conclusion: The study revealed that the Facilitated Tucking improves the emotional security and reduces the pain perception. The nurse or care givers can effectively implement facilitative tucking for reducing pain during vaccination in any setting as it is a very simple technique.

Introduction

Pain in newborns is a complicated, individualized, subjective, and universal finding[1]. The most common painful procedures performed during infancy are routine injections without pain management[2]. Vaccinations are first administered when babies are very young. An immunological product used to confer active immunity to a person against a particular disease is called vaccination. The process of producing artificial immunity in a subject is called immunisation[3]. Studies have shown that uncontrolled pain experienced during the early stages of life has negative and long-term side effects, such as distress, and that such pain negatively affects the development of the central nervous system[4].

The most important problem encountered while evaluating pain in newborns is the inability of babies to express pain verbally. Physiological parameters, behavioural method, and stress hormones have been evaluated to define the pain felt by newborns[5]. Pain experienced by newborns affects the heart rate, respiration rate, blood pressure, and tissue oxygenation,

Ph. No.: 8281528714

potentially causing these parameters to decrease or increase [6].

Pharmacological method used to relieve pain in newborns are reported to have side effects . Non-pharmacological and pharmacological method are considered for pain relief by health stuff [7]. One method of non-pharmacological method is the facilitated tucking; it is defined as "a sub-form of method of nesting the baby and the procedure of bringing the body to middle or even close position by holding the upper and lower extremities of the baby in flexion with hands." An infant can be held in the lateral, supine, or prone position while this method is performed [8]. It has been reported to prompt infants own regulatory systems, prevent painful stimulants coming from the outside world, and reduce the pain felt by the infant by enabling heat and touching stimuli [9]. In addition, this method stabilizes infants physiological parameters and helps them gain a feeling of safety based on the position, supports their motor development, and preserves their energy [10].

A semi–experimental study was conducted on the effect of Facilitated Tucking (FT) during Venipuncture on duration of crying in preterm infants. In this study, 70 preterm infants born at average 32 to 36 weeks' Gestational age (GA), who needed routine blood collection, were allocated to two intervention (35 neonates) and control (35 neonates) groups. In experimental group a nurse gave facilitated tucking to the infant. The results showed that the duration of crying after sampling in the two groups was statistically significant difference, this duration in control group was higher than the intervention group (P<0.05)The results of this study indicate that the facilitated tucking is effective in reducing the duration of crying infant.[11]

The primary responsibility of a nurse is to ensure that pain-relieving method are performed before and after a procedure during routine practices in addition to determining and relieving the pain. The purpose of this study was to evaluate the pain perceptions of infants during vaccinations performed in the facilitated tucking position and the classical holding position respectively.

Method

The present study used the quantitative approach with true experimental design and consecutive sampling technique. After obtaining the ethical committee clearance from the institution and informed consent by the mothers researcher selected 100 infants up to the age of 6 month receiving IM vaccination in the immunization clinic, AIMS, Kochi, and they are randomly assigned to control and experimental group . Demographic and clinical data was collected using structured interview schedule. Heart rate and SPO2 was monitored 2 minutes prior to the vaccination and facilitated tucking was given to the experimental group before and during the immunization and routine position was given to the control group, after that behavioural response was assessed by using neonatal infant pain scale and physiological response such as heart rate and SPO2 was assessed after 5 minutes.

Results

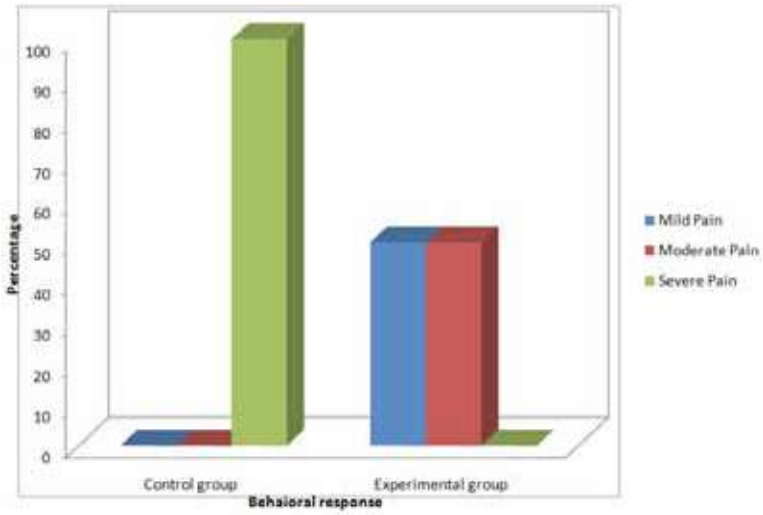

Fig 1: Distribution of subjects based on their behavioural response

The data depicts in the figure (1) shows that all the subjects in the control group had severe pain 100 %, whereas in the experimental group 50 % of the subjects had moderate pain and 50% of them had mild pain**.**

Table 1: Mean and standard deviation of physiological respons

	Control Group				Experimental Group			
	Min.	**Max.**	**Mean**	**Sd**	**Min.**	**Max.**	**Mean**	**Sd**
Heart rate before intervention	102	180	143.36	16.219	103	188	133.28	18.449
Heart rate after intervention	125	209	163.14	19.960	112	190	143.86	18.707
Oxygen saturation before intervention	97	100	99.82	.629	96	100	99.60	.857
Oxygen saturation after intervention	95	100	97.76	.938	97	100	99.16	.912

Table (2) shows that mean heart rate and SPO2 before and after the intervention in the control group were 143.36 +/-16.219, 163.14 +/-19.960, 99.82 +/--.629, 87.76 +/- .938, and the experimental group were 133.28 +/--18.449, 143.86 +/- 18.707, 99.60 +/- 0.857, 99.16 +/- 0.912 respectively .

Table 2 : Mean and standard deviation of behavioural response

	Control Group				Experimental Group			
	Min.	**Max.**	**Mean**	**Sd**	**Min.**	**Max.**	**Mean**	**Sd**
Behavioral response	6	7	6.92	0.274	6	7	6.92	0.274

The mean and standard deviation of behavioural response in the control and experimental group were 6.92 + 0.274, 6.92 + 0.274 respectively.

Table 3: Effectiveness of facilitated tucking on behavioural response

Behavioral response	**t –value**	**Df**	**p value**
Control group	-29.190	98	.0001**
Experimental group			

**: Highly significant

The above table (4) reveals that there was a significant difference in the mean score of the behavioural response between the control and experimental group after the intervention.

Table 4: Effectiveness of facilitated tucking on physiological response

Physiological response	**t -value**	**df**	**P value**
Heart rate	-4.983	98	.0001**
SPO2	7.568	98	.000**

** : Highly significant

The above table (5) reveals that there was a significant difference in the mean score of the physiological response between the control and experimental group after the intervention

Table 5 : Correlation between the behavioural and physiological response

Variable	**r value**	**p value**
Heart rate	0.489	0.001
Behavioral response		
SPO2	-0.630	0.001
Behavioral response		

Table (6) shows that there is a positive correlation between heart rate and behavioral response (r value is 0.489, p value is < 0.001 and there is negative correlation exits between SPO2 and behavioral response (r value is -0.630, p value is < 0.001)

Table 6: Association between physiological response with selected demographic variables

	Value	df	Level of significance
Age of the child	16.964	2	.0001**
Birth weight of the child	4.010	4	.405
Type of vaccine	18.721	2	.0001**
Order of vaccine	12.176	4	.016 *

*: Significant, **; Highly significant

The above table (7) reveals that there is a significant association between the physiological response and selected demographic and clinical variables such as age of the child, type of vaccine, order of vaccine.

Discussion

Facilitated Tucking is one of the simplest non pharmacological and cost effective techniques simulating the condition of being in uterus. This makes the infant comfortable, more secure with controlled response. It facilitates self-regulation by decreasing the physiologic response like prolonged heart rate elevation that contributes to the disequilibrium associated with pain and stress.

A study was conducted on a cohort of preterm infants (n = 42), divided into control (n = 21) and treatment (n = 21) groups, to determine the effect of facilitated tucking on pain relief during venipuncture on preterm infants in the neonatal intensive care unit. The severity of pain was measured using the Premature Infant Pain Profile score. The primary outcome measure was reduction in the Premature Infant Pain Profile scores. The Premature Infant Pain Profile score for the treatment group was significantly lower (M = 6·62, SD 2·598) than for the control group (6·62 ± 2·60, 8·52 ± 2·99 respectively, t = −2·202, p < 0·05).[12]

In the present study, the result shows that all the subjects in the control group had severe pain 100 %, whereas in the experimental group 50 % of the subjects had moderate pain and 50% of them had mild pain**.** Also there was a significant difference in the mean score of the physiological and behavioural response between the control and experimental group after the intervention

The above two studies shows that the facilitating tucking is very effective way of non –pharmacological method for reducing pain in infants. Therefore, the health care professionals must identify the distress and discomfort shown by babies to routine immunization, regarding pain perception, assessment and management in infants.

Conclusion

Facilitated Tucking improves the emotional security and reduces the pain perception. The nurse or care givers can effectively implement facilitative tucking for reducing pain during vaccination in any setting as it is a very simple technique. This motivated the investigator to take up an iniativeness to teach the health care professionals to practice facilitated tucking while giving vaccination. In this study the investigator aims to assess the effect of facilitated tucking on physiological and behavioural responses of neonates undergoing IM vaccination and it was concluded that the non-pharmacological method used was very effective

A Cross-Sectional Study to Estimate the Presence of Anxiety in Injured Cricketers

Bindya Sharma[1], Yashasree Patil[2]

[1]*Assistant Professor, D.Y. Patil Deemed to be University, School of Physiotherapy, Nerul, Navi Mumbai, India,*
[2]*Intern, D.Y. Patil Deemed to be University, School of Physiotherapy, Nerul, Navi Mumbai, India*

Abstract

Purpose: State anxiety is an unpleasant psychological state experienced by cricketers due to perceived performance stress. It is often an overlooked criterion for return to sports after an injury. There is a need to evaluate presence of anxiety as it leads to physical symptoms and hence injury. Mental training is a very important tool for handling anxiety but there is lack of training which further predisposes players to re-injury. This study aims to evaluate presence of anxiety in cricketers who have suffered sport-related injury and have returned to play. It also explores the method used by these cricketers to handle anxiety.

Method: 60 injured cricketers were selected based on inclusion and exclusion criteria. A baseline questionnaire was prepared to collect basic demographic data and Sports Anxiety Questionnaire (SCAT) which is a self-administered scale was included to determine presence of anxiety. Anxiety scores were calculated to determine the players level of anxiety.

Results: It was found that 65% players experience high anxiety, 32% had average anxiety and 3% had low anxiety levels. 45% of players reported re-injury.

Conclusion: Undiagnosed anxiety was found to exist in injured cricketers which may predispose them to re-injury. All the players were aware of mental training techniques but reported lack of guidance and professional help.

Keywords: *Anxiety, SCAT, cricket, injury, mental skills training, return to sport.*

Introduction

A sports injury has both physical and psychological consequences for the athlete. It can be viewed as part of a continuum where psychological factors are known to predispose an athlete to physical injury and physical injury can, in turn, lead to deteriorating psychological reactions. Psychological factors have been shown to be an important antecedent to the onset of athletic injuries and also play an important role in injury rehabilitation and ultimately successful return-to-play.[1] Evidence suggests that competitive athletes returning to sport following injury rehabilitation may experience a range of psychosocial concerns, like anxieties associated with re-injury, concerns about an inability to perform to pre-injury standards, feelings of isolation, a lack of athletic identity etc. These may adversely affect their return to sports performance.

Anxiety is an unpleasant psychological state experienced by cricketers due to perceived performance stress[1]. Cricket is a popular game in India wherein the demands of the game is more mental than physical. On one hand, it requires speed and precision and on the other hand, it requires strategic planning, focus and concentration. There is ample evidence suggesting the

Chunabhatti, Sion, Mumbai–400071
e-mail: bindya.sharma@dypatil.edu

positive effects of anxiety on sporting performance in terms of physiological and physical readiness of the athlete. Smith and Smoll's proposed a conceptual model stating that when faced with a competitive sporting situation, an individual will make cognitive appraisals of the situation. These cognitive appraisals have a reciprocal relationship with physiological arousal. Hence anxiety, which causes a positive physiological arousal can turn into a negative outcome, if it remains unchecked.[2]

The concept of sports performance traditionally included participation in activities related to regular practice and competition; however, more recently, this has also included performance in activities that relate to sport injury prevention, rehabilitation, and the return to sport process[1,3]. To date, research has focused extensively on the role of anxiety in sports performance, to greater extent in injury occurrence and to some extent on injury rehabilitation. There is scarcity of studies on the presence of anxiety and its role in return to sports.

The deteriorating psychological responses are generally greatest immediately after sports injury and lessens during the rehabilitation process. However, they often rebound prior to return to sports, consistent with a U- pattern of recovery. If unaddressed and unresolved, these elevated psychological responses to the injury can slow rehabilitation progress and delay return to sports.[4]

After an injury, emphasis is often placed on the physical ability as a criterion to return to sport and not the psychological component. Psychosocial readiness is one criterion for return-to-play and it is essential the team physician understand that physical clearance to return-to-play may not correlate to psychological readiness. It is desirable that the team physician coordinate the athletic care network to monitor the psychological readiness of athletes who are preparing to return-to-play or have returned-to-play and coordinate psychological support services as needed.[3] Some of the most commonly used psychosocial interventions practiced by sportsmen include goal setting, imagery, relaxation strategies, and positive self-talk. Mental training is a very important tool for handling anxiety but there is lack of training for its correct application, which further predisposes players to re-injury.

With the above background in mind, there is a strong necessity to evaluate the presence of anxiety by means of easy clinical measures or pre-participation screening after an injury. There is a need to incorporate psychological readiness as a return to sport criteria. The need for our study was to find out presence and degree of anxiety in injured cricketers and the strategies implemented to handle their anxiety.

Methodology

The STROBE guidelines for reporting cross-sectional study was followed in writing this article. The study is a descriptive cross-sectional design. The objective of this study was to specifically identify anxiety in cricketers who have sustained an injury or injuries related to their sport. A minimum sample size of 60 was calculated. With regard to the primary aim of the study, sample size calculation indicated that at least 60 participants were needed to detect with a precision of 10% that 1 out of 20 cricketers suffer from a sports injury (power of 80%; confidence interval of 95%).

Independent Variables:

Injury in cricketers: Research has indicated that muscle injuries such as hamstring strains, groin strains and low back pain are the most common cricket injuries. On average, around 9% of cricketers have an injury at any given time, although in fast bowlers over 15% are injured at any given time. These injuries are due to the repetitive functional demands of the sport like sprinting and ball throwing

While injury incidence of these injuries has been largely studied in professional cricket, knowledge about the mental health among professional cricketers in general and specific to the impact of injury is still lacking.

Dependent variable:

Anxiety: Anxiety is one of the conditions seen as part of the common mental disorders seen in high performance athletes. In our study Sports Competitive Anxiety Test was used to measure levels of anxiety in the injured players. This scale was developed by Martens in 1977 and it aimed at measuring situation specific (competitive) trait anxiety. Trait anxiety predisposes one to perceive certain situations as threatening and to respond to these situations with varying level of state anxiety. Thereby implying that individuals with high trait anxiety tend to translate that anxiety into state anxiety. The SCAT is a self-administered Likert scale which contains 15 items, 10 of which measure symptoms associated with anxiety, with five others that

are not scored were included to reduce the likelihood of an internal response-set bias. The scores for the 10 items are summed to provide an overall measure, with a high score reflecting a greater tendency to experience competitive anxiety. A score of less than 17 indicates a low level of anxiety, 17 to 24 an average level of anxiety, and more than 24 a high level of anxiety.[9,10.]

Re-injury: It has been extensively suggested by researchers that anxiety leads to cognitive and somatic changes. These physiological changes hamper one's ability to focus and increases muscular tension.[1,12] This predisposes the cricketer to further injury. In our study, the cricketers were asked to self-report any injury or injuries experienced after the primary injury.

Procedure: Sixty participants were approached based on the selection criteria as semi-professional cricketers, having injury while playing cricket or during practice sessions, age group of 20-40 years and exclusion criteria of injury unrelated to the game. An electronic based form was administered to them which collected baseline information on demographic data, position in the game, injury related information, areas of injury, re-injury after the primary injury, mental training practices along with SCAT, which is a self-administered scale. It had instructions to answer how one feels when competing in sports. Out of 60, 12 participants did not respond even after verbal consent to participate in the study. We received 48 responses out of which 5 responses were above the age criteria as calculated by their date of birth and 3 responses had an injury about 8-9 years back. These responses were not taken into account as outliers in the study. Thesecricketers played 3 hours ± 1.8 on an average for 4 days a week ± 2, mean age of 28 years ±4.5, playing cricket since 10 years. They reported having injury since mean 4.5 years ±2.8. According to their position in the game, 45% were all-rounders, 22% batsman, 20% bowlers and 12% wicket-keeper. Descriptive statistics in the form of mean, median and standard deviation was used to calculate the results of this study.

Graph 2 inference: 45% of the population had re-injury and 55% did not suffer any re-injury

Graph 3 inference: Rate of re-injury incricketers suffering from high anxiety and moderate anxieties.

Inference: Commonly practiced mental training techniques.

Discussion

The findings of our study suggest that there was presence of anxiety in almost all players, with 65% (27±1.7) representing high level of anxiety and 32% representing average level of anxiety (22±2.36) Findings of similar study done in footballers suggests that the prevalence of mental health complaints ranged from 5% (burnout) to 26% (anxiety/depression) in 149 current players and from 16% (burnout) to 39% (anxiety/depression) in 104 former footballers.[13] Studies also suggest that injured players had higher scores for depression and anxiety than uninjured players, as previously described.[14] SCAT is a tool to measure trait anxiety which is an innate and relatively stable part of one's personality.[5,8,9] Individuals who have high level of trait anxiety have a tendency to perceive situations as potentially threatening and they consequently tend to experience more state anxiety. Evidence appears to affirm the role of not only trait anxiety but, other psychosocial factors such as stress, state anxiety, and daily hassles as potentially contributing to injury.[7] The SCAT scale has known to demonstrate a strong reliability (0.77–0.95).[5]

In our sample, we found out most common areas of injury were shoulder (28%), knee (21%), back (19%), wrist (16%), ankle (13%) and foot (2%). Since the sample size was very small, there was inconclusive results to link the of site of injury to the position of the players in the game of cricket. Maximum players were all-rounders.

Re-injury was reported in 45% of the players. This finding is supported by Podlog and Eklund who stated that re-injury anxiety during the return to sport phase can be detrimental for an athlete as it can lead to an increased risk of re-injury or secondary injury. Maximum players who had re-injury were found to have high anxiety levels. It is an established fact that high anxiety equates to high arousal. The spiraling effects of uncontrolled arousal are well documented as feelings of stress, unease, and worry that narrows the visual field, increase muscle tension, and increase distractibility, which in turn would subsequently disrupt the feed-forward and feed-back neuromuscular control required throughout athletic participation, leading to injury. it has been stated that reinjury anxiety, as compared to fear of reinjury, is more of a negative thought or worry of the consequences of injury (eg, additional surgery and more time in rehabilitation) while fear of reinjury is specific to fear of the injury itself. As there is no certainty about the extent of reinjury risk and situations, athletes possibly have more reinjury anxiety as opposed to fear of reinjury or these can occur together.[12] According to a study carried out at the IAAF World Championships in Athletics 2015, the anxiety experienced by elite athletes over illness symptoms is linked to the risk of being injured during competition and should be taken seriously.

An interesting finding of our study was the awareness and usage of mental training techniques. The cricketers reported using mental training to cope with anxiety, however it was not under guidance of a professional. The most used technique followed by our sample was positive self-talk and goal-setting. This highlights another lacuna in the domain of psychosocial rehabilitation of injured cricketers and as clinicians we should make efforts to work with sport psychology professionals in understanding and implementing techniques to improve athletes' coping mechanisms with the goal of decreasing anxiety.

Limitations and strengths of the study: There were drop-outs in our study leading to a smaller sample size. Additional samples could not be collected as this project was part of a time-bound internship completion for one of the authors.

Our sample consisted of club cricket/ semi-professional players; hence generalization of the results cannot be made, especially for elite cricketers. Elite cricketers would have better coping mechanisms and more awareness about the implementation of mental training strategies as compared to our sample.

The scale used to measure anxiety (SCAT) is a very old version. There are several new scales available but the author of this study has gone through the work of Martens (1977) and was convinced that this scale had the robustness to measure trait anxiety leading to state anxiety, thereby dealing with both components of anxiety. SCAT is also a Likert scale which accurately gives the level or degree of agreement on an item that is being measured. Hence more definitive responses are achieved. It justified the objective of our study which was the determine the presence and level of anxiety in the players.

The dependent variable of re-injury was self-reported by the players and we did not measure the intensity of either the primary injury nor the re-injury. This maybe a confounding variable in the interaction between anxiety and re-injury.

Our study implicit anxiety as one of the factors that may have contributed to re-injury. The confounding variable of physical strength, as criteria to return to sport, was not explored in our study. However, our baseline questions included use of physiotherapy rehabilitation services after injury to which the mean responses were positive.

Also, due to limitation of sample size, there was inconclusive findings on level of anxiety in different types of players in the game of cricket. Future research can be directed towards exploring the level of anxiety in bowlers, batsmen, fielders and wicket-keepers.

Conclusion

Undiagnosed anxiety was found to exist in injured semi-professional cricketers which may predispose them to re-injury. All the players were aware of mental training but reported lack of proper guidance and professional help.

Implications: The findings of this study can help physiotherapists to identify anxiety as a potential risk for re-injury. It also highlights the importance of mental/ psychological rehabilitation along with physical rehabilitation.

Conflict of Interest: There is no conflict of interest

Abstract

Vasculitis where underlying cause is not known is often related as Kawasaki Disease. It's important to know about such auto immune conditions as it directly affects the vessels of the heart and is responsible for death at an early age. The peculiarity of the disease is its characteristic oral manifestations which are often misdiagnosed as an oral disorder. Dental examination has a vital role in improving the diagnosis of auto immune conditions as auto immune conditions primarily manifest oral signs in their early stage. So, early diagnosis can drastically improve the treatment outcome of the disease and quality of life.

Keywords: *Kawasaki, vasculitis, Z score, auto immune.*

Introduction

Acute diffuse vasculitis without underlying etiology targeting mainly infants and young kids is known as Kawasaki Disease or Mucocutaneous Lymphnode Syndrome[1] and appearance of partial signs and symptoms is known as Incomplete Kawasaki Disease.[2]

The disease is not specific to any race but usually Asians are comparatively at a higher risk of getting affected.[3] By year 1990 only 3 published reports of Kawasaki disease existed in India but the number increased to 161 publications in span of twenty years.[3] First two case series in India were reported from Thiruvanthapuram and Chandigarh.[3] Incidence of 0.51 per 1,00,000 children under 15 years of age increased to 4.5 per 1,00,000 children under 15 in 2007, as reported by hospital based study in Chandigarh.[3] Till date an increased incidence rate of KD is seen in Northeast Asian and South Central Asian countries including India. As mentioned incidence has increased from 0.51 to 4.5 per 1,00,000 children under 15 by 2007. The uniqueness of the disease is that it is still often misdiagnosed and due to oral manifestations either the patient continues to receive treatment from a dental professional or due to persistent fever patient receives treatment for the commonly prevalent bacterial or viral infections. The most common reason for this has been identified is the lack of awareness about the disease.[2]

Kawasaki is often misdiagnosed with common febrile illness, viral or bacterial infections. The oral manifestations of the disease like bleeding gums, inflamed oral mucosa, coated tongue etc. Also often misleads the diagnosis. Lack of appropriate treatment can even lead to death.

Case History:

Patient's History: A 3 year old baby girl patient presented with the history of high grade fever recorded maximum of upto 104°F accompanied with chills. The oral acceptance of food was compromised and decreased urine output. There was a history of cold and cough and chronic recurrent tonsillitis, redness of oral mucosa and tongue with black coated appearance and inflammed papillas and Enlarged Tonsils **(Figure 1, 2 and 3).** Warm saline rinses, oral prophylaxis and multivitamins were started on consultation with a dental specialist and ENT. Patient was given Paracetamol, Augmentin syrup

Corresponding Author:
Kuldeep Dhanker
Assistant Professor, Public Health Dentistry, School of Dental Sciences, Sharda University, Greater Noida

and cough syrup at home for 8 days but, there was no improvement.

Clinical Manifestations (Table 1): Tongue had a characteristic strawberry appearance. Throat was congested with conducted sounds from the chest and abdomen was soft on examination. Bilateral cervical lymphadenopathy of size 1.5 * 1.5 cm and Bilateral tonsillar enlargement was present.

Diagnosis and Treatment: Patient was diagnosed with fever of unknown origin. Immediate hospitalization of patient was done and I/V monocef, amikacin and rantac was given. Patient was unresponsive and no improvement was observed so 2-D Echo, X-Ray chest, Ultrasound of Abdomen and Blood Investigations comprising of Fever Panel 3 was advised for the patient **(Table 2 and 3)** Echo revealed the Z score of 2.18 and other blood investigations were suggestive of Incomplete Kawasaki Disease. There was no history of conjunctivitis, skin peeling, burning micturation and loose stools.

Immediately after diagnosis immunoglobulin G I/V, 2gms/kg,over 24 hours for a period of four days under hemodynamic monitoring was administered to the patient and tablet aspirin 30 mg/kg/day was given orally.

Treatment Outcome, Evaluation and Follow up: Child well tolerated the infusion and initial investigations post IVIG revealed raised ESR (102 mm in 1st hour), serum prolactin 1.96 ng/ml, Hb was 8.1g/dl, platelet was 6.38 lakhs and CRP was raised to 70mg/L. Liver and Renal functions were normal. Repeat ECHO was done which was normal. There were episodes of fever and 3 episodes of vomiting post I/V IG but it subsided with supportive management. Post IG therapy patient was kept on 75 mg Aspirin half tablet for 6 weeks OD. Patient was on constant follow up for the period of 6 months in which blood levels and an echo finding appeared to be normal and after that patient was advised for a review yearly with the basic blood test and 2-D echo.

Discussion

Kawasaki was described for the first time in the year 1967 by Tomisaku Kawasaki in the Japanese literature and in the year 1974 in the English literature.[4] He published a report of 50 patients and since then it has been one of the commonest factor for heart disease in Japan and North America.[5] In Asian continent the incidence of Japan, South Korea and Taiwan has been maximum.[6] In Japan the incidence of the disease was stated to be around 239 cases in 1,00,000 children under the age of 5 years.[2] Incidence of KD is also on rise in the Indian subcontinent as now more number of cases is reported in the literature.[7]

The underlying etiology of Kawasaki is still not clear but often individuals with compromised immunity become the target. Some of the most common organisms that are usually considered to originate the infection in such individuals are parvovirus, staphylococcus aureus, EB virus and mycobacteria.[1] Recent data correlates the severity of the disease with genetic predisposition. Superantigens like toxic shock syndrome is found to be the most suspected cause.[4]

The diagnosis of the disease is based on the characteristic history, physical findings followed by specific diagnosis kit. Raised inflammatory markers like ESR, CRP, neutrophil count are usually associated with the acute phase of the disease. Differential diagnosis of KD can be measles, scarlet fever, CMV, EBV etc.

Disease course is divided into three phases:[1]

1. Acute Febrile Phase: it exists for 7 to 14 days and ends with the resolution of fever. Conjunctivitis, erythematic changes in the oral cavity and extremities, rashes and cervical lymphadenopathy.
2. Subacute Phase: Time span from resolution of fever till end of 25 days. Desquamation of fingers and toes is observed, arthritis and thrombocytosis.
3. Convalescent Phase: clinical symptoms begin to disappear and ESR becomes normal.

In Classical case of KD fever persists for a minimum period of 5 days along with characteristic features of different phases. Cardiovascular manifestations mainly coronary aneurysms can be prominent in the acute phase and if untreated can be the leading cause of mortality. If the clinical criteria of the disease are not complete than Kawasaki is referred as Incomplete Kawasaki. The patient was categorised as the case of Incomplete Kawasaki as the changes in Z score were there but not that significant and the clinical features were also partially visible like strawberry tongue, cervical lymphadenopathy, rashes and fever. But incomplete Kawasaki should not be considered as mild form of KD.

Kawasaki has another important clinical sign usually seen in babies less than a year, reaction at BCG vaccination site but is not included in the classical

clinical criteria of KD.[8] Any redness or crust formation on site of inoculation should never be ignored as it can be suggestive of KD and should always be considered as the differential diagnosis of any febrile illness of unknown etiology or vasculitis.[8] American heart association suggests that children with fever not subsiding for 5 days or more, elevated CRP and ESR levels should go for Echocardiographic findings to rule out KD.[9]

The management of Kawasaki includes I/V immunoglobulin G and aspirin followed by periodic check up and repeated echocaridography. Standard dose of IVIG is 2g/kg of body weight in first 10 days along with high oral dose of aspirin around 80 to 100 mg/kg/day divided in different doses.[2]

06.07.2018 (Boston Score)	3.1mm (Z score = + 1.74)	2.3 mm (Z score = + 1.4)		2.3 mm (Z score = + 1.17)
23.11.2018 (Kobayashi Score)	2.3mm (Z score = + 0.26)	1.9 mm (Z score = + 0.23)	1.4 mm (Z score = -0.7)	2mm (Z score = + 0.25)

Figure 1: Erythematous changes observed on the tonsils.

Figure 2: Erythematous changes observed on the palate (Red Petechiae present on Soft Palate).

Figure 3: Blackish Discoloration of Tongue

Conclusion

The presentation of this case is with the motive to raise awareness about the fact that self medication can sometime prove to be fatal and conditions presenting with characteristic features should not be ignored. Oral health opens the door to systemic health so oral manifestations should be dealt carefully.

Abstract

The analysis of the inspection of the employees of Uzagrotehmash JSC was performed. A total of 1495 people aged 25-75 years have been examined (average age 46.3±0.3 years). The frequency of hypertension was 598 people. High blood pressure was recorded more often in women (25.9%) than in men (16%), hypertension is much more common at the age of 44-60 years and older, and hypertension has been found to be common in overweight people (31, 6%), a large proportion was found in the structure of hypertensive patients with hypodynamia (50.2%). Among the protesters, 26.9% of people know about high blood pressure, but do not treat it, and in 20.0%, high blood pressure was detected for the first time. The role of serum lipoproteins in the hypertension development was confirmed, which allows patients to be assigned to a high-risk group for the formation of cardiovascular diseases in subsequent life periods.

Keywords: *Blood pressure, risk factors, hypertension, dyslipidemia, prevention, risk, apolipoproteins A1 and B.*

Introduction

Arterial hypertension is a serious public health problem due to a further increase in its prevalence, as well as a lack of adequate control[1]. The prevalence of arterial hypertension in economically developed countries is 20-50% and is one of the main factors of disability and mortality in the population[2]. At the same time, the continuing increase in the incidence rate and the defeat of people of an increasingly young age makes cardiovascular diseases a major medical and social problem.[3]

Arterial hypertension leads to myocardial infarction and stroke, hear and renal failure[4]. Blood pressure at the preclinical stage in most cases is increased moderately, which is accidentally detected during preventive examinations[5].

Official statistics in assessing the disease prevalence are based specifically on the reversibility analysis, when the fact of the disease has already happened, and preventive measures are not so effective[6]. The registered incidence rate in the adult population is 2.3 times lower than the actual prevalence of this pathology. Thus, the appealability analysis does not allow us to evaluate the entire scope of the problem facing practical healthcare[7]. The most complete picture of the disease prevalence, its structure, severity can be given by epidemiological studies, and new preventive technologies development suitable for a specific age group can be realized only by analyzing a real existing epidemiological situation[8].

The situation is complicated by inadequate hypertension control in the population. At the same time, it is known that effective control of high blood

pressure reduces cardiovascular morbidity and mortality in patients with arterial hypertension. However, other factors influence the prognosis of the disease, which is reflected in the classification of arterial hypertension[6].

Epidemiological studies conducted in various countries showed the presence of ethnic characteristics in the prevalence of cardiovascular diseases[1]. The presence of these features, in addition to lifestyle, culture, environmental factors, etc., is determined, among other things, by genetics, whose role in the formation of cardiovascular pathology has been convincingly proved[4]. An important place in the development of cardiovascular diseases is occupied by overweight and metabolic disorders associated with it, smoking, stress, lack of exercise[2,5].

According to statistics, in Uzbekistan, among the causative factors of disability and mortality are diseases that occur with an increase in blood pressure[6].

Serum lipid values are the main tools for risk stratification in dyslipidemia. Serum cholesterol concentrations of low-density lipoproteins (LDL cholesterol) and high density (HDL cholesterol) are the most used lipid classes for this purpose[7]. Meanwhile, the quantitative indicators of LDL and HDL particles - apolipoproteins B (ApoV) and A1 (ApoA1), may be better risk markers than their cholesterol concentrations - LDL cholesterol and HDL cholesterol and the atherogenicity index (AI) traditionally used in domestic medicine[8].

Based on the foregoing, the study of the arterial hypertension prevalence and its risk factors, the creation of an adequate system for the prevention of cardiovascular diseases seems relevant for public health of the Republic of Uzbekistan.

The Aim of Research: To study the prevalence of arterial hypertension and risk factors for its development, using the example of Uzagrotehmash JSC employees examination, as well as assess the possibility of different classes of serum lipids in predicting its development.

Materials and Method

A total of 1,495 people aged 25-75 years have been examined (average age 46.3±0.3 years). The response was 63% (942 people) for men and 37% (553 people) for women. The quality control of the received information was carried out. Only representative data were selected for the analysis. Data is standardized by age structure.

The survey included: a survey on a standard questionnaire to identify passport data, level of education, profession, information about physical activity, the presence of bad habits, chronic noncommunicable diseases and their treatment, blood pressure measurements, anthropometry, it was found out whether a person knows about his blood pressure and if it is increased - is treated or not.

Blood pressure was measured twice on the right hand in a sitting position after 5 minutes of rest. The average of 2 measurements was analyzed as the level of systolic and diastolic blood pressure (SBP and DBP). The following criteria for arterial hypertension were used: SBP is equal to or greater than 140 mm Hg. Art. and/or DBP is equal to or greater than 90 mm Hg. Art., or the patient receives antihypertensive therapy.

The list of factors that were taken into account when assessing the risk of developing cardiovascular complications in patients with arterial hypertension included: age over 55 for men and 65 for women, smoking, obesity, low physical activity (NPA), lower-secondary education associated with low social status. Active smokers included people who smoked more than 100 cigarettes during their life and who currently smoke every day or sometimes, as well as people who smoke now less than once a week. Passive smoking was recorded in the presence of smoking relatives living with respondents. Overweight was recorded with a body mass index (BMI)> 25.0 kg/m2, including obesity - with a BMI> 30.0 kg/m2.

The level of total cholesterol (TC), high density lipoprotein cholesterol (HDL cholesterol) and triglycerides (TG) were determined in blood serum taken in the morning on an empty stomach after 12-14 hours of hunger on the EPOLL-20 semi-automatic analyzer (Austria). Reagents of the Human company (Germany) were used. The study included 111 people, 62 of them - the main group, 49 patients - the control group. The average age of the patients of the main group was 42.0±2.0 years, the age of the control group was 41.3±2.0 years. Criteria for inclusion of patients in the main group: the presence of arterial hypertension.

Statistical analysis of the results was performed using method of variation statistics. The significance of differences in the means was estimated based on Student's test at a 95% confidence interval ($p < 0.05$).

Results and Discussion

A comparative analysis of the arterial hypertension prevalence revealed a high prevalence of arterial hypertension among both men and women in all age periods.

The frequency of hypertension was 598 people, which corresponds to 67.7% for women (405 people) and 32.3% for men (193 people). Among them, 26.9% of people (161 people) are aware of high blood pressure, but are not treated, and 20.0% (120 people) were diagnosed with high blood pressure for the first time.

When studying the structure of arterial hypertension, it draws attention that increased blood pressure was recorded more often in women (25.9%) than in men (16%) ($p < 0.05$).

Age gradation was performed according to the classification of the World Health Organization (2012), the following age groups were identified: 18-44 years (youth); 44-60 years (average age) and 60-75 years (old age).

A comparative analysis of the frequency of hypertension occurrence depending on age is presented in table 1.

Table 1: The hypertension prevalence (in %) and the age of people in the studied groups

Age	Men		Women		Total	
	Abs.	%	Abs.	%	Abs.	%
Youth	32	16,6	53	13,1	85	14,2
Average age	68	35,2*	136	33,6*	204	34,1*
Elderly age	93	48,2*	216	53,3*	309	51,7*
Total	193	32,3	405	67,7	598	100,0

Note: *Reliability of data by a young age (P<0,05)

As can be seen from the data presented, most patients with hypertension are in advanced age (60-75 years). With increasing age, both among women and among men, the incidence of hypertension increases ($r = 0.569$ and $r = 0.609$, respectively).

The study revealed that arterial hypertension is often found in overweight people - 189 (31.6%) (Table 2). Hypodynamia was observed in almost half of the examined patients with hypertension (50.2%). Among patients with hypertension, the frequency of stressful situations occurrence is 54.5%, with women being more likely than men (62.5% and 37.8%, respectively). Dyslipidemia as one of the risk factors was noted in 41.5% of cases. Smoking was recorded in 37.5% of cases, in men in 95.3% of cases. A similar picture is observed in the analysis of alcohol abuse cases (9.4% and 29.5%, respectively).

Associations of cardiovascular risk factors with the prevalence of hypertension were evaluated using logistic regression. For this, the most significant risk factors were selected that have a reliable association with the prevalence of hypertension, regardless of age and gender, namely: body mass index ($p < 0.05$), alcohol abuse ($p < 0.05$), current smoking and past ($p < 0.05$), lack of exercise ($p < 0.05$), dyslipidemia ($p < 0.05$), stress ($P < 0.05$). In multiple logistic regression, risk factors affecting the prevalence of hypertension, regardless of age and gender: present and past smoking ($p > 0.05$), dyslipidemia ($p > 0.05$) did not reach statistical significance and were excluded from the analysis. The final model of risk factors affecting the prevalence of hypertension, regardless of age and gender, was body mass index ($p < 0.05$), stress ($p < 0.05$), and physical inactivity ($p < 0.05$).

Table 2: The prevalence of risk factors (in %) in the studied groups

Leading factors	The number of patients examined					
	M (n=193)		W (n=405)		Total (n=598)	
	n	%	n	%	n	%
Smoking	184	95,3	40	9,9	224	37,5
Hypodynamia	47	24,4	253	62,5	300	50,2
Overweight	25	13,0	164	40,5	189	31,6
Dyslipidemia	82	42,5	166	41,0	248	41,5
Stress	73	37,8	253	62,5	326	54,5
Alcohol abuse	57	29,5	38	9,4	95	15,9

In the study of blood lipid parameters revealed significant differences between the studied groups (table 3).

Table 3: Indicators of the lipid spectrum of blood plasma

Lipid Profile	Main Group (n = 62)	Control Group (n = 49)
Total cholesterol (mmol/l)	5,59±1,2	3,65±0,1*
Triglycerides (mmol/L)	1,9±1,1	0,71±0,03*
LDL cholesterol (mmol/L)	3,96±1,44	1,78±1,6*

Lipid Profile	Main Group (n = 62)	Control Group (n = 49)
Apolipoprotein B, g/l	1,07±0,02	0,73±0,01*
HDL cholesterol (mmol/L)	0,767±0,21	1,78±0,26*
Apolipoprotein A1, g/l	1,31±0,06	1,7±0,02*

Note: * P<0,01

The level of total cholesterol in the main group was significantly higher than in the control group (p <0.001), mainly due to an increase in atherogenic lipid fractions. At the same time, the average level of HDL cholesterol in the main group was below the normative values (p <0.001). Levels of lipoproteins A1 and B were significantly different in groups (<0.001).

Deviations in HDL cholesterol (36%) and TG (26%) were most often recorded, which is a marker violation of lipid metabolism in hypertension. Deviations in the concentration of ApoA1 were found in 24%, only 22% had deviations in the concentration of TC, this reflects the significance and necessity of studying the full lipid spectrum in patients with obesity. Increases in the concentration of LDL cholesterol and Apo B were recorded in 14% of patients in the main group. At the same time, 17.7% of patients (11 people) had normal lipid profile, thus, more than 80% of patients with hypertension had secondary lipid metabolism disorders.

The basis of atherogenesis is subendothelial deposition of particles containing LDL cholesterol[13]. Secondary dyslipidemia in hypertension is highly atherogenic for several reasons: small dense LDL particles are not effectively captured by the liver using LDL receptors, an increased number of circulating LDL particles increases the risk of their deposition in the subendothelial matrix, and a decrease in HDL content limits the reverse transport of cholesterol from tissue to liver.

The analysis showed that the ratio of ApoB/ApoA1 is a reliable predictor of atherogenesis in patients with hypertension and can be used to predict the disease development. The highest sensitivity and specificity corresponded to the value of the ratio ApoB/ApoA1 equal to 0.45.

Thus, with values of this lipid index greater than 0.45, it can be reliably assumed that this person is at risk for the hypertension development.

Conclusion

1. Arterial hypertension is a common disease - 40%. Among men, this disease occurred with a frequency of 32.3%, among women - 67.7%.
2. In the structure of arterial hypertension, both men and women in all studied age intervals revealed the presence of risk factors - overweight, physical inactivity and stress.
3. It is necessary to perform preventive examinations among the population, which will allow to identify the initial stages of arterial hypertension, and people with overweight, with physical inactivity and who have undergone stress should be considered a risk group for the hypertension development.
4. Among individuals at risk for the hypertension development, it is necessary to conduct a full lipid screening, including an assessment of the apolipoproteins A1 and B level.

Abstract

The article is devoted to the study of the professional activities characteristics of university teachers, the possible risk factors that affect the state of teacher's health in the course of his work are considered, solutions for protecting the health of the teaching staff and the increase in the labor efficiency of teachers of higher educational institutions are proposed.

It was revealed that the actual time costs of teaching staff exceed the established standards of the teacher's working time; however, the teacher's work does not have clear regulation (except for scheduled classes); all types of work performed take up 95% of the working time and are integral elements of the teacher's activities. A general assessment of working conditions by the tension level, the harmfulness and danger degree, performed in accordance with SanPiN 0141-03, considering the most significant factors (the labor process intensity), allows to classify the labor of university professors in our republic as class 3 (harmful), 3 degrees of harmfulness.

Keywords: *Teacher, professional activity, working day timing, working conditions, fatigue, health.*

Introduction

Ensuring the safety of life and health of workers by improving working conditions in the labor process is one of the most important tasks of our State. The work of university teachers belongs to a field of activity that is not directly involved in the production process but continues to be one of the most widespread varieties of mental labor. It is well known that mental stress leads to fatigue much faster than physical ones[1]. Today in our country more than 22 thousand teachers share their knowledge with students.

What our country and the younger generation will become tomorrow, directly depends on those who teach us. The teacher in a higher educational institution (university) is a key figure in the educational process, the effectiveness of which is determined not only by the teacher's professional competence but also largely depends on his physical health.

The teaching profession deserves comprehensive and in-depth study, as it has several characteristic features. After analyzing a large number of literature sources, we can say that today the work on studying the working conditions of teachers of higher educational institutions, assessing their health status is extremely insufficient and they relate mainly to the period of 60-80s of the last century. In these works, adverse sanitary and hygienic working conditions of educational institutions' teachers were noted due to the mismatch of microclimate parameters in the classrooms in the winter, insufficient level of artificial lighting in the classrooms. A decrease in the education financing level in the 90s of the last century led to a reduction in the construction of new classrooms, laboratories and complexes, the impossibility of repairing and rehabilitating existing ones, replacing equipment, furniture, and ensuring the required levels of lighting and air-thermal conditions in lecture halls. In addition, in recent years there has been

a significant change in the labor process in educational institutions due to the introduction of some innovations in the educational process, and the teachers' working conditions remained the same as 20-30 years ago[2].

Now, a fairly limited number of studies have been conducted on the health of universities' teaching staff and the factors that shape the health[3], however, based on these works, we can conclude the significance of this kind of research.

The aim of research: Study and assessment of teaching staff's working conditions in various universities of the Republic of Uzbekistan.

Research Method

The objects of research were 3 largest universities of the Republic, located in Tashkent - the National University of the Republic of Uzbekistan named after Mirzo Ulugbek (NUUz), the Tashkent Medical Academy (TMA) and the Tashkent State Technical University named after Islam Karimov (TSTU), as well as the faculty of these educational institutions.

The assessment of social factors affecting teaching staff was performed according to the survey-questionnaire results of 430 teachers (15.9% of the average teachers' number among the three universities studied); the survey was based on a questionnaire recommended by the WHO regional office. To assess the content and intensity of teaching staff work, the working hours were timed (10-12 teachers in each university). Hygienic working conditions are studied in each university at the main workplaces; microclimate indicators (by seasons - 95 measurements), lighting of workplaces (88 measurements), noise level (90 measurements), electrostatic field (16 measurements), the number of aero ions in 1 m^3 of air (28 measurements), its anthropogenic pollution (content CO2 - 123 measurements), radiation environment (radon content, radiation dose rate - 30 measurements). Studies of hygiene factors were performed by generally accepted instrumental and laboratory method; all research results were subjected to statistical processing with the calculation of indicators M±m, and their assessment - according to the relevant SanPiNRUz.

Results

Work content and teaching staff employment level during the working day: During scientific research, we had the opportunity to compare the organization and working conditions of the teaching staff in our republic and in South Korea. During 2017-2019, in TMA, in the framework of international cooperation with the *State University of South Korea*, *3 business visits* of the teaching staff were organized (with our participation) to the above mentioned university in order to familiarize themselves with the organization and conduct of the educational process at the *State University of South Korea*.

During the working meetings, attention was paid to the peculiarities of the teaching staff and the organization of student tutoring. It was noted that the educational process is performed in well-equipped rooms with a favorable microclimate, good ventilation, proper lighting, and physiologically adapted furniture. With all types of work performed, there is widespread computer equipment use, and modern technical equipment and laboratory equipment are applied during the educational process. The teaching process is performed in accordance with very dynamic programs that consider both modern knowledge and requirements for specialists, and the wishes of students (master's program). Teachers perform only those tasks that require teaching, and the schedule of their work is not rigid, although in general the teaching load of teachers is quite large. The profession of a university teacher is considered very prestigious and, accordingly, the teacher's work is highly paid.

An important feature of the universities' teaching staff work of in our republic is that due to the versatility of the teacher's functions, he is forced to constantly change his workplace, so during the working day he can work in the classroom, in the office, in the laboratory, in the vivarium, in the hospital ward (medical university), in a hostel, etc.

To characterize the work content and the employment degree of the modern university teacher in Uzbekistan, we conducted a direct timing of the teacher's working day in each university under study. The study involved 9-12 teachers in each university, after which the averaging of the teaching staff in general was performed.

Timekeeping of the teacher's working day in all the universities studied has shown that the university teacher's work is currently characterized by a very wide range of work. In addition to classes with students in accordance with the schedule, the teacher performs many different types of work related not only to the

main areas of his activity. This includes preparation for lectures, workshops, seminars, advisory work, work with lagging students, a large amount of methodological work, scientific research, educational work, fulfilling public assignments, preparing reference and reporting materials, etc. All these activities are associated with the need of working with literature, applying modern information technologies and modern office equipment, working with a huge amount of information that requires analysis and relevant conclusions. It should be noted that, in addition to classes that are strictly regulated by the schedule, it is almost impossible to regulate other types of the teacher's work - they are performed either as necessary, or considering the temporary capabilities of the teacher.

The determination of the time spent on the performance of certain work types showed that for 80% of the teachers included in the study, the working day goes beyond the statutory 6-hour working day. The average statistical indicators of the teacher's time spent on various work types are characterized by Table 1.

Table 1: The results of the working timing day of a university teacher, M±m (n=20)

No	Work implemented	Actual elapsed time, hour (min- ′)	% of total time
1.	Lecturing	0,4±0,1 (24′)	4,6
2.	Lecture preparation, including presentation preparation	0,2±0,1 (12′)	2,3
3.	Conducting practical (seminar) classes	3,0±0,5 (180′)	34,5
4.	Preparation for practical exercises (laboratory base, handouts)	0,5±0,3 (42′)	8,0
5.	Preparation of training documentation, rating calculations	0,5±0,3 (48′)	9,2
6.	Consulting work	0,2±0,1 (12′)	2,3
7.	Verification of student work	0,3±0,1 (30′)	5,7
8.	Work on the Internet (reference materials, new data)	0,5±0,1(30′)	5,7
9.	Reception of missed classes	0,2±0,1 (12′)	2,3
10.	Preparation of materials at the request of deans, administration, scientific part, ministries, etc.	0,5±0,2 (30′)	5,7
11.	Preparation of teaching materials	0,5±0,2 (30′)	5,7
12.	Scientific work (Internet, library, collection of scientific data)	0,6±0,2 (36′)	6,9
13.	Educational work (curatorial, visiting dormitories, extracurricular activities)	0,2±0,1 (12′)	2,3
14.	Lunch break, personal distractions	0,4±0,2 (24′)	4,6
	Total	**8,0±0,2 час**	**100**

The data presented allow to determine that the teacher spends 95.0% of the total working time for all types of work, which is already 2 hours longer than the officially established working time of the teacher.

At the same time, it was revealed that the work of teachers is mainly accompanied by a static muscular load while in 30±4.6% of the working time in a free working position (standing or sitting), which allows us to characterize such work as a lightly stressed light physical work (except for physical teachers education, as well as teachers of certain medical disciplines (surgeons, traumatologists) requiring significant physical effort) - class 1b in SanPiN 0325-16.

When assessing the nervous load, it was determined that the teacher's work is characterized by high tension, due to both the mandatory fulfillment of the class schedule and the lack of time, increased responsibility for the work results, prolonged strain of visual functions, the need for large random access memory (a set of many changing elements that must be memorized during hours and a working day), high intellectual stress associated with performing creative work, frequent unrepeatable stressful situations when working with a large and diverse student population. The indicated labor characteristics of the teaching staff allow to determine the intensity of such work as hazardous (very hard) work of 3 degrees (SanPiN 0141-03).

It can be assumed that the teacher's actual work schedule in the universities under study, even with favorable hygienic factors of the working environment, can have an adverse effect on the body and, above all, on the central nervous system (CNS). It should be borne in mind that a high neuropsychic stress for a teacher is a factor affecting his body every day throughout the entire academic year and throughout his work at a university.

Hygiene factors' characteristics in workplaces: Based on the timing of the working day, we can assume that the main jobs of the teacher are classrooms and study rooms, and therefore, to characterize the main hygienic factors of the teaching staff environment, we studied these factors precisely in classrooms, laboratories and study rooms.

During a visual examination of these workrooms, it was noted that the rooms dimensions generally meet hygiene requirements. At the same time, despite the fact that the main part of the investigated premises is located and equipped in specially constructed buildings, violations of hygiene requirements were noted at many workplaces. Most often this relates to insufficient ventilation of the premises, the presence of idle lamps, non-compliance with the hygienic requirements of the furniture used, malfunctions of the water supply and sewage, i.e. the operating conditions of buildings and premises.

To characterize hygienic working conditions, we evaluated the microclimate, the workplaces illumination, the noise level, the electromagnetic field magnitude, the carbon dioxide concentration, measured the dose rate of external radiation and the content of radon in the working area air.

The microclimate parameters of the premises, which we studied in the cold and warm periods of the year, are presented in Table 2.

It was revealed that in the cold season the optimal parameters of air temperature as the main indicator of the microclimate take place only in the clinic, which is understandable, since for patients the requirements for the microclimate are more stringent. In all classrooms at the school day beginning, the air temperature was 4-5 degrees below the optimal values and approached those only at the end of the day. At the same time, in no case have we recorded air temperature below the established SanPiN 0324-16 border for the cold season (170 C). With regard to air humidity and its speed, the parameters of these indicators in all cases were within the established hygiene standards.

In the warm season, the air humidity at the measured points was within acceptable limits, but the air temperature was 1-4 degrees higher than the optimal parameters. The air movement speed in all rooms was 1.5-2 times lower than the recommended values. The indicated microclimate parameters in the warm season can be the cause of some tension of the thermoregulation function and increase the already high emotional stress level of teachers.

The work of most university teachers is associated with the need for long-term high voltage of the vision organs, with objects of discrimination 0.3-0.5 mm (fonts), high contrast on a light background, which allows to classify this work as a 3rd category of high-precision work, sub-category "G" (KMK 2.01.05- 98 "Natural and artificial lighting"), for which the normalized value of daylight factor with natural side lighting is 1.2, and the general level of illumination of workplaces is 200 lx (fluorescent lamps).

Table 2. The microclimate parameters of educational facilities in the universities studied in the cold and warm seasons

University	Place of measurements	Cold season, M±m			Warm season, M±m		
		Air temperature, °C	Air humidity, %	Air speed, m/s	Air temperature, °C	Air humidity, %	Air speed, m/s
TMA	Building 1	18,3±3,1	71,3±4,8	0,2±0,04	27,4±1,2	54,3±1,2	0,1±0,08
	Building 3	17,8±2,2	72,6±5,2	0,3±0,04	26,8±2,4	51,8±2,3	0,1±0,09
	Clinic (Department of Cardiology)	20,1±1,1	70,4±6,1	0,1±0,05	25,2±3,1	54,2±2.4	0,1±0,07

University	Place of measurements	Cold season, M±m			Warm season, M±m		
		Air temperature, °C	Air humidity, %	Air speed, m/s	Air temperature, °C	Air humidity, %	Air speed, m/s
NUUz	Building 1	17,2±2,2	71,6±5,1	0,2±0,06	26,4±2,2	60,0±0,8	0,2±0,04
	Pavilion 2	18,1±3,1	72,4±5,1	0,3±0,04	27,5±2,4	54,3±0,8	0,3±0,01
TSTU, main building	1st floor	17,1±2,2	73,0±1,5	0,3±0,09	26,2±0,8	55,6±0.9	0,3±0,08
	2nd floor	17,5±2,4	70,8±2,6	0,3±0.07	27,1±0,9	59,1±0,9	0,4±0,04
Hygienic norm (SanPiN 0324-16)		Optimal-21-23 Permissible-17-25	40-75	0,1-0,2	Optimal-24-26 Permissible-22-32	40-60	0,3-0,6

In the premises examined, the workplaces illumination parameters were determined both by the nature and purpose of the premises, their orientation, and the time of day and year (Table 3).

The best lighting parameters were identified in NUUz and TSTU, which are built according to individual projects developed for these universities. Both the daylight factor value and the combined illumination level of classrooms in these universities mainly correspond to hygienic standards, but the artificial lighting level in 32% of cases was 60-70 lux lower than hygienic requirements. This is mainly due to the fact that in some audiences there are faulty lamps.

As for TMA, we have studied the premises of buildings 1 and 3, which are the premises of former dormitories adapted for classrooms. In the studied rooms, the daylight factor value was 25% lower than the norm, and therefore artificial lighting is widely used in these buildings, which makes it possible to bring the general illumination level of classrooms to a hygienic norm. In the absence of artificial lighting, the level of illumination is 90-120 lux, which greatly complicates the work of both teachers and students.

Table 3: The illumination state of teachers' jobs in the universities studied, M±m

University	Place of measurements	Number of measurements	Daylight Indicators		The illumination level of working places	
			Room orientation	Daylight factor	Combined lighting, lux	Artificial lighting, lux
TMA	Building 1	14	East	0,8±0,1	170±50	150±60
	Building 3	14	Southwestern	0,9±0,1	170±48	154±50
	Clinic	10	Northeastern	1,1±0,1	134±60	132±60
NUUz	(Department of Gastroenterology)	10	Western	1,3±0,2	184±40	130±40
	Building 1	10	Northwestern southwestern	1,4±0,3	180±50	140±40
TSTU, main building	Building 2	10	Northeastern	1,4±0,2	180±49	140±38
	1st floor	10		1,5±0,2	188±50	138±42
	3rd floor	10	Northeastern	1,8±0,2	180±49	140±40
Hygienic norm (KMK 2.01.05-98)				1,2		200

No sources of intense noise were found in all the educational institutions studied - the noise level in the premises is mainly due to the presence of a large number of fairly active young people, whose communication, especially during breaks, creates a noise background in the rooms, which can be characterized as intermittent broadband noise. The measured total noise level in classrooms and classrooms (n = 12-14 in each university) during classes was 50±8 dBA, and during breaks - 60±7 dBA, which corresponds to hygiene requirements for highly skilled work requiring concentration (60 dBA according to SanPiN No. 0325-16). At the same time, attention is drawn to the fact that in the TMA buildings 1 and 3, in rooms whose windows face a street with heavy traffic, the noise level averages 72±4 dBA, reaching 85-87 dBA in separate time intervals (building 1), which is 12-27 dBA higher than the established hygiene regulations.

The widespread use of computer technology in various educational institutions suggests the possibility of forming electrostatic fields in the area of their location. We measured the electrostatic field value in the area where computers of both the old type (CRT screens) and new generations (LCD screens) are located. In accordance with SanPiN RUz No. 0303-12, when working on a computer for up to 8 hours, the permissible electrostatic field value should not exceed 10 V/m. Measurements made by us at the TMA Department of Communal Hygiene and Department of Informatics (16 measurements) showed that in the area where computers with CRT screens are located, the electrostatic field is 7.4±0.3 V/m, and with LCD screens - 2.05±0.5 V/m.

In most classrooms of the universities under research there are no man-made sources of intense chemical air pollution, but during some laboratory studies small amounts of various chemicals can be released into the air, and therefore, such laboratories must be provided with effective ventilation, including equipment for working fume hoods. During our research, we considered the fact that such equipment is practically absent in classrooms.

When conducting research, we did not reveal any classrooms of artificial chemicals in the air, which, in our opinion, is due to the fact that only demonstration chemical studies were conducted in classrooms during this period. At the same time, in the air of classrooms, we constantly revealed chemical components of anthropogenic origin - carbon dioxide, ammonia.

Table 4: Carbon dioxide concentration in classrooms, %, M±m

University	Time of measurements	Warm season		Cold season	
		Number of measurements	M±m	Number of measurements	M±m
TMA	Before class	15	0,05±0,01	12	0,08±0,03
	12^{00} - 13^{30}	15	0,12±0,08	12	0,09±0,03
	16^{00} -16^{30}	15	0,16±0,08	12	0,21±0,06

The determination of an indirect indicator of anthropogenic air pollution in classrooms - carbon dioxide - at various time intervals (Table 4) indicates that, both in the warm season and in the cold season, natural ventilation of the premises does not provide the necessary air purity. The CO2 concentration, indicating the absence of anthropogenic air pollution in residential and public buildings, is assumed to be 0.1% or lower. According to our data, such carbon dioxide concentration in classrooms is only before classes and, partually, in the classroom. By the end of the school day, an increased CO2 concentration (up to 0.24%) is detected in almost all classrooms.

The airborne content of the air ions indicates air pollution throughout the working day (Fig. 1.).

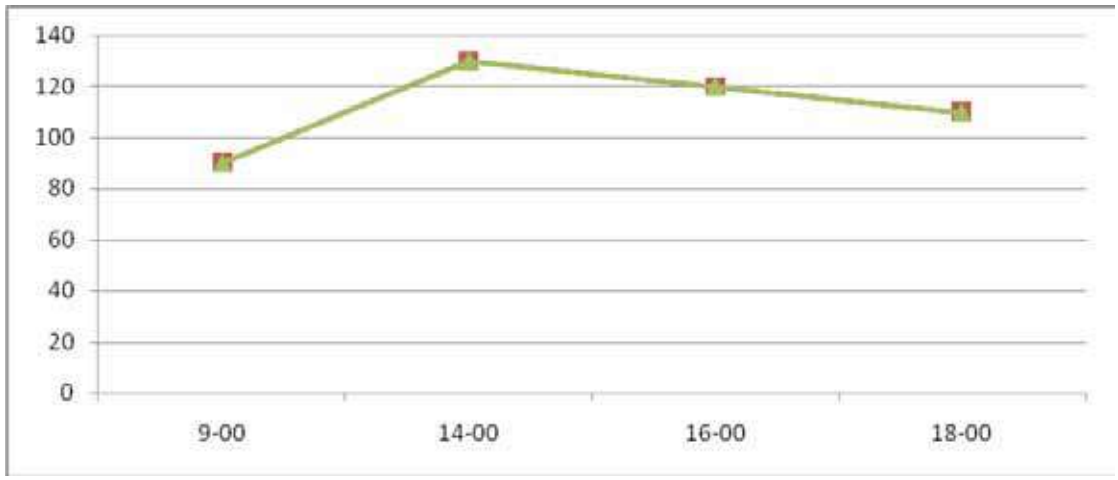

Fig. 1. The dynamics of the positive ions number in 1 m^3 of TMA classrooms air during the day.

Low-quality ventilation of classrooms is also evidenced by the results of measuring the concentration of radon in the air of these rooms (Table 5).

Table 5: The concentration of radon in the air of classrooms, Bq/m^3

University	Place of Measurements	Level	Number of Measurements	Concentration of Radon, M±m
TMA	1-Educational building	1	7	40,8 ± 4,5 Бк/м^3
		3	7	38,8 ± 3,8 Бк/м^3
		4	7	30,8 ± 2,5 Бк/м^3
	3- Educational building	1	7	39,8 ± 3,5 Бк/м^3
		3	7	34,6 ± 2,9Бк/м^3
		4	7	30,2 ± 5,1 Бк/м^3
	TMA hospital (Department of Cardiology)	2	7	36,7 ±,5 Бк/м^3
NUUz	Building 1	1	6	44,1 ± 4,5 Бк/м^3
	Building 2	2	6	35,8 ± 2,5 Бк/м^3
TSTU	Main building	1	6	40,6 ± 6,6 Бк/м^3
		3	6	31,8 ± 2,7 Бк/м^3
		5	6	30,5 ± 4,5 Бк/м^3

According to Zaredinov D.A. (2001), the average radon content in indoor air in the Republic of Uzbekistan is close to the national average - 30.8+3.5 Bq/m^3, but higher concentrations of radon are detected on the first floors of multi-storey buildings, where the underlying source of radon is : on the 1st floor up to 48.5 + 2.9, above - up to 25.7 + 1.6 Bq/m3.

The data obtained by us indicate that, despite the absence of high values of the measured indicators, their dynamics indicates a gradual deterioration in the quality of the air in the classrooms during the working day. These data reflect not only the quality of ventilation, but also the radiation exposure due to radon.

The level of general unprofessional radiation exposure on a person is determined not only by the incorporation of radon, but also by external background γ - radiation. The gamma background measured by us at the university premises was in TMA (n = 20) - 18-26 μR/hour, NUUz (n = 16) - 16-21 μR/hour, TSTU (n = 14) - 16-22 μR/hour.

We did not reveal higher indicators of external

exposure in computer labs in which the measured dose rate of external exposure was 23.5±2.8 μR/h. Only at one of the TMA departments (the former Department of General and Radiation Hygiene) during classes in radiation hygiene, during which a demonstration of exemplary radiation sources is conducted, a radiation dose rate of up to 42 μR/hour is recorded directly near the teacher's hands.

According to Zaredinov D.A. (2001), in our republic, the exposure dose rate of gamma radiation outdoors is 13 mcr/h-1, whereas in rooms it is higher (up to 23 mcr/h-1); our data confirm the results of D. Zaredinov's studies and indicate that the external gamma radiation level in the educational premises of universities is small and does not go beyond the background radiation, typical for the climatic and geographical conditions of the republic.

The above radiation factors characteristics, measured at the main teaching staff's workplaces in universities, allow to classify working conditions by this factor as optimal values that do not have a harmful effect on the body of workers.

Conclusions

Thus, the study of the universities' teaching staff content and the hygienic conditions of their work allows to draw the following conclusions:

1. The actual time costs of teaching staff exceed the established standards of the teacher's working time; however, the teacher's work does not have clear regulation (except for scheduled classes); all types of work performed take up 95% of the working time and are integral elements of the teacher's activities.
2. The general assessment of working conditions by the employment level, performed in accordance with SanPiN 0141-03, considering the most significant factors (the labor process intensity), allows to classify the university teachers' labor in our republic as class 3 (harmful), 3 degrees of harmfulness, whereas other hygiene factors, we have described working conditions as optimal or acceptable (table 6).

Table 6: Working conditions classes of universities' teaching staff in the Republic of Uzbekistan (according to SanPiN 0141-03).

Researched Factors	Working Conditions Classes					
	Optimal (1 Class)	Permissible (2 Class)	Harmful (3 Class)			
			1 Deg.	2 Deg.	3 Deg.	4 Deg.
Total noise	+	+				
Microclimate		+				
Lighting			+			
Ionizing radiation	+

Analysis of the Interrelation of Speed and High-Speed Endurance in 14-17 Years of Football Players

Shokhrukh Sh. Erkinov

2nd year PhD student, Department of Theory and methods of soccer, Uzbekistan State University of Physical Education and Sport, University, Address: 111709, 19, Sportchilar Street, Chirchik City, Uzbekistan, Uzbekistan

Abstract

In the analysis of the optimal interrelation between the general and special high-speed physical qualities of young footballers of 14-17 years old, normative tests were used to measure speedy physical performance. It was determined the optimal age group in the test analysis processes of general and special speedy performance young group footballers.

Keywords: *Shuttle running 5*30m, standard "8" ("eight"), "high-speed equipment", complex coordination movement, sensitive period, "microgate" device, correlation coefficient, intensity.*

Introduction

From the first days of independence of Uzbekistan by the state, special attention, as well as other sports, was given to football. A clear confirmation of the above statements is that, according to the Decree of the Cabinet of Ministers of the Republic of Uzbekistan No. 144 of March 18, 1993 "On Measures for the Further Development of Football in the Republic of Uzbekistan", several measures have been outlined to restore the traditions of the Pakhtakor football club and determine the educational training complex "Kibray" the main training base of the national team. After one year after the adopted resolution, at the 1994 Asian Games held in Hiroshima and Nagasaki, the Uzbekistan national football team was successful in becoming champions. All this testifies to the increased attention of the state to football[1].

The further favorable condition of qualitative growth of football in republic became the Decision of the President of Republic Uzbekistan from March, 16th, 2018 for №ПП3610 "About measures on the further development of football", accepted with the purpose of formation of national team of Uzbekistan, and also perfection of preparation of gifted young shots and their inclusion in structure of a national team. The same decision provides specific instructions for the establishment of children's and youth football academies in the Republic of Karakalpakstan. These academies are created with the aim of training highly qualified football cadres from young talented players[2].

Relevance: In recent years, on the world stage, during international competitions, there has been an annual increase in the intensity of the pace of the game, i.e. the increase in the speed of the implementation of technical and tactical actions during the struggle for the possession of the ball. The growth trend of the game speed leads to the universality of the players' actions. At the same time, defenders of the flanks, who even perform the tasks of playmakers in the attack, take part in the attack (as a creative participant in organizing the attack and as a football player directly organizing the start of this attack). And this, over the course of many years of preparation, requires approaching the intensity of training loads to the pace of the speed requirements of the playing period, and this is especially necessary to consider when developing speed endurance for young players.

Such physical quality as speed must be developed from 13-14 years. The reason for this is that this age is considered a sensitive period in the development of speed[3].

The speed of young football players is developing at different rates depending on their abilities. In the growth of sportsmanship of young football players aged 12-13 years, the growth of physical performance, the integrated

development of speed and coordination qualities, and the implementation of special coordination of complex technical actions are of great importance.

14-15-year-old players are distinguished by their speed abilities, high activity of training and competitive actions, dribbling with complex coordination movements, and high-speed qualities.

And for 16-17-year-old players, physical performance, the integrated development of speed and coordination, the ability to perform complex coordination movements during the game are well developed.

- Due to the intensity of games during competitions, it can be very difficult to maintain a high level of speed qualities. In the process of training during the competition, it is necessary to develop their individual speed qualities taking into account the abilities of each player. In D. Sirenko's researches most suitable development of speed qualities was carried out by separate groups taking into account individual abilities and age of players, as a result of which speed qualities were developed optimally after application of the following exercises:

- Running from a high start on 15 meters: - 15 summer defenders, - 15-16 summer midfielders, 17 summer strikers;
- Running at 60 meters: - 16 summer defenders and midfielders, - 15-17 summer strikers;
- Run for 100 meters by 15 summer players;
- Driving the ball at 30 meters: - 14 and 15-year-old defenders, 13.15 and 17-year-old midfielders, 14.16, 17-year-old attackers [4].

Object and Subject of Research: As the object of the study, the study was chosen to study the development of general and special high-speed quality for 48 students of football players of the Republican boarding school of the Olympic reserve, aged 14 to 17 years, 12 people in each group. The subject of the study is the study of the correlation between general and special physical qualities by adopting standards: 30-meter running, 5 * 30m shuttle running, and the "8" («eight») test.

Aims and Purposes: The research aims to study the most suitable interrelation between general and special speed qualities of 14-17-year-old players, taking into account their age characteristics.

Based on the purpose of the research, the following tasks were selected:

- Application of norms of high-speed running without a ball for 30 meters and shuttle running 5*30m with a ball for studying the correlation between general and special high-speed qualities of 14-17-year-old football players;
- Using correlation analysis of features with general and special speed qualities of 14-17-year-old football players.

Research Practice: The research was conducted in July 2018 at the Republican School of Olympic Reserve with 12 football players in 4 age groups. Using a Microgate measuring instrument (Misrogate) during the study, 3 standard tests were applied (table 1):

The first standard test is "30 meters running." when starting a run from a high start, speed measuring instruments are installed at the "Start", "10 meters from the start" distances and on the "Finish" line. In the standard, 30 meters running, the speed of overcoming distances of 10 meters and 30 meters are determined simultaneously.

The second standard test is a shuttle running 5x30m. Microgate speed measuring instruments are installed at the intersection of the "Start" and "Finish" lines, where time is detected only when the football player has completely crossed these lines. This method determines the completeness of the intersection of the start and finish lines by football players.

The third standard test is the "8" ("eight") test. Four cones are placed on four sides in the form of a quadrangle and one cone is placed in the center. The distance between the cones is 10 meters. The soccer player must speed the ball from the cones in the corner to the cone in the center. The micro-gate speed meter shall be installed on the Start and Finish lines.

Methodologies

Tests have been used to check physical properties: Start speed "Running at 10 m", Longdistance speed - Running at 30 m", Shuttle running 5*30m, special coordination - Test "8".

Microgate Method:

The average result according to the standards is given in Table 1 which expressed in histogram 1 for each age group. Where marked: high scores of 17-year-old footballers in "30-meter speed"; it is noted that the highest results according to the standards are "10-meter speed", in "shuttle running 5x30m", "8" 16-year-old players.

Histogram 1: The average standard, running 10 meters from a high start, speed running 30 meters, shuttle running 5x30 m and test "8" for 14-17-year-old players (n = 12 in each age group)

- However, these indicators do not meet the standard level. In the book by Professor I. Koshbakhtiev "Department of Footballers' Training" the following standards are given in the race for 30 meters by age groups:
- Normative indexes in running for 30 meters for players of 15 years old: 4.4-4.45 seconds;
- Normative indicators in running for 30 meters of players of 16 years of age: 4.3-4.2 seconds;
- The standard rate of running for 30 meters for players of 17 years of age: 4.1-4.15 seconds.

From the above results (histogram 1) it can be seen that I. Koshbakhtiev's implementations do not meet regulatory requirements [5].

Research Results and their Comparative Analysis: For 14-year-old players in the "30-meter speed run" without the ball and the "5x30 meter shuttle race" with the ball, the correlation coefficient is r = 0.7. Compared with data of other ages, this is the best indicator r = 0.7, which indicates the presence of a high statistical relationship.

And for 15-year-old players, the result of the indicator is r = 0.6. It can be seen that the average correlation between the general and special speed qualities of 15-year-old football players is lower than that of athletes of 14 years of age.

The 16-year-old football players have r = 0.5. r = 0.5 indicates the existence of a weakly-average statistical relationship. It can be seen that the average correlation between the general and special speed qualities of 16-year-old football players is at a slightly-average level lower than that of athletes of 15 years of age.

The 17-year-old football players have r = 0.08. r = 0.08 indicates the absence of a correlation. However, although the results of a group of 17 summer athletes running 30 meters were higher than other age groups (table 1), we can observe a disproportionate relationship between overall speed and special endurance. And therefore, the correlation between general and special endurance shows a weak statistical result (table 2).

Table 2: In calculating the correlation between the general special and speed qualities of the players, the participants in the standard "high-speed running at 30 meters" -X and "shuttle running 5x30" - Y

	$\overline{X}$ (30m/s running)	$\overline{Y}$ (5x30 m/s shuttle running)	$X_i - \overline{X}$	$Y_i - \overline{Y}$	Xσ	Йσ	r
14 years old	4,74	33,58	0,11	0,09	0,220	2,525	0,7
15 years old	4,60	31,92	0,02	0,01	0,296	1,336	0,6
16 years old	4,47	30,89	0,02	0,07	0,138	0,934	0,5
17 years old	4,37	31,20	-0,02	0,18	0, 195	1,795	0,08

X_i – following the group of each age (n = 12) means one football player.

$\overline{X}$ – on the run for 30 meters on average n = 12.

Y_i – following the group of each age (n = 12) means one football player.

$\overline{Y}$ – in the shuttle run 5x30 meters on average n = 12.

average difference from n = 12 contingent results.

XσваYσ – sigma rate $\overline{X}$и$\overline{Y}$.

r - an indicator of the correlation coefficient.

Conclusions

At the current stage of intensive football - speed, one of the main conditions for organizing the effectiveness of the game quality. In professional football speed quality must be developed from childhood. At present, the world practice is developing more and more new tools and method used in the education of speed quality young football players. Performing technical movements (techniques) at a fast pace (in a high-speed mode) during training shows that the pace of training sessions adapted to the pace of the game. At the same time, modern football emphasizes the fact that a football player, in case of difficult situations during the game, can demonstrate high skill in performing technical moves at high speed.

From the accepted standards (high-speed running for 30 meters further running for 10 meters from a high start, shuttle running 5x30m, as well as the test "8") it is clear that 16-17-year-old players, with high performance, can be traced a weak proportional relationship between the overall high-speed (10 meters and 30 meters) and special endurance (shuttle running 5x30m).

Although, according to the adopted 4 standards, 14-year-old young football players had the lowest results in the group of players aged 14-17, their level of suitable interrelation between general and special endurance turned out to be the highest to other older age groups. From the literature studied during the study, it became known that with age, the process of neurohumoral regulation occurs in the athlete's body, in which, due to an increase in muscle mass, an increase in speed abilities occurs. However, their overall speed quality should be developed in proportion to (commensurate) special endurance. We can observe a similar development at a high growth rate for 14-year-old players (table 2). In measuring the standard of general speed quality "speed running 30 meters", to the standard for measuring special endurance "shuttle running 5x30 meters", they have an optimal correlation equal to r = 0.7.

If we take a group of football players of 16 years of age who, according to the four accepted standards, had the highest results in three, we can observe an average degree of the proportional statistical relationship between the general speed and special endurance (r = 0.5), although they had good results general speed qualities.

Athletes 16-17 years of age do not have enough time to develop special qualities.

Annotation: The article uses speed test physical criteria to analyze the degree of optimal correlation between the general and specific speed physical qualities of players between the ages of 14 and 17. As a result of the analysis of the tests, the age groups with the optimal correlation of general and specific speed quality were identified.

Abstract

The goal of research was to study the cytokine status in women with a combination of fibroids and adenomyosis to determine their role in the course of the disease. Method 165 women with uterine myoma and/or adenomyosis were examined. Patients were divided into 3 groups: 1-group - 75 women with a combined form of myoma and adenomyosis, 2-group - 47 women with diffuse adenomyosis, 3-group - 43 women with uterine myoma. The study was conducted in 2017-2018, on the basis of the Tashkent Medical Academy in the department of gynecology of the obstetric-gynecological complex No. 9 of Tashkent city.

The research method were a dynamic study of node blood flow by ultrasound with dopplerometry and an immunological blood test. For myoma 5 mg ulipristal acetate was prescribed for treatment for 3 months for at least 2 courses by 3 months with a 2 month break, and for adenomyosis - 2 mg dienogest for 6 months continuously. For the combined form of myoma and adenomyosis, treatment was started with dienogest for 6 months continuously, then UPA was prescribed for 3 months.

Results: The determination of the level of pro-inflammatory cytokines in patients before treatment showed the following results: the level of IL-1, IL-6 and TNF-α was higher in all three groups than in the control group, and in the group with combined pathology IL-6 was 1,5 times higher than in groups with isolated pathologies. After therapy, the decrease in the levels of IL-1, IL-6, and TNF-α was observed in all three groups. Also the level of anti-inflammatory cytokines IL-10 and VEGF exceeded significantly the control group, especially in the group with combined pathology, after the treatment, their level decreased significantly.

Discussion: An increase in the level of cytokines in the blood is most pronounced in combined forms of myoma and adenomyosis compared with isolated forms of myoma and adenomyosis.

Keywords: *Uterine myoma, adenomyosis, pro-inflammatory cytokines IL-1, IL-6, TNF, anti-inflammatory cytokines IL-10, VEGF.*

Introduction

This indicates the participation of the immune system in the development and progression of such hyperplastic processes of the uterus as myoma and adenomyosis[1].

Uterine fibroids and adenomyosis are ranked among the hyperplastic processes and diseases of the uterus[2]. However, each of these diseases has its own pathogenetic features, clinical implications and is characterized by various laboratory parameters. Uterine myoma have clinical symptoms more often with a proliferating node type. The most characteristic signs of it are menstrual irregularities, infertility and, in some cases, functional abnormality of adjacent organs[3]. Uterine adenomyosis is also manifested by disorder of menstrual and

reproductive function, pain syndrome[5]. At the same time, each of these pathologies has its own therapeutic approaches, including conservative prevention, which allows achieving positive results [6].

Modern ultrasonographs can not only distinguish myoma and adenomyosis, but also determine the degree of activity of the process[4]. However, over the past decades there has been an increase in the frequency of combined forms of myoma and adenomyosis among patients of reproductive and climacteric age. Often the presence of adenomyosis in the setting of myoma is detected only after a histopathological examination of the extirpated uterus. The relevance of the question lies in the fact that when identifying the combined form, the specialist raises the question: what diagnosis is a priority, what preparations the patient should be treated with, because not all preparations are uniquely effective for myoma and adenomyosis.

Recent studies have shown that the condition and function of various body systems, including the immune system is important in the development of myoma and adenomyosis,. The participation of the immune system has been studied well in endometriosis, but few studies have been conducted with its combination with uterine myoma, and their results are contradictory.

All this indicates the necessity for further research to improve the diagnosis of combined forms of diseases, to study the role of the immune system in the pathogenesis of these diseases.

The goal of this research was to study the cytokine status in women with a combination of myoma and adenomyosis to determine their role in the course of the disease.

Material and Research Method

The study was conducted in 2017-2018, on the basis of the Tashkent Medical Academy in the department of gynecology of the obstetric-gynecological complex No. 9 of Tashkent city. We examined 165 women with uterine myoma and/or adenomyosis. All the patients were divided into 3 groups: 1-group - 75 women with a combined form of myoma and adenomyosis, 2-group - 47 women with diffuse adenomyosis, 3-group - 43 women with uterine myoma. The study groups were formed according to the results of ultrasound, while the number of myomatous nodes and the degree of adenomyosis were payed attention to. The control group consisted of 29 healthy women. The age of the examined ranged from 20 to 45 years, the average age was 36.1±0.9 years.

The research method were a dynamic study of node blood flow by ultrasound with dopplerometry and an immunological blood test. An ultrasound study with dopplerometry made it possible to determine the presence of a simple or proliferating type of myoma node in patients and to establish the degree of adenomyosis, as well as to evaluate the effectiveness of the treatment by comparing the results of ultrasound before and after treatment. The effectiveness of treatment was also evaluated when questioning patients after treatment for the disappearance or decrease in the intensity of the pain syndrome.

An immunological study allowed us to determine the characteristics of the parameters of the immune system, including determining the level of pro-inflammatory cytokines IL-1, IL-6 and TNF and anti-inflammatory cytokines IL-10 and VEGF, to determine their role in the development of combined forms of uterine myoma, and in some cases infertility in women of reproductive age, compare indicators before and after treatment.

Interleukin-1 (IL-1) - a cytokine, a mediator of inflammation and immunity, is synthesized by many cells of the body, primarily activated macrophages, keratinocytes stimulated by B-cells and fibroblasts.

Interleukin-6 (IL-6) is a cytokine, an indicator of the immune response in diseases accompanied by inflammation, i.e. inflammatory mediator. IL-6 is a cytokine that coordinates immune and acute phase inflammatory responses, as well as oncogenesis and hemogenesis. Cytokines are specific proteins by which cells of the immune system can exchange information with each other and coordinate activities. Cytokines include some protein molecules - interferons, tumor necrosis factor (TNF), a number of interleukins, colonie-stimulating factor (CSF) and others.

Interleukin-10 anti-inflammatory cytokine is a human gene product. IL-10 has multiple pleiotropic effects on immunoregulation and inflammation. It reduces the expression of Th1 cytokines, increases the survival of B cells, their proliferation and antibody production.

Vascular endothelial growth factor (VEGF) is a signaling protein produced by cells to stimulate vasculogenesis and angiogenesis (the growth of new

vessels in an existing vascular system). The main functions of VEGF are the creation of new blood vessels, the enhancement of muscle growth after exercise, the maintenance of collateral circulation (the creation of new vessels by blocking existing ones). But, increased VEGF activity can lead to various diseases. Tumors (as well as uterine myoma and adenomyosis) cannot grow larger than a certain limited size without receiving adequate blood supply; and the tumors themselves are capable of expressing VEGF in order to grow.

Tumor necrosis factor (TNF - alpha, cachexin, cachectin) is an extracellular protein, a multifunctional pro-inflammatory cytokine, synthesized mainly by monocytes and macrophages. It affects lipid metabolism, coagulation, insulin resistance, endothelial function, stimulates the production of IL-1, IL-6, IL-8, interferon-gamma, activates leucocytes, one of the important factors of protection against viruses and intracellular parasites.

Excessive production of TNF causes hemodynamic disorders, diffusely increases the capillary permeability, the cytotoxic effect on body cells.

In our study, we performed a quantitative analysis of pro-inflammatory and anti-inflammatory cytokines in blood serum in 60 patients. 15 patients of each studied group, as well as in the control group donated blood for immunology research before treatment and after the course of therapy. The treatment was carried out depending on the revealed pathology: for myoma, ulipristal acetate 5 mg (UPA) was prescribed for 3 months at least 2 courses of 3 months with a two-month break, for adenomyosis - 2 mg dienogest for 6 months continuously. For the combined form of myoma and adenomyosis, treatment was started with dienogest for 6 months continuously, then UPA was prescribed for 3 months.

The Results of the Research

Ultrasound studies showed that the 1st group patients with the combined form of adenomyosis and myoma with clinical symptomatology (algodismenorrhea, infertility) revealed single (30 cases) or multiple (from 2x to 5 nodes - 45 cases) myomata.

Dopplerometry of the blood flow in nodes made it possible to determine a simple or proliferating myomatous node by the degree of quality of its blood supply. So in the 1st group with a combined form, about half of the patients (46.7%) had several myomatous nodes in combination with diffuse adenomyosis. A single myomatous node was combined often (25.3%) with a diffuse form of adenomyosis, and in some cases (14.7%)-combined with a diffuse focal form of adenomyosis. Several nodes of proliferating fibroids were also combined with a diffuse focal form of adenomyosis (13.3%).

Determination of pro-inflammatory cytokines level in patients before treatment showed the following results: the level of IL-1 in all three groups was almost equal (Table 1). In the 1st and 3rd groups, the level of IL-1 was 3.4 times, and in the 2nd group, IL-1 was 3.0 times higher than in the control group (P <0.001). A high level of IL-6 was observed more often in patients of the 1st group and was 3.3 times higher than in the control group (P <0.001).

Table 1: The level of pro-inflammatory cytokines in the blood serum of the examined patients before and after treatment (M±m)

№	Group	IL-1		IL-6		TNF-α	
		Before	After	Before	After	Before	After
1	The combination of myoma and adenomyosis n = 15	7,5±0,39* P<0,001	3,5±0,12[a] P<0,001	8,2±0,45* P<0,001	4,6±0,24[a] P>0,05	8,7±0,93* P<0,001	10,3±1,02 P<0,001
2	Adenomyosis n=15	6,7±0,38* P<0,001	3,2±0,22[a] P<0,01	6,0±0,79* P<0,01	4,3±0,26[a] P<0,01	12,7±1,12* P<0,001	14,6±0,95 P<0,01
3	Uterine myoma n=15	7,4±0,68* P<0,001	3,4±0,25* P<0,05	5,1±0,24 P<0,01	3,6±0,19 P<0,01	11,3±1,91* P<0,001	12,6±1,21 P<0,001
4	Control group n=15	2,2±0,15		2,5±0,21		1,5±0,07	

Note: *-acurate compared with the control group, [a] - acurate compared with the data before treatment

Also, compared with 2- and 3-groups, IL-6 exceeded 1.5 times. In the 2 group, this indicator exceeded the control group by 2.4 times (P <0.01), and in the 3 group 2 times (P <0.01).

In the 1-group with combined pathology TNF-α was 5.8 times, and in the second group for women with adenomyosis it was 8.5 times, in the 3-group it was 7.5 times higher than the control group, the accuracy was P <0.001.

After the therapy, decrease in the levels of IL-1 and IL-6 was observed in all three groups. The decrease in IL-1 was observed in all groups by an average of 2 times and the average values closed in on the control values. Also, a decrease in the cytokine IL-6 in the 1 group was observed by 1.8 times, and in the 2 and 3 groups by 1.4 times.

After treatment a decrease in the average of TNF-α, which is a pro-inflammatory cytokine was revealed in all groups. In the 1st group, the cytokine level was increased now only 2 times. The increase in its level was noted only 1.1 times in the 2nd and 3rd groups. accuracy P <0.001.

Determination of anti-inflammatory cytokines level showed that the level of IL-10 in patients with combined pathology was 3.2 times higher than in the control group (Table 2). In patients with isolated pathologies, the indicator was 1.9 times higher than in the control group. After treatment, the level of IL-10 decreased by 2 times in the 1-group. In the second group, a decrease was observed by 1.6 times and in the third group by 1.4 times.

A study of vascular endothelial growth factor (VEGF) indices showed that the highest indices were in patients of groups 1 and 2 and almost 4 times exceeded the control group (P <0.001). In the 3-group there was also a high indicator, but lower than in the 1- and 2-group, and 2.2 times higher than in the control group (P <0.001).

After the treatment, an accurate decrease in VEGF level was noted, compared with the indicators before treatment. In the 1st group the VEGF level decreased by 2 times, in the 2nd group by 1.9 times and in the 3rd group by 1.8 times.

Table 2: The level of anti-inflammatory cytokines in the blood serum of patients before and after treatment (M±m)

№	Group	IL-10		VEGF	
		Before	After	Before	After
1	The combination of myoma and adenomyosis n = 15	10,6±0,67*	5,0±0,3[a]	1282,6±119,8* P<0,001	628,7±27,4[a] P<0,05
2	Adenomyosis n=15	6,2±0,24*	3,8±0,21[a]	1243,5±127,4* P<0,001	653,2±30,36[a] P<0,01
3	Uterine myoma n=15	6,3±0,74* P<0,001	4,4±0,37[a] P<0,05	725,4±35,2* P<0,001	410,2±20,2[a] P<0,05
4	Control group n=15	3,3±0,14		325,0±22,0	

Note: * - the differences are accurate compared with the control group, [a] - the differences are accurate compared with the data before treatment

Discussion

Thus, the presence of diseases such as myoma, adenomyosis, or their combined forms in the examined patients contributes to the development of an imbalance of pro- and anti-inflammatory cytokines. The increase in their level in the blood is the most significant with combined forms of myoma and adenomyosis compared with isolated forms of myoma and adenomyosis. This indicates the participation of the immune system in the development and progression of such hyperplastic processes of the uterus as myoma and adenomyosis.

The choice of priority for prescribing preparations depended on the activity of myomatous nodules. With proliferating myomata, the preparation UPA was

prescribed first, then dienogest, and for simple myomata – vice versa. The treatment of these diseases contributed to the incremental recovery of pro- and anti-inflammatory cytokines level, which was close to the indicators of the control group.

Simultaneous ultrasound with dopplerometry after the treatment showed that stabilization of the growth of nodes in diameter of 5 and> cm and decrease in the size of small nodes were noted. The grade of blood flow in myoma nodes and in focal adenomyosis worsened, which was characterized by a decrease in the level of VEGF in the blood serum of patients, i.e. indicated the positive changes.

According to the patients survey, the clinical picture of the disease after treatment has also changed. Algomenorrhea disappeared in 24.2% of cases and its intensity decreased significantly in 61.8%, a slight improvement was noted by 14.0%. Reproductive function recovered in 67.9% within a year after the treatment.

Conclusions

1. The combined forms of myoma and adenomyosis in women of reproductive age are characterized by more significant imbalance of pro- and anti-inflammatory cytokines.
2. After the treatment, an accurate decrease in the level of pro-inflammatory cytokines is noted, which confirms the role of immunity in the development of myoma and adenomyosis.
3. The effectiveness of the treatment of combined forms of myoma and adenomyosis is characterized by the improvement in the clinical progression of the disease and restoration of fertility in 67.9% of cases.

Abstract

Introduction: There are several forms of successful treatment and prevention for obstruction of the pyelourethral segment in pediatric patients. However, each method has its advantages and disadvantages. Namely, some those widespread surgical techniques frequently associate with different complications and subsequent financial deprivations. Therefore, the optimal method of external trans-anastomotic drainage is still disputable. In this study, we studied the results of pyeloplasty in children using a transanastomotic catheter.

Method: In this observational study, which was conducted from 2013 to 2018, we evaluated the outcomes of pyeloplasty in 132 childrenunder 3 years old. For all patients a trans-anastomotic catheter for urinary evacuation was used during the postoperative period. The observation period ranged from 6 months to 3 years (an average of 22±6,8 months). Antegrade pyelography was performed in 119 patients on the 6th day of postoperative period. The average hospital stay was 8.4 days (ranging from 6 to 16 days), most of the patients were discharged from hospital 7 days after surgery.

Results: 137 pyeloplasty was performed on 132 patients using a transanastomotic catheter. The observation lasted from 6 months to 3 years. Antegrade pyelography was performed in 119 patients on the 6th day after surgery. Of those 119 pyelograms taken, 108 (91 percent) showed adequate drainage after pyeloplasty. In 11 patients, partial obstruction was revealed, while in 8 (73 percent) children the possibility of the anastomosis returned to normal on its own about within 12 days. The transanastomotic catheter was removed on average 7-8 days after surgery. The average hospital stay was 8.4 days.

Conclusion: Urine evacuation with transanastomotic catheter after pyeloplasty in pediatric patients is highly effective and safe. Other comprehensive studies may be required to prove the further upsides of this technique.

Keywords: *Pyeloplasty, hydronephrosis, ureteral obstruction, children, drainage.*

Introduction

Dividing pyeloplasty is a common method of surgical treatment for obstruction of the pyelourethral segment in children with a success rate of 94% to 99% (Shahzad et al, 2014)[1]. As with all surgical interventions on the urinary tract, there are various method of urine diversion after pyeloplasty. Currently, many surgeons use an internal double pig tail stent (Elmalik et al, 2008 and Hsu et al, 2016)[2], or Salle's transanastomotic external stent, and some authors prefer non-drainage pyeloplasty (Kagantsov et al, 2012)[5]. According to some authors'

results on postoperative drainage of the upper urinary tract using a nephrostomy tube showed an increase in the incidence of urinary tract infections, the hospitalization period of patients, and the risk of secondary obstruction of the pyelourethral segment (Sibley et al, 1987)[8]. At the same time, there are ongoing discussions in the scientific literature regarding the optimal method for urine diversion after dissecting pyeloplasty in pediatric patients.

In this study, we studied the results of pyeloplasty in children under 3 years old using a transanastomotic catheter.

Materials and Method

This retrospective study was conducted from 2013 to 2018, included data from children under the age of 3 years with obstruction of the pyelourethral segment. After surgery, a transanastomotic catheter for postoperative urine evacuation was installed in all patients. In all patients, dividing pyeloplasty was performed through lateral access. After the first suture of the anastomosis placed between the pelvis and ureter, the distal end of the transanastomotic catheter (PVC catheter with a diameter of 8-10Fr) was inserted into the ureter, the other end of the catheter was taken out as a pyelostomy through the anterior wall of the pelvis. With further stitches the posterior semicircle of the anastomosis was formed, then the anterior one. When forming the anastomosis, a synthetic polyfilament suture material (6/0) was used. At the end of pyeloplasty, the intubating catheter was not fixed to the pelvis, since excessive fixation can significantly complicate its removal in the postoperative period. At the same time, a transanastomotic catheter adequately provided urine evacuation in two directions. Urine with a hemorrhagic shade, extending through the urinary catheter and the absence of urine discharge through the safety drainage, were indirect signs of the adequate function of the transanastomotic catheter. With adequate catheter function, ultrasound monitoring and antegrade pyelography were performed on the 6th dayafter operation in order to check the location of the catheter and the passabilityof the anastomosis. Then the catheter was clamped for 1 day. In the absence of parental complaints about the child's anxiety and negative dynamics during the control ultrasonography, the catheter was removed on the 7th day after the surgery.

Results

In 132 patients, 137 pyeloplasty was performed using a transanastomotic catheter (Table 1). The observation period ranged from 6 months to 3 years (average 22–6.8 months). Antegrade pyelography was performed in 119 patients on the 6th day after surgery. Of those 119 pyelograms taken, 108 (91 percent) showed adequate drainage after pyeloplasty. One patient experienced a slight extravasation of urine, which resolved independently after 1 week. In 11 patients, partial obstruction was revealed, while in 8 (73 percent) children the possibility of the anastomosis returned to normal on its own about within 12 days. The anastomosis impassibility lasted longer only in 3 patients, however, in two of them, normal urodynamics recovered after 16 days. Persistent obstruction of the pelvic ureteric segment was detected in one patient, which required installation of an internal stent. Ultimately, with intravenous urography 6 months after surgery, this patient had a good urine evacuation through the anastomotic zone. The transanastomotic catheter was removed on average 7-8 days after surgery. The average hospital stay was 8.4 days (ranging from 6 to 16), and discharge from the hospital occurred mainly on the 7th day after surgery.

Table 1: Clinical distribution of patients

Clinic course	Number of patients	
	n	%
Asymptomatic course	115	87
Palpable formation	4	3
Anxiety in the child (abdominal/lumbar pain)	1	0,8
Urinary tract infection	12	9,2
Total amount	**132**	**100**

Postoperative complications are provided in Table 2. None of the patients had progressive postoperative obstruction and re-pyeloplasty was required. Renal function did not deteriorate during postoperative examination, and no patient was noted soreness or anxiety associated with postoperative drainage with a transanastomotic catheter.

Table 2: Postoperative comlications

Complications	n	%
Urinary tract infection	2	1,5
Temporary obstruction of the ICP (internal stent)	1	0.7
Insignificant extravasation	1	0.7
Total	**4**	**2.9**

Discussion

Despite the presence of numerous method of urine derivation in the postoperative period, the optimal choice of the method of postoperative urinary evacuation after pyeloplasty remains under debates. While some authors argue that when using a nephrostomy, the risks of developing urinary tract infections increase and the length of hospitalization of patients elongates. other researchers, on the other hand, argue that using internal stents requires repeated anesthesia to remove the latter (Sibley et al, 1987)[8]. However, in many publications devoted to postoperative urinary diversion after pyeloplasty, the influence of the derivation method on the total number of long-term results of pyeloplasty is not well studied. They just comparedthe results with each other. So, Hsu et al (2016)[3], comparing the radiological results of pyeloplasty with nephrostomy and drainage pyeloplasty, did not note the significance of the differences between them. It should be emphasized that the improvement of surgical method, as well as the accessibility of modern suture materials, led to a significant improvement in postoperative results (Mendrek et al, 2019)[6]. The use of prophylactic antibiotic therapy also reduces the incidence of urinary tract infections, as evidenced by the results of our study. Thus, the incidence of urinary tract infections in our study was marely 1.5 percent. Therefore, in our opinion, preventive antibiotic therapy should be continued throughout the entire period of urine diversion. In this case, catheterization of the bladder in the early postoperative period is extremely important for adequate evacuation of urine from the bladder.

Wollin et al (1989)[9] believed that an empty bladder (low intravesical pressure) prevents the newly formed anastomosis from increased pressure, thereby reducing the risk of extravasation through the anastomosis. In addition, low intravesical pressure improves urodynamics in the anastomotic zone in the early postoperative period.

The literature describes the shortcomings of external method of urine evacuation, such as a longer period of hospitalization of patients after pyeloplasty (Hussain et al, 1994)[4]. The average hospital stay, in these earlier studies ranged from 9.8 to 24.8 days. However, in our study, the average hospital stay was 8.4 days. Meanwhile, removal of the transanastomotic catheter was usually performed without any difficulties, which allowed to avoid repeated anesthesia. In addition, external method of urine derivation have recently been criticized due to the increased frequency of various postoperative complications. However, the results of this study prove that using a transanastomotic catheter has several advantages. At the same time, the transanastomotic catheter provides urine derivation in two directions, allowing surgeons to adequately assess the state of the anastomosis. It also prevents the postoperative bending of the anastomosis zone, acting as an internal stent. In addition, it completely eliminates the need for repeated anesthesia during its removal, which is mandatory when removing the internal stent.

Conclusion

In our patients, the number of postoperative complications did not differ from those presented in the literature. The transanastomotic catheter serves as a reliable protective mechanism against postoperative edema and kink in the anastomotic zone, and prevents the extravasation of urine. And also makes it easy to perform x-ray examinations to assess the possibility of the pyelourethral segment. Furthermore, using a transanastomotic catheter completely eliminates the need for re-anesthesia for the removalof it.

Study Limitations: Further researchesare required to clarify the other advantages of transanastomoticcathetering in children. This was an observational study. Further comperative studies and secondary researches are needed to identify the most optimal therapy for children after pyeloplasty.

Abstract

Introduction: Significant allergic reactions and anaphylactic type cytotoxicity are registered in the pathogenesis of cell damage in pregnant women with hypertensive conditions. Determining role of indirect mast cell degranulation and allergic changes in neutrophils during pregnancy that complicated by preeclampsia, allows to identify the allergic status of the body, which is very importance for improving the quality of early diagnosis, treatment and prevention. The purpose of the study was to identify the allergic reactivity of pregnant women suffering from hypertensive disorders and to develop practical recommendations to improve the quality of early diagnosis.

Materials and Method: We observed 6 group of participants: pregnant women with clear allergy clinic, uncomplicated preeclampsia, pregnant women with light stage of preeclampsia, latent sensitization, pregnant women with preeclampsia combined with clear allergy clinic, conditionally healthy pregnant women – 1st control group, practically healthy non-pregnant women – 2nd control group, practically healthy men – 3rd control group. Using non-infection allergens, we called different types of allergic reactions and conducted clinical and allergic examinations, general test of bleed, urine, feces, indirect mast cell degranulation test and neutrophil alteration test.

Results: Within all control groups, the rate of positive reaction against the allergic agents made up less than 10 percent. In all pregnant women with clear clinical picture of allergies complicated or uncomplicated preeclampsia, as well as in pregnant women with preeclampsia with latent sensibilization, mast cell degranulation indexes were 4.5-8.6 times higher than that of control group. Among 90 examined pregnant women, positive reactions of indirect mast cell degranulation were observed in 204 cases.

Conclusion: In cell damage pathogenesis during preeclampsia, anaphylactic and cytotoxic type allergic reactions play important role. The positive reactions of indirect mast cell degranulation in pregnant women with an explicit allergy complicated by preeclampsia is significantly higher than in pregnant women with preeclampsia with hidden sensitization.

Keywords: *Hypertensive conditions in pregnancy, preeclampsia, allergy.*

Introduction

Preeclampsia of pregnant women has been continuing to be one of the urgent problems of modern medicine. This pathology, giving different complications during pregnancy and childbirth, remaining as one of the causes of maternal and perinatal morbidity and

mortality. Preeclampsia is especially lasts severely in pregnant women who permanently live in ecologically unfavorable regions (Sukhikh et al, 2015)[1]. According to world statistics, about half a million women die due to the different complications related to pregnancy and childbirth (Tumanova et al, 2017 and Mukhamedkhanova et al, 2019).[2]

According to results of researches conducted by Stokoz et al (2016)[3] and Chulkov et al (2015), about 1–4% of women aged 18–29 years and about 5–15% of women aged 30–39 years suffered from chronic hypertension between 1999 and 2004 in the United States. Along with this, in 2004, compared to 1998, the number of pregnancy complications caused by preexisting arterial hypertension increased by 50% and reached up to 1.7% of the total number of complications (Wang et al, 2019). Moreover, the number of preterm births and newborns with low weight for gestational age, as well as perinatal mortality rates in such pregnant women were 2-3 times higher compared to normotensive women (Perfilova et al, 2014; Paidas et al, 2016; and Wang et al, 2019)[4],[7]. The incidence of gestational hypertension increased from 10.7 to 30.6 per 1000 births, and 17% of pregnant women with gestational hypertension subsequently developed preeclampsia (Mosimann et al, 2019 and Wang et al, 2019).[5] However, it should also be mentioned that the maternal risks associated with gestational hypertension are usually less than 2 times lower than those of women suffering from chronic hypertension or moderate preeclampsia.

According to the data provided by WHO, the proportion of hypertensive syndrome in the structure of maternal mortality is about 20-30%, every year more than 50 thousand women die during pregnancy owing to complications associated with maternal arterial hypertension. Arterial hypertension increases the risk of detachment of a normally located placenta, massive coagulopathic bleeding. It can also cause eclampsia, impaired cerebral circulation, and retinal detachment as well (Marotti et al, 2017)[6].

The frequency of preeclampsia development is not same in different countries and depends to a large extent on the criteria used for its diagnosis. Although the problem of preeclampsia is studied from different perspectives, many of its aspects remain poorly understood (Stokoz et al, 2016)[4]. Among them, in our opinion, the allergy, more precisely, allergic reactivity of the body, plays very importance in the etiology, pathogenesis, clinic of preeclampsia and its complications. Chulkov et al, 2015; Perfilova et al, 2014; and Paidas et al, 2016)[8].

The prevalence of hypertensive conditions during pregnancy is ranges around 7–30 percent. This pathology worsens the prognosis in mother and in children, and is also causes perinatal mortality. Different complications like placental insufficiency, premature detachment of a normally located placenta, eclampsia, cerebral hemorrhage, acute heart failure, acute renal failure, syndrome of DIC develop with arterial hypertension (Perfilieva et al, 2015)[7].

Introduction of specific, clinical and allergological examinations of pregnant women with preeclampsia: collection of an allergic history, clinical and functional studies, in vitro allergy tests (indirect mast cell degranulation test, neutrophil damage index, determination of the functional activity of neutrophils by tetrazole recovery techniques dye and phagocytosis) into the complex of clinical and laboratory studieswill contribute to the early detection of allergic diseases in pregnant women, which has a great diagnostic, therapeutic and preventive value.

A study of the regional characteristics of the prevalence of pre-eclampsia of pregnant women in different regions of Uzbekistan using the methodology of epidemiological studies under the ISAAC international program allows us to clarify the true disease incidence the population (Mukhamedkhanova et al, 2019)[3].

Purpose of the study is to determine the allergic reactivity of the pregnant women body suffering from hypertensive disorders and to develop practical recommendations that improve the quality of early diagnosis of this serious illness based on the allergological concept. To determine the importance of combining allergies with hypertensive conditions in pregnant women. To determine the role of regional pollen factors in the development of an immediate type allergy in the pathogenesis of cell damage in pregnant women with pre-eclampsia using tests of indirect mast cell degranulation and allergic neutrophil alteration.

Materials and Method

168 individuals were under observation, including pregnant women with a clear clinic of allergy, uncomplicated preeclampsia (n=30), pregnant women with a slight degree of preeclampsia, latent sensitization (n=30), pregnant women with preeclampsia combined

with a clear allergy clinic (n=30), conditionally healthy pregnant women (n=30) - control group No. 1, practically healthy non-pregnant women (n=23) - control group No. 2, practically healthy men (n=25) - control No. 3. The age of pregnant women ranged from 17 to 39 years. The age of non-pregnant women and healthy men was 20-35 years old. We studied pregnant women with gestational age from 19 weeks to 40 weeks of their pregnancy. Among them, the first pregnancy - n=42 (35%); re-pregnants n=44 (36.7%); multiparous women n=34 (28.3%).

Among the allergic diseases in the examined pregnant women there were: allergic rhinitis, sinusitis, conjunctivitis-24 (20%); urticaria, Quincke's edema, neurodermatitis-15 (12.5%); drug allergy 8 (6.7%); food allergy 6 (5%); bronchial asthma 6 (5%); anaphylactic shock 1 (0.8%).

The results of studies in all pregnant women with allergic diseases were approximately the same. The numerical differences between the indicators were unreliable. Therefore, we combined them into one group: pregnant women with hypertension, combined with a clear clinic of allergic diseases.

The following standard non-infectious regional allergens were used: pollen (wormwood, quinoa, chinar, kenaf, aylanthus), household (house dust), epidermal (cat, dog hair, bird feather). Tissue allergens (placenta, kidneys) were prepared in a well-known way. The following method were used: clinical and allergic examination of patients, general blood tests, urine, feces, indirect mast cell degranulation test, neutrophil alteration test.

Allergy in the examined women was manifested in the form of allergic rhino conjunctivitis, allergic dermatoses, and even anaphylactic reactions[8]. In those cases, when pollen allergens were important in the etiology of allergies, a clear seasonality of the disease was observed (mainly in spring and summer seasons)[9]. With sensitization by household and epidermal allergens, the seasonality of the disease was not observed. When sensitizing to food allergens, patients indicated a connection between exacerbation of the symptoms of the disease and the intake of certain foods[10]. When eliminating causally significant foods, a remission of the disease was observed. Specific allergy diagnostics was carried out on the basis of a comprehensive clinical and allergological examination of patients, as well as in vitro allergic tests. The complex principle of specific diagnosis compares favorably with the fact that it allows you to identify specific allergic antibodies, establishes the specificity of the sensitization of an organism to a particular allergen, and conduct differential diagnosis[11]. An allergic history was collected on the basis of a specially compiled questionnaire. An allergic test for indirect mast cell degranulation (MCD) was performed according to generally accepted method. Anti-tissue antibodies were determined by the conventional photometric method. The phagocytic activity of neutrophils in the peripheral blood of patients was determined according to A. Shteltsner. An allergic neutrophil alteration test was performed according to V.A. Fradkin. To determine the functional activity of neutrophils, we used the Nitro Blue-Tetrazolium Test (NBT test)[12].

Results

In all control groups examined (conditionally healthy pregnant women, practically healthy non-pregnant women and practically healthy men), the frequency of positive reactions to tested pollen, domestic and epidermal allergens was below 10 percent and ranged from 4.4 + 0.2 - 3. 6 + 0.23. These indicators are non-specific and indicate the absence of sensitization of the body, since there are no examined specific IgE in the blood serum.

In all pregnant women with a clear clinical picture of allergies complicated or uncomplicated preeclampsia, as well as in pregnant women with preeclampsia with latent sensitization, mast cell degranulation values were significantly higher by 4.5-8.6 times compared to the control, and were within 30.2 + 0.92 - 38.0 + 0.44 ($p < 0.05$).

In general, among 90 examined pregnant women, positive reactions of indirect mast cell degranulation were observed in 204 cases, including pollen allergens in 115 (56.4±3.4%), household (house dust) in 50 (34.5±4.9%), epidermal - in 39 (19.1±2.7%).

The degree of mast cell degranulation in most pregnant women (92.1±3.8 - 94.5±10.1%) with anexplicit allergy clinic, regardless of the presence or absence of preeclampsia, was expressed in ++ and +++, while as in the majority of pregnant women with preeclampsia (91.7±7.9%) with latent sensitization, the degree of mast cell degranulation was weakly expressed (+).

In the vast majority of pregnant women with a clear allergy clinic, cases of combined polysensitization predominated, that is, simultaneous increased sensitivity to several unrelated allergens. For example, pollen+household, pollen+epidermal, etc. Only monosensitization to a particular allergen was observed in pregnant women with latent sensitization. Neutrophil damage in conditionally healthy pregnant women (control group No. 1) and practically healthy non-pregnant women (control group No. 2) were in the range of 0.019±0.001 - 0.002±0.001 (when using placental antigen) and 0.035±0.003 - 0.04±0.002 (when using renal antigen). The difference in the digital data of these two groups of controls is unreliable ($p > 0.05$). This fact indicates that the examined control groups of women have a minimal amount of anti-tissue antibodies in their blood serum. However, these antibodies do not cause serious tissue damage. Pregnant women with overt allergies, uncomplicated preeclampsia, showed an increase in neutrophil damage to 0.04±0.003 - 0.1±0.03, which is 2-2.5 times more than the controls ($p < 0.05$). In pregnant women with preeclampsia, neutrophil damage indicators are also greater than in pregnant women with latent sensitization 3-4 times (0.08±0.004 - 0.13±0.004), and in pregnant women with overt allergies - 4-5 times (0.1±0.002 - 0.19±0.004). These facts indicate the development of autosensitization in pregnant women, complicated by preeclampsia to the tissues of the placenta and kidneys.

First of all, we were interested in the issue of the presence of an immediate allergy. To clarify this issue, we used a methodological technique that allowed us to identify specific allergic antibodies belonging to the IgE class. In all pregnant women with allergies, regardless of the presence or absence of symptoms of hypertension in the blood serum, specific allergic antibodies to the tested allergens were detected. The frequency of positive reactions to the studied allergens in pregnant women with allergies without hypertension and in pregnant women with allergies combined with hypertension was approximately the same, respectively, 15.5-73.0 and 25.6-80.0 percent. The frequency of positive reactions in pregnant women with hidden sensitization combined with hypertension to pollen allergens was 8.6%, domestic - 13.3 percent, epidermal - 6.7 (average 0.6±2.0). The results of studies of this category of patients indicate that in pregnant women with latent (latent) sensitization, the titer of allergic antibodies, in comparison with pregnant women with an explicit allergy clinic, is significantly low ($p < 0$ 05).

However, they are all potential allergy sufferers, that is, at any moment the symptoms of allergies can occur. In addition, these data allow us to conclude that the presence of hypertension cannot serve as an obstacle to the synthesis of specific allergic antibodies in patients.

Discussion

In our opinion, in case of hypertensive conditions of pregnant women, there is no inhibition of the functional activity of immunocompetent cells responsible for the synthesis of specific allergic antibodies. This is evidenced by the absence of a difference in the frequency of positive reactions of indirect mast cell degranulation in two groups of pregnant women with an explicit allergy clinic: combined and not combined with hypertension, as well as positive reactions in pregnant women with latent sensitization combined with hypertension[11].

In the process of formation and development of allergic reactivity of the body, the inhibition of the functional activity of neutrophilic leukocytes is noted, which negatively affects the factors of cellular nonspecific protection of the body (i.e., the phagocytic activity of leukocytes decreases, the phagocytic number, phagocytic index, and the strength of phagocytosis).

Allergy in most cases is characterized by the development of polysensitization. In this regard, it was of some interest to analyze our data from these positions. In the literature, polysensitization means the presence of hypersensitivity in the same patient to two or more types of allergens. From our point of view, “the degree of development of an allergy clinic depends on the nature, nature and types of allergens. In this regard, depending on the nature of allergens, the following polysensitization options should be distinguished: 1) true - when one organism is sensitized to two or more related allergens at the same time: only pollen, or only domestic, or only epidermal, etc.; 2) combined - when one organism is sensitized to two or more non-infectious allergens of different nature: pollen and household, pollen and epidermal etc.; 3) mixed - when one organism is simultaneously sensitized to two or more allergens of non-infectious and infectious nature. According to our data, in pregnant women with a clear allergy clinic, cases of true and combined polysensitization predominated regardless of the presence or absence of hypertension: 93.3 and 76.7 percent respectively.A similar pattern was also observed in patients with latent sensitization - 90.0 percent.

At least two types of allergies in pregnant women with hypertensive conditions are noted: a clear clinical manifestation of allergic diseases and latent (latent) sensitization of the body without clinical manifestations of allergic diseases.

The clinical forms of allergy manifestation are diverse: pollinosis, allergic rhinitis and sinusitis, allergic dermatitis, bronchial asthma, anaphylactic shock. Hypertensive conditions associated with allergies are more likely to occur in repeatedly and multiparous women.

With a combination of hypertensive conditions with allergies, cases with a more severe clinical course of the underlying disease predominate, induced, premature and belated deliveries are more common, and surgical interventions are more often used.

In the etiology of allergies in pregnant women with gestosis, exogenous non-infectious allergens are essential. In the pathogenesis of cell damage during gestosis of pregnant women, a complex combination of allergy mechanisms of immediate (chimeric) and delayed (cellular) types is detected.Thus, the conducted studies allow us to come to the following generalizations - preeclampsia often occurs and develops against the background of an allergically altered body reactivity. It can be assumed that the severity of the clinical course of preeclampsia and its complications depends on the presence of a latent or overt allergy. The sensitization of the body in pregnant women is confirmed by a positive reaction of indirect mast cell degranulation, which indicates the presence of specific allergic antibodies (IgE) in the blood serum of the examined. With clinically pronounced forms of allergy, the sensitization of pregnant women, regardless of the presence or absence of preeclampsia in them, is clearly multivalent. The frequency of mixed forms of polysensitization is significantly higher. With latent forms of sensitization of the body of pregnant women, only monosensitization is noted.

The introduction of specific, clinical and allergological examinations of pregnant women with hypertensive disorders into the complex of clinical and laboratory studies: collecting an allergic history, clinical and functional studies, and setting up allergic tests in vitro will contribute to the early detection of allergic diseases in pregnant women, which has a great diagnostic, therapeutic and preventive value.

Conclusion

In the pathogenesis of cell damage during preeclampsia of pregnant women, allergic reactions of anaphylactic and cytotoxic type are of significant importance. The degree of positive and sharply positive reactions of indirect mast cell degranulation in pregnant women with an explicit allergy clinic complicated by preeclampsia is significantly higher than in pregnant women with preeclampsia who have hidden sensitization. Allergies in pregnant women are polyvalent in nature. Furthermore, determination of the parameters of the test for indirect mast cell degranulation and allergic neutrophil alteration in pregnant women complicated by preeclampsia, in combination with other clinical and laboratory studies, makes it possible to identify the allergic state of the body, which is of great importance in improving the quality of specific diagnostics, therapy and prevention.

Study Limitations: Further research is needed to clarify various aspects of the pathogenesis of preeclampsia from the perspective of modern allergology.

Acknowledgements: Many thanks to the staff of Department of Obstetrics and Gynecology, Pediatric Gynecology of Tashkent Pediatric Medical Institute for the cooperation in our research. The patients kindly gave full written permission for this report. We are thankful for that.

Abstract

Introduction: The number of HIV infected children exceeds 3 million worldwide. The most severe clinical manifestations and complications of the disease are HIV-associated neurocognitive disorder and HIV encephalopathy. These factors make the scientists search for method of optimizationin the diagnosis of neuro-HIV and identifying various pathological processes that determine the clinical course.

Materials and Method: 154 children were tested with HIV diagnosis. All patients were examined for neurological, psychological and cognitive disorders. Quality of life of sick children were examined by the questionnaire of PedsQL. In order to compare the results, study included 20 healthy adolescents (control group - CG), who also tested using the above method. Using the MS Excel software average values summarized and their standard deviations were calculated.

Results: All patients were diagnosed with 3rd and 4th stages of HIV. HIV-associated neurocognitive disorder: grade 2 in 100 patients – 64.94% and grade 3 - in 54 patients - 35.06%. Epilepsy was diagnosed in 31 patients, peripheral polyneuropathy in 7, vacuolar myelopathy in 8, and consequences of acute cerebrovascular accident in 9 with focal neurological deficit in 2. The Raven test: average test result was 18.68±4.51%. Aggressive behavior: negativism prevailed in 74 patients, and in 11 cases (7.14%) it was combined with physical aggression, and in 12 cases (7.79%) - with resentment. In addition, indirect aggression was detected in 18 patients (11.69%), resentment in 41 patients (26.62%), suspiciousness in 10 patients (6.49%), and 19 patients (12.34%) - irritation. Quality of life questionnaire revealed difficulties associated with physical activity (18.30±4.51 with maximum score of 32 points), with emotional states (15.50±2.23 with maximum of 20), social activity (14.10±2.93 with maximum of 20) and life in school (19.29±1.23 with maximum of 20).

Conclusion: HIV-associated neurocognitive disorder is manifested by a deterioration in intelligence, various forms of aggressive behavior and is associated with a decrease in the quality of life in terms of physical, emotional, social activity and learning at school.

Introduction

About 3.4 million children worldwide are infected with the human immunodeficiency virus (HIV)/ AIDS. A significant part of them who have indications for antiretroviral therapy does not receive it today (UNAIDS, 2012)[1]. Neurological manifestations of HIV infection are common in both children and adults. A wide range of neurological conditions can be caused by the HIV, however, damage of the central nervous system

due to this virus, which affects the development of the brain in the embryo and baby, leads to the most severe complication of damage to the nervous system - HIV encephalopathy. In children not receiving treatment, the prevalence of the disease varies from 20% to 60% (Donaldet al, 2015; Foster et al, 2006 and Van Rie et al, 2007)[2]. The range of neurological complications that occur in children infected with HIV is quite wide and complex. One of the most common manifestations is HIV-associated neurocognitive disorder. In 18% of patients infected with HIV, it is the first clinical manifestation of AIDS (Saidkhodjaeva et al, 2019)[3];in 12 – 23 percent of them develop severe encephalopathy, usually during the first year of their life (Van Rieet al, 2008; Chiribogaet al, 2005; and Tardieu et al, 2000)[4]; in 35-50 percent of those children will develop encephalopathy in the future (Van Rie et al, 2007)[5]; in 50–90 percent of all HIV-infected infants and children develop anti-retroviral therapy deficiency (Kovacs, 2009).[6] Behavioral disorders are observed in 35 percent of all HIV-infected patients (Govenderet al, 2011), psychiatric manifestations - in 48-61 percent (Mellinset al, 2006; Wood et al, 2012; and Musisi et al, 2009).[7]

HIV affects the central nervous system shortly after the onset of systemic infection. Penetration into the central nervous system is largely mediated by infected macrophages-monocytes or $CD4^+$-T-lymphocytes (the effect of a Trojan horse), or both. Viral replicas isolated in the brain are predominantly CCR5-trophic, suggesting that virus invasion is driven by monocytes (Kramer-Hämmerleet al, 2005 and Banks et al, 2006). Once it penetrates the central nervous system, HIV basically infects perivascular macrophages and microglia, and blocks the proliferation of nerve progenitor cells. The expression of inflammatory neurotoxic neurotransmitters occurs in various types of CNS cells. Pathological changes include the formation of microglial nodules and large multinucleated cells, reactive astrogliosis, and the loss of a specific subpopulation of neurons. Damage and death of neurons are caused by several direct and indirect pathogenetic mechanisms. The consequences are the development of neurological and neurocognitive disorders.

These factors make us look for approaches to optimizing the diagnosis of neuro-HIV and identifying various pathological processes that determine the clinical picture (Mellinset al, 2006)[8]. Children with particularly weak cognitive and psychomotor functioning were most at risk of developing the disease. Prospective observational studies have found that significant neurocognitive impairment leads to a worse outcome of the disease and an increased risk of death, even against the background of combined etiological and pathogenetic treatment (Pearson et al, 2000).[9] Compared to healthy children, HIV-infected children have a much weaker development of early motor and cognitive skills. Although no clinical or clinical prognostic prediction scheme has yet been proposed, risk factors associated with HIV encephalopathy include maternal and child immune status, high plasma viral load, high levels of circulating monocytes, infection time, transmission route, and treatment options at an early stage (Le Doaréet al, 2012 and Abubakar et al, 2008).[10]

A study in the Democratic Republic of Congo examining the effect of HIV on the development of the nervous system in preschoolers found that HIV-infected children had a severe delay in cognitive function, motor skills, speech, and understanding[11]. Illustrating the complexity of the etiology of HIV-related cognitive and behavioral problems, the study also found that AIDS-infected orphans and HIV-negative children whose mothers had AIDS show a strong delay in their neurocognitive development, albeit to a lesser extent, in the area of development. than HIV-infected children (Van Rie et al, 2008)[12]. A review article of all studies in South Africa, evaluating the development, knowledge and behavior of HIV-infected children as their primary outcome, found evidence of a delay in cognitive function, speech and motor skills in children suffering from HIV[13]. However, this article also emphasizes the lack of information in this area, as well as the fact that almost all studies focus on a group of preschool children[14]. Also, according to the results of the study, it was shown that HIV affects all areas of the child's functioning, motor development is most obvious in terms of severity, early onset and resistance in all age groups. However, the development of motor skills was the most widely evaluated area, while the development of the language was less vigorously evaluated, therefore an accurate quantitative assessment of the effect cannot yet be made. (Abubakar et al, 2008).[15]

Purpose of the study is to evaluate the diagnostic significance of various testing method in assessing the severity of HIV-associated neuro-cognitive impairment in adolescent patients.[16]

Materials and Method

Study Population: The study included 154 children (92 boys - 59.74% and 62 girls - 40.6%) who are registered with HIV infection and are hospitalized in a Specialized Clinic of Infectious Diseases of the Republican AIDS Center (Tashkent, Uzbekistan) and receiving antiretroviral therapy (HAART). The mean age of the patients was 14.53±1.58 years (12-18 years), the duration of HIV diagnosis was 7.05±3.36 years (1-13 years), the duration of antiviral therapy was 6.41±3, 47 years old (1-13 years old). In 23 patients (14.94%), the vertical route of infection was diagnosed, and non the mother took HAART during pregnancy. In other children, the infection pathway is identified as parenteral. The average virus concentration was 345.85±181.45 copies/ml, while in 23 patients (14.94%) HIV RNA in the blood was not determined. The average number of $CD4^+$ cells was 461.91±230.32 in 1 mm^3 of blood.

Neurological Examination: A neurological study included a standard neurological examination, including an assessment of consciousness and some mental functions (speech, praxis, gnosis), functions of the cranial nerves, the state of the motor and sensory spheres, the autonomic nervous system, as well as neurophysiological and neuroimaging method of research (electroencephalography and magnetic resonance imaging).

Psychological and cognitive examination: All patients included in the study underwent the test aimed for studying the psychological and cognitive status, including test method: "The Raven progressive matrix scale" (state of intelligence), the Bass and Darki test modified by G.V. Rezapkina (diagnosis of various forms of aggressive behavior), and a pediatric quality of life questionnaire (PedsQL) for adolescents 13-18 years old.[17]

Intelligence Test: The Raven test, proposed for assessing the level of intelligence, is based on the use of the ability to learn based on the generalization of one's own experience and the creation of schemes to handle complex events, logical thinking. This test, convenient in application and simplicity in interpretation, repeatedly confirmed high indicators of validity and reliability.[18] The test allows it is not associated with linguistic abilities and skills and does not depend on the level of education. The Raven matrix consists of 60 images combined into 5 matrices, in each of which it is necessary to select the missing fragment, using the identified patterns.[19] In each matrix, tasks are progressively complicated. test tasks are performed without time limit, but it is noted how many tasks are completed correctly in the first 20 minutes. Thus, the Standard Progressive Raven Matrices test can be used both as a speed test (with time constraints on task execution) and a performance test (without time constraints).[20] The choice of the test application regimen should be made depending on the purpose and diagnostic conditions (first of all, the possibility of ensuring long-term continuous work of the test subject). The assessment is the percentage of correct answers, expressed as a percentage. Interpretation of the test allows us to distinguish 5 degrees of intellectual development: 1st degree - more than 95% - high intelligence; 2nd degree - 75-94% - intelligence is above average; 3rd degree - 25-74% - average intelligence; 4th degree - 5-24% - intelligence is below average; 5th degree is a defect.[21]

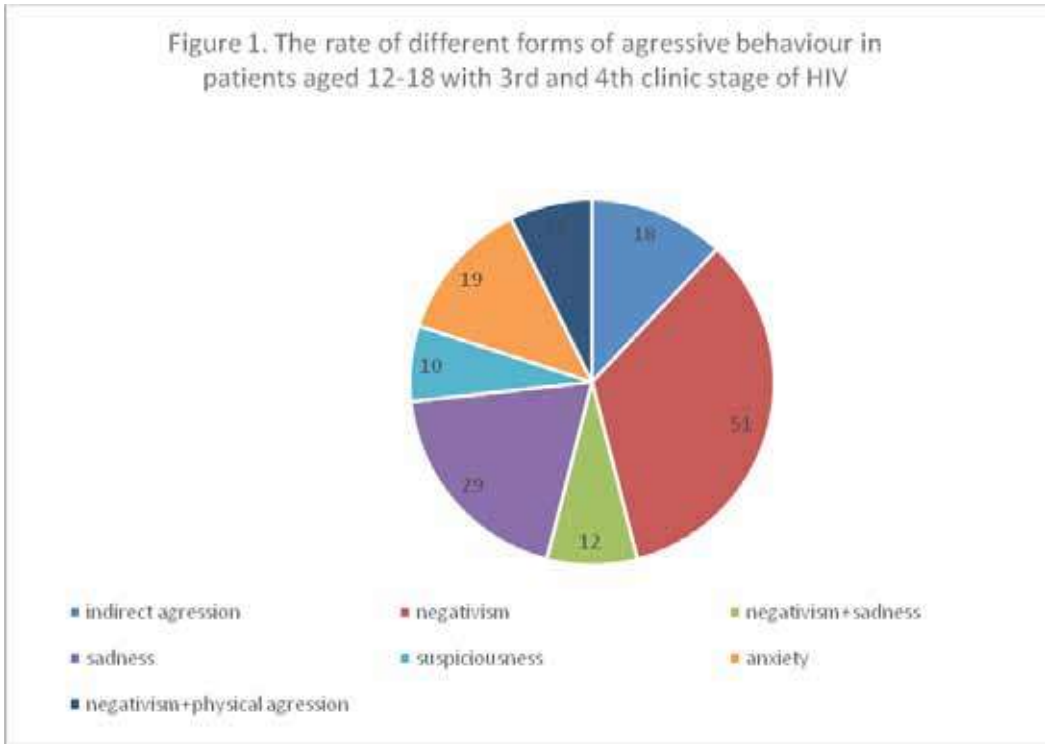
Test for behavior: Bass-Darki test, modified by G.V. Rezapkina, proposed in 2006, allows you to diagnose various types of aggressive behavior. The test includes 35 statement questions. The test subject is invited to apply the statement to patients.[22] If he reacts in a similar way, the answer is assigned 1 point. During the interpretation, all issues are divided into 7 forms of aggression. The form that received more than 3 points is recognized as dominant in the subject. According to the test results, the following forms of aggressive behavior are distinguished: physical aggression (statements 1,8,15,22,29), indirect aggression (2,9,16,23,30), irritation (3,10,17,24,31), negativism (4,11,18,25,32), resentment (5,12,19,26,33), suspiciousness (6,13,20,27,34), verbal aggression (7,14,21,28, 35).[23] The test is based on self-esteem. Its accuracy depends on the frankness of the subject. According to the results of the testing (increased level of aggression, inability to control emotions, etc.), it is not recommended to choose professions related to communication, maintenance, education, training - that is, all professions related to people. Low values for this test testify to your delicacy, pliability and non-conflict. However, these indicators may indicate a lack of perseverance in achieving their goals and defending their position.[24]

Quality of life Examination: The study of the quality of life of children is a new topical area of interdisciplinary research in domestic health care. The development of a methodology for studying the quality of life in pediatrics opens up the possibility of a comprehensive analysis of the physical, psychological

and social functioning of children. For this, our study used the pediatric quality of life questionnaire PedsQL, version 4 (for children aged 13-18), published in 1998 and translated into Russian, includes 23 situations that describe physical, emotional, social activity and school life. The questionnaire is recommended for studying the quality of life of healthy and sick children; using these tools, normative indicators of quality of life for the child population can be obtained. The use of the created tools in children with various diseases allows to expand knowledge about the attitude of children of a given age to their own health problems, treatment, degree of satisfaction with treatment; opens up new possibilities for assessing the impact of various diseases on the physical, psychological and social functioning of sick children. The test subject is asked to rate how each of these situations created difficulties in the past month. At the same time, 0 points are assigned to a situation that has never created difficulties, 5 points - in the case of constant difficulties with the described action. Thus, the maximum score for each situation is 5 points (almost impossible activity), the minimum score is 0 (no difficulty). The maximum score in terms of physical activity is 32 points, emotional social and complex activity is 20 points, the total maximum score is 92 point.

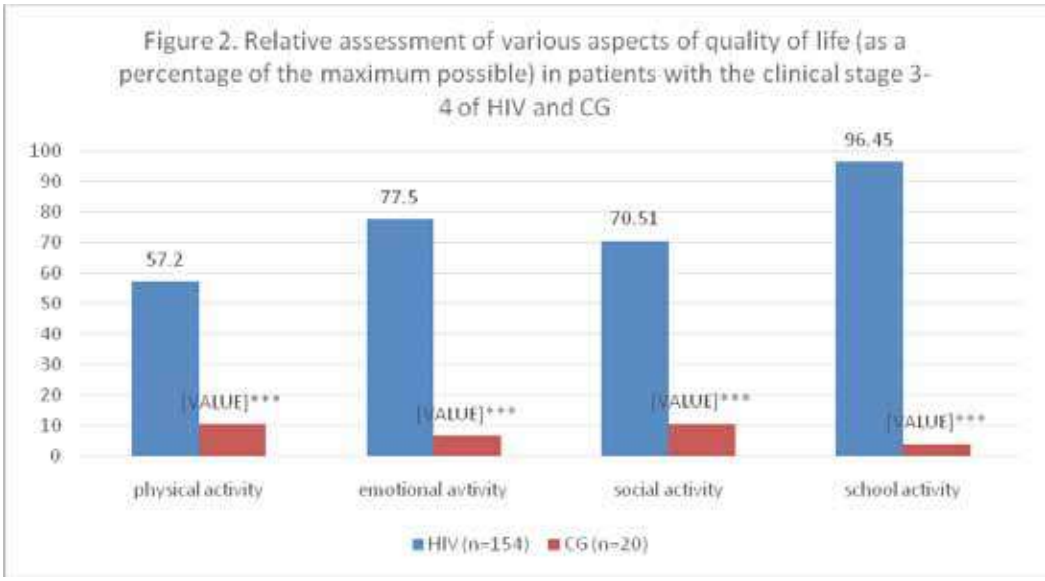
For comparison, the study included a group of 20 healthy adolescents of comparable age (control group - CG), who also tested using the above method.

Statistical Analysis: All data was entered into the software of MS Excel tables to calculate average values and their standard deviations. Intergroup difference was evaluated using Student's t-test for 2 comparisons. Frequency comparison was carried out using the chi-square table criterion.



Results

During the study, all patients were diagnosed with 3rd and 4th (77 patients each — 50%) clinical stages of HIV infection involving the nervous system disorders in the form of an HIV-associated neurocognitive disorder (grade 2 in 100 patients — 64.94% and grade 3 - in 54 patients - 35.06%). In addition, epilepsy (20.13%) was diagnosed in 31 patients, peripheral polyneuropathy (4.55%) in 7 patients, vacuolar myelopathy (5.19%) in 8 patients, and consequences of acute cerebrovascular accident in 9 patients with focal neurological deficit (5.84%), in 2 patients - the consequences of herpetic meningoencephalitis (1.30%).



A neurological examination revealed a syndrome of autonomic dysfunction with impaired skin innervation and functional disorders of the gastrointestinal tractin 142 patients (92.21%), coordinating disordersin 96 patients (62.34%), in 52 patients (33.77%) focal motor disorders, including hemiparesis, in 22 patients (14.29%), in 48 patients (31.17%) speech disorders and elements of apraxia were noted, in 32 patients (20.78%) - insomnia and parasomnia syndromes. At the time of the examination, all patients were diagnosed with a lag in psycho-motor development, although in the period of 1-3 years these disorders were detected only in 26 patients (16.88%). Convulsive syndrome was diagnosed and confirmed by electroencephalography in 11 patients (7.14%).

The test using the Raven progressive matrix scale revealed a significant decrease in the intellectual level in the patients included in the study: the average test result was 18.68±4.51%, with a spread from 6 to 26%. At the same time, in 8 patients (5.19%) the indicator was within the boundaries of average intelligence (25-74%), in the remaining patients (146 patients - 94.81%) - below the average (5-24%). In the CG, the average score obtained in the Raven test was 52.31±4.38% ($p<0.001$, the significance of the difference with the index of the main group).

Some forms of aggressive behavior were observed in all patients included in the study (Fig. 1), while, according to the Bass and Darka test in the modification of Rezapkina, negativism prevailed (74 patients - 48.05%), and in 11 cases (7.14%) it was combined with physical aggression, and in 12 cases (7.79%) - with resentment. In addition, indirect aggression was detected in 18 patients (11.69%), resentment in 41 patients (26.62%), suspiciousness in 10 patients (6.49%), and 19 patients (12.34%) - irritation. Indirect aggression (5%) was found in CG in 1 teenager, negativism in 3 (15%) and resentment in 2 (10%) ($p <0.001$ significance of the frequency of aggressive behavior between the main and CG according to the tabular chi-square criterion).

The quality of life questionnaire, adapted for adolescents 13-18 years old, revealed difficulties associated with physical activity (18.30±4.51 points with a maximum score of 32 points, Fig. 2), with emotional states (15.50±2.23 points with a maximum of 20 points), social activity (14.10±2.93 points with a maximum of 20 points) and life in school (19.29±1.23 points with a maximum of 20 points). For an objective assessment of the quality of life in patients with HIV infection, CG was included in the study, in which the average quality of life scores were 3.27±0.26 (difficulties associated with physical activity), 1.28±0.07 points (difficulties associated with emotional state), 2.11±0.03 points (difficulties associated with social activities) and 0.74±0.02 points (difficulties associated with school activities, $p < 0.001$, significance of differences with the average value in the main group for all four parameters).

Note: *** - significance of differences between HIV and CG groups $p < 0.001$.

Discussion

There are several neuropsychological and neuroimaging studies of HIV-positive children with a safe CD4 count (more than 25%). A neuro-visual study found that such children showed far worse results than an HIV-negative control group using the Wechsles Abberviated Scales of Intelligence Verbal and Preformance IQ test and standardized testing of visual-spatial processing of information, visual memory, and executive functions [21], which found in this study in adolescents with 3-4 stages of HIV infection. Significant motor and cognitive impairments were also found in HIV-infected children[22]. HIV in older children is currently associated with more narrow and specific cognitive impairments, including difficulties in visual-spatial and motor integration, memory lapses, impaired attention, speech and socio-emotional deficit [23]. These features (in particular, violations of the executive function) can lead to profound functional impairment in the classroom.

Adult literature on HIV-related CNS damage supports a range of HIV-related neurocognitive disorders, including HIV-related dementia, mild neurocognitive disorder, and asymptomatic neurocognitive impairment [24]. The criterion is clinically useful, since it takes into account the conceptualization of a number of functional disorders and helps to formulate an individual treatment plan for adult patients with HIV-related problems. Similar spectrum criteria are needed in the case of HIV in children in order to better understand the effect and the social and educational management needed to support children infected with HIV. As a result of these improvements in HIV treatment, many children now live to a young age. Therefore, neurocognitive profiles appear in HIV-infected older children and adults. Given that HIV is a chronic disease, and given the limitations of antiretroviral therapy, a significant proportion of these patients are expected to develop neurocognitive deficits and symptoms of HIV-related dementia, which is reported in the adult HIV literature.

Conclusion

In adolescents with a 3-4 clinical stage of HIV infection, damage to the nervous system in the form of HIV-associated neurocognitive disorder is manifested by a decrease in intelligence, various forms of aggressive behavior and is associated with a decrease in the quality of life in terms of physical, emotional, social activity and learning at school. To assess the severity of these disorders, method of neuro-psychological testing using the Raven matrix scale, the Bass-Darki emotion test modified by Rezapkina and the PedsQL-4 questionnaire are accessible and diagnostically informative.

Study Limitations: The amount of participant in the control group was less than that of main group to compare. It might have affect some of our results. Thus, further researches can be conducted with same amount of participants in each arm.

Acknowledgements: We are grateful to the staff of Department of Neurology, Pediatric Neurology and Medical Genetics, Department of Faculty Internal Medicine, Professional Pathology, Hospital of Internal Diseases and Propaedeutics of Internal Diseases, Department of Epidemiology, Infectious Diseases of Tashkent Pediatric Medical Institute for the cooperation in our research. The parents of the participants kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from all participants' parents of the research for publication of this paper and any accompanying information related to this study. A copy of the written consent is available for review by the authors.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Abstract

The study relies on data received during treatment of 128 children and teenagers suffering idiopathic scoliosis. The subjects' median age is 10,2±0,39 years old. In the treatment group (90 juvenile subjects), treatment of scoliosis has been carried out according to an optimized conservative integrated algorithm with reliance on bone mineral density indicators and the Cobb's angle. The length of treatment averages 1,5±0,2 years (1 to 3 years).

The control group (30 subjects) has undergone traditional correction on an outpatient basis with the use of standard method: therapeutic exercise, massage, physiotherapy. The length of treatment averages 1.7±0,1 years (1 to 3 years).

Compared to traditional method, optimized conservative integrated treatment of idiopathic scoliosis demonstrates a 29% higher occurrence of positive results. Efficacy of brace treatment of moderate and severe progressive juvenile/adolescent scoliosis has been observed, as it has reduced spinal deformation and eased socio environmental adaptation.

Keywords: *Idiopathicscoliosis, conservative treatment, brace treatment, children.*

Introduction

Idiopathic scoliosis (IS) is a common and serious spinal disorder, which affects children and teenagers (T.N. Sadovaya, 2010; M.V. Mikhailovsky, et al., 2017, Brooks Smyrnis P. et al., 2009),[1] and causes cardiovascular and pulmonary disorders, severe postural abnormalities, earlydisabilityand, consequently, affects mental health (V.S. Mironov, 2010; H. Bouloussa. etal., 2019)[2]. Based on statistical data on idiopathic scoliosis, it can be noted that they have not changed much over the last decades: 1% to 12% of juvenile population are affected by scoliosis (Sadovaya T.N., 2010; Brooks Smyrnis P. et al., 2009)[3]. According to Sadovaya T.N. (2010),[4] idiopathic scoliosis accounts for 80% to 85% of all spinal deformities. It means that idiopathic scoliosis is one of the most frequently occurring juvenile musculoskeletal conditions. A more detailed statistical analysis reveals other features of idiopathic scoliosis as well: for the most part, it is diagnosed in children aged 10-15 years old, i. e. into adolescence. This is exactly when spinal deformation takes on the most formidable form – adolescent scoliosis (Grivas T.B. et al., 2009) affecting one out of every three or four patients.[5]

Based on the clinical picture and X-ray patterns, idiopathic scoliosis can be defined as typical and atypical. Typical scoliosis is diagnosed when there are curvatures of the vertebral column, mostly right thoracic and left lumbar curves with pronounced physiological

lordosed thoracic kyphosis and increased physiological lumbar lordosis. This type causes an abnormal convex side rotation of vertebrae. One out of every three casesis progressive, and it accounts for the majority of cases of structural heart defects, cardiac, respiratory, digestive and central nervous system disorders (Grivas T.B. et al., 2009).[6]

Fragmentation and disintegration of approaches explains the low efficacy of treatment of this spinal disorder.[7] The main problem affecting interdisciplinary interaction is limited use of fundamental knowledge within each healthcare field, which impedes development of fairly effective treatment method.[8] The huge number of existing symptomatic treatment method target separate stages of the pathological process sporadically and do not provide any ultimate solution.[9]

This study is aimed at optimizing the process of conservative treatment of juvenile and adolescent scoliosis.

Materials and Method

We have investigated 128 juvenile and adolescent subjects with IS. The patients were hospitalized to the Republican Center of Juvenile Orthopedics. Age groups have been formed according to the WHO classification, and the obtained data is shown in Table 1.

Table 1: Distribution of IS patients according to age

Age	Male subjects		Female subjects		Total	
	Abs.	%	Abs.	%	Abs.	%
0 to 3	5	45.5	6	54.5	11	8.6
4 to 6	5	25.0	15	75.0	20	15.6
7 to 9	11	40.7	16	59.3	27	21.1
10 to 13	15	41.7	21	58.3	36	28.1
14 to 17	16	47.1	18	52.9	34	26.6
Total	**52**	**40.6**	**76**	**59.4**	**128**	**100.0**

The majority of cases (28.1%) have been observed in children ages 10-13. The median age is 10.2±0.39 years old. According to some sources, this can be due to rapid skeletal growth during puberty and an increased risk of progressive scoliosis at this particular age. Sex distribution, as follows from the table, is biased towards the female sex (by a factor of 1.5), which corresponds to the data obtained from the sources.

Distribution according to the severity of deformities has been made according to the V.D. Chaklin's classification (1965). The study has involved children with spinal deformities with 31.3% (40/128) of them diagnosed with scoliosis Grade 1, 23.4% (30/128) - Grade 2, 17.2% (22/128) - Grade 3, and 28.1% (36/128) – Grade 4. Most juveniles have thoracic (35.2%, 45/128), thoracolumbar (27.3%, 35/128), combined(23.4%, 30/128), and lumbar(14.1%; 18/128) scoliosis.

In the control group, 66 children ages 5-17 have been examined. Based on the examination results, no spinal deformities have been observed in these children. Median age in the control group is 13.8±2.1 years old ($p<0.05$).

During the physical examination, doctors have checked patients for uneven shoulder height, shoulder-blade asymmetry, spinous process rotation,torsion in the form of a rib hump and muscular embankment in the lumbar area. It is important to check spinal mobility and stability through the pulling of the head. Pelvic tilts and lumbar lordosis are diagnosed in a standing position; abdominal muscles are checked in a lyingface-up position; back muscles are examined in a lying face-down position.

Scoliosis patients are examined in a standing position from back and front, in a side-lying position from back, in a standing position from a sagittal perspective, and in a bent-forward position from back and front (Fig. 1).

X-ray imaging has been conducted at the Department of Radiology of the JMDS-Service Clinic on a Silhouette radiographic system (General Electric), (128 images).

Of 128 children, 120 have been examined. A group of 8 children have failed to follow recommendation and regime and therefore have not completed the conservative treatment. The 120 juvenile subjects have been divided into two groups: the treatment group and the comparison group.

The *treatment group* has included 90 children: 33 (36.7%)boys and 57 (63.3%) girls. Treatment of the group's subjects has been administered with the use of the conservative integrated idiopathic scoliosis treatment method developed by us. The treatment has lasted 1 to 9 years (1.5 years on average), the follow-up period has lasted 1 to 13 years, averaging 2.2 years.

Fig. 1. Examination of patient A., 14 years old

The *control group* has included 30 children – 4 (13.3%) boys and 26 (86.7%) girls. The control group subjects have been treated on an outpatient basis according to standard method: therapeutic exercise, massage, physiotherapy. The treatment has lasted 1 to 6 years, on average – 2.1 years. The follow-up period has lasted 1 to 9 years, on average – 3.4 years.

Both control and treatment group subjects diagnosed with scoliosis, along with clinical symptoms, had ragiological signs indicating structural changes in vertebrae. Both groups have shown a 100% occurrence of spinal torsion. Wedge-shaped deformities of vertebrae and intervertebral cartilages have been observed in 43.3% and 63.3 control group subjects respectively and in 38.9% and 73.3% treatment group subjects respectively.

Therapeutic exercise is applied as essential therapy to patients with scoliosis Grade 1 and Grade 2 and as adjunct therapy to patients with scoliosis Grade 3 and Grade 4. Exercises are chosen individually depending on the severity of case, presence or absence of underlying diseases and contraindications. Exercises are intended for stimulation and strengthening of back muscles, which help straighten out the spine and other bones. No workouts, racing, jumping and spine-twisting exercises are allowed. Gym ball exercises and use of specific training devices have proved useful. The length of training courses varied between 2 and 6 months (3.5±0.01 months on average).[10]

Massaging scoliosis-affected areas helps muscles regain tone, improves blood circulation and metabolism. Therapy lasts 10 days, and it is repeated every two months over a 12-month period. Physiotherapy is prescribed for patients with a Cobb angle of 10 degrees or more. This kind of therapy improves blood flow and nerve conduction, eliminates pain and normalizes tissue metabolism. Treatment group patients have used Almagand Duna devices, as well as a Vitafon vibration massage device to stimulate core back muscles. Therapy lasts 10 days and it is repeated every two months over a 12-month period.

Brace therapy has been carried out with the use of a Cheneau type functional correcting brace. Measurements have been made individually on each patient. The use of an orthopedic brace is prescribed to patients with steadily progressing scoliosis and a Cobb's angle of 25-40 degrees (Grade 3 and Grade 4). Braces have been made on the basis of individual measurements for 18 subjects in such a way as to minimize discomfort. A brace should be worn several hours a day and removed only during

gymnastics and hydrotherapeutic procedures (Fig. 2) It should be used for a period of 12 months.

Рис. 2. Patient M., 13 years old. Scoliosis Grade 3. Brace therapy, view from the rear and front (a Cheneautype brace)

Late fate has been evaluated based on the results of clinical, X-ray and instrumental method of diagnosis, as well as based on patients' posture and appearance. We have included in the late fate the results of treatment achieved after 12 month of therapy.

The obtained data has been subject to statistical analysis on a Pentium-4 computer with the use of Excel package featuring statistical functions. Differences between median values have been deemed relevant with P-value *P<0.05.*

Results

Throughout the treatment, all patients have shown a quick improvement as early as by the fifth session, having less pain in the back, neck and legs. A clinical examination revealed a decrease in waist asymmetry in both groups (Table 1). In the comparison group, the asymmetry has decreased by 0.44±0.08 cm (the decrease ratio (DR)=41.0%, p<0.005), in the treatment group – by 0.33±0.07 cm (DR=56.3%, p<0.005). In the comparison group, the discrepancy between shoulder-blade and shoulder angles decreased by 1.0±0.5 cm (DR=30.1%, p<0.005), in the treatment group – by 1.4±0.6 cm (DR=54.3%, p<0.005).

Thus, the treatment group has shown a less severe spinous process rotation in the lumbar area, and the deterioration has been fairly rarer according to 3 out of 5 parameters. In the Grade 1 group, the clinical effect has been achieved both in the comparison and treatment group. In the treatment group, waist asymmetry has decreased by 58.4±1.4%, shoulder asymmetry – by 57.3±1.2%, while in the comparison group it has decreased by 23.5±1.3% and 24.4% respectively (p<0.005).

Table 1: Dynamics of clinical signs of scoliosis in the groups

Common signs	Treatment group (n=90)		P	Comparison group (n=30)		P
	Pre-treatment	Post-treatment		Pre-treatment	Post-treatment	
Deviation of the body	76 (84.4%)	56 (62.2%)	<0.05	25 (83.3%)	22 (75.9%)	>0.05
Thoracicspinous process rotation	82 (91.1%)	61 (72.2%)	<0.05	27 (90.0%)	25 (83.3%)	>0.05
Lumbar spinous process rotation	88 (97.8%)	75 (83.3%)	>0.05	29 (96.7%)	27 (90.0%)	>0.05
Shoulder-blade asymmetry	76 (84.8%)	38 (42.2%)	<0.05	28 (93.3%)	23 (76.7%)	>0.05
Breastbone-to-superior-iliac-spine asymmetry	90 (100%)	46 (51.1%)	<0.01	29 (96.7%)	21 (70.0%)	>0.01

Pisthecriterion of significance of the difference between pre-treatment and post-treatment indicators within a group.

The Grade 2 group has shown a somewhat lower effect than the Grade 1 group. In the comparison group, waist asymmetry has diminished by 34.3±1.2%, in the treatment group – by 42.4±1.4% (p<0.005). Shoulder-blade and shoulder asymmetry has decreased by 52.5±1.3% in the treatment group and by 45.4±1.1% in the comparison group. Clinical symptoms in juvenile and adolescent subjects with scoliosis Grade 3 have changed as follows: in the treatment group, waist asymmetry has decreased by 25.3±1.2%, in the comparison group - by 20.1±1.2%.

The treatment group has demonstrated a 6% increase in active spinal flexibility while performing forward bends and a 14.1% increase while performing backward leans. The asymmetry of left-side and right-side tilt depth values in patients with early stage and mild scoliosis has not exceeded 10%. The asymmetry has

been more pronounced in Grade 2 and Grade 3 groups (14.5%±6.2%).This category of patients has shown the best result in the treatment group, where the asymmetry ratio has decreased by 42%, while in the comparison group the ratio has decreased by 23%.

The conservative integrated treatment has boosted muscular endurance, raised tolerance to physical workload, as the subjects have done well in back therapy training and had no back pain after exercising. The investigation has revealed a potential for a longer abdominal muscle workout in the treatment group. At the lower end, the maximal increase – by 59% - has been observed in the treatment group (27.1±22.1 seconds before treatment vs. 86.0±29.3 seconds, p>0.05), while in the comparison group – by 20.2% (67.1±35.5 seconds before treatment and 86.0±29.3 seconds after treatment,p>0.05). The endurance of back muscles in a lying-straight position has increased in both groups by 27% to 30% (82.0±34.9 seconds before treatment and 103.0±34.3 seconds, p<0.05)

Discussion

A comparative analysis of the results of the therapy achieved by the treatment and control groups has shown that positive changes have been more pronounced in the treatment group. These changes have been observed both during a clinical and radiological examination. The biggest achievement is that the obtained data correlate and demonstrate mitigation of structural scoliosis symptoms. [11]

A review of the results achieved by the comparison group reveals mild positive clinical dynamics in juvenile and adolescent subjects. The Cobb's angle dynamics observed across the groups, which takes into account the degree and localization of curvatures, is presented in Table 2.

As follows from the table, the juvenile and adolescent subjects of the treatment group show a more pronounced decrease in the Cobb's angle regardless of grade, relative to the comparison group.[12]

The comparative analysis has revealed the most prominent positive results in the treatment group. The changes have been observed both during clinical and following radiological examinations.

A frontal radiograph made in a lying position (Fig. 2c) is used to evaluate frontal imbalance and determine the Kazmin's index of stability, which can be deemed as orthostatic interdependence of deformation parameters. The frontal images (Fig. 2d, e) made in maximal right- and left-side bending positions are functional *bending test* type radiographs.

It is advisable to plan orthopedic tests at this stage, depending on the clinical picture and bone maturity, at a two to six-month interval. During treatment, radiographic imaging is carried out as part of brace therapy; frontal and lateral images are made in a standing position (Fig. 3) The following radiographs reflect the result of the correction therapy, and their data is compared to initial curvature parameters, particularly with those of the bending test images, which are actually the target parameters for the correction therapy.

Table 2: Cobb's angle dynamics during the treatment

	Type of scoliosis	Severity of curvature (degrees)		Correction		P
		Pre-treatment indicators	Post-treatment indicators	Degrees	%	
Comparison group (n=30)	Grade 1 (n =7)	7.6±0.3	6.6±0.2	1.0±0.01	6.0	>0.05
	Grade 2 (n=8)	17.7±2.5	16.1±2.5	1.6±0.1	9.0	>0.05
	Grade 3 (n=9)	50.4±3.6	50±3.8	0.4±0.08	0.79	>0.05
	Grade 4 (n=9)	73.2±4.1	72.3±5.6	0.9±0.06	0.81	>0.05
Treatment group (n=90)	Grade 1 (n =29)	7.2±0.2	4.9±0.09	2.3±0.01	9.2	<0.05
	Grade 2 (n=20)	18.75±1.3	14.5±1.5	4.25±0.3	22.7	<0.05
	Grade 3 (n=11)	18.2±1.1	14.2±1.4	4±0.4	22	<0.05
	Grade 4 (n=30)	44±4.7	40.6±4.3	3.4±0.5*	7.7	>0.05

Fig. 2. X-ray images of an idiopathic scoliosis patient requiring brace treatment: frontal image made in a standing position (a); lateral image made in as tan ding position (b); frontal image made in a maximal right-side bending position (d); frontal image made in a maximal left-side bending position (e).

Fig. 3. Pre-treatment (a) and corrective brace therapy (b) radiographs of the spine: effect achieved following frontal major curve correction Th11-L3 on the left

Fig. 4. A 8-year-old girldiagnosed with moderatescoliosis: a –case record; b –a Cheneau type brace; c) radiograph received during initial medical examination; б) radiograph received following the brace therapy

In all 18 subjects deformities have improved. In 12 patients, the positive effect has lasted throughout the follow-up period (Fig. 4 a, b, c, d).

In five subject deformities continued to deteriorate throughout six months due to failure to follow brace treatment requirements. Correction has required two additional braces on average.

Two subjects needed a surgery, one due to refusal to undergo brace treatment; the other had a severe case of scoliosis without a possibility of curve correction.

Conclusion

Therefore, treatment of children suffering idiopathic scoliosis Grade 3 and Grade 4, with a Cheneau brace in combination with individual therapeutic exercises, in most cases helps eliminate scoliosis symptoms. However, in cases when a visibly good effect is achieved, which is purely cosmetic, without actually progressing in the correction of spinal deformities, surgical treatment is still admissible. Refusal to wear a brace is the most common cause of deteriorating deformities. It is necessary to carry out socio-educational work to provide early diagnostic of IS to avoid progressive spinal deformities and reduce the risk of having to undergo surgeries.

1. Juvenile and adolescent idiopathic scoliosis is characterized by a spinal dysfunction, as in 85.2% of scoliosis subjects deflection of spinous processes from the axis has been observed, 78.9% have shoulder-blade asymmetry, and 53.1% of subjects have shoulder asymmetry. The Nash and Moe method has helped reveal torsion in 13.3% of children.
2. Children and teenagers with IS have bone tissue pathologies resulting in a 2.8 times lower Z-score in mineral bone density tests, which signifies low osteosynthesis and structural changes in the spine.
3. Data obtained during mineral bone density tests on children and teenagers with IS can be used as prognostic criteria to evaluate the likelihood of deterioration.
4. The newly developed conservative integrated IP treatment method is more effective than traditional method, as it helps achieve a positive effect in 89.4% of cases compared to traditional method providing 56.9% of such cases.
5. The study has proved the efficacy of brace therapy in juvenile and adolescent IS subjects, as it has stopped the deterioration and helped correct axial spinal deformities.

Abstract

The article represents the results of the observation oft he comparative clinical examination of herpetic infection coupled with HIV infection in 57 children aged 1 to 15 years. There have been 41 boys (71,93%) and 16 girls(28,07%). The comparison group included 23 children oft he same age infected with HIV without herpetic infection.

The following laboratory research method have been used: a general analysis of blood, urine, feces, the study of the immune status, level of CD4 cells; Serological: by ELISA method antibodies to CMV and HSV (Herpes Simplex Virus) have been detected in blood. The results obtained indicate that coexisting diseases with the formation of complications and immunodeficiency development have been worsening the course of herpetic infection in HIV infected children and leading to a severe relapsing course.

Keywords: *Herpeticinfection, HIV infection, children, Herpes Simplex Virus.*

Introduction

The most significant group of opportunistic infections in HIV-infected children is the herpes group[3]. Infections caused by herpetic viruses draw attention by high prevalence in the human population. The most significant group of opportunistic infections in HIV-infected children is the herpes group[3]. Infections caused by herpetic viruses attract attention with a high prevalence in the human population. Among human viral diseases, herpetic infection (HI) occupies one of the leading places, which is explained by its ubiquitous transmission[4]. Herpeticinfectionis a group of diseases caused by herpes simplex viruses (HSV) of type 1 and 2. Atherpeticinfectionnotonlyepithelial, hematopoietic, nerve cells are affected, but also T-lymphocytes, which leads to the development of secondary immunodeficiency and generalized forms of the disease[5]. Herpes viruses are widespread in the human population, they are able to infect almost all organs and systems of the host organism, causing latent, acute and chronic forms of infection[3]. The cytopathogenic effect of herpes viruses is enhanced against the background of immunodeficiency condition. HIV infection is accompanied by the development of opportunistic diseases, among which herpes viruses take one of the leading places. The most common among them are lesions associated with herpes simplex viruses, zoster varicella, cytomegalovirus[1]. Herpes viruses can activate HIV, which is in the provirus stage, and is a cofactor in the progression of HIV infection and AIDS. In this regard, herpetic infection (HI) is one of the important AIDS-indicator disease. AIDS currently ranks third in the world in the group of deaths after diseases

of the cardiovascular system and neoplasms, and among children with HIV/AIDS it is the leading cause of death. The incidence of HI in the general population is 650-720 per 100 thousand population. Among HIV-positive, the same indicator is almost 10 times higher[2]. The viral etiology of the herpes group causes anabnormality of the functions of the immune system, resulting in the progression of immunopathological reactions, which reduces the control of virus replication, causing a manifestation or relapse of the disease[6].With herpes, immunodeficiency states develop due to the insufficiency of various parts of the immune system and its inability to eliminate the virus from the body. Persistent throughout life, sometimes in considerably high titres, virus-neutralizing antibodies if rather embarrass the spread but do not prevent the occurrence of relapses[6].

The urgency of the problem is determined by the high mortality rate of HIV-infected children with herpes infection, the absence of clear criteria for the diagnosis itself, as well as the natural difficulties in establishing this diagnosis.

The aim of the researchis to study the comparative clinical signs of herpes infection coupled with HIV infection.

Materials and Method

A clinical examination of herpetic infection in HIV-infected children has been conducted. 57 patients aged 1 year to 15 years registered at the Research Institute of Virology of the Ministry of Health of the Republic of Uzbekistan were under the supervision. Primary HIV diagnosis: a) Serological studies - the determination of antibodies to the human immunodeficiency virus has been carried out in the laboratory of the AIDS Center of the Ministry of Health of the Republic of Uzbekistan. The diagnosis of HIV infection has been verified in accordance with the National Protocol of the Republic of Uzbekistan, No. 117 as of March 17, 2005. The comparison group included 23 children of the same age infected with HIV withouth erpeticinfection. The results of repeated HIV tests were negative. Laboratory research method included a general analysis of blood, urine, feces, the study of the immune status, level of CD4 cells; Serological method: by ELISA, antibodies to CMV and herpes simplex virus (HSV) have been determined in the blood.

57 children aged 1 to 15 years have been under our examination: 41 boys(71,93%)and 16girls (28,07%).57 HIV-infected children with herpesvirus infection who have been HIV positive and herpesvirus infection has been serologically confirmed. The control group consisted of 23 children with HIV infection without herpes virus. Observations and general clinical studies have been conducted on the basis of the Research Institute of Virology of the Ministry of Health of the Republic of Uzbekistan. In terms of age, the children have been divided as follows: from 1 year to 6 years – 34children (59.65%), from 6 years to 10 years - 13 children(22.81%) and from 10 to 15 years - 10 children (17.55%). The diagnosis of HIV infection has been established on the basis of epidemiological, clinical and laboratory tests, confirmed by double detection of antibodies (AB) to HIV by enzyme-linked immunosorbent assay (ELISA). The diagnosis of HI has been established on the basis of the disclosed changes in the organs and systems taking into account the polytropy of the pathogen and the generalized nature of the lesions in the terminal stage of the disease. For each child, an examination card has been filled out, in which the passport part, the date of admission of the child, a detailed clinical diagnosis, medical history, infection routes, therapeutic measures, as well as the results of laboratory and instrumental research method throughout the observation period have been noted. Clinical and laboratory examination included: examination, thermometry, ultrasound of the abdominal organs, a general blood test, a biochemical blood test to determine the content of total protein, bilirubin and its fractions, AlAT, AsAT, sedimentary sample.

Statistical processing of the results has been carried out using the STATISTIKA V.5.5A program with the Student's t-criterion. The etiological interpretation of HI has been based on the results of polymerase chain reaction (PCR). A comparative analysis of the severity of the disease has been carried out with HIV-infected patients without HI[23], having similar HIV infection experience and similar sex and age characteristics. This group of patients (HIV + HI)[57] has undergone a comprehensive clinical and laboratory examination.

Results

The results of there search haves how nth at in the structure of coexisting diseases in young children frequent acute respiratory viral infections prevail with the formation of complications (18.7%), digestive tract infections (27.1%), fungal skin lesions (2.1%), in the group of children from 7 to 15 years there has been less

complications (p<0,05) rather than in younger children. An analysis of the results has disclosed that the most common in HIV-infected children without herpes infection are coexistingdiseases in the form of anemia in 19 (82.61%) cases, damage to the nervous system in 16 cases (69.57%), 14 cases of pneumonia(60.87%), 10 cases of tuberculosis (43.48%), 9 cases of intrauterine infection (39.13%), as well as 7 cases of chronic viral hepatitis B + C (30.44%),5 cases of thrombocytopenia (21.74%), 3 cases of sepsis (13.05%), 3 cases of chronic viral hepatitis C (13.05%), 2 cases of chronic viral hepatitis B (8.70%), 1 case of syphilis (4.35%). As HIV infection progresses, the severity of herpetic lesions worsens, which requires timely diagnosis[33] and therapeutic antiviral therapy[43]. From the epidemiological data, the identification of children at risk has been of great importance[75]. The characteristics of the children included in the researchhave been based on the classification of herpetic infection proposed by V.F. Uchaykin. The severity of the course of RHI has been determined by the frequency of relapses (Masyukova S.A. and others. 2007). The results of the research have shown that herpes simplex type 1 and type 2 occurred in 59.65–80.71% of HIV-infected people without herpes infection, causing mucocutaneous ulcerative lesions, diseases of the nervous system[14]. Herpes zoster is observed in 15.79–31.58% of patients with HIV infection and is one of the earliest markers of immunosuppression[12]. Coexisting diseases such as anemia (54 cases - 94.74%), nervous system damage (41 cases - 71.93%) pneumonia (38 cases - 66.67%), tuberculosis (33 cases - 57.90 %), toxoplasmosis (28 cases - 49.13%), intrauterine infection (26 cases - 45.62%), as well as chronic viral hepatitis B + C (24 cases - 42.11%), sepsis (20 cases - 35.09%), thrombocytopenia (15 cases - 26.32%), trichomoniasis (11 cases - 19.30%), chronic viral hepatitis C (10 cases - 17.55%), chlamydia (7 cases - 12.28%), syphilis (6 cases - 10.53%) are the most frequently met in HIV-infected children with herpesvirus infection[32]. The simultaneous action of such unfavorable factors as an early age at the time of infection, premorbid background, intensive parenteral loads exacerbated the course of herpes virus infection in HIV-infected children and also led to an early lethal outcome[50].

Discussion

An analysis of the clinical stages of HIV-infected patients with clinical signs of herpes virus infections shows that most of them 78.96% have been at stage 2 (stage 2B - 36.85%, stage 2C - 8.78%).

Studies conducted have shown that the prevailing form of relapse of herpetic infection in HIV-infected children is herpes of skin (52.64%).

The results of the researchhave shown that in children under 6 years of age complications have been significantly more likely to be detected than in the group of children from 7 to 15 years of age, where complications have been less common (p <0.05). Overcooling in 61.41% of cases, insolation in 8.78%, psychoemotional stress in 3.51%, acute respiratory viral infection in 57.90%, mechanical trauma to mucous membranes in 7.02%, and exacerbation of allergic dermatosis in 8.78% of cases have become provoking factors for the development of relapses of infection. Severe RHI course has been recorded more often in children under 6 years of age, the duration of relapse in children under 6 years of age has been significantly higher (p <0.05). The occurrence of relapse has been accompanied by intoxication signs, more pronounced in young children. The terms of epithelialization of defects have been delayed in children under 6 years of age by 7.4±1.7 days from the onset of the disease, and in the group of children from 7 to 15 years of age by6.4±2.8 days. The number of leukocytes in children under 6 years of age during the onset of relapse has been characterized by moderate leukopenia (5.0±1.76 *) (p <0.05) with relative lymphocytosis (64.9±1.40) (p <0.01) preserved in remission (61.4±1.82) (p <0.05). In the period of exacerbation of the disease in children over 7 years old, leukocytosis (6.4±2.15) (p <0.05) with relative lymphocytosis (40.1±1.22) (p <0.01) has been noted. The remission period has been also characterized by an increase in the percentage of lymphocytes (38.7±0.11) (p <0.05). The subpopulation composition in children from 1 year to 6 years of age with RHI during the period of exacerbation has been characterized by a pronounced decrease in the relative (22.6±1.35) and absolute (0.74±0.15) levels of CD4,% cells compared with the control group (37.7±1.47) (1.47±0.06) (p <0.001). During remission, their absolute number corresponded to (1.01±0.03) (p <0.05), the control group (1.47±0.06). In the group of children from 6 years to 15 years, there has also been a significant decrease in the relative content of SD4,% cells during periods of exacerbation (23.4±2.51) (p <0.001) and remission (27.3±3.09) (p <0.01). Their absolute number during exacerbation decreased moderately (0.63±0.12) (p <0.05), during remission it has corresponded to the norm (0.75±0.12). The indices of the absolute and relative content of T-cytotoxic lymphocytes during exacerbation

(40.1±1.22) and during remission (38.7±0.11) have not differed from the control values (34.2±1.35) in the group 6 years to 15 years. In children from 1 year to 6 years, there has been a significant increase in the relative content of SD8,% cells throughout the observation period (27.7±1.73) (p <0.01). Their absolute content has sharply increased during the exacerbation of the disease (1.14±0.17) (0.91±0.07) (p <0.001). In children from 1 year to 6 years, a decrease in the relative content of SD16,% cells during exacerbation (9.3±1.02) (p <0.01) and remission period (10.1±1.11) (p <0.05) of the disease has been noted. In children from 6 years to 15 years, the level of MK cells has decreased only during relapse (8.1±0.92) (p <0.05). The absolute number of CD16 cells in children from 1 year to 6 years and in the group from 6 years to 15 years has also decreased during the period of relapse (0.33±0.05) (0.26±0.06) (p <0, 05). In both groups, normal values of the relative number of B-cells have been recorded. Their absolute content has significantly decreased in children from 1 year to 6 years during remission (0.90±0.09) (0.51±0.03) (p <0.05).

The humoral immunity has been characterized by an increase in the values of all classes of immunoglobulins. The IgM level mg/μl in children from 1 year to 6 years has increased during the period of exacerbation of the disease (1.5±0.68) (p <0.05), and in remission period as well (1.5±0.19). In children from 6 years to 15 years, an increase in IgM mg/μl has been more pronounced during the exacerbation period (1.6±0.19) (p <0.01), normalizing during remission of the disease (1.3±0.15) (p <0.05). High values in children from 1 year to 6 years have been recorded throughout the course of the disease (p <0.01). In the group of children from 6 years to 15 years, an increase in the level has been observed only during exacerbation (p <0.01). The IgA content mg/μl in both groups has had a similar dynamics, increasing during an exacerbation of the disease (1.3±0.11) (1.8±0.22) (p <0.01). In remission, IgA hyperimmunoglobulinemia has persisted in both groups (1.2±0.26) (1.7±0.19) (p <0.05).

The results of the research have shown that in all HIV-infected children with herpes infection that we have observed, various forms of chronic HI have been diagnosed, the reactivation of which has occurred in 21 cases(36.85%), and the relapsecourse in 36 cases (63.16%). A comparative assessment of the severity of the disease shows that HI has been more often detected in HIV-infected patients at stages 2B and 3B, which means that the number of patients with a progressive course of HIV infection has prevailed. HI coupled with HIV with damage to skin and mucous membranes has been characterized not only by more abundant and widespread elements of the vesicular rash, but also by its slowed regression, lasting more than 1 month (from 6 to 8 weeks).

The results of the research have shown that with herpetic infection of HIV-infected children, severe immunosuppression is observed. The number of leukocytes in children under 6 years of age during the onset of relapse has been characterized by moderate leukopenia (5.0±1.76 *) (p <0.05) with relative lymphocytosis (64.9±1.40) (p <0.01) preserved in remission (61.4±1.82) (p <0.05). The subpopulation composition in children from 1 year to 6 years with RHI during the period of exacerbation has been characterized by a pronounced decrease in the relative (22.6±1.35) and absolute (0.74±0.15) levels of CD4,% cells compared with the control group (37.7±1.47) (1.47±0.06) (p <0.001). In the group of children from 6 years to 15 years, there has also been a significant decrease in the relative content of SD4,% cells during periods of exacerbation (23.4±2.51) (p <0.001) and remission (27.3±3.09) (p <0.01). The humoral immunity has been characterized by an increase in the values of all classes of immunoglobulins. The IgM level mg/μl in children from 1 year to 6 years has increased during the period of exacerbation of the disease (1.5±0.68) (p <0.05), and in remission (1.5±0.19).

Clinical case: Boy,GiyasovKomil, 3 years. Diagnosis at admission: Herpetic infection, HIV infection, stage 3 (persistent generalized lymphadenopathy, persistent hepatosplenomegaly, recurrent aphthous stomatitis, enlargement of the parotid salivary glands, recurrent upper respiratory tract infections, persistent fever, persistent diarrhea, ıpersistent oral candidiasis, severe recurrent bacterial pneumonia, HIV-associated encephalopathy). Coexistingdiagnosis: congenital heart disease (ventricular septal defect), Sturge-Weber phacomatosis, mild anemia (hemoglobin level - 98 g/l). A child has had multiple developmental stigmas. Immunological parameters: CD4 level - 23.6 cells/μl. Virological research method have not been available. ART initiated, scheme: lamivudine, zidovudine, nevirapine. In 2 months after the beginning of therapy, its clinical, immunological (CD4 - 27.7 cells/μl), virological (viral load has not been determined) effectiveness has been noted. The hemoglobin level has been 14 g/l, that caused the replacement of the medication.

Thus, the occurring immunological changes in herpes infection in HIV-infected children have disclosed signs of combined immune deficiency. The data presented in the research indicate that, with herpetic infection in HIV-infected children, the cellular and humoral immunity systems are suppressed and unbalanced. However, there is a functional inadequacy of the body's natural resistance system. The emerging immunological shifts of herpes infection in HIV-infected children indicate severe immunosuppression - leukopenia, lymphocytosis, a significant 1.3 times decrease in the content of CD3-, CD4-, cells, an increase in the levels of all classes of immunoglobulins in the period of exacerbation of the disease, signs of combined immune deficiency have been revealed. The data presented in the research indicate that, with a herpetic infection in HIV-infected children, the cellular and humoral immunity systems are suppressed and unbalanced. However, there is a functional inadequacy of the body's natural resistance system

Thus, the action of such unfavorable factors as an early age at the time of infection, coexisting diseases with the formation of complications, with the progression of immunodeficiency has worsened the course of the disease in infected children, and led to a severe recurrent course of herpes infection in HIV-infected people. Against the background of secondary immunodeficiency due to HIV, HI becomes generalized with multiple lesions of the internal organs and central nervous system.

Conclusion

It has been established that herpetic infection in HIV-infected children especially of the young age, has a course of severe and continuously recurring forms.

It has been found that the prevailing form of recurrence of herpes infection in HIV-infected children is herpes of skin (52.64%). Against the background of progression of immunodeficiency, a worsening of the course of the disease has been noted, the frequency, severity and complication of herpetic infections and their relapses increase, becoming generalized with multiple lesions of the internal organs and central nervous system.

It has been established that with herpes infection in HIV-infected children, severe immunosuppression is observed - leukopenia, lymphocytosis, a significant 1.3 times decrease in the content of CD3-, CD4-cells, an increase in the levels of all classes of immunoglobulins in the period of exacerbation of the disease.

Abstract

This article highlights the results of research, which help reveal high-risk groups to suicide among adolescents based on types of family relationships and provide timely medical, psychological and psycho-correction help for parents and children, predict suicidal behavior at early stages. An major role in prevention of adolescent suicides is played by the family and healthy family relationships, as they ensure harmonious development of a personality.

Keywords: *Adolescents; teenagers; personality specifics; emotional disorders; suicidal behavior; self-damage.*

Introduction

According to the World Health Organization (2018), over the past 30 years the number of suicide attempts committed by children and teenagers in the world continues to grow, especially in highly developed countries of Europe and America [12]. The necessity of studying suicidal behavior is explained by the growing number of suicides and suicide attempts among children and adolescents resulting from the negative influence of mass media and the virtual Internet environment, through which suicides are projected as role models and objects of worship[2]. Juvenile and adolescent suicide appears to be the most tragic manifestation of the weakness of existing anti-suicide barriers and young generation's inability to understand the value of life[8]. In this age group, suicide is the fourth (to injuries, infections and cancer) most common cause of death[3]. Along with the high rate of completed suicides, there are a growing number of those committed as a protest resulting from conflicts within a family[4]. Intrafamilial relationships and family climate are significant factors, which determine a child's family and social behavior and affect his/her future relationships with other people[1]. In puberty, symptoms of depression accompanied by inferiority complexes[10] interspersed with dysmorphophobic manifestations and proneness to suicidal behavior, tend to increase, in cases whereby they have not been diagnosed in time due to poor emotional climate in families and lack of harmony between children and parents[9]. In their research, Russian psychiatrists and psychologists highlight[3] a correlation between suicidal tendencies, deviant/delinquent behavior and socialized conduct disorders[6]. Suicidal behavior is triggered by depression, which is expressed in teenagers by somatic symptoms and behavioral incidents[11]. According to Zhukova N. Yu., suicidal tendencies result from progressing intrapersonal conflicts that develop due to the influence of external stress factors, as well as from psychopathological disorders, which trigger self-destructive behavior and are not related to any outer factors[7]. According to research conducted by Grigorenko E.A., adolescents at risk of suicide have specific traits of character: lack of confidence, timidity, social rejection, feeling useless and worthless, focusing on appearance imperfections, passive attitude, feeling helpless in difficult situations and conflicts, which occur in the rapidly changing society[5].

The goal of the research is to study family-related risk factors contributing to suicidal tendencies in teenagers to ensure early prevention and outline optimal psychocorrection tactics for this population category.

Materials and Method

The study has involved a group of 86 adolescent subjects ages 15 to 19 with depression-related behavioral disorders and suicidal intentions. The group has included patients with diagnostic criteria typical of ICD-10–F91.2 socialized conduct disorders. A structural personality query, developed by the Psychiatry Department in cooperation with clinical and social psychologists, has included a list of psychological test questions, which help identify suicidal behavior risk factors with reference to personality traits and severity of depression. To diagnose the parameters of a family system, the Family Adaptation and Cohesion Evaluation Scales (Olson and Portner) have been applied. The Columbia Suicide Severity Rating Scale (Posner K., Brent D., Lucas C., 2009) has been used to evaluate suicidal tendencies. The Zung Self-Rating Depression Scale has provided the most relevant measurements of depression symptoms in teenagers, and to evaluate anxiety levels, the Spielberger-Khanin State-Trait Anxiety Inventory has been used. To evaluate constitutional specifics of adolescents' personality, Lichko's Pathocharacterological Diagnostic Questionnaire has been applied.

Results

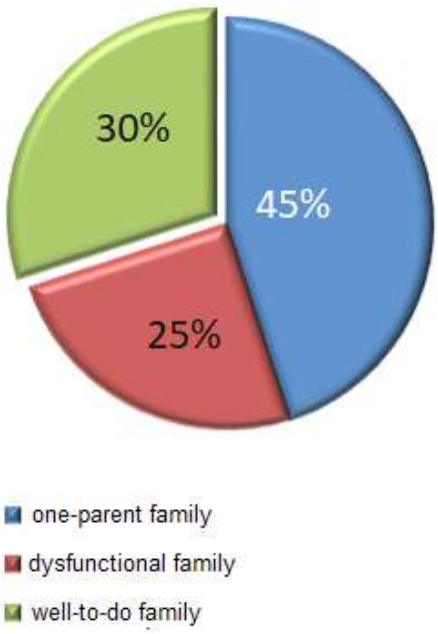

Fig. 1. Types of families, in which the subjects have been raised.

The psychological testing has shown that 45% of adolescents have grown up in one-parent families, 25% - in troubled family situations, 30% have been bred in well-to-do nuclear families. Chronic alcoholism and psychopathologies have been family affairs for 37% of the group. They have lived in conflict-ridden households, witnessed antisocial and amoral behavior and poor living conditions. The analysis of data obtained during the study has shown that 26% of teenagers, who veer toward antisocial behavior and minor felonies, have hedonistic inclinations and have been raised in dysfunctional families with destructive parenting habits, which have contributed to pathocharacterological protest reactions in the form of suicide attempts. Demonstrative, dramatic and manipulative suicidal behaviors have been observed in 28% of adolescents raised in well-to-do families n easy circumstances, yet emotionally detached and having poor interpersonal relationships with parents. The Family Adaptation and Cohesion Evaluation Scale has diagnosed the largest number of families practicing incorrect extreme parenting, which have upset family systems and caused a crisis in interpersonal relationships; 70% of subjects have been raised in emotional depravity and suffered lack of parental care and love (Fig. 1).

Discussion

Research of ambivalent family relationships has revealed a complete and utter detachment between family members, which has predetermined depression in teenagers, accentuation of personality traits and personality pathologies. Conflicts in destructive families have given rise to affective mental blocks with a negative perception of the world, which has exacerbated the disharmonic personality development and often caused negative emotions and involvement in so called virtual "death groups," which are controlled by online game managers. Comprehensive medical histories have confirmed the role of incorrect parenting and control in the formation of deviant behavior, including self-destructive behavior and its extreme manifestation–suicidal behavior. According to the Lichko A. E. classification, the following incorrect parenting and control practices have been detected: underprotection, dominant hyperprotection, promoting hyperrprotection, emotional parental rejection, increased moral responsibility. According to the study, most teenagers in the group have grown up in overprotective families (46%) and faced emotional rejection (25.5%). There have been a smaller number of cases of hyperprotection–dominant (14%), promoting (10%), and high moral

responsibility imposed on children (4.5%). Incorrect parenting has resulted in pronounced characterological personality changes. Underprotective parents have been indifferent to their children and failed to control their behavior, provide due attention, care and supervision, to demonstrate sincere interest in their businesses, emotions and hobbies. In extreme cases, this has been observed in utter disregard for a child's immediate needs like food, clothes, etc. There have been cases of concealed underprotection, when parents did actually control their children's behavior and lives, but formally. This style of parenting would result in a child being left completely unattended in the surrounding micro-social environment, where he/she would fall under seniors' influence and become a victim of early alcohol and drug abuse. Dominant hyperprotection has been caused by excessive protection by parents, their trying to control every little move, endless supervision and control, which have contributed to lack of confidence in children. These have been accompanied by excessive taboos, restrictions on children's scopes of activity and lack of independence. This type of hyprprotection goes hand in hand with authoritarian parenting with parents often perceived as iconic figures, whose word would be law. Families, where children have been treated as "golden children," would practice excessive patronage, overindulgence, and cater to his/her every desire and whim. Not only would these children be exempt from hardships and unpleasant duties – they would be praised for every little success and talent, and parents and relatives would always give a very high status to even minor abilities. From early childhood, these teenagers have believed that they are the best, most gifted and talented, and have been urged to strive for leadership and perfectionism. The study classifies this as promoting hyperprotection. Emotional rejection would result in a child feeling like he/she is a burden for his/her parents. The feeling tends to be more pronounced in families with younger brothers and sisters, who take the biggest part of attention and care. An extreme version of emotional rejection would be keeping a firm hand on children with disproportionately tough punishments and psychological abuse. Increased moral responsibility would take place in families with parents putting too much hope in their children, their performance and talents. Besides, some parents would attempt to get their children to realize their own uncompleted dreams, impose their opinion on them, limit their right of choice and force them to strive for perfection and success. The use of incorrect parenting tactics has resulted in the appearance of accentuated personality traits in adolescents, which are likely to evolve into personality pathologies (Fig. 2).

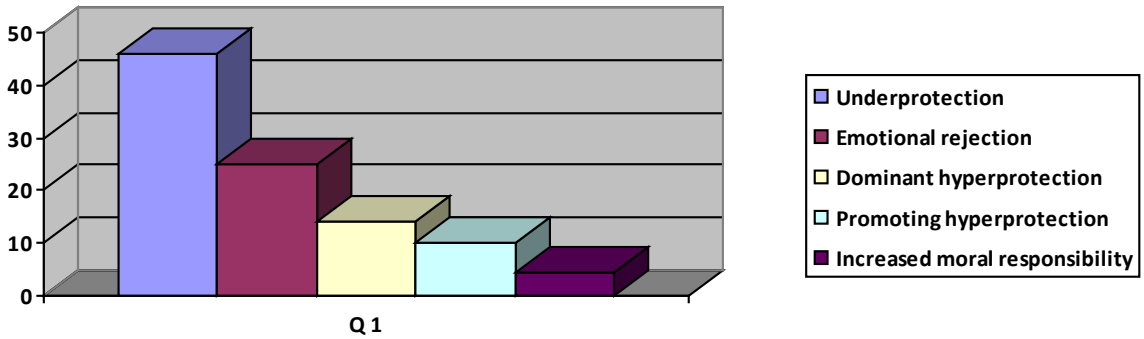

Figure 2. Parenting styles

The Lichko's pathocharacterological diagnostic questionnaire has helped identify the following types of accentuation: hysteroid accentuation has been observed in 9 subjects (10%), psychoasthenic accetuation – in 22 subjects (25.5%), labile accentuation – in 40 subjects (46%), epileptoid accentuation – in 12 subjects (14%), and in 4.5% of cases unstable accentuation has been observed. Labile personality accentuation has shown the highest percentage. These teenagers demonstrate mood swings, emotional instability, rapidly changing affective reactions, a long-standing focus on negative situations and memories from the past. Depression deemed as moderate on the Zung Self-Rating Depression Scale, has been observed in 6 subjects with hysteroid personality accentuation, who have striven to be recognized as the best among their peers, challenging for leadership and perfectionism. The hysteroid subjects have been characterized with conspicuous appearance, profanity,

falsehood, ostentatiousness and dramatic behavior. In terms of instability of personality, the most prominent signs of affective and emotional lability combined with pronounced impulsive outbreaks, antisocial activities, sometimes deviant inclination, and inability to build friendly relationships with peers have come to the picture. Of all subjects, 25.5% have been psychasthenic type, and common to these has been moderate depression accompanied by anxiophobic disorders. Psychasthenic adolescents are pursued by doubts, fears, obsessive memories, episodes of irrational anxiety, difficulty socializing, aloofness and hesitation.

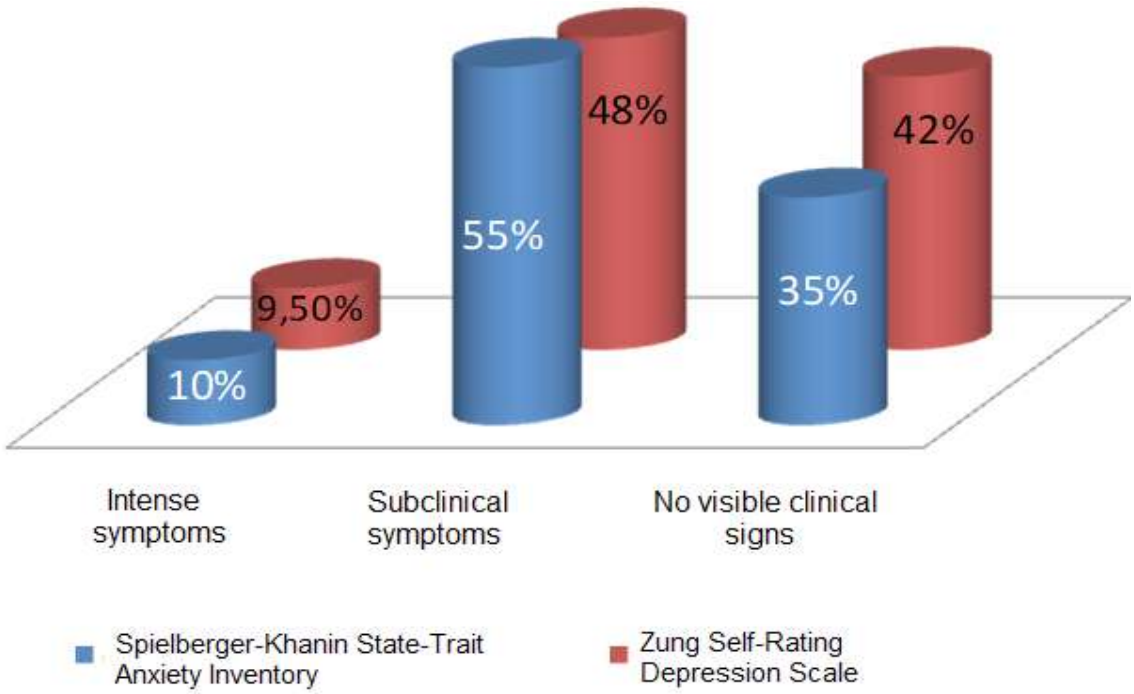

Figure 3. Structure of emotional disorders

The study of intensity of affective disorders on the Zung Self-Rating Depression Scale has revealed mild depression in 71% of the subjects and moderate depression in 29% of the subjects. The clinical picture of the depressive pathology would be manifested in low school performance, poor sleep and appetite, behavioral changes, unstable relationships with teachers and peers, detachment from parents and aloofness. The Spielberger-Khanin State-Trait Anxiety Inventory has revealed anxiety disorders of different intensity in 93% of subjects. Medium severe anxiety has been diagnosed in 56% of adolescent subjects, 27% have shown no clinically meaningful symptoms, and 16% of the subjects have demonstrated severe anxiety (Fig. 3). The most common factor contributing to self-destructive behavior consisting in suicidal thoughts and tendencies in adolescents, was incorrect parenting, which has resulted in interpersonal conflicts. The Columbia Suicide Severity Rating Scale (Posner K., Brent D., Lucas C., 2009), which has been used to evaluate suicidal tendencies, has determined 15% of the subjects as purely suicidal, 42% - as prone to suicidal thoughts and plans, 33% of the subjects are subjects with suicidal thoughts, who have made demonstrative, dramatic and manipulative suicide attempts. Most of them have been surface wounds near the bend of the arm or swallowing a large number of pills. Manipulative suicidal behavior has been triggered by the following factors: conflicts with parents (50%), with school and college teachers and mentors (25%), with peers (15%), and personal issues (10%). Most subjects would conceal suicidal intentions from parents and relatives, and they have been traced in social media dialogues, diaries and pictures. The study has revealed a correlation between teenagers' personality traits and type of suicidal attempts. Affective suicidal attempts have been observed in emotionally labile and psychasthenic personality types. Manipulative parasuicidal behavior has been diagnosed in hysteroid and emotive subjects. Impulsive suicide attempts have been made by epileptoid adolescents (Fig. 4)

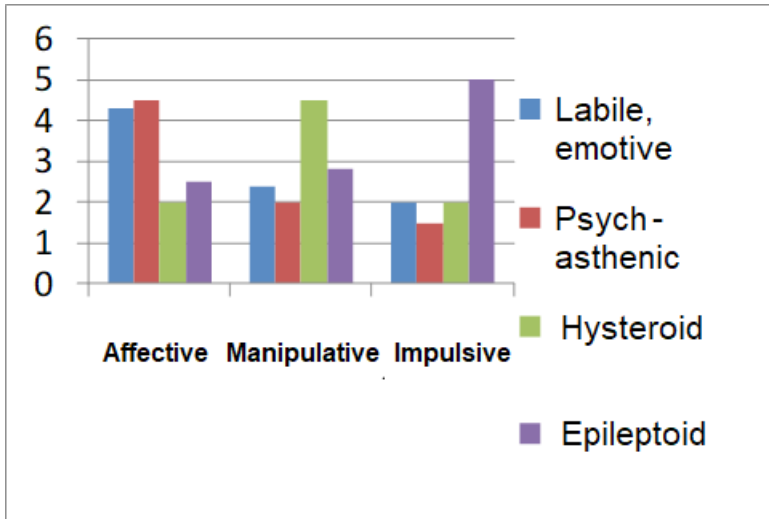

Figure 4. Correlation between types of personality and types of suicidal behavior

Clinical manifestations of self-destructive behavior mainly result from behavioral and stress-related disorders; they are associated with non-psychotic psychopathological conditions and are mostly demonstrative and manipulative by nature. Anxiodepressive and depressive neurotic disorders have been observed in emotionally labile teenagers. Mild depressive disorders have been diagnosed in hysteroid personality types. Moderate depressive disorders have been discovered in psychoasthenic adolescents. Dysphoric conditions have been found in epileptoid subjects.

Conclusion

The study of family-related risk factors of suicidal tendencies in teenagers has revealed that various manifestations of incorrect parenting in dysfunctional families contribute to development of labile, epileptoid and psychoasthenic personality accentuation in adolescents with intense personal and situational anxiety combined with proneness to depression-range suicidal behavior. Early detection of dysfunctional and ambivalent families and destructive parenting is paramount for adolescent suicide prevention and reduction of the suicide potential in this population group.

Abstract

Introduction: Much attention is paid to pharmacokinetic (FK) researches for studying the processes of supply, distribution, biotransformation and excretion of medications at the present time, as well as identifying links between medical substances concentration and (or) its metabolites in biological fluids and tissues, and its pharmacological effect. In the treatment of rheumatoid arthritis (RA), non-steroidal anti-inflammatory drugs (NSAID) are widely used for a symptom therapy, where Diclofenac Sodium (DS) is most commonly prescribed. Duration of anti-inflammatory effect, effectiveness of NSAID in whole are directly dependent on the level of effective concentration of medications and circulation duration in blood in free form.

The Aim of the present research work is to study in a comparative aspect certain indicators of Diclofenac Sodium pharmacokinetics in patients with rheumatoid arthritis with gastric microbiocenosis disorders (gastric dysbiosis) and without disorders (without dysbiosis).

Materials and Method: 38 patients at the age from 18 to 60 years were examined, with I-II-III degree of disease activity. In addition to the general clinical examination, an immune-enzyme method and urease test were carried out to determine Helicobacter Pylori and highly effective liquid chromatography to determine Diclofenac pharmacokinetics.

Results: Conducted researches and analysis of their results indicate that in conditions of rheumatoid arthritis, particularly, in the presence of comorbid states, there is a decrease in the metabolism rate and an extension of NSAID half-excretion period, which increases the risk of side effects, especially to the gastrointestinal tract, and significantly affects the disease course and the results of the treatment.

Conclusion: In conditions of rheumatoid arthritis with comorbid states, there is more frequent occurrence of the NSAID side effects. Research conducted and analysis of their results indicate that in conditions of rheumatoid arthritis, particularly at comorbid states, there are reasonable changes in the NSAID pharmacokinetics. The decreasing of metabolic rate and the extension of the NSAID half-excretion increases the risk of side effects, especially on the side of the GIT, which significantly affects the disease course and results of the treatment. This circumstance dictates the need to take these results into account in the treatment of the studied pathology and in the development of a personalized approach to the treatment of rheumatoid arthritis.

Keywords: *Rheumatoid arthritis, Diclofenac Sodium, highly-effective liquid chromatography, pharmacokinetics.*

Introduction

Now a days a greatattention is paid to pharmacokinetic (FK) researches for studying the processes of supply, distribution, biotransformation and excretion of medications, as well as identifying links between medical substances concentration and (or) its metabolites in biological fluids and tissues, and its pharmacological effect. Clinical pharmacokinetics determines which dosage of medicines provides their necessary concentration in body media to achieve optimal therapeutic effect. For the present time several method for determining Diclofenac in biological fluids are known: potentiometric analysis[1], highly effective liquid chromatography (HELC)[2], capillary zone electrophoresis[3], spectrophluometry[4], thin layer chromatography[5], polar-graphic analysis[6].

It is generally known that in the treatment of rheumatoid arthritis (RA), non-steroidal anti-inflammatory drugs (NSAID) are widely used for a symptom therapy, where Diclofenac Sodium (DS) is most commonly prescribed. Duration of anti-inflammatory effect, effectiveness of NSAID in whole are directly dependent on the level of effective concentration of medications and circulation duration in blood in free form. These parameters in clinical practice determine a number of pharmacokinetics indicators, in particular, Cel (constant of elimination), Cl (medication clearance), T1/2 (half-excretion of medication), etc. In human body Diclofenac undergoes biotransformation under the influence of the cytochrome P_{450} enzyme system with formation of three primary metabolites: 3-hydroxydiclofenac, 4-hydroxydiclofenac, and 5-hydroxydiclofenac. Primary metabolites are conjugated to form two secondary ones - 4,5-dihydroxy-diclofenac and H-hydroxy-4-methoxydiclofenac (3,4-HMD)[9]. All metabolites significantly assign to the primarymedication in therapeutic activity[8]. The half-excretion of Diclofenac Sodium and four of its five major metabolites ranges on average from 1 to 3 hours, but for 3,4-HMDit reaches 80 hours. DS does not cumulate on long-term using, all its metabolites are excreted with urine and bile. 95.7% of the medication is bound with the serum proteins[7]. According to previous research works, the concentration of Diclofenac Sodium reached a maximum after intramuscular injection after 15 and 25 minutes[10]. Besides, it should be noted that most of NSAIDs belong to the category of medications metabolized in the liver, which makes the problem of metabolism studying in the body particularly relevant in practical terms.

Rheumatoid arthritis is often accompanied by visceral manifestations from other organs and systems, as well as concomitant diseases (comorbid state)[11], which can affect pharmacokinetic parameters of used NSAIDs.

The aim of the study is to research in a comparative aspect certain indicators of Diclofenac Sodium pharmacokinetics in patients with rheumatoid arthritis accompanied by gastric microbiocenosis disorder (gastric dysbiosis) and without gastric microbiocenosis disorder (without dysbiosis).

Materials and Method

There were 38 patients with reliably established RA at the age of 18-60 years, with disease duration of more than 5 years. RA patients were divided into 3 groups: RA patients without dysbiosis - 28.6%, RA patients with dysbiosis -42.8%, RA patients with dysbiosis and H.pylori- 28.6%.

For determination of Diclofenac in blood plasma a highly effective liquid chromatography (HELC) was used with mass spectrometry (MS). The Agilent 6420 Ultra Highly Effective Liquid Chromatograph (UHELC) device with triple quadrupole mass spectrometer was used (produced by Agilent Technologies, USA). HELC pure acetonitrile was supplied by Sigma-Aldrich Trading Co. (Schnelldorf, Germany). Ultra-pure water was obtained by a water purification system produced by Sartorius LabInstruments GmbHЄtCo.KG (Goettingen, Germany). All other chemical substances were of analytical purity and were used without further purification.

Preparation of Samples: Control blood samples were taken from the patients after Diclofenac tablets application (50 mg) (positive control) after 0.5, 6 and 12 hours. The blood samples were centrifuged at 2000 rpm during 6 minutes. After these measures the blood plasma was injected into HELC tube for the analysis.

For preparing standard Diclofenac samples, the substrate was dried, then the exact amount was weighed, and a basic water solution was prepared at a concentration of 1 mg/ml. Samples of different Diclofenac concentrations were prepared from this solution for both qualitative and quantitative analysis.

HELC-MS/MS screening: HELC analysis was performed with samples volume 1mcl,which was injected with the help of an automatic sampler. As a

mobile phase only water acidified with 0.01% formic acid or acetonitrile water added 0.01% formic acid for positive ion control at a flow rate of 0.2 ml/min was used.

Analysis were performed by Full Scan Mode (Fullscanmode) for determination of the chemical composition of the substance.

Qualitative and quantitative analysis of Diclofenac Sodium: Standard solutions of Diclofenac were newly prepared by diluting the base solution (1 mg/ml) in ultrafine water. Samples ranging from 0.01 to 1000 ng/µl were prepared for quantitative analysis for calibration, detection limit (DL) and quantitative limit (QL). These solutions were stored at 4ºC before the analysis. DL and QL were determined experimentally from the signal-to-noise ratio by diluting the basic concentration (1 mg/ml)

Results

The results of these studies are shown in Figures 1,2,3: As it can be seen from the Fig.1, in patients with rheumatoid arthritis without gastric dysbiosis, Cel is decreased for 34.4%. compared to the control index. At the same time in patients with rheumatoid arthritis with gastric dysbiosis this indicator is decreased to a greater extent (almost 1.5 times compared to the control). Considering that this indicator of pharmacokinetics reflects the rate of medication excretion from the body, it becomes obvious that in condition of rheumatoid arthritis the rate of medication excretion from the patient ‘s body is slowed down. And in accompaniment ofgastric dysbiosis this process is highly aggravated.

It is generally known that the rate of xenobiotics excretion, including medications metabolizing in the liver,first of all depends on the rate of their biotransformation (metabolism) in the body. In this regard, we studied the Cl indicator, which reflects the degree of body purification from the medication. Analysis of this indicator results also shows a significant inhibition of this body function in rheumatoid arthritis conditions, especially in the presence of comorbid states (Fig. 2).

Inhibition of medicine metabolism in the body and decrease of the rate of their excretion from the body is accompanied by accumulation of the applied medicine in the blood. Indeed, as it can be seen from the data presented in the figure, in patients with rheumatoid arthritis the indicator T1/2 is extended 1.5 times in comparison with the control. And in conditions of gastric dysbiosis, almost 2 times, respectively (Fig. 3).

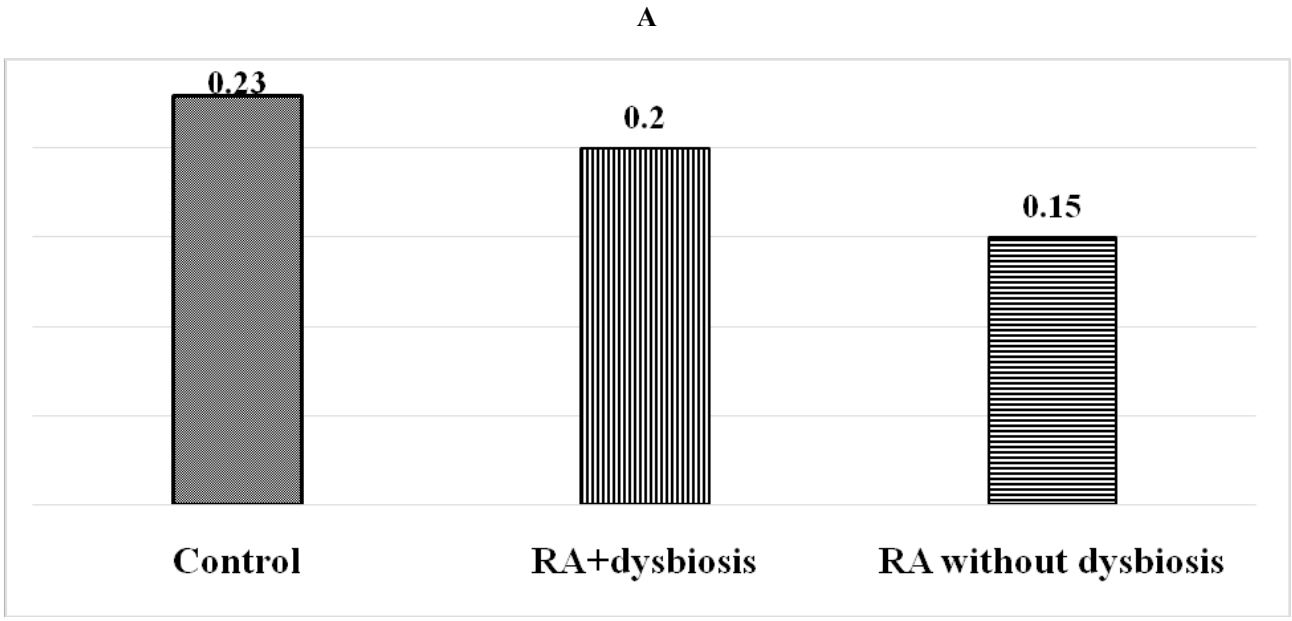

Fig. 1. Indicators of Diclofenac Sodium pharmacokinetics in patients with rheumatoid arthritis: A – indicator ofConstant Elimination (Cel)

B

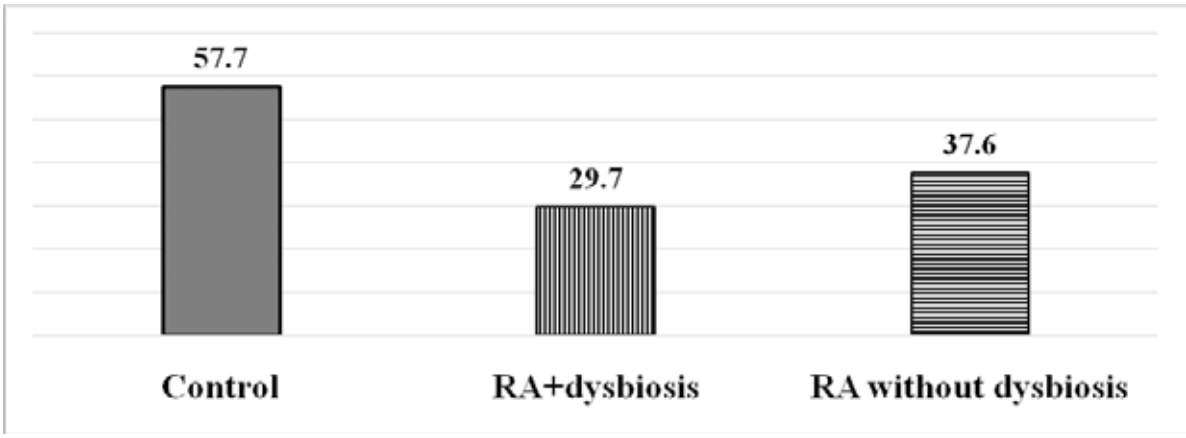

Fig. 2. Indicators of Diclofenac Sodium pharmacokinetics in patients with rheumatoid arthritis: B – clearance of the medication (Cl)

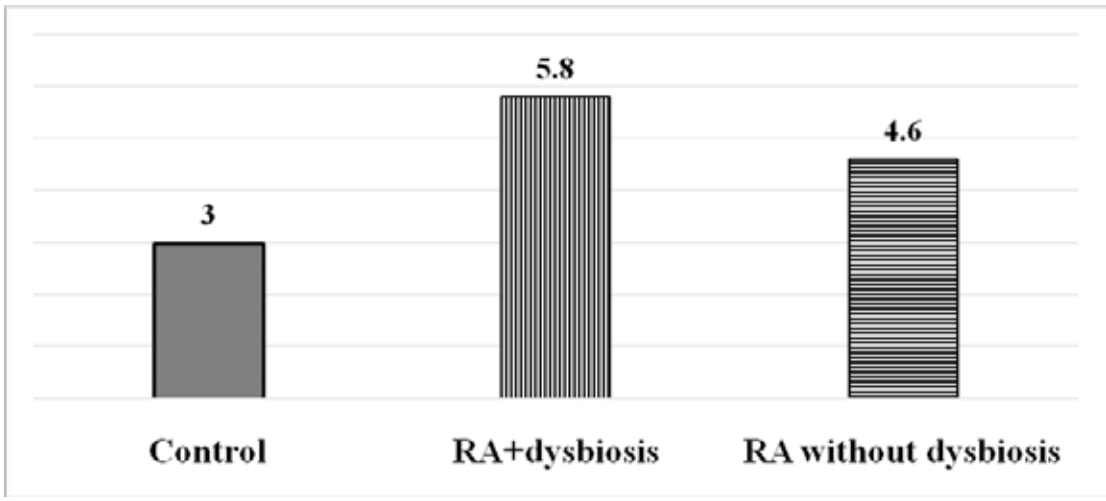
C



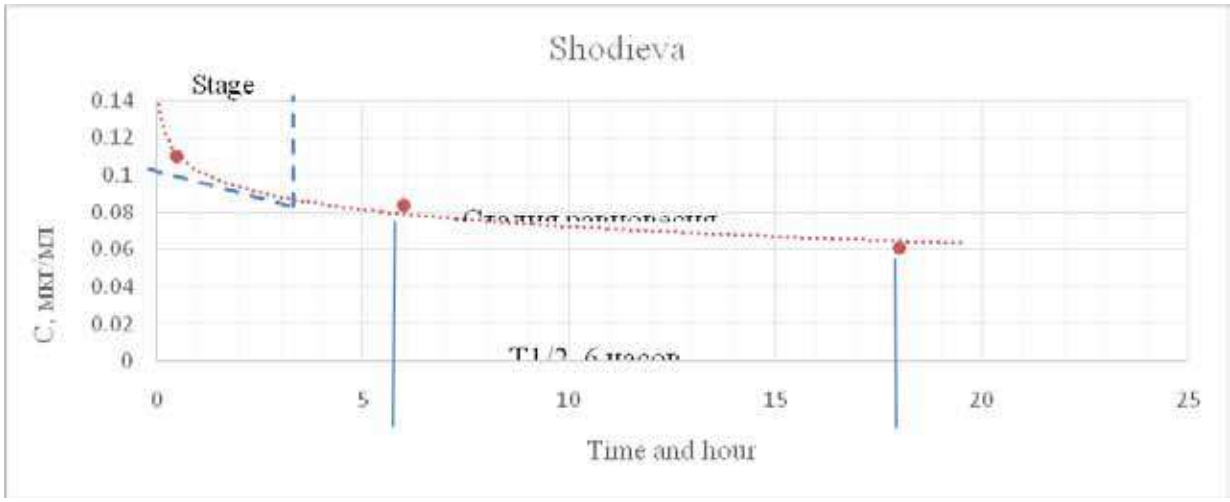


Fig. 3. Indicators of Diclofenac sodium pharmacokinetics in patients with rheumatoid arthritis: C –half-excretion period ($T_{1/2.}$).

The following is the example of calculating of the pharmacokinetic indicators of the patient with RA (Fig. 4)

V_p = Dose/C_0 = 25 mg/0,1 = 250 l

C_{el} = 0,693/$T_{1/2}$ = 0,693/6 hour = 0,1155h^{-1}

Cl = $V_p \times C_{el}$ = 250 l×0,1155h^{-1} = 28,875 l/h

Normally, Diclofenac is excreted in 2-3 hours. Let's assume, if this processtakes 2.5 hours, then

C_{el}(norm) = 0,693/$T_{1/2}$ = 0,693/2,5 hour = 0,2772 h^{-1}

$C_{el} < C_{el}$ (norm)

Cl(norm) = $V_p \times C_{el}$ = 250 l×0,2772h^{-1} = 69,3 l/h

Cl<Cl (norm)

Discussion

Therefore, in patients with rheumatoid arthritis there is a significant extension of the half-excretion of the researched medication, and in the condition of comorbid states this indicator grows even greater,that increases the risk of development of side effect.

Considering the results of pharmacokinetics, there are two variants for possible decrease of the NSAID side effects:

1. It is necessary to reduce the NSAID dose without changing the medicine taking intervals; or
2. Without changing the dose, to extend the intervals, i.e. reduce the multiplicity of medication appointment.

Besides, to protect gastric mucosa, it is preferable to add antacids, proton pump inhibitors, M-cholinoblocators and H2-histamine receptor blockers to the general treatment.

Thus, accordingto the above mentioned, we have also studied and analyzed the structure and frequency of side effects of the conducted treatment against the background of NSAID appointment in the examined groups of patients. The results of this analysis are given in the Table 1.

Table 1: Structure and frequency of manifestations of NSAID side effects in patients with rheumatoid arthritis

Lesion of GDZ	Group of patients		
	RA without dysbiosis	RA with dysbiosis	RA with dysbiosisand H. pylori
Heartburn (%)	50	58	80
Burp (%)	18	33	12
Heaviness in epigastrium (%)	12	42	50
Pains in epigastrium (%)	58	54	68
Constipation (%)	-	14	4
Poor appetite (%)	10	15	18
Esofagit (%)	77	50	88
Gastric ulcer and DPC (%)	10	25	28

Conclusion

As itis seen from the presented data above, in the group of patients with rheumatoid arthritis accompanied by gastric dysbiosis, the frequency of occurrence of the most characteristic signs of side effects becomes significantly higher than in the group of patients with rheumatoid arthritis without gastric dysbiosis. At the same time such manifestations as heartburn, heaviness in epigastria, pain in epigastria in the group of patients with rheumatoid arthritis and gastric dysbiosis increase for 38%, 19% and 26%, respectively. They also have a relatively high incidence of esophagitis and gastric and duodenal ulcers.

Therefore, in conditions of rheumatoid arthritis with comorbid states, there is a more frequent occurrence of the NSAID side effects.

Thus, researches conducted and analysis of their results indicate that in conditions of rheumatoid arthritis, particularlyat comorbid states, there are reasonablechanges in the NSAID pharmacokinetics. The decreasingof metabolic rate and the extension of the

NSAID half-excretion increases the risk of side effects, especially on the side of the GIT, which significantly affects the disease course and results of the treatment. This circumstance dictates the need to take these results into account in the treatment of the studied pathology and in the development of a personalized approach to the treatment of rheumatoid arthritis.

Repeated Reconstructive Surgeries for Postoperative Complications of Anorectal Malformations in Children

Abdurashid Z. Khamraev[1], Dilshod B. Rakhmonov[2]

[1]MD, Doctor of Medical Sciences, Professor of the Department, Hospital Pediatric Surgery, the Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [2]Deputy Chief Physician of the Regional Multidisciplinary Children's Hospital, Samarkand, Uzbekistan

Abstract

The causes of postoperative complications in the correction of anorectal malformation were studied according to follow-up, general clinical and additional research method in 65 operated sick children. In the process of diagnosis and surgical correction, a number of diagnostics, tactical, and combined errors and shortcomings were identified that caused postoperative complications, which required a large number of repeated reconstructive operations. The authors recommend various options for tactical and operational - technical treatment approaches when solving the problems of repeated reconstructive operations. At the same time, it is proposed to study the causes, analyze errors, complications and failures, indications, terms, accesses, the volume of the operation and evaluate their effectiveness. The authors, thanks to the optimization of tactics, method of surgical and rehabilitation treatment, were able to improve the results of postoperative complications to 81.4%.

In the course of the study of catamnestic and examination data 65 of children with postoperative non-NAS in the process of diagnosis and surgical correction errors and deficiencies were revealed as: unreliable primary diagnosis, insufficiency of preoperative preparation, inadequate indication and choice of the method of operation, inadequate postoperative rehabilitation. All these had diagnostic, tactical, technical and combined character, which led to the formation of the postoperative HCA, which required a large number of repeated operations. Therefore, the authors suggest that to solve the problems of repeated operations is not limited to the improvement of surgical techniques, and to study the causes, analysis of errors, complications and failures that lead to repeated interventions, indications, timing, access, scope of surgery and their evaluation of effectiveness, medical and social rehabilitation of patients.

The authors, thanks to the optimisation of tactics, method of surgical and rehabilitation treatment, managed to correct the post-surgical NAC up to 80,4%.

Keywords: *Anorectoplasty, postoperative complications, anorectal malformation. Children, proctoplasty, postoperative failure of anal sphincter, anorectal malformations.*

Introduction

In the surgical treatment of anorectal malformations (ARM), reducing the number of postoperative complications (PC) remains a problem in pediatric surgery[18], which is far from being resolved[11] .According to the literature[1], after the initial surgical correction of the ARM, functional disorders of the sphincter apparatus of the rectum occur in 30-60% of patients, subsequently[9] accompanied by fecal incontinence and chronic constipation[2].

At the same time, the main cause of unsatisfactory results[10] in the treatment of ARM are diagnostic[6], tactical and technical errors[15], which often lead to anal incompetence (AI)[5] in children which requires repeated reconstructive surgery (RRS). Therefore, the optimization of surgical tactics, indications and the choice[18] of RRS method to reduce complications of ARM in children is an urgent problem in pediatric colorectal surgery[20].

The objective of the study was to improve the results

of repeated[4] reconstructive surgery for postoperative complications of ARM, based on[11] a study of the causes of complications, ways to optimize diagnosis, treatment tactics and develop preventive measures in children[17].

Materials and Method

For the period 2007-2020 In the departments of pediatric surgery 1st CCCH in Tashkent and MACH in Samarkand (clinical bases of the Department of Pediatric Surgery TashPMI and SamMI), 65 patients were hospitalized for re-correction of complications of ARM. The age of patients is: 3 - 12 months. - 6 (9.2%); 1-3 years - 27 (41.5%); 3 - 7 years - 20 (30.7%); 8-14 years old - 9 (13.8%); 14 - 18 years old - 3 (4.6%). A total of 139 RRS were conducted, of which: twice in 30 (46.1%); three times in 20 (30.7%); four times or more in 15 (23.9%) cases. At the same time, surgical approaches were: STD - 14; ASARP - 23; PSARP - 21; PP-81. The colostomy before RRS was imposed on 37 (57%) patients. Boys - 28 (43%) and girls - 37 (57%).

Concomitant pathologies and regional malformations had been noted in all re-operated, in 18 (40%) patients: agenesis and aplasia of the coccygeal and sacrococcygeal vertebrae, disorders of the innervation of the pelvic organs due to thickening of the terminal filament and spinal cord, etc.

Comprehensive examinations were carried out for all patients: general clinical examinations (medical history, follow-up, clinical examination with rectal examination and laboratory diagnostics); radiological (irrigography, fistulography); additional (ultrasound with doppler, MRI of the abdominal cavity and pelvis, electromyography of the sphincter apparatus of the rectum, rectal reflex and endoscopy). At the same time, we revealed defects, tears, relative thinning of the width, shortening of the length and asymmetry of the puborectal muscles and the external anal sphincter.

We carried out a clinical analysis of the causes of the occurrence of PC in the primary and repeated correction of ARM; The diagnostic tactical and technical errors that were made, the risk of complications during the operation were studied, and optimal method for their repeated correction were developed.

Patients had been divided into two groups. The first group consisted of 47 (72.3%) patients, the use of operations, against the background of mistakes and complications after the initial radical and repeated corrective surgery, leading to anal incompetence (AI). The second group - 18 (27.7%) of patients, against the background of combined regional malformations and congenital inferiority of the obturator apparatus of the rectum.

The study was carried out in accordance with the principles of the Declaration of Helsinki. The study protocol was approved by the Local Ethics Committee of all participating institutions. Parents of the children had been informed about the studies and agreed to carry them out.

Results and Discussion

In the course of studying follow-up and clinical examination data of patients, the causes of complications in the correction of ARM, the clinically manifested AI (fecal incontinence) and stenosis of the anus and rectum (constipation), which needed to be carried out, were identified.

The identified causes of mistakes and complications were diagnostic, tactical, technical and combined.

I. Diagnostic: unreliable verification of diagnostics; insufficient assessment of malformations of neighboring organs; X-ray: improper laying of the patient or the absence of a mark on the anus when determining the height of atresia and the extent of stenosis, omission of deviation of the anorectal angle; clinically unrecognized congenital rectourethral fistula (RUF) and anus ectopia; inaccurate identification of anomalies in the initial diagnosis; inadequate identification of the causes and analysis of complications arising from the primary radical correction of the ARM; unreliable verification of the diagnosis during secondary correction.

II. Tactical: lack of preoperative preparation; wrong choice of indications; inadequate choice of operational access; non-optimal choice of the method of radical surgery or colostomy during the correction of the defect and in the event of complications; excessive attempt to search for perineal access to the high atresized end of the intestine; Inadequate postoperative rehabilitation and lack of surgeon qualifications.

III. Technical: defective implementation of the primary radical classical form of operation technique; damage to the muscles of the sphincters; underestimation

of the anomalies of the arcade vessels, significant intersections of the major vessels, too much tension or overextension of the mesenteric vessels during mobilization of the colon; extrafincter reduction of the distal part of the colon; accidental wound of the urethra with repeated mobilization of the colon; inferior fixation of the intestine during reduction; defective mobilization of the fistula, insufficient implementation of the plastic technique in rectovestibular (RVF) and RUF; technical mistakes during repeated operations.

IV. Combined, this type includes combinations of two or more types of groups of mistakes and complications at the same time. In some cases, the diagnostic mistakes made led to tactical ones, and they, in turn, to technical ones.

The results of the study showed that the causes of AI in the postoperative period were identified in the group of patients and are directly related to diagnostic, tactical and operational-technical errors (Fig. 1-2).

Fig. 1. Postoperative AI due to diagnostic, tactical, technical mistakes and complications in the correction of low forms of ARM

Fig. 2. Postoperative AI due to diagnostic, tactical, technical mistakes and complications in the correction of high forms of ARM

In the other group, not related to them: a combination of malformations of the nerve trunks, plexuses and fibers, defects in the distal part of the spine and chair, anomalies of neighboring organs.

The first group of causes of postoperative AI included intraoperative trauma, unsuccessful re-correcting operations and purulent-inflammatory complications due to diagnostic, tactical and technical errors that led to stenosis or dystopia of the anal canal, deformation of the perianal region, extinction of the mucosa of the reduced intestine, relapse of the fistula into the urinary tract or the reproductive system in children.

The second group of causes of postoperative AI was revealed in the background: disorders of the innervation of the pelvic organs due to thickening of the terminal filament and spinal cord in 4 cases; underdevelopment of the caudal vertebrae (aplasia or agenesis of the sacrum and coccyx) - in 10; underdevelopment of the muscular structures of the sphincter apparatus (aplasia or hypoplasia of the muscle complex) - in 4. These concomitant pathologies had been found among 18 operated patients in a separate and combined form (Fig. 3).

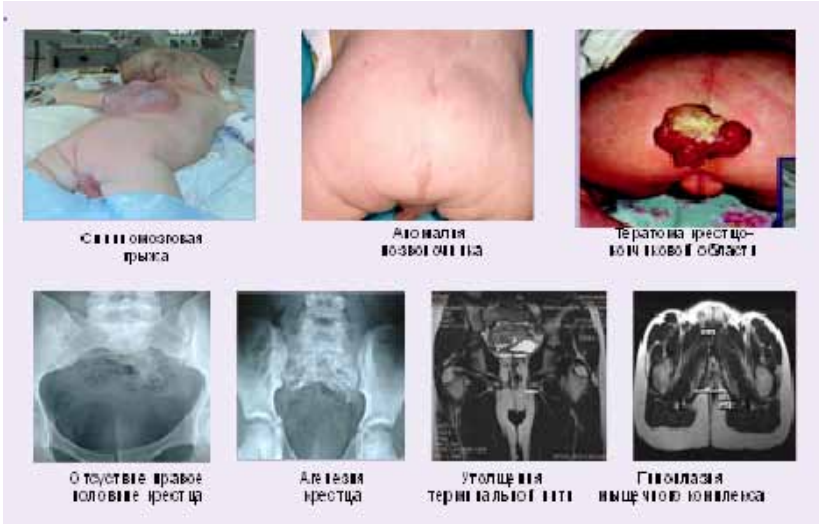

Fig. 3. Uncontrolled AI against the background of violation of the innervation of the pelvic organs, underdevelopment of the caudal spine and muscle structures of the sphincter apparatus.

In these groups of patients, despite an ideally performed primary radical anorectoplasty or RRS, AI was constantly left with the clinical course of fecal incontinence.

Thus, after the initial and repeated ARM correction, all PC for the period differs by: early and late.

Early Complications Include:

– *Suppuration with divergence of sutures of the perineal wound* - with poor-quality preoperative preparation, poor care and management of patients in the postoperative period.

– *Necrosis of the stump of the reduced intestine* - as a result of underestimation of the anomalies of the arcade vessels, significant intersection of the major vessels, too much tension or overextension of the mesenteric vessels in STDs, leading to impaired blood supply in the reduced intestine, its necrosis and sometimes pelvic peritonitis in the early postoperative period

Late Complications Include:

– *Stenosis* of the *anus and rectum*, *secondary megarectum* - arising in the late term, with a long inflammatory process in the area of the perineal wound, chronic ischemia of the wall of the reduced colon and after multiple perineal and peritoneal perineal proctoplasty, which clinical is manifested by chronic constipation.

– *Cicatricial deformity of the anus, cicatricial degeneration of the external sphincter and defects*

of the perineal septum in the form of an "artificial cloaca" ***- arising after a cicatricial process due to impaired blood supply to the wall of the reduced intestine and after multiple perineal proctoplasty due to relapse of the fistula, which clinical manifests by fecal and gas incontinence.***

– *Excess (standing) of the reduced intestinal mucosa* that arose after various types of proctoplasty and with technical errors in the formation of the neonus. The excess mucosa was represented by a small area or a large fragment of it, which clinically proceeds with fecal incontinence

– *A pararectal fistula* arising against the background of increased pressure by fecal masses in the rectum or clogging of it with "stones", with retraction of the reduced intestine, with an enema to create a false move. It usually opens far from the anus or gluteal region, which clinically occurs with fecal incontinence.

On the basis of complex method of examining patients and using ultrasound, MRI and EMG, we revealed anatomically: localization of defects, tears, relative thinning of the width, shortening of length, asymmetry and physiologically: impaired contractility of the puborectal muscles and external anal sphincter.

These data made it possible to assess the degree of damage to the sphincters in postoperative AI, to determine the tactics of choosing method for repeated surgical correction, intraoperative and postoperative measures for the prevention of complications.

In tactical terms, in all cases, in order to improve blood circulation and reduce the scar process, stiffness of perineal tissues, restore the tone of sphincter muscles of the 2-3-degree AI, a stage rehabilitation treatment was performed before each RRS. The rehabilitation treatment complex included: electrophoresis with lidase, electrical stimulation (ESM) of the anal sphincter and pelvic floor, LED laser in a separate and combination form. A sigmostomy, transversostomy and colostomy were applied in 57% of patients as a preoperative preparation. This allowed to improve the clinical results of surgical treatment by 2 times compared with the RRS

When conducting missile defense in the anorectal region, anterior and posterior sagittal access was often used, which allowed intraoperatively assessing the damage state, eliminating the defect of the sphincter of the anus and under visual control of plastic surgery. At the same time, muscle structures, blood vessels and nerves with minimal blood loss are minimally injured; local tissues are used to the maximum to restore the sphincter apparatus; significant mobilization of the rectum, which made it possible to carry out sphincteroplasty and sphincterolevoplasty and allowed to avoid excessive STDs.

The types and number of late complications leading to AI and the choice of RRS method in children are presented by us in table 1.

Table 1: Types and number of late postoperative complications and method of repeated surgical correction in children.

№	Types of postoperative complications	Amount-%	Method for repeated correction
1	Reduced stenosis of the anus and rectum	11 -16,9%	Elimination of stenosis with reconstruction of the anus and rectum
2	Extended stenosis of the anus and rectum	5 -7,6%	APR Elimination of extended stenosis with reconstruction of the anus and rectum.
3	Cicatricial deformity of the anus	7 -10,7%	Sigmostoma. Elimination of cicatricial deformity with reconstruction of the anus
4	Cicatricial deformity anus and vagina	4 -6,1%	Sigmostoma. Elimination of cicatricial deformity of the anus with reconstruction of the perineum
5	Defect of the rectovaginal septum	6 ()	Sigmostoma. PSARP. Sphincterolevatoroplasty
6	Acquired «Esthetic cloaca»	2 -3%	Sigmostoma. PSARP. Staged anorectoplasty

№	Types of postoperative complications	Amount-%	Method for repeated correction
7	Relapse of the RVF	8 -12,3%	Sigmostoma. PSARP. Stone's anorectoplasty.
8	Relapse of the RUF	3 -4,6%	Transversostomy. Epicystostomy. APR with the elimination of RUF
9	Acquired "Dystopia of the anus"	4 -6,1%	Displacement of the dystopic anus. Sphincteroleoplasty
10	Extrasphincterous lowering of the colon	4 -1%	APR With repeated lowering of the colon
11	Acquired pararectal fistula with anus deformity	2 -3%	Elimination of pararectal fistula Sphincteroplasty with reconstruction of the anus
12	Protrusion of the mucosa of the lowered intestine	7 -10,7%	Ablation of the protrusion of the mucosa of the lowered intestine
13	Deformation of the anus with cicatricial degeneration of the external sphincter	2 -3%	Transversostomy. APR with excision of cicatrix. Sphincteroplasty
	Total	65 -100%	100%

When conducting RRS in order to reduce postoperative AI, we drew attention to the following tactical aspects of a local nature: determining the degree of damage to the sphincter of the anus and rectum; the nature of cicatricial deformity of the anorectal region; the degree of protrusion of the mucosa, optimization of indications, choice of method, timing, ways of access to surgery. At the same time, ensure the preservation of the sphincter apparatus of the rectum; understand the intricacies of topographic and anatomical relationships of the perineum; to conduct adequate rehabilitation treatment and restoration of the physiological state of the newly created neo-anus and rectum.

In cases where there was no damage to the sphincter of the anus and direct and severe deformity, treatment was started with rehabilitation measures and only with inefficiency, RRS was performed.

In the presence of deformity (stenosis, ectopia, fistulas, defects) and mucosal standing, direct indications for RRS were determined regardless of the degree of damage to the sphincters.

When conducting RRS in children, we had based on the following techniques and intraoperative treatment tactics:

– If it possible, do correcting complications without abdominal access;
– Rehabilitation treatment was performed in the preoperative period to restore blood supply and innervation of the perineum;
– Strive for minimal tissue dissection when access to perineal;
– Exact removal of the rectum through the center of the retaining muscle complex;
– Strive to restore the anorectal angle with anorectoplasty, by maintaining the balance between puborectal and anococcygeal muscles;
– To ensure the elimination of tension of the reduced intestine in the area of the newly formed neo-anus.

It should be noted that RRS in children is performed in more difficult conditions than primary, and with less ability to perform proctoplasty in a classic form, with gross cicatricial changes in perineal tissue and chronic ischemia of the intestine. Moreover, with each repetition of RRS, the situation begins to deteriorate prognostically. Therefore, we recommend that in difficult situations (defects, cicatricial deformities) with pronounced AI for the effectiveness of RRS, it is imperative to apply a colostomy, conducts rehabilitation and comprehensive treatment of anemia and inflammatory diseases of the genitourinary, respiratory and cardiovascular systems.

Tactical moments of a general nature. This tactical approach significantly improved treatment outcomes with a decrease in the number of reoperations in children.

Thus, due to optimization of diagnostics, preoperative preparation tactics, method of intraoperative surgical correction, postoperative measures for the prevention of complications and rehabilitation, we obtained significant improvements in the results of treatment of postoperative AI. Long-term treatment results were rated as good, satisfactory and unsatisfactory.

The results of surgical treatment of postoperative NAS in children are presented in table 2.

Table 2: Results of surgical treatment of postoperative AI

Pathological conditions of complications by degrees of AI	Method of RRS	Results (Amount and %)			Total (%)
		Good	Satisfactorily	Unsatisfactorily	
1. AI of 1-degree, without significant damage to muscle structures and deformities of the anus.	Conservative (rehabilitation) treatment	16-23,2%	5-8,9%	-	21-32,2%
2. AI of 1-2 degrees, without significant damage to muscle structures, protrusion of the mucosa.	Removal of excess mucosa + sphincteroanoplasty + rehabilitation treatment	10-16%	8-10,7%	-	18-26,8%
3. AI of 2-3 degrees, with cicatricial deformity of the anorectal region.	Colostomy, ASARP or PSARP + sphincteroleo plasty + rehabili tation	4-5,4%	7-10,7%	6-7,3%	17-25%
4. AI of 3 degrees, with damage to all elements of the obturator apparatus.	Colostomy, APR, ASARP or PSARP + ARP with resto ration of the puborectal loop + sphincterolevato roanoplasty with reconstruction of ana tomical defects + multiple and phased rehabilitation treatment	-	3-5,4%	6-10,7%	9-16%
Total		**30-46,1%**	**23-35,3%**	**12-18,6%**	**65-100%**

As can be seen from the table 1., thanks to the optimization of tactics, surgical and complex rehabilitation treatment method, we had good results in 30 (46.1%) patients; satisfactory - at 23 (35.3%) and unsatisfactory - at 12 (18.6%).

Thus, we were able to adjust the AI in 53 cases out of 65 patients, which is 81.4% with good and satisfactory results. The optimal criteria were: optimization of the quality of preoperative diagnostics, preparation of the patient for surgery, timely detection of concomitant abnormalities of the neighboring organs, professional competence of the surgeon, adequacy of the choice of tactics, technique of performing corrective surgery, corrective surgery.

The second group - 18 (27.6%) patients, due to congenital inferiority of the obturator apparatus of the rectum against a background of a combination of regional malformations (aplasia, agenesis of the sacrum and coccyx, hypoplasia of the muscular complex) and violation of the innervation of the pelvic organs, an AI, despite an ideally performed primary radical anorectoplasty, RRS and prolonged stage rehabilitation treatment, unsatisfactory results were preserved in the form of fecal and urinary incontinence, to varying degrees and for long periods.

In these groups of patients, prolonged ESM of anal incontinence, rectal gymnastics, training enemas using the principles of biofeedback (in children older than 5 years), the development of an individual lifestyle up to 5 years and long courses of complex neurological treatment led to a satisfactory condition of patients, only in 5 (27.7%) cases.

Thus, in the first group of patients without concomitant pathologies against the background of purulent-inflammatory complications and diagnostic, tactical and technical errors as a result of which, they led to stenosis and dystopia of the anal canal, deformation of the perineum, extinction of the mucosa of the reduced intestine, relapse of the fistula into the urinary and reproductive system, RRS was provided in children. In the distant period, against the background of complex treatment, in these categories of patients, good results were obtained in 30 (46.1%) patients; satisfactory - in 23 (35.3%) and unsatisfactory - in 12 (18.6%).

In the second group of patients, in addition to

the correction of ARM, against the background of a concomitant disturbance of the innervation of the pelvic organs due to thickening of the terminal filament and spinal cord, underdevelopment of the caudal region of the vertebrae and the arm and levator muscle structures, good results were not noted, satisfactory - in 5 (27.7 %) and unsatisfactory - in 13 (72.3%) of the 18 cases.

Results

1. Indications for missile defense are determined taking into account 2-3 degrees of AI and deformation of the anorectal region.
2. By analyzing the causes, errors and complications, optimizing preoperative diagnostics, optimizing tactics, method of surgical and comprehensive rehabilitation treatment and postoperative preventive measures, it was possible to improve the results of RRS treatment by 81.4%.
3. For the prevention of postoperative complications of ARM during repeated correction in children, it is necessary to avoid possible diagnostic, tactical and technical errors by applying optimal tactics and techniques of repeated corrective surgery and ensuring high-quality rehabilitation treatment.

Abstract

The article presents the literature data, results of diagnostics and treatment of 219 children with various morphologies of spinal herniation and neuroorthopedic disorders. It characterizes in detail motion disorders and deforming arthrosis of the lower extremities in 88.1% and 26% of patients. The authors state that the genesis of disorders can include the manifestations of spinal cord fixation syndrome in patients with spinal hernias with combined congenital and acquired forms of latent spinal dysraphism. The article confirms the feasibility of early preventive and therapeutic measures corresponding to the nature of the combined pathology, with the participation of specialists.

Keywords: *Spinal cord anomalies, spinal hernias, joint deformities, children.*

Introduction

Spinal cord (SC) anomalies are essential in the structure of the neural tube pathologies in children. They can occur in the form of isolated anomalies or combined with other spinal malformations[12]. Today, they are usually referred to as spinal dysraphism, spinal malformations, or vertebromedullary abnormalities (VMA). SC open anomalies are manifested in the form of a spina bifida with the formation of cystic SH [10](spina bifida cystica), and closed anomalies - with spina bifida and soft tissue cleavage with spinal cord extension along the entire length of the spine or in its segment (spina bifida occulta) [Voronov V. G., 2002; 2016; A.V. Rudakova, S.N., Larionov 2012]. VMA can also occur in any spinal segment, but more often in the lumbosacral region, mainly combined with other malformations that are located, in particular, in the brain. VMA is mainly caused by lipomyelomeningocele, terminal filament lipomas, medullary cone, diastomatomyelia[7], dorsal band fixation for patients with spinal hernia, or dermal sinus tracts. It is also followed by tethered spinal cord (TSP), which term had been proposed by H. J. Hoffmann et al., (1976)[11]. With normal intrauterine development of the fetus, in the third month, the spinal cord occupies the entire length of the spinal canal. In the next months, the spine grows faster than the spinal cord. As a result, in a newborn's body, the spinal cord ends at the level of the third lumbar vertebra[5], and by the age of 12-18 months it reaches only the lower edge of the LI or upper edge of the LII vertebra[8]. When the cone and epiconus of the spinal cord are located below the normal level and in the presence of corresponding clinical symptoms, the pathological component is considered tethered cord syndrome (TCS). In a series of 5.5 thousand pediatric patients, the frequency of TCS was equal to 0.1 % [Fariborz Samini et al., 2014]. The pathophysiological basis of this syndrome is mechanical traction of the caudal spinal cord, which is followed by a decrease in blood flow in the involved area, and causes ischemia and depression in the electrical activity of the spinal cord[2]. At the biochemical level, it causes inhibition of oxidative phosphorylation in the neuronal mitochondria[17]. Acquired forms of TCS occur after operations for SH, in children with post-traumatic or post-infectious conditions, that may include fixation and tension of the

caudal spinal cord ('spinal cord postfixation syndrome', or SCPS). [Kushel Yu. V., Zemlyansky M. Yu. 2010; Rudakova A.V. et al., 2011;]. This pathology is dynamic in its nature[3]. So, as a child grows, it prevents the age-related displacement of the spinal cord cone, and exacerbates neurological deficits[14]. The characteristic signs of this pathology include an increase in existing function disorders in a pelvic system or appearance of new ones, as well as sensory, motion and trophic manifestations with bone-articular deformities of the lower extremities[9], autonomic disorders and internal dysfunctions[15]. Up to date, there are no reliable data on the frequency and distribution of this syndrome in large localities. According to some authors, in 30-50% of pediatric patients with effects of spinal hernias, disturbances in the muscular equilibrium of paresis or paralysis of the muscles of the lower extremities lead to subluxation or dislocation in the hip joint during their whole life[1]. In children, during the load in extremities, the neutralization of deforming efforts decreases, and the joints of the corresponding spinal cord injury area become deformed[6]. With age, the type and severity of disorders, their deterioration or improvement depend on the severity and extent of the neurosegmental lesion[4]. For example, confounding static and dynamic factors without orthopedic prophylaxis aggravate deformations of the musculoskeletal system[13] (Ivanov S.V., Kenis V.M., 2013; Erol B, et all., 2005; Baindurashvili A.G. et al. 2013[16].

The aim of the study is to determine the frequency and nature of paralytic deformities of the lower extremities in children with spinal hernias.

Materials and Method

We have examined 219 pediatric patients (116 male, 103 female) with various forms of spinal hernias (SH), aged from 1 day to 18 years, and have determined the clinical and neurological manifestations of the disease. This pathology has been verified taking into account the data of functional and instrumental studies: ultrasound, MSCT, MRI of head, spinal cord and vertebral spine; electroneuromyography (ENMG) of the lower extremity muscles. The study was carried out in the Department of Elective Surgery of the Second Children's Surgical Clinical Hospital of the city of Tashkent and the Republican Specialized Scientific and Practical Medical Center of Traumatology And Orthopedics, Tashkent, Uzbekistan, in 2014-2019. The severity of the lower extremity motion disorders in children diagnosed with the peripheral link of the reflex arc has been evaluated using Modified Rankin Scale (mRS) ranging from 1 to 5. The nature and type of deformations of the body and limbs have been evaluated in accordance with generally accepted criteria.

Results

The diagnostic criterion for SH is a hernial protrusion of various sizes and shapes without neurological deficits, urological or proctological disorders with the musculoskeletal system deformations. Age distribution of hospitalized patients with SH is the following: up to 28 days - 24 (11%), up to 1 year – 113 (51.6%), from 1 to 3 years – 31 (14.2%) from 3 to 7 years - 17 (7.8%), from 7 to 12 years – 27 (12.3%), from 12 to 18 years - 7 (3.2%). Localization of pathology in the cervicothoracic region of the vertebrae has been observed in 5 (2.3%) patients; in the thoracic – 9 (4.1%), lumbar – in 76 (34.7%), lumbosacral - in 92 (42%), and sacral – 37 (16.9%). In 158 (72.0%) patients, diseases were manifested in cystic form, as a combination of hernia with teratoid and lipomatous formations (spina bifida complicate) in 32 (14.6%) patients, Chiari malformation (MK) – in 26 (11.9%), rachisis – in 3 (1.4%). Of 219 patients, the shell molds (meningocele) have been observed in 24 (10.9%) of patients, various types of meningocerebral forms - in 192 (87.7%), rachishisis - in 3 (1.4%). In the case of MK, the hernial sac contained meningoradiculocele in 13 (50%) patients and meningomyelocele in 13 (50%).

Up to date, spinal hernia or manifestations of latent spinal dysraphism are a marker for potential malformations of the central nervous and other body systems. Children should be examined in order to identify combined anomalies of the central nervous system and other organs and systems. Skin markers (lipomas, dermal sinus, hemangiomas, hypertrichoses and asymmetric gluteal folds) were signs of spinal dysraphism in 20 (6.3%) patients. In 10 (50%) patients, one or more skin stigmas were located in the zone of reticular protrusion, in 10 (50%) - in various areas along the spine. In 140 (63.9%) patients, diseases formed isolated malformations, in 79 (36.1%) mainly with meningoradiculocele - 53 (67.1%) and MK - 26 (32.9%). With the expanded applicability of special examination method, the detectability of combined abnormalities of the spinal cord, spine and other organs and systems increased. In 38 (48.1%) patients, signs of spinal cord fixation syndrome have been observed, in 41 (51.9%) - specific forms of myelodysplasia: hydromyelia - 9

(11.4%), diastematomy - 8 (10.1%), syringomyelia - 17 (21.5%), the combination of several forms - in 7 (8.8%). In some of these patients, the hidden myelodysplastic syndrome had been established long time after the surgery, at the rehabilitation therapy stage. This is due to the insufficient volume for preoperative examinations or surgery complications. Combined anomalies of other organs and systems have been revealed in 89 (40.6%) of 219 patients, of the musculoskeletal system – in 73 (82%), in the form of various vertebral disorders determined by radiation diagnostic method. In 219 patients, clinical and neurological manifestations of various forms of cystic spinal dysraphism depended on the location, size and anatomy of the defect. Their frequency was the following: cutaneous stigma - 4.5%, internal abnormalities - 14.6%, autonomic disorders - 19.2%, cranial nerve injuries - 22.4%, pelvic system dysfunctions - 76, 7%, sensitivity disorders - 53.9%, motion disorders - 88.1%, trophic-orthopedic disorders - 39.7%.

Discussion

According to MRS, in 18 pediatric patients (9.3%), motion impairment score was 4; in 119 (61.7%) – 3, in 18 (9.3%) – 1-2, in 38 (19.7%) - 0. In severe isolated hernias, abnormalities have been found in 94 (48.7%) children; in combination of SH with other spinal cord abnormalities - in 79 (40.9%); with spina bifida complicate - in 20 (10.4%). In 164 (85%) patients, abnormalities were bilateral in nature, in 29 (15%) - unilateral. Of 193 patients, 87 (45 %) had motion disorders followed by other abnormalities: 30 (34.5 %) - trophic disorders, 35 (40.2 %) - trophic disorders and joint deformities, 22 (25.3 %) - joint deformities and trophic ulcers. This is due to the fact, that in severe and combined osteoneural anomalies, spinal cord malformations increase with the corresponding increase in the frequency and severity of disorders. Motion disturbances - from the complete loss of functions or weakness of some muscle groups to an increased tone of other ones - cause deformations of different fixation and severity of the individual components. In 57 (26%) of 193 patients with motion disorders, various types of deforming arthrosis in the lower extremity joints have been observed, more often in the distal direction. Combined deformity of the hip, knee and foot joints has been observed in 4 (7%) patients; gluteal deformity - in 4 (7%) cases. In these patients, dislocation or subluxation in the hip joint has been also revealed. Knee joint pathologies, in the form of flexion contracture in the range of 150°-90°, have been observed in 2 (3.5%) patients. In 47 (82.5%) cases, polymorphic paralytic foot deformities have been revealed, in 28 (59.6%) cases - bilateral deformities with the prevailing equinus component of the heel-valgus or flat-valgus deformity. In 19 (40.4%) patients, unilateral pathology has been diagnosed. Musculoskeletal disorders combined with deformation in the lower extremity joints indicates a common pathogenetic mechanisms, aggravated by associated spine cord and vertebral anomalies. Early treatment and preventive measures can improve the patient quality of life in some way. The revealed disorders and their combinations depended on the localization and severity of myelodysplasia in the segmental innervation area of the spinal cord, to a certain extent. Of 57 patients with various deformities, 24 (42.1%) had movement disorders. In 6 (10.53%) children with a lumbar lesion due to the absence or weakness of the extensor and abductor muscles of the thigh, a subluxation or dislocation of the femur has been revealed, combined with the absence of arbitrary movements of the lower extremities and wheelchair ambulation. 18 (31.58%) patients with severe peripheral paresis (injuries to all lower extremity muscles with the knee jerk preserved and the Achilles and plantar reflexes absent, in some cases) were able to stand up with support for the upper limbs and bear weight on their knee joints, moving with crutches or other devices. 33 (57.89%) children with various feet deformations were able to move independently, even with limping.. Of 219 patients with severe and prolonged osteoneural anomalies in the thoracolumbar spine, 8 (3.6%) children with unproportioned body parts were bedridden (Fig. 4.16). The data presented indicate that static and dynamic disorders contribute to the formation of musculoskeletal system pathologies in the form of joints deformations. This occurs depending on the level and severity of the neurosegmental lesion, as a result of muscle traction and antagonist-synergist muscles imbalance. Electromyography performed in 98 (30.5%) patients have showed that the prevalence of neuromuscular disorders depended on the severity of spinal motion segment injuries. The topography of these disorders was determined by comparing the electromyography data and the scheme of segmental innervation of the lower extremity muscles, taking into account the proximal border of the spinal cord lesion. It was largely determined by the upper segment, which innervated the muscles with the complete function loss.

In such a way, we may conclude that a frequent combination of musculoskeletal and trophic disorders

combined with deformation in the lower extremity joints indicates a common pathogenetic mechanism, aggravated by associated vertebromedullary anomalies. Early treatment and preventive measures can improve the patient quality of life in some way. A comprehensive examination of patients is aimed at establishing the nature of spinal and combined pathology, revealing latent spinal dysraphism and related functional neuroorthopedic disorders. Early preventive and therapeutic measures should be carried out with the participation of specialists with the combined pathology competencies.

Conclusions

In 26% of patients diagnosed with meningeal forms of SH against the background of motion disorders, neuro-orthopedic manifestations have been observed. They are considered associated with the spinal cord fixation syndrome due to congenital or acquired latent spinal dysraphism.

Localization, nature of neuroorthopedic manifestations, and severity of disorders in dynamics depend on the level and extent of the neurosegmental lesion and myelodysplasia severity. For example, confounding static and dynamic factors without orthopedic prophylaxis aggravate deformations of the musculoskeletal system.

Paralytic deforming arthrosis with myelodysplasia has been mainly observed in the distal parts of the lower extremities, with the ankle joint affected in most of cases.

Abstract

This article presents the specific features of clinical and radiological abnormalities in the mixed dentition. Individuality of such features is determined by the parameters of the maxillofacial region and the maxillary dimensions, in the form of late milk dentition abrasion, shape of the submaxillary retromolar area and the eruption level of the lower first and second multi-cuspid teeth according to the dental panoramic radiogram. All above was used as a basis for the assessment algorithm development for children with the dentofacial anomalies. Based on the results obtained, the recommendations has been proposed that allow to perform individual treatment for the children with this pathology.

Keywords: *Dentofacial anomalies, orthodontics, sagittal anomalies, anterior occlusion, distal occlusion.*

Introduction

According to WHO data, the prevalence of dentofacial anomalies is on average at least 50% (WHO, Geneva, 2016)[1]. According to the National Institute of Dentistry, USA, 40% of the total population have abnormalities in the teeth development and various dental formation disruptions[2]. Moreover, 15% of these individuals require surgical intervention for its elimination. The issues of timely elimination and removal of factors that adversely affect the normal formation of the dentofacial complex are rather relevant[10].

According to the world scientists, the occlusion anomalies affect the general and local diseases[5] of the human body and cause malfunctions of chewing, breathing, speech and swallowing[8]. The early diagnostics problem of latent forms of the sagittal dentofacial anomalies and its timely prevention and treatment is of undoubted practical interest[3]. It is due to the profound morphofunctional lesions that affect the proper development of chewing function, maxillary formation and occlusion[9].

This impairment is characterized by an unaesthetic appearance of the patient's face: a convex or concave profile, an unpretty smile, availability of a sagittal overjet between the jaws, speech impairment and open-mouth breathing, narrowing of the supramaxillary base, narrow Gothic palate[6] and malocclusion[4]. Obviously, this type of impairment has a skeletal and dentoalveolar nature that requires different treatment approaches to achieve a good result[7]. In order to achieve a satisfactory, aesthetic and functional result, the orthodontist needs to carefully analyze the diagnostic data, pay attention to all the morphological structures of this impairment and not to make mistakes that may deliver the inconvertible results when planning the treatment stages[11].

Most studies demonstrate that the incidence of sagittal occlusion abnormalities depends on the age of the patient[1], since some researchers believe that the incidence of occlusion abnormalities varies from 7 to 10 years at the early stages of mixed dentition[10]. It should be taken in into account that, most often, in addition to the functional maximum, adolescents and adult patients expect the maximum aesthetic result[6] from orthodontic treatment, which affects their psychosocial status in positive way[8].

In that respect, it seems promising to review the diagnostic and therapeutic measures aimed at improving the quality indicators of orthodontic care for children.

The development of the approach that is closest to the diagnostics and treatment of occlusion abnormalities to achieve an acceptable result, combined with the excessive growth of the upper or lower jaw and the anterior position of the supramaxillary dentoalveolar complex will help to achieve a stable aesthetic outcome during the treatment and avoid relapse. Therefore, the modern method of eliminating the factors affecting the normal dentofacial system formation are relevant.

The aim of this study is to determine the early latent forms of occlusion anomalies in children and to substantiate the effectiveness of treatment and preventive measures.

Materials and Method

The study is based on data from a survey of 90 patients during the period of mixed (6-12 years) and permanent dentitions (13-18 years), with the average age 13.4±0.3 years. 52 children (57.8%) had the posterior occlusion, and 38 - the anterior occlusion (42.2%). In order to compare the results obtained for the patients in the examined groups, we used the control group consisting of 19 children with the orthognathic occlusion.

The diagnosis was determined on the basis of data from the history of clinical, biometric, radiological examination of the patients, in accordance with the diagnostic criteria.

The clinical examination included a survey, facial and dental examination. The etiological and pathogenetic factors were identified that contributed to the malocclusion occurrence and development in the sagittal plane. During the facial examination, the attention was paid to the symmetry of its left and right halves, the intensity of the nasolabial and genial folds, and lip seal with the rest position of the mandible.

The particular attention was paid to the identification of morphological and functional disorders that led to the occurrence of a gap between the upper and lower dentitions in the frontal area, and a decrease in the height of its lower part.

In order to determine the structural features of the facial skull, and to determine the changes in the sagittal dimensions of the facial skull, the lateral teleroentgenograms of the patients' heads have been studied, as a result of orthodontic treatment.

On the basis of clinical examination, anthropometric measurement data of diagnostic maxillary models and analysis of the head teleroentgenograms performed in a lateral projection, the diagnosis and the treatment plan have been determined.

The orthodontic treatment consisted of the use of removable intraoral and extraoral devices (myobraces, cervical bandage, Delaire face mask, non-removable device for maxillary expansion), and edgewise techniques based on the brace systems of foreign manufacturers. The dentition correction was performed by the straight-wire technique of the Roth system. The results of instrumental correction controlled on the stone models determined the ability to complete the elimination process for the dentition occlusion abnormality and form the orthognathic occlusion.

Treatment stages for patients of the 1st study group with the distal occlusion:

1. **Early mixed dentition - 6-9 years:**
   - myobrace;
   - cervical bandage;
   - rapid maxillary expansion device.
2. **Late mixed dentition - 10-13 years:**
   - cervical bandage;
   - rapid maxillary expansion device;
   - braces with tooth extraction.
3. **Permanent dentition - 14-18 years:**
   - cervical bandage;
   - rapid maxillary expansion device;
   - braces with tooth extraction.

Treatment stages for patients of the 2nd study group with the distal occlusion:

1. Early mixed dentition - 8-12 years;
   - Frankel functional regulator;
   - high pull;
   - rapid maxillary expansion device.
2. **Late mixed dentition - 12-14 years:**
   - high pull;
   - rapid maxillary expansion device;
   - braces with removal of the upper first premolars.

3. Permanent dentition - 14-18 years:

- high pull;
- rapid maxillary expansion device;
- braces with removal of the upper first premolars.

Treatment stages for patients of the 1st study group with the anterior occlusion:

1. Early mixed dentition - 6-9 years:
   - myobrace;
   - Delaire face mask;
   - rapid maxillary expansion device.
2. Late mixed dentition - 10-13 years:
   - Delaire face mask;
   - rapid maxillary expansion device;
   - braces with the removal of the first premolars.
3. Permanent dentition - 14-18 years:
   - Delaire face mask;
   - rapid maxillary expansion device;
   - braces with removal of the lower first premolars.

Treatment stages for patients of the 2nd study group with the anterior occlusion:

1. Early mixed dentition - 8-12 years:
   - head-chin strap;
   - Frankel functional regulator;
   - plate with an inclined plane;
   - Delaire face mask.
2. Late mixed dentition - 12-14 years:
   - head-chin strap;
   - Frankel functional regulator;
   - Delaire face mask;
   - braces with removal of the lower first premolars.
3. Permanent dentition - 14-18 years:
   - head-chin strap;
   - Delaire face mask;
   - braces with removal of the lower first premolars.

The data obtained were subjected to statistical processing using the statistical analytic application software package with the calculation of arithmetic mean (M), mean square deviation (σ), standard error (m), and relative values (frequency, %). The confidence level of $P<0.05$ was accepted as the statistically significant changes.

Results

The clinical examination have revealed that 79 patients (87.8%; 79/90) were not previously consulted by an orthodontist and only 11 (12.2%; 11/90) performed regular medical check-ups. With that, the patients used the removable orthodontic appliances, but the treatment was not completed, for various reasons.

The prevalence of dentofacial anomalies is relatively more common with the mixed dentition than with the permanent dentition (42.2% versus 57.8%), however, the statistical analysis has showed that these differences are unreliable ($P>0.05$). When assessing the condition of the dentition and alveolar processes, the change in the dental arch (upper and lower) shape was determined. The maxillary V-shaped and trapezoidal, and the mandibular trapezoidal abnormal forms mainly predominated.

When analyzing the patient profiles, we found that in most cases, the children at the age of 6-12 years had a convex facial profile. Moreover, this effect occurs with almost the same frequency both in the case of the submaxillary underdevelopment and the maxillary overdevelopment. In the case of the submaxillary overdevelopment and the maxillary underdevelopment, the straight and concave profile was observed in children at the age of 6-12 years. In children at the age of 13-18 years with the distal occlusion, the convex profile was observed in all cases, while the children with the anterior occlusion had the concave profile.

During the analysis of the intraoral photographs, we identified the following specific features of the submaxillary development. 39 children at the age of 6-12 years had the specific features of the submaxillary retromolar area, among which 19 children had the alveolar crest narrowing, and 20 children showed the prominence of the retromolar area.

As a result, the data specifying the lack of space or dentition excess in the patients have been obtained. In the case of lack of space in the mandible, the alveolar crest shape of the retromolar surface of eruption of the submaxillary second molars is ill-defined and narrow. The reverse effect is observed in the children at the age

of up to 9 years: the more thickened the alveolar process crest, the closer the second molar germ is located to the eruption, thus, the clinical evidence demonstrates the excessive submaxillary growth and a wide submaxillary apical base (Fig. 1).

Fig 1. Premature eruption of the lower second molars resulted in excessive submaxillary growth (the patient is 11 years old).

Therefore, among the analyzed orthopantomograms, the largest number of patients with the delayed eruptions of the second molars is at the age of 12 to 14 years old, with the premature eruptions from 8 years to 11 years old. The severity of teeth overcrowding in the case of delayed eruptions of the second supramaxillary molars is increased with aging. The older the patient, the more difficult it is to prevent the anomaly development and occlusion deformation and vice versa.

In summing it up, it may safely be said that the computed tomography with 3D reconstruction forms the modern diagnostic method for anterior occlusion. The anterior occlusion treatment for the adolescents is possible without surgical intervention during early mixed dentition when using the extraoral devices (Delaire face mask), based on the growth modification, applied forces and with the false anterior occlusion.

The other reasons for the anterior occlusion development include the following: maternal illnesses during pregnancy, birth trauma, underdevelopment of the intermaxillary bone, maxillary adentia, retention and loss of the upper teeth, supernumerary teeth in the lower jaw, delayed second dentition, various children diseases, shortening of the lingual frenulum, hypertrophy of the palatine and lingual tonsils, macroglossia, bad sucking habits and some other bad habits, uneven abrasion of the temporary tooth cusps and uneven second dentition on the upper and lower jaws, irregular teeth position, infantile swallowing type, impaired tongue articulation during speech, acromegaly, impaired miodynamic balance (Fig. 2).

Fig 2. Occlusion contact disruption with the combined occlusion anomaly: anterior occlusion and cuspidate dystopia caused by excessive maxillary development and the submaxillary underdevelopment

Occlusively, the anterior molar contact in the sagittal plane (50% - 25 patients) prevailed with the neutral Angle's molar occlusion (50% - 25 patients). The palatine occlusion has been found in 20 patients (40%), and vestibulo-occlusion - in 11 patients (22%).

The teeth abnormalities in the transversal plane has been diagnosed in 62% of cases of the dentition anterior occlusion. In the frontal area, the incisor invert correlation has been detected in 23 patients (46%), sagittal mismatch has been diagnosed in 10 patients (20%), and direct occlusion - in 2 patients (4%).

In 50% of cases, there was a decrease in percent of the angle indication between the mandibular plane and the Frankfurter plane (25.43% - 25.27%). The mismatch in the relations between the upper and lower jaws was (79.7% - 80.13%). The indicators before and after the distal occlusion treatment in percent were equal to 112.7% - 116.4% (Table 1).

Table 1: Cephalometric study results among the examined patients

	Normal range	Before treatment	After treatment
FMIA	67±0,01	63,23±1,17	65,30±1,31
FMA	25±0,01	25,43±0,83	25,27±0,41
IMPA	88±0,02	89,27±1,26	88,37±0,73
AO-BO	2±0,0 мм	0,88±0,99	1,59±0,40
SNA	79±0,01	79,77±0,79	80,13±0,53
SNB	77±0,01	78,15±0,61	78,80±0,45
ANB	2±0,0	4,93±1,19	3,57±0,72
Effec. max. lengh	85±0,01	93,03±1,25	94,42±1,09
Effec. mand. lengh	105±0,01	112,69±1,61	116,37±0,90
Upper pharynx	8,58±0,65	8,78±0,61	8,58±0,65
Lower pharynx	11,23±0,50	12,25±0,65	11,23±0,50

An analysis of the parameters specifying the facial soft tissue profile has revealed an increase in the nasolabial angle of 15.8%, its decrease with the distal ratio of 25%, a decrease in the convexity angle of soft tissues and a decrease in the facial profile convexity of 33% with an anterior dentition relation. In summing it up, it is safe to say that the cephalometric data in lateral projection is the modern anterior occlusion diagnostic method. The anterior occlusion treatment for adolescents is possible without surgical intervention during the early mixed dentition using the extraoral devices (Delaire face mask) based on the growth modification, applied forces and with the false anterior occlusion.

Determination of the first maxillary premolar germ migration on a cephalometric image. According to Beamler's data, in the non-growing patients with the harmonious facial development and a normally formed permanent orthognathic occlusion, the 'stress axis' passes through the vertical axis of the first maxillary premolar. If the erupting first premolar was in front of the stress axis, it was indicated to remove the first premolars, and the cases of posterior position indicated the maxillary underdevelopment (Fig. 3).

Determination of the first maxillary premolar germ migration on the profile teleroentgenogram. 16 children at the age of 6-9 years old with the early clinical signs of sagittal abnormalities were subjected to cephalometric analysis of the upper premolar germ position. As a result, 7 children showed the anthroposition of the first premolar germs that was an early latent sign of rapid maxillary development or early migration of the upper posterior teeth (Fig. 4). 9 children demonstrated the retroposition of the first premolar germs being an early latelt sign of the delayed maxillary development, the distal position of the upper permanent posterior teeth germs or excessive supramaxillary development (Fig. 5).

Fig. 3. Determination of the first maxillary premolar germ migration on the profile teleroentgenogram

Fig. 4. Position of the upper premolar germs: a child at the age of 7 years

Fig. 5. Retroposition of the first premolar germs: a child at the age of 9 years

In some cases, the doctor may need a CT scan. This image only allows to estimate the spatial teeth arrangement relative to each other. This is necessary when planning the impaction movement, when it is extremely important to understand which tooth is located more superficially, and to select the right displacement vector so as not to touch the roots of other teeth. When using the OPTG, an assessment of the tooth position is possible only in one – frontal - plane.

In the course of the therapeutic measures performed for the children and adolescents, the neutral relations of the first molars according to Angle's class I was achieved. When evaluating the treatment outcomes, we noted the coincidence of the central line between the upper and lower teeth, formation of an interincisal angle within 118° and overlapping by the upper incisors of more than 1/3 of the height of the lower incisors.

The high level of satisfaction of the patient and his/her parents with the treatment results made it possible to positively evaluate its results. The formation of physiological dentition occlusion increased the chewing function efficiency. The results are presented in Table 2.

One year after the follow-up commencement, we recorded an increase in the number of people with physiological occlusion in the second group - in children who used a cervical bandage and non-removable orthodontic appliances. After two years, the treatment efficiency in children in the second group reached a maximum value that had a significant difference with the treatment results after one year. However, this indicator differs significantly from the similar indicators in the comparison group.

Table 2: Dentition condition dynamics during the treatment process

Treatment terms	Physiological occlusion				Anomaly at the formation stage				Formed abnormality			
	Control group		Comparison group		Control group		Comparison group		Control group		Comparison group	
	Abs.	%	Abs.	%	Abs.	%	Abs.	%	Abs.	%	Abs.	%
Commencement of treatment	0	0	0	0	13	52	11	44	12	48	14	56
After 1 year	15	60	11	44	8	32	8	32	2	8	6	24
After 2 years	23	92	17	68	1	4	6	24	1	4	2	8
After 6 years	24		19		1		7		1		7	

After 24 months of active treatment, the malocclusion was corrected in the control group in 90% of cases, and in the comparison group - in 78% of cases. The patient profile was significantly improved, and the intermaxillary deviation was readjusted. The upper jaw was placed in its natural position. The cephalometric images showed the clear pattern of the correct maxillary growth direction in 23 patients (92%) of the control group and in 20 patients (80%) of the comparison group (Fig. 6).

The treatment results after two years show that in 92% of patients in the control group, occlusion stability was preserved, and the facial profile also remained aesthetically pleasing. In the comparison group, the stability was maintained only by 68% of children.

Therefore, the orthodontic treatment success in the growing patients with class II malocclusion depends on its growth direction and the appropriate selection of treatment time. That is why it is important to diagnose

an early accurate diagnosis, the degree of skeletal discrepancies, in order to prepare a treatment plan that is most suitable for the patient.

Class II or bite elastics can be used simultaneously and assist in changing the dentofacial growth direction. The combination of a cervical bandage is an effective approach to the early treatment of skeletal impairments. In addition, the achieved correct anterior teeth occlusion from the anterior position of the upper teeth and jaw has contributed to the mandibular growth.

Analysis of the study showed that in the control group of patients, in 94% of cases we achieved the good treatment results, in 6% - satisfactory, and in 0% - negative. In the comparison group, it was 68%, 24% and 8, respectively. The patients from the control group have also demonstrated a 3-fold increase in the treatment efficiency.

Fig. 6. Intraoral images of a patient with prognathia (a) before treatment, (b) after treatment, (c) 7 years after treatment

During the repeated studies, we found that in patients of the control group the relapses occurred in 6.7% of cases (3 patients), while in the experimental group - in 20.0% (9 patients).

Therefore, during the treatment process for the dentition distal occlusion, it is sustainable to use the proposed treatment with myofunctional devices such as myobrace, a non-removable maxillary expansion plate with a cervical bandage for the upper jaw and without certain teeth extraction. That allows to expand the upper dentition, while providing the lower jaw with the constructional occlusion.

Discussion

In most cases, the high occurrence of dentofacial abnormalities in children is characterized by the availability of morphologically immature structures. This opinion is supported by T.F. Vinogradova [1] and other researchers. According to T.F. Vinogradova, an eight-year-old child has a simultaneous growth of the coronal section of permanent molars, the premolar root system against the background of changes of the temporary molars that indicates the availability of various tissue maturity degrees. It is also noted that under the same influence of external and internal factors, the different forms and growth reactions are noted[3, 5].

According to our data obtained, the prevalence of dentofacial anomalies is relatively more common with the mixed dentition than with the permanent dentition (42.2% versus 57.8%). Gowever, the statistical analysis showed that these differences are unreliable (P>0.05).

According to the research performed by Listopadov M.A. et al., it has been found that the use of tomography allows to determine the anatomical and topographic features of the temporomandibular joints with the distal occlusion. This data must be considered during the treatment of patients with this impairment [4].

As a result, we have obtained data characterizing the lack of space or excess dentition in the patients. In the case of lack of space in the mandible, the alveolar crest shape of the retromolar surface of eruption of the submaxillary second molars is ill-defined and narrow. The reverse effect is shown by the children at the age of up to 9 years: the more thickened the alveolar process crest, the closer the second molar germ is located to the eruption. In such a way, the clinical evidence demonstrates the excessive submaxillary growth and a wide submaxillary apical base.

Voskanyan A.R. developed and implemented the express diagnostics of deviations in the teeth position, shapes and dimensions of the dental arch and its segments from the individual normal values. It is based on the use of template sets that provide complete information on monitoring the orthodontic treatment results [2]. Our data show that the severity of teeth overcrowding with the delayed eruption of the submaxillary second molar is increased with aging. The older the patient, the more difficult it is to prevent the development of occlusion abnormalities, and vice versa.

The delayed treatment of abnormal changes in the primary and mixed dentitions contributes to the formation of severe dentofacial abnormalities in the case of permanent dentition [3, 5], while the treatment initiated at the early stages reduces the implementation of comprehensive orthodontic treatment, including the permanent teeth extraction [7, 9]. In the course of our treatment of the dentition distal occlusion, it is sustainable to use the proposed treatment with the removable extraoral and intraoral devices with the cervical bandage for the upper jaw, with and without the certain dental extraction. All above allows to expand the upper dentition, while providing the lower jaw with the constructional occlusion.

Conclusions

1. The cephalometric indicators in the early diagnosis of sagittal occlusion in children helps to obtain the proper treatment planning and achieve the consistent long-term results. Due to the early diagnostics and treatment of sagittal occlusion anomalies, a significant improvement in aesthetics can be achieved.
2. Among the analyzed orthopantomograms, the largest number of patients with the delayed eruptions of the second molars is at the age of 12 to 14 years old, with the premature eruptions from 8 years to 11 years old. The severity of teeth overcrowding in the case of delayed eruptions of the second supramaxillary molars is increased with aging. The older the patient, the more difficult it is to prevent the anomaly development and occlusion deformation, and vice versa.
3. During the treatment process of the dentition distal occlusion, it is sustainable to use the proposed treatment with the removable extraoral and intraoral devices with the cervical bandage for the upper jaw, with and without the certain dental extraction. All above allows to expand the upper dentition, while providing the lower jaw with the constructional occlusion.
4. The economic efficiency of the proposed treatment method is aimed to reduce the number of relapses of this impairment by almost 3 times.

Abstract

In the article, the authors present the results of their studies of mental health in children with vitiligo. The examination has been performed with 94 pediatric patients involved, using the 'House-tree-man', 'Kinetic drawing of the family' and 'Non-existent animal' projective method. According to the results of the study, it has been found that the mental health of children significantly affects the course of their disease.

Keywords: *Vitiligo, drawing test, mental health, severity of disease, aggression, low self-esteem.*

Introduction

Vitiligo occupies a special place among dermatological diseases that lead to severe cosmetic defects and mental suffering[2]. Vitiligo is a psychosocial problem that significantly affects the quality of life of patients[1]. Many researchers believe[4] that vitiligo is a serious cosmetic defect that occurs among people with a genetic predisposition to it and emotional disorders, in most cases[3]. Only in 4-7% of patients, vitiligo is combined with autoimmune thyroiditis. According to S. Mattoo, with vitiligo, adaptation and depression disorders are more common (75 and 18%, respectively)[6]. According to E. Colon, 39% of patients with localized foci on the skin face, are diagnosed with depressive disorders, and the same proportion of patients - with generalized anxiety disorder against the background of the manifestation of a skin disease. According to the data of the Research Institute of Dermatology and Venereology of the Ministry of Health of the Republic of Uzbekistan, in recent years, the number of vitiligo patients in our country has increased 3.4 times[8]. Within the territory of the Republic of Uzbekistan, dyschromia cases account for 21% of all skin diseases, and vitiligo cases account for 15.1%, while in other countries it does not exceed 3-4%. In 70% of cases, the disease primarily occurs at the age of 10 to 25 years. The number of children under 10 years, including newborns and infants, account for approximately 25% of all vitiligo patients[9]. In the midst stage, patients with vitiligo experience severe psycho-emotional imbalance, stress, irritation, socio-psychological discomfort, and inadequacy. Up to 5% of vitiligo patients suffer from severe depressive disorders, and in some cases, have suicidal thoughts. In children with vitiligo, emotional stress, low self-esteem and a deterioration in the quality of life are usually observed, which has negative impact on therapy and the course of their disease[5].

The purpose of the research has been to assess the mental health of children with various clinical manifestations of vitiligo.

Materials and Method

We have performed a mental health assessment for 94 children with vitiligo, aged 6 to 16 years, using

drawing tests. For many children, drawing is one of the ways to express their internality. This method makes it possible to assess the mental health and intelligence of children with vitiligo. The drawing tests were the following: 'Nonexistent animal' (NA), 'House-tree-human' (HTH) and 'Kinetic drawing of the family' (KDF). While studying the children' drawings, we took into account the whole drawing process, its details, structure, the features of graphic presentations, the positive or negative assessment of elements drawn by the patients themselves. We also paid attention to the verbal assessment of the drawing process by the children. The practical application of this method is effective due to its information value and the ability to track the dynamics of the children' mental state. During the study, behavioral characteristics such as self-doubt, insecurity, sensibilities, anxiety, fear, conflict, depression, low self-esteem, indecisiveness, problems in interpersonal relationships, lack of sociability, and social interaction difficulties have been revealed.

Results

During the drawing tests, 24 out of 90 children with vitiligo refused to perform the tasks, referring to a) lack of drawing skill b) discomfort due to the assessment of the drawing by the people present c) unclear purpose of the test proposed. These children were interviewed in confidence and were explained that the purpose of the study was not to evaluate their artistic or creative abilities. After that, they agreed to participate in research. Some children asked for a ruler to draw a straight lines. We explained to them that, according to the DTH test conditions, the drawing should be done by only manual means.

The ratio of the drawn picture in relation to a sheet means the psychological significance, value and importance of things, situations or relationships represented - both directly or symbolically - in the DTH drawing. 16 (17.02%) children drew a very small picture with weak lines, which signified a self-distrust and a feeling of inferiority. 21 (22.34%) children drew a picture at the bottom of the sheet, which was indicator of depressive state.

Analysis of the DTH test in the examined patients has showed the following results. 24 (25.53%) children drew a small house, standing far away, which characterized the feeling of loneliness or rejection of the patients. 13 (13.82%) of children drew a house without doors and windows, which indicated family relationship problems, and difficulties in being confident with their relatives. The chimney of a house with a puff of thick smoke, present in 20 (21.27%) cases, indicated the significant internal psychoemotional stress of children. Thin stream of smoke or the absence of a chimney in 26 (27.65%) cases indicated a feeling of lack of warmth and care at home. Closed windows of the house, drawn by 14 (14.89%) patients, mean alienation, hostility, difficulties in interpersonal relationships within the family. Clouds drawn by 25 (26.59%) children above the house indicated internal anxiety, fears and depression. Drawing details also reflect the level of emotions and intelligence of the patients. 14 (14.89%) children drew a human with a small amorphous head, which indicates their feeling of insecurity and concern about intellectual inadequacy. 8 (8.51%) of the children drew a human with small shoulders, which symbolized their shyness, a sense of their insignificance, and over diligence. An indinstinct and pale face in 17 (18.08%) drawings was indicative of fear and insecurity of children. Long arms in 10 (10.63%) cases were a sign of addiction, indecisiveness, the need for a family care and guardianship. As for the trees, we drew attention to such details as a shaded trunk, which meant an internal fear to be alone or hidden aggression. The lowered down tree branches meant the absence of aspirations, reluctance to make an effort, the difficulty in making decisions.

Discussion

When interpreting the results of the HTH drawing test, it is necessary to take into account the integrity of all the picture details. The presence of only one element does not indicate the presence of a certain psychological feature. According to the recommendations of R.F. Belyauskaite, all the qualitative indicators of the HTH drawing test have been combined into the following symptom complexes: 1) anxiety; 2) insecurity; 3) hostility; 4) depression; 5) self-distrust; 6) aggression; 7) communication difficulties; 8) sense of inferiority.

Table 1: Symptom complexes of HTH drawing in children with vitiligo

Indicators	Males (45)		Females (49)		Total (94)	
	Absolute.	%	Absolute.	%	Absolute.	%
Anxiety	13	13.82	16	17.02	29	30.08
Insecurity	9	9.57	16	17.02	23	24.46
Hostility	9	9.57	10	10.63	19	20.21
Depression	8	8.51	13	13.82	21	22.34
Self-distrust	8	8.51	11	11.70	19	20.21
Aggression	14	14.89	17	18.08	31	32.97
Difficulties in communication	9	9.57	10	10.631	19	20.21
Feeling of inferiority	12	12.76	15	15.95	27	28.72

After the analysis of the HTH drawing test, the following symptom complexes of different severity have been found: anxiety (30.08%), insecurity (24.46%), hostility (20.21%), depression (22.34%. The less pronounced symptoms were self-distrust (20.21%), a sense of inferiority (28.72%), aggression (32.97%), communication difficulties (20.21%) (Table 1).

'Kinetic drawing of a family' is a type of drawing test that illustrates the subjective situation of children with their family and friends. It helps to find out the children' relationship with their family members, and how significant they feel in their families, in their own opinion. The method of KDF drawing test makes it possible to identify difficulties in family relationships and emotional problems. 19 (20.21%) children did not draw faces of some their relatives, which means staying in an unhappy relationship and frequent conflicts with them. In 13 (13.82%) cases, the children did not draw themselves in the picture, which means notoriety, difficulties in self-expression in the family. When the children were asked why these or other relatives were absent in the drawing, some of them showed direct aggression towards their brothers, sisters or parents. Other children explained it by excuses: 'I forgot about him (her)', 'There wasn't enough space', 'I find him (her) difficult to draw'. In 19 (20.21%) patients, the drawing did not correspond to its verbal description, In this case, the family situation of the patients was considered as a conflict. If children drew all family members without exception, we paid attention to the size of the children themselves in the drawing, as well as their family members. The more attention and care is given to the children, the larger or proportional to other details they depicted themselves, and the less significant members of the family were painted small and distorted. We have also noted that in 20 (21.27%) cases, they drew themselves small, which means low self-esteem, insecurity among family members, and a sense of inferiority of the children. In 12 (12.76%) drawings, the children painted some family members fragmented, and the pictures were not integral. This indicates unfavorable family relationships, frequent conflicts, and sometimes hostility between some family members.

Aggressive attitude towards the family, fear towards certain family members has been determined in 29 (30.85%) cases. On the drawing, it was expressed by their isolated position from the family on a piece of paper, separation from the main picture by lines, frequent use of dashed or broken lines and dark colors. Quantitative assessment of KDF was carried out by the following system of symptom complexes: 1) family hostility 2) family conflicts; 3) anxiety; 4) a sense of inferiority in a family; 5) a favorable family situation.

After KDF drawing test, we identified the following main symptom complexes: a sense of inferiority in a family (37.23%), anxiety (25.53%). To a lesser extent, family hostility (26.59%) and family conflicts (30.85%) were present. A favorable family situation has been observed in families of 20 patients (21.27%) (Table 2).

Table 2: Symptoms of KDF drawing test in children with vitiligo

Indicators	Males (45)		Females (49)		Total (94)	
	Absolute	%	Absolute	%	Absolute	%
Family hostility	9	9.57	16	17.02	25	26.59
Family conflicts;	13	13.82	16	17.02	29	30.85
Anxiety	8	8.51	18	19.14	24	25.53
Feeling of inferiority in the family	19	20.21	16	17.02	35	37.23
A favourable family situation	9	9.57	11	11.7	20	21.27

The next drawing test is a projective research method - 'Non-existent animal'. This test is based on the theory of the psychomotor development of the children and expresses their psychoemotional state, anxiety and feelings. We invited children with vitiligo to draw a non-existent animal, which they had never seen before, and give it a name. Analyzes of NA drawing tests have been carried out with determining several parameters: position of the picture on the sheet, the central or supporting parts of the animal, the contours, lines of the figure, a positive or negative attitude, matching the animal's name with its image. 17 (18.08%) patients drew a non-existent animal in the lower part of the sheet, which indicates self-distrust and insecurities, depression or indecisiveness. In 13 (13.82%) children, the head was depicted with an open or crossed mouth with a rounded shape, which means that the children feel anxious and worried. In 23 (24.46%) cases, the head was depicted with horns, and there were claws on the extremities, which meant that the children are prone to self-defense and aggression. In 6 (6.38%) cases, uniformity of animal's legs was noted, which indicates conformity of judgments and a penchant for standards and commonplace. In a verbal survey and objective analysis, all animals were divided into three types: threatened, in need of protection - 26 (27.65%) cases, safe or neutral - 47 (50%) cases, and aggressive or threatening - 35 (37,23) cases. The mental health of patients was determined by the following symptom complexes: 1) irrationality 2) irrationality; 3) depression; 4) fear; 5) deliberation in decision making; 6)self-confidence; 7) feeling of insecurity from others; 8) asthenic feeling; 9) low self-esteem; 10) diffidence;

Table 3: Indicators of the 'Non-existent animal' drawing test in children with vitiligo

Indicators	Males (45)		Females (49)		Total (94)	
	Absolute	%	Absolute	%	Absolute	%
Irrationality.	16	17.02	21	22.34	37	39.36
Low self esteem	14	14.89	19	20.21	33	35.10
Oppression	9	9.57	11	11.70	20	21.27
Fear	14	14.89	12	12.76	26	27.65
Deliberation in decision-making	4	4.25	8	8.51	12	12.76
Self confidence	8	8.51	12	12.76	20	21.27
Feeling of insecurity from others	7	7.44	12	12.76	19	20.21
Asthenic feeling	12	12.76	18	19.14	30	31.91
Low self esteem	12	12.76	17	18.08	29	30.85
Diffidence	9	9.57	14	14.89	23	24.46

In NA drawing tests, such symptom complexes as diffidence (41.13%), low self-esteem (30.85%), asthenic feeling (31.91%), fear (27.65%), depression (21.27%), feeling of insecurity from others (20.21%) have been revealed to a lesser extent (Table 3).

An analysis of the results of drawing tests gives information about the mental health of children with vitiligo in a chronic somatic disease. The symptom complexes noted above form either the result of the vitiligo process, or a trigger factor leading to the manifestation or exacerbation of dermatosis.

Table 4: The severity of general - school, self-esteem, interpersonal - anxiety of children with vitiligo

Level	Males (45)		Females (49)		Total (94)	
	Absol	%	Absol	%	Absol	%
Extrinsic	4	4.25	4	4.25	8	8.51
Normal	9	9.57	15	15.95	24	25.53
Insignificantly increased	16	17.02	15	15.95	31	32.97
Increased	17	18.08	20	21.27	37	39.36
Very high	2	2.12	3	3.19	5	5.31

In order to determine the level of anxiety, we used the anxiety scale developed by A. M. Prikhozhan [11]. Types of anxiety included three types of situations: 1) school anxiety (incidents related to classmates, school, and communication with teachers); 2) self-assessment (situations actualizing self-identification); 3) interpersonal (situations that depend on the communication of children in the family, with their parents). After analyzing the general level of anxiety of the studied children of children with vitiligo in children, we have determined (Table 4) that anxiety was present in the majority of children - in 84 (89.36%) cases, as a relatively stable personality formation, with various degrees of severity. Patients with a high and very high level of anxiety are considered a risk group, and in our case, their number was 35 (37.23%). the cause of the occurrence in patients with such anxiety can be due to low self-esteem, traumatic for the child's psyche, real ill-being caused by the chronic course of the disease, problems in interpersonal situations, difficulties in school and family situations, an illness unnatural for healthy children, accompanied by great experiences. Children with increased timidity complain about the difficulty of adaptation in society, a decrease in the stability and effectiveness of education. Due to the long and frequent periods of treatment of children with vitiligo, their rhythm of life is violated, they lag behind their peers, and refuse to attend school for some time. All these factors increase emotional stress and create a kind of vicious circle. Some patients have a higher level of anxiety. These children can be attributed to a risk group related to the development of more pronounced forms, since negative situations associated with the disease, with its vivid clinical manifestations, relapses, will increase emotional distress and psychological discomfort. The number of such patients in our studies was 29 (28.72%).

Conclusions

Our studies prove the important role of the mental health of patients, which depends both on their personal qualities and the influence of the surrounding society, as well as the course, development, and prognosis of the disease. Timely identification and elimination of these psych emotional factors, correction of the psychological state of patients will undoubtedly contribute to improving the quality of life and will have a beneficial effect on the course of vitiligo.
