Various changes of tooth with advanced aged: After full maturation of tooth structure, slowly its changes with advanced age. The demineralization process starts of tooth structure. Due to long term demineralization enamel layer lost totally. Micro changes occur inside the tooth surface. Loss of occlusal surface of the tooth and facial surface of tooth seen in mostly old age group. Looks of the tooth different from newly erupted teeth. Refractive index of light in tooth structure also changes due to increasing age. The normal thickness of tooth dentine also decreases. Various defects found on tooth structure. Tooth pigmentation also found. Due to a lack of proper oral hygiene, the color of teeth change in old patients.[8]

Various ion exchange phenomena take place in the upper surface of the tooth (enamel). Tooth became highly brittle and porous due to increasing age. Restoration is the process by which we can make the prognosis of the tooth good in old age. The structure of pulp is different in old group people than young people.[8] The volume of the pulp chamber decreased due to less pulp cells. Repair capacity of pulp decrease with increasingage. Calcification of pulp chamber occurs, with aging in most of the case. Electronic microscopic images of the pulp chamber of old patients look different from young patients. Thin root canal found in old people. More amount of F and Mg found in old patients. Some biomarkers also found in the cementum of old people. Micro annular ring found in old patients and that helps in forensic investigation. Morphology of tooth changes with increasing age which linked with clinical examination. Restorative treatment has a good impact on tooth structure. Around five to seventy percent of old people throughout the globe have CPI score four. Most study data says that periodontal disease increase with aging. Periodontal disease is not considereda special disease but it started from a young age reaches chronic periodontitis in old age. Periodontal disease is due to the accumulation of sub and supragingival biofilm formation. Breakdown of periodontium creates more oral problems in old ages. Bleeding gum, swelling of gingival found some time discharge of pus found.[9,10]

Need for preventive services: In recent prevalence of oral disease is increasing day by day. Disease like gingivitis, periodontitis, dry-mouth, root caries are increase in the old generation. Most of the old people think that mobility of tooth, tooth loss are natural phenomena and cant be prevented. Many people think that in old age when it emergency then go to dentists for check-up. Few people go for regular dental check-ups. Some important causes that keep most of the old people from getting oral care such as health issues like- Oral health condition, Filling discomfort, long term illness, physical disability, Socio-economic causes, residence places, Education level, amount Income, Age issue, gender, Culture factor, communication facility, doctor behavior, cost of service, self-interest

Conclusion

The topmost problem regarding the oral care facility in the older population is underestimated the oral disease. This underestimate nature towards oral health is found mostly in India. Barrier in getting oral care in India is lack of proper communication, lack of education, language barrier, cultural barrier, belief in various myths regarding oral diseaseetc, Political census etc. Awareness knowledge regarding oral disease may change the attitude of our people to focus their attention on oral health. Home care of elder patients by caretaker can improve the oral health of older people. India should implement a proper program for oral health. Proper dentist population ratio throughout our nation to provide better dental care. Regular screen camps in different places to find the older patient and gave them special care because due to rapid dental caries, periodontal disease, tooth loss the old people facing various problems.

Facial Transformation in a Class III Surgical Case

Smruti Bhusan Nanda

Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, India

Abstract

Orthodontic problems that cannot be treated by growth modification/camouflage treatment needs to be corrected by surgical method. The envelope of discrepancy needs to be respected while handling these cases. This case report presents an adult female patient with Skeletal Class II malocclusion.

Keywords: *Decompensation, skeletal, Class III.*

Introduction

It is a dream of every young girl to look good. The pleasant facial appearance is directly proportional to the self-confidence of a person, which in turn is very essential for a successful life in terms of carrier and quintessence.

We received a20yrs old female patient named Miss Sweta Samatray, at our dental office with a chief complaint of improper chewing and unacceptable facial appearance. She had a very low self-esteem. Reasons for Orthodontic treatment was esthetics.[1]We could sense the internal motivation of the patient who is about to graduate as an engineer and the amount of peer pressure to excel in each field, she is going through. In this situation to treat her to achieve a more pleasant face was superlative.

Clinical Findings: Clinically, she had Angle's Class III malocclusion on skeletal class III jaw bases. On extra-oral examination she had a concave facial profile, anterior divergent face, acute nasolabial angle, flat mentolabial sulcus, thick protruded lower lip, deficient malar prominence. A clinically insignificant amount of facial asymmetry was present.

On intraoral examination she had bilateral Class-III molar and canine relation, crowding in the maxillary and mandibular anterior region, anterior open bite, mandibular midline shifted to right side by 2mm (Figure 1). Cephalometric findings are presented underneath in table 1.

Table 1. Cephalometric findings (pre and post-treatment)

	Pretreatment (Degrees)	Posttreatment (Degrees)
SNA	78	83
SNB	87	81
ANB	9	2
GOGN-SN	45	37
Y AXIS	48	61
U1-NA	33	32
LI-NB	20, 2mm	21, 3 mm
UI-LI	122	130
IMPA	89	91
NASOLABIAL ANGLE	88	91

Figure 1: Pre-treatment extraoral and Intraoral Photographs

Treatment Plan: The patient had undergone upper premolar extraction, leveling and alignment, maxillary space closure, followed by bijaw surgery to achieve a good functional occlusion as well as harmonically esthetic face.

Treatment Progress: Leveling alignment done with the wire sequence as depicted in Figure 2. The wire sequence includes: 0.014 NITI, 0.016 NITI, 0.016 SS, 0.019x025 NITI, 0.019X0.025 Stainless steel wires.

Remaining space closure was done with the bilateral active tie backs, on 0.019X0.025 SS

Figure 2: Pre-surgical Intraoral & Extraoral photographs

After the maxillary space closure the pre-surgical OPG & lateral cephalogram was done to do the cephalometric evaluation and the paper surgery. Surgical VTO was done suggesting a maxillary advancement of 5mm & mandibular setback of 7mm. A mock surgery was performed on a cast after proper face bow transfer and articulation (Figure 3).

Figure 3. Face bow transfer

The two-stage mock surgery was done with simulation of maxillary advancement first, which resulted in the fabrication of the first interim splint. The second stage mock surgery simulated the bilateral sagittal split osteotomy set back of mandible and resulted in the fabrication of final surgical splint (Figure 4).

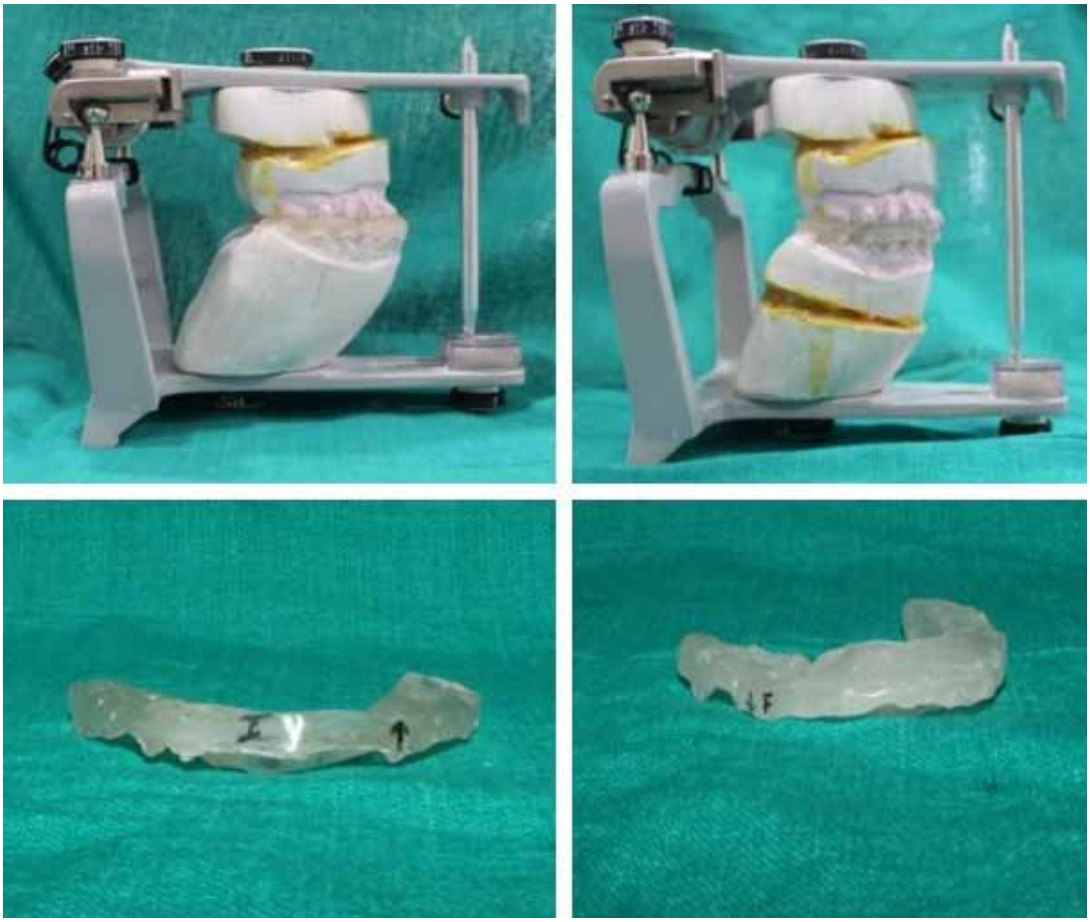

Figure 4. Surgical splints & mock surgery

The Orthognathic surgery was performed as per the plan and on table facial appearance was satisfactory. Illiaccrest bone grafting was done bilaterally to improve the malar prominence. The post-surgical healing was uneventful for the patient. Post-surgical Orthodontic finishing done for 4 months along with bracket repositioning and vertical settling. Debonding was done after 20 months of treatment. (Figure 5). Comparative radiographs are provided as shown in figure.6.

Figure 5. Pretreatment and post-treatment comparison photos

Figure 6: OPG and Lateral Cephalogram (Pretreatment & Posttreatment)

Conclusion

The intention of treating the case was purely to give a more esthetically acceptable face to the patient.[2,3] The patient's facial divergence changed from the concave to straight profile with a more prominent malar area of the face. The step formed by the maxillary and mandibular lips due to the prominent mandible became better. The throat chin angle became more pleasant.[4] We achieved all these extraoral features with a balanced occlusion at the end of debonding.[5,6] Now the girl is ready to face the world with more confidence and the proof of this lies in her eyes as noticed in the post-treatment extraoral photographs.

Conflict of Interests: The authors declare they have no conflicts of interest.

Morphometric Analysis of Coracoid Process in Adult Human Scapula in Eastern Odisha Population

Saurjya Ranjan Das[1], Sreepreeti Champatyray[2], Gyanaranjan Nayak[3], Sitansu Kumar Panda[3]

[1]Associate Professor, Department of Anatomy, IMS and SUM Hospital, [2]Associate Professor, Department of Oral Pathology & Microbiology, Institute of Dental Sciences, [3]Professor, Department of Anatomy, IMS and SUM Hospital, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003 (Odisha) India

Abstract

Background: Coracoid process is a bird's beak like projection which arises superolaterally from the upper border of the head. It plays an important role in shoulder function. The aim of our study is to measure the dimensions of the coracoid process of the scapula.

Method: The study was performed on 104 specimens of human scapula of unknown sex obtained from the Department of Anatomy of Institute of Medical Sciences & SUM hospital. The dimensions recorded were breath, length, height,thickness and types of coraco-glenoid space by using digital vernier calipers. These parameters were compared on both the sides.

Results: The most predominant coraco-glenoid space was found to be the round bracket (Type I). Statistically insignificant difference was noted in all four parameters between right and left. Though all the four parameters have higher values on right side in comparison to left side but the difference was statistically insignificant. The results are as such length of coracoid- 39.91±3.16 mm; width of coracoid- 14.00±2.03 mm; tip thickness of coracoid- 8.32±1.87 mm; height of base coracoid- 22.87±3.55 mm; width of base of coracoid- 10.50 ±2.64 mm;

Conclusions: The study of variation of dimensions of coracoid process provides valuable information regarding the role of these parameters in etiology of subcoracoid impingement syndrome which will help the radiologist and orthopedic surgeons for diagnosing various pathologies and plan for surgical procedure on coracoid process.

Keywords: *Coracoid, Coraco-glenoid, morphometry, Subcoracoid impingement syndrome.*

Introduction

The scapula is a large triangular flat bone which lies posterolaterally on the chest wall corresponding to second to seventh ribs. It has 2 surfaces-dorsal and costal surfaces; 3 borders-superior, medial and lateral borders; 3 angles, superior inferior and lateral angles and three processes called spine, acromion and the coracoid process. Each process has its separate importance.

The Coracoid process is a bird's beak like projection which arises superolaterally from the upper border of the head and is bent sharply so as to project forwards and slightly laterally.[1] The shoulder joint is highly mobile joint with less stability. It is a ball and socket type of synovial joint in which the large head of humerus articulates with the shallow glenoid cavity. So, the coracoid process is often referred to as the 'lighthouse of

e-mail: sreepreetichamatyray@gmail.com

shoulder' in orthopedic literature.[2] The coracoacromial anatomy includes acromion, coracoacomial ligament and tip of coracoid process. The disparity in the height and length of coracoid process is responsible for altered shape of space between rotator cuff and coracoacromial arch. [3] The coracoid process is involved in many surgical procedures on the glenohumeral joint which forms an important part of the scapular glenoid structure. [4] The anatomy of the coracoids process and its related structures in the glenohumeral joint is required to study the radiological images and tocarry out surgical procedures in various shoulder pathology. The detail study of the dimensions of the coracoids process will help the surgeons for surgical procedures like drill hole placement, hardware fixation and prosthetic positioning.[5] Morphology of the coracoids process plays an importantrole in understanding impingement syndrome and pathogenesis of rotator cuff diseases.[6]

This study will also help the Forensic experts in determination of gender from these parameters.

A very few studies has been done regarding the morphometric values of coracoid process in eastern Indian population, so, the present study was planned to study the different parameters of coracoids process and types of coraco-glenoid space in adult human scapula of Eastern Odisha population.

The scapula is the anchoring point for the postural muscles of the shoulder; it provides stability necessary for a huge combination of movements around the shoulder joint. The coracoid process is rarely injured. It has a 3 dimensional orientation which makes it difficult to interpret in radiological images.[2] Any congenital variations and minimal iatrogenic changes in orientation can predispose to subcoracoid impingement.[7]

Material and Method

The material for the present study comprised of 104 adult dry scapulae of unknown age and sex, obtained from the Department of Anatomy of Institute of Medical Sciences & sumhospital.

The dry adult scapulae taken for study were labeledwith suffix R (right) or L (left). All the scapule were cleaned thoroughly and complete in all aspects were included in this study and broken and deformed ones were excluded. The following parameters were measured on the coracoid process with help of digital Vernier caliper accurate up to 0.01 mm. The parameters taken were as follows

1. Length of coracoid process: (distance from the tip to the of horizontalpart)

2. Width of coracoid process:(Antero-posterior distance at the midpoint of coracoidprocess).

3. Thickness of coracoid process (supero inferior distance 1cm posterior to the tip)

4. Base height (maximum superoinferior distantance of the base)

5. Base width (maximum lateral-medial distantance of the base).

Coraco-glenoid space was classified by Gallino et al.[8]into

1. Round bracket (Type I),

2. Square bracket (II)

3. Fish hook (III)

Result

All the measurements were taken and the data was tabulated and analyzed using Microsoft Excels software. P value was calculated by using unpaired t test for various parameters. Difference was considered to be statistically significant if p value obtained was less than 0.05.

The shape of the coraco-glenoid space was found to be round bracket like (Figure 1) in 58 cases (55.76 %), square bracket like (Figure 2) in 33 cases (31.74 %) and fish hooked like (Figure 3) in 13 cases (12.50 %). All the measurements are displayed in Table 1

Length of coracoid process: The mean length of coracoid process was observed to be 39.91±3.16 mm in the present study. The mean length was more on left side in comparison to right side but the difference was statistically insignificant.

Breadth of coracoid process: The mean breadth of coracoid process was observed to be 14.00±2.03 mm in the present study. The mean breadth was more on left side in comparison to right side but the difference was statistically insignificant.

Thickness of coracoid process: The mean thickness of coracoid process was observed to be

8.32±1.87 mm in the present study. It was more in left side in comparison to right side but the difference was statistically insignificant.

Height of base of coracoid process: The mean height of base of coracoid process was observed to be 22.87±3.55 mm in the present study. The mean height was more on left side in comparison to right side but the difference was statistically insignificant.

Width of base of coracoid process: The mean width of base of coracoid process was observed to be 10.50 ±2.64 mm in the present study. The mean width was more on right side in comparison to left side but the difference was statistically insignificant. All the measurements are displayed in Table 2.

Table 1: Different shapes of coraco-glenoid shapes.

Shape	Right Side	Left Side	Total
Rounded	38(63.33%)	20(45.45%)	58(55.76%)
Square	18 (30%)	15(34.10%)	33(31.74%)
Hooked	4(6.67%)	9(20.45%)	13 (12.50%)
Total	(100%)	(100%)	(100%)

Table 2: Observations of different parameters of coracoid process.

Parameter	Range of Measurements (mm)		Mean±SD (mm)		Average Mean±SD (mm)	P value
	Right (n=60)	Left(n=44)	Right	Left		
Length	34.5 -44.04	35.72 – 41.84	39.66 ± 3.0	40.27 ± 2.30	39.91 ± 3.16	0.18
Breath	10.58- 17.86	10.84 – 17.08	13.93 ± 2.1	14.11 ±3.21	14.00 ± 2.03	0.09
Thickness	6.1 – 10.32	7.36 – 10.56	8.09 ± 1.42	8.64 ± 1.00	8.32 ± 1.27	0.77
B. Height	12.6 - 26.75	6.36 - 17.84	22.59 ± 3.75	23.24 ± 3.41	22.87 ± 3.55	0.46
B. Width	16.42 – 28.82	6.76 – 13.84	10.66 ± 2.89	10.29 ± 2.37	10.50 ± 2.64	0.73

Figure 1: Type-I (round bracket) coraco-glenoid space

Figure 2: Type-II (square bracket) coraco-glenoid space.

Figure 3: Type-III (fish hooked) coraco-glenoid space.

Discussion

Coracoid process plays important role in functions of scapula. The coracoid process acts like a lever through which the muscular action of the biceps, coracobrachialis, and pectoralis minor muscles exerts a force on the glenoid. The shoulder joint is a most frequently dislocated in adults as well as children, the injury of thecoracoid process is very rare.So fractures of coracoid present a challenge to repair by the operating surgeons. The frequency of fracture ofcoracoid process was between 3% and 13% of all the fractures involving scapula. The base of the coracoid is most commonly fractured. The results obtained in the presentstudy demonstrates the dimensions of the coracoid process can help in deriving appropriate strategy for repair of the fracture. Various ways of open surgical and arthroscopic access to the shoulder involves the coracoid process. So, its morphometry is of pivotal importance in surgeries of the shoulder joint.

Various studies have shown that the skeletal morphometry is influenced by different factors such as race and sex.[9,10] The study of the morphometry of coracoid process shows that it as a key structure and potential mediator in shoulder surgery and pathology.[11]

The mean length of coracoid process was found to be 39.91±3.16 mm with mean of 39.66 ± 3.0 on right side and 40.27 ± 2.30 on left side. The findings of the current study is similar to those found out by Kavita et al[12],Kour et al[13] and Rajan et al[3]. While the findings of Gallino et al[6]; and Burke et al[14] are slightly higher than present study and the results found by, Piyawinijwong et al[15] and Gumina et al[16] is less than our study.

The mean breath of coracoid process was found to be 14.00±2.03 mm in the present study with mean of 13.93 ± 2.1 on right side and 14.11 ± 3.21 on left side. This findings is similar to those found by Rajan et al,Kour et al and Verma et al[3,13,17] but the studies done by Piyawinijwong et al[15] found slight lower value than the current study.

The mean thickness of coracoid process was observed to be 8.32 ± 1.27mm in the present studywith mean of 8.09 ± 1.42mm on right side and 8.64 ± 1.00mm on left side which is almost equal to that of the findings of Verma et al[17] and S. Kalra et al.[18]The findings of Coskun et al, and Piyawinijwong et al is lower than the present study[1,15].

The mean height of the base of coracoid process was observed to be 22.87 ± 3.55 mm in the present study with mean of 22.59 ± 3.75 mm on right side and 23.24 ± 3.41mm on left side. Our findings are higher in comparison to the studies done byRajan et al, Piyawinijwong et al and Gumina et al[3, 15, 16] and it is similar to the findings of Verma et al.[17]

The mean width of the base of coracoid process was observed to be 10.50 ± 2.64 mm in the present study with mean of 10.66 ± 2.89 mm on right side and 10.29 ± 2.37mm on left side. Our findings are similar to the studies done by FathiM et al.[19]

Shape of coraco-glenoid cavity: In the present study Type I(round bracket)was the most common type seen in 55.78% of the scapulae out of which 63.33% of sample on right side and 45.45 % on left side. The second most common type was Type II(square bracket)seen in 31.74 % which was found 30 % on right side and 34.10 % on left side and least is Type III (fish hooked)vshape in 12.50 % which was 6.67% % on right and 20.45 % on left side. The findings of the current study was similar to the findings of the Verma et al and Gumina et al.[17,16]

Conclusion

The morphometric analysis of the coracoid process should be used like a tool for surgical procedure on coracoid process. A very few studies has been done to demonstrate the various dimensions of coracoid process. It will help the orthopedic surgeons to operate the gleno-humeral joint during impingement syndrome, rotator cuff rupture and for shoulder prosthesis in total shoulder arthroplasty. The study of the dimensions of coracoid process helps the radiologists to interpret any pathological conditions associated with it. These findings might also be useful in determination of gender by the forensic experts. The various scapular dimensions obtained in this study will also be useful in comparative anatomy and manufacturing prosthetic products. The current study will be of immense help in orthopedic surgeries on the shoulder joint and in biomechanical engineering for designing implants for total shoulder replacement

Management of Bilateral Ectopic Canines: A Case Report

Smruti Bhushan Nanda[1], Sumita Mishra[2]

[1]Professor & Head, [2]Associate Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

An ectopic canine tooth may originate due to genetic/environmental aberrations. These teeth demand correction as they can move in the jawbone and damage the adjacent bone, roots of the teeth, pose esthetic concerns. Timely diagnosis and treatment play a pivotal role. The case report stresses on an extraction treatment approach for correction of ectopic canine in a patient posing severe crowding in both upper and lower arches.

Keywords: *Ectopic Canines, Bilateral, Orthodontic Mechanotherapy.*

Introduction

Orthodontic practice envisages ectopic canines very frequently with a prevalence rate of 1-2% in the general population.[1,2] They occur with a variety of local and systemic issues. The long tortuous path of a canine might be an explanation for the etiology of this phenomenon. Any associated disturbance with the follicle of the unerupted tooth may displace the maxillary canine tooth.[3,4]

Canine Impactions and Classification:

A. ARCHER'S

It may be:

1. CLASS I: Partially Impacted
   a. Horizontal
   b. Vertical
   c. Semi vertical
2. CLASS II: Buccally impacted canine
   a. Horizontal
   b. Vertical
   c. Semi vertical
3. CLASS III: Impacted canine in both palatal and labial surfaces
4. CLASS IV: Impacted canine located in the alveolar process
5. CLASS V: Impacted canine located in the edentulous maxilla
6. CLASS VI: Canine in aberrant position

Case Report:

Diagnosis and Etiology: A 12-year-old male patient named Soumya Ranjan Mitra reported to the Department complaining of irregularity in the upper and lower teeth. Extraorally, the patient had a convex profile with incompetent lips (Figure 1) with an asymmetrical face.

Figure 1. Patient with convex profile

Corresponding Author:

e-mail: sumita.mitali@gmail.com

He had a normal gait with a thin physique. The patient was cooperative and was keen for braces treatment. On intraoral examination, the patient had Angle's Class I molar on the right side and Angle's Class II molar on the left side with 2 mm of overjet (Figure 2.a & 2b.).

Figure 2a. Class I molar

Figure 2b. Class II molar

Maxillary (upper) archand mandibular (lower) archexhibited severe arch crowding (Figures 3 & 4).There was minimal attached tissue with the ectopically erupting right and left upper canines. Cast analysis showed arch length discrepancies in the maxillary as well as mandibular arches.

Figure 3. Maxillary anterior crowding

Figure 4. Mandibular anterior crowding

There was an absence of any pathologies in the panoramic radiographic image. Lateral cephalometric analysis showed skeletal Class II relationship with normodivergent pattern. The patient had upright maxillary incisors.

Treatment Objectives: The main objective of treatment was the correction of ectopic canines with a cuspid guided occlusion preserving the normal overjet and obtaining a proper overbite.

Treatment Plan: The rationale of treatment was to extract the first premolars, preserve the profile of the patient and obtain a stable treatment result.

Treatment Alternatives: Several treatment options are available for the correction of ectopic canines. The first and most popular would include the extraction of all first premolars as seen in our case. The other would include the distalization of the upper premolars and the extraction of the lower premolars. The least preferred would be a non-extraction treatment plan but the disadvantages would include proclining the incisors, longer treatment duration and enamel demineralization as a result. There can be a change in profile adversely affecting the esthetics of the patient. Arch form maintenance is predictable with extraction treatment.

Treatment Progress: Patient's dentition was checked for any signs of dental caries, periodontal degradation. The amount of attached gingiva was evaluated over the ectopic canine region. Full bonded MBT 022 system fixed appliances were placed on both the arches. The extraction of all four premolars was carried out. Initial leveling and alignment were carried with 0175 multistranded wire followed by 014 NiTi and other 17*25 NiTi and stainless steel wires. Light elastic forces were used to retract the buccally placed canines into the arch. The total treatment time was 20 months. After completion of treatment, removable retainers were given for the maxillary and the mandibular arches.

Treatment Results

A canine protected occlusion was achieved with ideal overjet and overbite. The canines were in Class I occlusion with correction of crowding in both the arches (Figure 5 & 6).

Figure 5. Class I Canine with canine protected occlusion

Figure 6. Ideal overjet and overbite

Discussion

Timely interception of the ectopic canines can be made possible by periodic panoramic radiography, careful clinical examination, and intraoral palpation.[5] Proper set up of Orthodontic records helps in a space analysis. Space can be gained via several method: maxillary arch expansion, proclination of maxillary incisors, other treatment strategies. It is important to check forthe mobility of the adjacent teeth.[6,7] If the deciduous canine id mobile, there are chances of its replacement by permanent canines.

If the permanent lateral incisor is mobile, it might indicate that the impacted canine has resorbed its roots. We were able to effectively manage the case by extraction treatment.[8] Non-extraction treatment would have proclined the maxillary incisors and worsened the soft tissue profile of the patient. Easy correction of crowding was possible with extraction expecting stable results post debonding. The factors dictating crowding include tooth size and dental arch dimensions.[8] Proper clinical examination and diagnostic radiographs are essential for the diagnosis of these ectopic canines.[8]

Conclusion

The success of Orthodontictreatment posesa great challenge to the Orthodontist in terms of ectopic canine correction. The extraction treatment plan is more predictable, stable giving importance to the esthetics of the patient.

Glossopharyngeal Neuralgia: A Comprehensive Update

Shamimul Hasan[1], Rajat Panigrahi[2], Sk. Tarique Ajiz[3]

[1]Professor, Department of Oral Medicine and Radiology. Faculty of Dentistry, Jamia Millia Islamia, New Delhi, [2]Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Project Officer, International Institute for Population Sciences, Mumbai, Maharashtra, India

Abstract

Glossopharyngeal neuralgia (GN) is an unusualclinical condition where severe paroxysmal pain of the glossopharyngeal nerve. GN pain should be differentiated from trigeminal neuralgia pain, as the two neuralgias share several similar features. Thorough medical history coupled with a detailed clinical examination and hematologic and radiographic investigations is necessary for early and accurate diagnosis. Anticonvulsants form the cornerstone of the medical management, and surgical interventions (microvascular decompression and gamma knife surgery) is needed in cases resistant to pharmacotherapy.

Keywords: *Carbamazepine, glossopharyngeal neuralgia, microvascular decompression, neuralgia.*

Introduction

Neurologica non-nociceptive pain or pain which does not relate to the activation of pain receptor cells in the body. It's a type of pain due to a lesion or any disorder of the somatosensory system.[1]

As per ICHD-3 (International Classification of Headache Disease-3) classification, glossopharyngeal neuralgia (GN) is a disorder characterized by a brief periodic unilateral pain, with sharp and piercing in character, with abrupt onset and cessation, in the glossopharyngeal nerve distribution (angle of the jaw, ear, tonsillar fossa and the tongue base). It falls under the International Classification of Diseases (ICD) category as ICD-10-CM-G52.[1 2]

The International Association for the Study of Pain (IASP) defines it as sudden, severe, brief, recurrent pain along the glossopharyngeal nerve distribution.[3]

GN is an extremely uncommon occurrence and accounts for only 0.2%–1.3% of the cases with facial pain.[4,5] GN usually affects the male individuals above 50 year-age, and the reported incidence of GN is roughly 0.8 per 100,000 persons per year.[4,6-11]

It must be asserted that GN is not as rare as reported in the literature due to non-familiarity with the disease, diagnostic obstacles, and more so with the escalating number of patients with Eagle's syndrome.[12]

Historical Background: Theodore H. Weisenburg (1910) was the first to provide the classic description of GN in a patient who reported with a lancinating ear and neck. Autopsy reports revealed that the pain was due to a cerebellopontine angle tumor, which presses the trigeminal nerve and stretches the glossopharyngeal nerve.[13]

After 10 yrs in 1920, Sicard and Robineau (1920) reported 3 patients with "Algie Velo-pharyngee essentielle" i.e. Pain along the distribution of glossopharyngeal nerve idiopathically[10,13]

The term "glossopharyngeal neuralgia" was framed by Wilfred Harris. He described GN as a painful condition characterized by episodes of severe lancinating, unilateral pain along the nerve division, which may be triggered by trigger point stimulation in areas supplied by the nerve.[10,13]

Two noteworthy advancements were reported for the efficient management of glossopharyngeal neuralgia in 1927. J. Doyle published a case series of 18 GN patients, and W. Dandy performed the first successful intracranial resection for glossopharyngeal neuralgia.[14]

Riley et al. (1942) reported an uncommon association of GN with life-threatening cardiovascular manifestations- asystole, transient/persistent bradycardia, syncopal episodes, and even seizures.[8]

Classification:

1. Based on the International Headache Society (IHS) Classification, GP is classified as (1) classical GPN (occasional or episodic pain) and (2) symptomatic GPN (persistent pain; persisting between the episodes of peaks and troughs of pain.).[15]
2. Based on the pain distribution, GN is classified as- (a) Otitic pain: Pain in (or around) the auricle/ ear lobe (b) Oropharyngeal pain: Pain of neck and maxillofacial regions. Nevertheless, these regions show considerable overlap inthe cranial nerve-supplied areas.[16]
3. Based on the causal factors, GN is classified as (a) Idiopathic/essential GN- The majority of GN cases are idiopathic, where no apparent lesion is noticed.[17] GN is caused by neurovascular compression of nerve IX by the postero-inferior cerebellar artery (PICA),[18] which was first observed postmortem by Brihaye et al.[19] (b) Secondary GN- where a demonstrable lesion is seen. Eagle's syndrome/ styalgia accounts for the most common secondary cause of GN .[13]

Eagle's syndrome is an unusual disorder, clinically alarger in size of the styloid process or stylohyoid ligament complex is mineralized.

Clinical Features: Glossopharyngeal neuralgia is a rare disease entity, characterized by pain paroxysms in the regions supplied by the glossopharyngeal nerve (auricular and pharyngeal). The GN pain is typically characterized as brief episodes of unilateral severe, piercing/lancinating pain, confined primarily of the ear, ventral surface of tongue, throat, tonsillar region, or beneath the angle of the jaw.[21]

The GN pain distribution is diagnostic: The pain generally commences from the pharyngeal, tonsillar, and posterior base of tongue and includes the eustachian tube and inner ear or spreads to the mandibular angle. Exacerbating factor in GN is generally deglutition, and cold liquids mainly evoke the pain.[21]

GN pain is transient and excruciating to begin with (lasts for 30sec), although it may recur after days, weeks/ months and persists in the same areas.[22,23] Swallowing, chewing, sneezing, talking, cleaning the throat, and light touch to the gums/oral mucosa, abrupt head movements, pain on lifting of the arm of the effected site, and the lateral jaw movement may also precipitate the pain.[24]

Vagoglossopharyngeal neuralgia refers to an uncommon linkage between GN and syncope,[2] where the affected individual presents with episodes of bradycardia, severe hypotension, syncope, and even cardiac arrest.[25] The probable reason for these life-threatening manifestations in GN may be attributed to the anatomical vicinity of glossopharyngeal nerve with the vagus and nervus intermedius.[26]

It is important to distinguish GN from trigeminal neuralgia (TGN), that shares some features with GN and can combined form in 10% of patients.[27] Spontaneous remission is seen in both GN and TGN.[8]

GN is an uncommon clinical entity as compared to TGN (Reported prevalence rate of GN and TGN is approximately 0.8/100,000 population and 4.7/100,00 population respectively).[9] The left side of the face is usually affected in GN in contrast to the right side in TGN.[28]

The two neuralgias can also be differentiated based on the site affected and triggering factors. GN has the predilection for the throat and tonsillar region, and TGN primarily affects check, ala of nose, vermillion border of lips (facial region along the trigeminal nerve division). GN pain is triggered by chewing and swallowing, whereas, a light facial touch while washing/brushing the teeth exacerbates the TGN pain.[16]

A dull ache usually persists between pain episodes in GN,[29] in contrast to symptom-free periods between pain paroxysms in TGN. Any individual experiencing a dull ache between pain paroxysm does not fulfill TGN diagnostic criteria.[30]

GN pain occurs mostly during the daytime, but the pain may disturb the sleep and the patient may wake up in the night. However, there is no pain during sleep in TGN.[29] Topical anesthetic application on pharyngeal mucosa may relieve GN pain, thus, distinguishing it from other neuralgias. Vasoglossopharyngeal neuralgia may be associated with life-threatening cardiovascular features- syncope, hypotension, cardiac arrhythmias, in contrast to trigeminal neuralgia.[29]

Diagnostic Aids: Characteristic clinical manifestations usually suffice for the diagnosis of GN, and definitive investigative tests do not exist. GN patients are usually recommended for an ear, nose, and throat (ENT) consultation to rule out a possible anatomical lesion.[2] The distinctive unilateral, severely piercing, episodic pain in the throat, triggered on swallowing provides confirmation for GN pain, and differentiates it from the pain of inflammatory origin (constant pain, lasts for minutes). Glossopharyngeal nerve involvement/ association with other cranial nerves may be evaluated by assessing the pain distribution. Ototic pain may be detected by injecting an anesthetic solution (2% Lignocaine or 0.5% bupivacaine) into the region with a close approximation to the trigger point.[11] Potential etiologies such as vascular compression/neoplasms may be demonstrated by radiographic evaluation of the brain stem. A high-resolution neck CT scan may demonstrate Eagle's syndrome.[2]

Treatment: GN may be treated with either Pharmacologic/non-pharmacologic interventions.[31]

Carbamazepine is regarded as the drug of choice in GN. The drug has an inhibitory action on the brain stem reflex activity.[32] Also, the drug has a possible action on preventing bradycardia.[33,34]

Gabapentin, pregabalin, and lamotrigine are the other pharmacotherapeutic agents used in GN. Gabapentin and pregabalin act on the α2δ subunit of calcium channels, and diminish the release of excitatory neuro-transmitters. Anticholinergic therapy, β2-adrenoceptor agonists (atropine, isoprenaline) and temporary pacing may be used to manage the bradyarrhythmia in GN.[35] Published literature has also elucidated the efficacy of selective serotonin reuptake inhibitors (20–50mg/day paroxetine and 50–200mg/day sertraline) and vitamin B12 in the management of GN.[36]

Only a few cases of GN have shown response to non-steroidal anti-inflammatory drugs (due to their probable action on unidentified acute inflammation) and opioids (as an ancillary agent to the anti-convulsants).[17]

Glossopharyngeal nerve block provides quick pain amelioration and acts as an excellent ancillary aid in the medical management of GN. It will bedone with either (local anesthetic agents) non-neurolytic agents with or without additions of (steroid, ketamine, etc.) or with(phenol, alcohol, glycerol, etc). neurolytic agents [37]

Surgical management is usually adopted in young aged, recalcitrant cases and is associated with high morbidity.[17]

Microvascular decompression (MVD) is the most preferred surgical technique associated with the highest success rates.[28] MVD is a more efficient treatment than Gamma knife surgery (GKS) due to both initial and long-term pain remission, lower relapse rates, and maintaining a pain-free status.[38]

Conclusion

Glossopharyngeal neuralgia is an uncommon neuropathic pain that occurs along the distribution of the glossopharyngeal nerve. GN can be classified based on the nature of pain, site predilection, and etiologic factors. This neuralgic pain mimics trigeminal neuralgia; hence, an early and accurate diagnosis is mandatory. The condition is seldom associated with life-threatening cardiovascular manifestations like bradycardia, hypotension, syncope and rarely cardiac arrest. Pharmacotherapy with anti-convulsants is usually sufficient, although surgical intervention may be required in resistant cases.

Hematoma Following Nerve Block of a Branch of Maxillary Nerve: A Case Report

Naomi Ranjan Singh[1], Rini Behera[1], Satabdi Pattnaik[1]

[1]Senior Lecturer, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

The nerve block given to obtain anesthesia in maxillary molars and its supporting structures is the posterior superior alveolar nerve (PSAN) block. One of the common complications of the block is extraoral hematoma which occurs because of the needle penetration to far posteriorly placing it in the vicinity of pterygoid plexus of veins, maxillary artery resulting in probable inadvertent nicking of the vessel causing effusion of blood into the surrounding soft tissue resulting in swelling and discoloration. This case report describes this complication and its management.

Keywords: *Hematoma; Posterior superior alveolar nerve; Local anesthesia.*

Introduction

Pain is a complex psychological phenomenon, and it becomes a challenge for each practitioner to supply care with less anxiety and discomfort to their patients. With the development of anesthesia, the science behind pain management has continued to evolve, although these anesthetics are thought-about safe, care should be taken regarding the administration of appropriate anesthetics along with correct technique. In the field of Dentistry, Posterior Superior Alveolar Nerve Block (PSANB) is a technique used to attain anesthesia before performing any surgical and non-surgical treatment on maxillary molars and its surrounding structures. A major sensory branch of the maxillary division of the trigeminal nerve, the Posterior superior alveolar (PSA) nerve supplies the buccal gingiva, periodontium, and alveolus related to the upper molar teeth as well as pulpal innervations of all the maxillary molar teeth except the mesiobuccal root of the first molar, that is equipped by the middle superior alveolar nerve in or so five-hundredths of people. Generally notwithstanding the care utilized in the administration of Posterior superior anesthetic technique, complications occur that include hematoma formation, transient visual impairment, blurred vision and temporary visual defect.[1]

Hematoma formation occurs when the needle nicks the vessels (artery or vein) in its vicinity unintentionally during the administration of anesthesia which ends in filling of blood into the extravascular spaces. A venous puncture by needle might not lead to the formation of hematoma that can be appreciated however the size of hematoma observed after arterial perforation can be appreciated clinically and rapidly because of considerably greater blood pressure within the artery. This article presents a case of hematoma formation following the Posterior superior alveolar nerve block (PSANB).

Case Report: A female patient age 33 years reported to our Department with a chief complaint of pain in the left maxillary posterior region for two days which did not alleviate even after the intake of prescribed medications. After a thorough medical and dental history, clinical and radiographic examination was done which

Corresponding Author:
Dr. Naomi Ranjan Singh

e-mail: singhnaomi23@gmail.com

revealed Class II (mesio-occlusal) carious involvement of enamel, dentin with exposure of pulp of maxillary left second molar (tooth#27) and endodontic treatment followed by a fixed prosthesis in the form of the crown was planned for the tooth. The patient was positioned so that the maxillary occlusal plane was at 45 degrees angle to the floor and 1.5 ml of 2% lidocaine with 1:100000 adrenaline was administered using the PSA nerve block technique following negative aspiration of the needle. After a few minutes of administration of anesthesia, a gradual swelling along the lower left mandibular region (Left Cheek) was observed (Figure 1) without evidence of breathing problems or impaired consciousness. The dental treatment was halted and the patient was enquired about any discomfort. As she became apprehensive, she was informed regarding the cause of the condition and was assured of it being temporary. She was advised to use ice pack 20-30 minutes per hour for the first 24 hours followed by intermittent use of hot moist packs to resolve the condition. The patient was also prescribed analgesics and antibiotics, along with the application of a heparin cream on the affected area. The follow up of the case was done and clinical examination five days after the incident revealed a discrete swelling with a visible outline of the regressing hematoma (Figure 2). A complete resolution of hematoma was observed three weeks post-incident (Figure 3) after which root canal treatment of tooth#27 was initiated.

Figure 1. Hematoma few minutes post administration of LA

Figure 2. Five days post-incident revealing a visible outline of the regressing hematoma

Figure 3. Complete resolution of hematoma three weeks post-incident.

Discussion

The problems associated with anesthesia of the maxillary nerve is attributed to the individual variances of traditional anatomic nerve pathways through maxilla. The failure of infiltration anesthesia in maxillary molars can be due to the flaring of palatal roots towards the midline of the palate. Thus, in these flared root cases and even in the presence of infection, PSANB provides

a reliable anesthesia to the pulpal innervations of maxillary molars.[2]

PSANB is a technique-sensitive procedure, and as stated by Malamed even after following strict administration protocol, complications occur because of the anatomic variation in patient's soft and hard tissue. The danger of hematoma formation in patients receiving PSANB is high, and it produces the biggest and most unappealing hematoma. The infra-temporal fossa into which bleeding occurs, could be a place which can accommodate an outsized volume of blood. There's a colorless swelling that appears at the side of the face, few minutes after LA administration, and this size increases and extends to include the lower front region of the cheek as well. As the blood vessels are settled posterior, superior, and medial to the maxillary tuberosity, it is difficult to use pressure wherever the trauma has occurred.

The application of digital pressure in the medial and superior direction within the mucobuccal fold as far as distally (without eliciting a gag reflex to the patient) is typically found to help counteract the gradual swelling.[3] But in the present case report, digital pressure couldn't be applied as the swelling had progressed inferiorly and anteriorly obliterating the maxillary left buccal vestibule. Employment of ice pack (extraorally) to the affected region was suggested to control the size of the swelling as it is believed to cause vasoconstriction of the vessels along with palliative effects followed by intermittent hot moist packs after twenty-four hours that induce dilatation of the vessels thereby increasing the speed at which the blood components are resorbed, although its advantages are debatable. As hematoma places pressure on lacerated tissues/wounds, it acts as a nidus initiating the event of infection and inflammation. Since the dimensions of swelling in the present case report was quite large, antibiotics were prescribed.[4]

To avoid the formation of hematoma, intensive information on the anatomy of that specific region is extremely necessary. The use of short needle and aspiration in two different planes keeping the needle in the same position before and during drug deposition are recommended as these avoid unintended intravascular injection into the approximating blood vessels. Few studies have conjointly prompted precurving of a 24-millimeter needle at a distance of ten to twelve millimeters that deposits the anesthetic solution near to the nerve at the posterior surface of the maxilla. This technique as expressed by the authors avoids over-penetration of the needle because of its curvature from the initial site of insertion. [5, 6]

Above all the precautionary measures and management mentioned, it is important to notify the patient concerning the attainable complications of PSA nerve block before administration of anesthesia to reduce the psychological impact of the complication as well as maintaining patient's trust about their capability regarding the management of the condition.

Conclusion

Complications with the employment of local anesthetics like hematoma related to PSANB cannot be completely prevented. However, the temporary nature of the complication ought to be assured to the patient as an unaesthetic look because of the discoloration and swelling on the side of the face causes psychological impact. Therefore, it's crucial for a practitioner to bear in mind of the clinical signs of hematoma and to suitably manage them.

Abstract

Hyperglycemia induces a higher rate of activation pathways responsible for inflammation which leads to microvascular and macrovascular complications, oxidative stress as well as apoptosis. In the pathological manifestation of hyperglycemic events, a raised level of inflammatory markers such as: IL6, TNF-α and C-reactive protein occurs which in turn promotes acute-phase of inflammation leading to signaling impairment of insulin function and insulin resistance. On the other hand, enhanced systemic inflammation due to periodontal diseases mediated by the release of IL-6 and TNF-α happens when associated with hyperglycemia. This review article deals with assessment on hyperglycemia and its correlation to dental pathologies with special reference to periodontitis and vice versa. Studies show that the paradigm shift in the oral microbiota due to hyperglycemic condition resulting in the increase in the pathogenicity of associated pathogenic microbes which results in increased inflammation and bone loss in periodontal pathologies.

The extensive studies about the association between inflammatory periodontal disease and diabetes show the cyclic relationship between the two. Diabetes predisposes the individual to periodontal infections and also the later exacerbates or worsens the glycemic control in diabetic patients. Routine periodontal examination provides an insight for the early diagnosis of diabetes in undiagnosed patients and may reduce the worsening of metabolic control thereby preventing serious complications. Also the oral health of diabetic patients may be improved and well maintained with proper management of blood glucose levels.

Although there are evidences in literature to establish correlation between Diabetes Mellitus associated with periodontitis and vice versa, still the outcomes are not conclusive. Therefore large-scale prospective epidemiological analysis are the only sought after approach to clearly bring in the connectivity between Diabetes and Periodontal disease

Keywords: *Hyperglycemia, Periodontitis, cytokines,IL6, HbA_{1C}, TNF-α, AGEs.*

Introduction

Hyperglycemia is a state of high blood sugar level in the body. Blood glucose levels shoots up in the body either due to decreased production of insulin in the body or when the body can't properly use the produced insulin. Several processes are involved in the development of the pathology of hyperglycemia that can lead to insulin deficiency or anomalies resulting to insulin resistance.[1] Hyperglycemic state is characterized by increased blood glucose levels ≥126mg/dl in fasting and in postprandial, blood glucose at 2 hr after intake of 75mg of oral glucose to be ≥200mg/dl, or HbA_{1C}≥6.5%[1]. Periodontitis is a process of resorption of periodontal ligament and alveolar bone, the structures that supports the teeth. The destruction of the collagen fibers leads to pocket

e-mail: kswapna@soa.ac.in

formation in the periodontal zone, the space created in between the tooth & the gingiva. Further deepening of the pocket due to continuous loss of periodontal fibers and alveolar bone resorption culminates finally in attachment loss. Various studies indicate the existence of reciprocating relationship between glycemic control and healing of periapical lesions. The increased prevalence and severity of periapical lesions suggests that hyperglycemic state to be a disease modifying agent for the periapical dental pathologies.[2]

This review article is a detailed assessment of the literature on hyperglycemia and its correlation to dental pathologies with special reference to periodontitis and vice versa. Studies show that the paradigm shift in the oral microbiota due to hyperglycemic condition resulting in the increase in the pathogenicity of associated pathogenic microbes which results in increased inflammation and bone loss in periodontal pathologies. However such periodontal diseases are manifested at a higher rate (3-4 times) in immune-compromised condition of patients especially individuals with diabetes when compared with non-diabetics. Therefore there lies increased risk in diabetes patient with periodontal disorders and thus control of glycemic levels in them is inevitable.[2]

Mechanism behind effect of hyperglycemia on periodontal tissues: Hyperglycemic state affects many functions of the immune system and is associated with compromised immune response and delayed healing. The condition results in changes of immune cell function, thereby producing inflammatory immune cell phenotypes such as either upregulation of pro-inflammatory cytokines from monocytes or polymorpho-nuclear leukocytes or downregulation of growth factors from macrophages. This predisposes to chronic inflammation, progressive tissue breakdown and decreased capacity to tissue repair.[3,4] The resulting increased levels of inflammatory cytokines especially IL-17 acts as a signaling molecule for the immune response and inflammation which are associated with periodontal disease resulting in rapid bone loss.[2] In individuals with diabetic complications, the release and accumulation of AGEs (Advanced Glycation End products) has been observed in periodontal tissues. This leads to increased rate of periodontal inflammation. The receptors RAGE present in the cell binds with the released AGEs and induce the formation of IL-1β, TNF-α, IL-6 (inflammatory mediators). AGE formation results in the production of ROS (Reactive Oxygen Species), a natural byproduct of the normal metabolism of oxygen that plays important role in cell signaling and hemostasis and contribute to vascular injury, a common diabetic complication. Also AGEs have detrimental effects on bone metabolism leading to impaired repair and bone formation.[2]

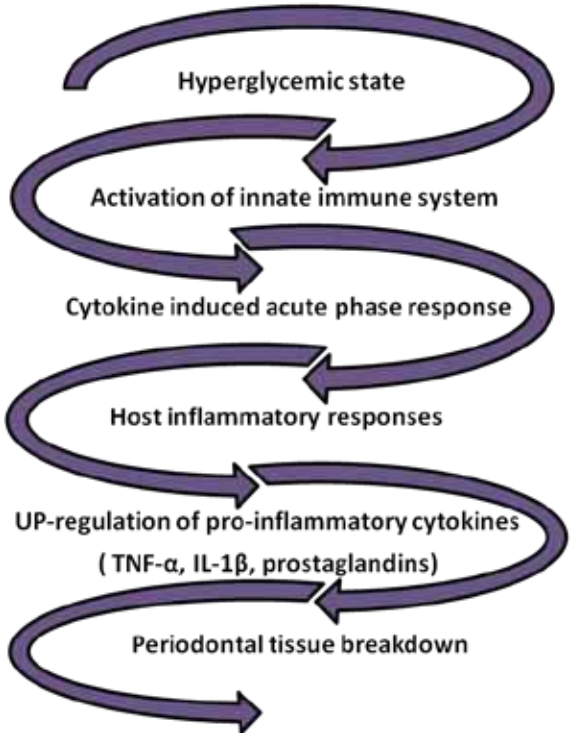

Fig 1: Series of events taking place in periodontal tissues breakdown due to hyperglycemia

Table 1: Animal studies illustrating correlation between hyperglycemic state and periodontal tissues:

Studies by	Model/subject	Analysis	Area of study/observation	Result
[5]	Animal study (rats) Streptozotocin induced diabetic rats.	Histologically & Histometrically	Pulpal and periapical tissue changes after pulp exposure in models	They observed that as compared to control group inflammatory changes in the apical PDL, root resorption and alveolar bone resorption in experimental group were more severe

Studies by	Model/subject	Analysis	Area of study/observation	Result
[6]	Female non obese diabetic mice	Histomorphometrically	They induced periapical lesions in 1st molars in experimental group and measured the size of the periapical lesion.	It was observed that the severity of the response in experimental group is more than the control group
[7]	Comparision between Goto-kakizaki rats with spontaneous non-insulin dependent DM and wistar rats as control group	Histologic analysis	Studied the development of periradicular lesions resulting from type 2 DM after exposing the pulp from occlusal surface in left mandibular 1st molars.	They observed the results after 4weeks. Alveolar bone loss and resorption and periapical lesions were severe in experimental GK diabetic rats.
[8]	Rats with steptozotocin induced hyperglycemia and control group injected with saline.	Histologic analysis	Studied the effect of hyperglycemia in exposed pulps over which MTA was placed.	Inhibition of dentin bridge formation and simultaneous increase in inflammatory cells in the exposed pulps. They observed an inverse relationship between dentin bridge formation and infiltration of inflammatory cells.

Table 2: Human studies illustrating correlation between hyperglycemic state and periodontal tissues:

Studies by	Analysis	Method and results
[9]	Radiographic analysis	They compared the outcome of healing of periapical lesions in poorly controlled DM and therapeutically controlled DM patients. The healing of the lesions of patients with DM under therapeutic control were similar to non-diabetics.
[10]	Radiographic analysis	Comparing the healing of periradicular lesion between low plasma glucose group and high plasma glucose group following root canal treatment, 30 weeks follow up shows 74% reduction in the lesion in low glucose levels where as only 48% reduction of lesion was observed in high glucose level groups.
[11]	Symptomatic analysis	Diabetic patients with abnormal glycemic levels showed a high rate of asymptomatic tooth infections.
[12]	Clinical and radiographic investigations	Diabetic patients of long duration showed greater prevalence of teeth with periapical lesions than other groups.
[13]	Clinical and radiographic investigations	Reported that Diabetic patients showed higher percentage of clinical symptoms relating to pulpal and periodontal infections thereby concluding that DM as a predisposing condition for endodontic infections.
[6]	Microbial analysis	Samples collected from root canals and necrotic pulp tissues of diabetic patients shows the association of *Porphyromonasgingivalis* and *Porphyromonasendodontalis*
[14]	Multivariate analysis, Endodontic diagnostic & treatment outcome	Diabetic patients following root canal treatment have more periodontal disease and also diabetic patients with pre-operative periradicular lesions exhibit lesser success rate of root canal treatment.
[15]	Radiographic analysis	Type 2 diabetic patients exhibited residual periradicular lesions in the radiographic periradicular radiolucencies.

Mechanism behind effects of periapical infection on glycemic control in diabetic patients: Over time the existence of periodontal diseases results in worsening of glycemic control in diabetic patients.[16] Chronic dental lesions or periodontal diseases exhibit similar characteristics as that of any other chronic infections of the body resulting in release of higher levels of pro-inflammatory mediators from harboring gram negative anaerobic microorganisms into the systemic circulation thereby predisposing to worsening of glycemic control in diabetic patients.[16] It has been proposed that the mechanism of insulin resistance developed in obesity induced diabetes and that in existence with periodontal disease are similar in manner i.e by enhancing activation

of the overall systemic immune response that are initiated by cytokines pro-inflammatory mediators.[17] Diabetes is a manifestation of host's inflammatory response resulting from cytokine induced acute phase response through the activation of innate immune system.[18]

The inflammatory manifestations due to periodontitis has been characterized to be mediated by uncontrolled secretion of IL-1β, IL-6, TNF-α, matrix metalloproteins (MMP-8, MMP-9, MMP-13), prostaglandin PGE2, cytokines, RANKL (Receptor Activator of Nuclear Factor Ligand). The periapical bone resorption has been observed due to enzymatic degradation of matrix and stimulated osteoclasts.[19]This could be due to TNF-α secretion in the cell that stimulates the fibroblasts resulting in above physiological and cytological changes. A correlation has been proposed that enhanced TNF-α level is the key factor in establishing the link between diabetic patients and their periodontal conditions.[20, 21]

Fig 2: Series of events taking place in periodontal tissues breakdown due to Periodontitis

Table 3 Animal and human studies supporting the association of periodontal disease and its treatment of Diabetes

Studied by	Results
[22],[23],[24]	Higher levels of HbA_{1c} & development of systemic complications of diabetes in periodontitis patients and also there is association of severe periodontitis and poorly controlled glycaemia.
[25]	It was observed that there is slight elevation in HbA_{1c} readings in non-diabetic patients with periodontitis and concluded that periodontitis may have the potential for the increase in the incidence of diabetes.
[26], [27]	The increase in resistance to insulin due to periodontal infections may impair the glycemic control. Also reducing the gingival inflammation by removing bacterial plaque accumulation can improve the glycemic levels
[26]	There is significant reduction in HbA_{1c} levels in type 2 Diabetic patients through non-surgical periodontal therapy.
[28]	Found that there is higher prevalence of IFG & lower homeostatic model assessment β in patients with chronic periodontitis than those with healthy periodontal tissues.
[29]	Tried to correlate between the albumin present in urine in diabetic patients with that of occurrence of periodontitis and found that the occurrence of periodontitis was relatively higher in albuminuria condition
[30]	Analyzed the risk involved in diabetic type 2 patients and correlated that there occurs severe periodontitis leading to alveolar loss in patients with uncontrolled glycemic condition to an extent of 6 times.
[31]	Suggested from a large scale study about reduction in the levels of HbA_{1c} in diabetic patients when subjected to periodontal treatment.
[32]	Interpreted the result of periodontal treatment in diabetes patients in terms of slight reduction of 0.29% in HbA_{1c} level leading to glycemic control. The study was conducted using Cochrane Database.
[33]	Found considerable improvement in glycemic control with reduction in HbA_{1c} to an extent of 0.46% when diabetic patients were subjected to effective periodontal treatment.
[34]	Showed decline in metabolism of glucose in ligature model (Zucker fatty rats) that are associated with periodontitis characterized by alveolar bone loss.
[35]	Marked higher production of cytokines (pro-inflammatory) in Diabetic patients with periodontitis and also observed a change in prevalence of macrophages as well as monocytes.

Inflammation: Central linking event between Periodontitis and hyperglycemic state: In hyperglycemic state, a higher rate of activation pathways responsible for inflammation has been observed which leads to microvascular and macrovascular complications, oxidative stress as well as apoptosis.[36] In the pathological manifestation of hyperglycemic events, a raised level of inflammatory markers such as: IL6, TNF-α and C-reactive protein has been reported which in turn induce acute-phase of inflammation leading to signaling impairment of insulin function and insulin resistance.[21,37,38] On the other hand, enhanced systemic inflammation due periodontal diseases mediated by the release of IL-6 and TNF-α has been also found to

be associated with enhancement of diabetic state. In addition, adipokines were known to regulate both the occurrence of periodontitis and diabetes.[39] Inflamed periodontal tissues of diabetes patients have higher level of prostaglandin E_2 and IL-1β when compared with the non-diabetics.[40] In another comparative study, a higher level of GCF(Gingival crevicular fluid) IL-1B was found in patients with higher percentage of HbA_{1c} (>8) and vice versa which establishes a correlation between the above two pathological state.[41]

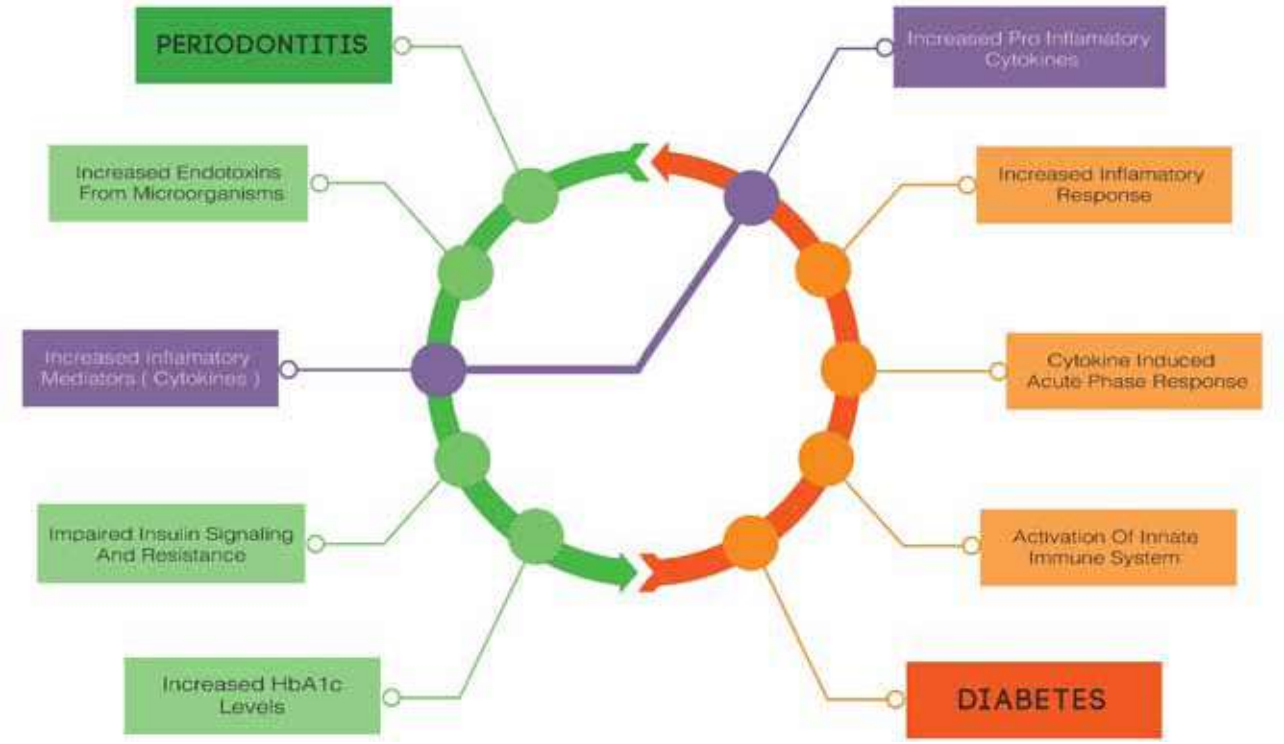

Fig 3: Central linking of events in the cyclic relationship between Periodontitis and Hyperglycemia

Conclusion

The extensive studies about the association between inflammatory periodontal disease and diabetes show the cyclic relationship between the two. One condition leads to the other and vice versa. Diabetes predisposes the individual to periodontal infections and also the later exacerbates or worsens the glycemic control in diabetic patients. Routine periodontal examination provides an insight for the early diagnosis of diabetes in undiagnosed patients and may reduce the worsening of metabolic control thereby preventing serious complications. Also the oral health of Diabetic patients may be improved and well maintained with proper management of blood glucose levels.

Although there are evidences in literature to establish correlation between Diabetes Mellitus associated with periodontitis and vice versa the outcomes are not conclusive. Therefore large-scale prospective epidemiological analysis are the only sought after approach to clearly bring in the connectivity between Diabetes and Periodontal disease

Proteomics and Genomics: An Awesome Diversity in the Periodontal World

Rashmita Nayak[1], Rinkee Mohanty[2], Anurag Satapathy[1], Abhaya C Das[3], Manoj Kumar[3], Gatha Mohanty[4]

[1]Professor, [2]Professor & Head, [3]Reader, [4]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Proteins are the base structure for both the microorganisms as well as for the periodontal tissue. The periodontitis complex array is chiefly built by the cascade of a myriad of protein molecules. Hence, the science as well as the study of the complex molecule proteins as biomarkers in the periodontal world, has brought into the main focus since. This complex protein is the main factor in the development of the pathogenesis of periodontitis. Thereby, it is very much used as a diagnostic biomarker. The sound and rich facts of many proteins concerned in oral pathogenesis can be applied in the analysis, avoidance and management of periodontal disease. Hence, this review topic has been considered to understand the basics of the role of Proteomics and Genomics in the field of Periodontology.

Keywords: *Proteomics, Proteins, Periodontitis, Biomarkers.*

Introduction

A human cell operates because of the protein molecules present in them. As we know, every organic molecule subsides in our body is in the form of either a protein or the total resultant activity by the protein molecules. The phrase "proteome" is anamalgamation of the phrases "protein" and "genome" found in the mid-1990s by Marc Wilkins, an Australian geneticist. The proteome is the whole balance of proteins, prepared to a meticulous set of proteins, formed by aliving being. The same will fluctuate with certain period and individual needs, that a cell or creature faces. The word "proteomics" was primarily focused in 1997 to create a comparison using genomics, the learning of the genes. Proteomics is described as the learning of every proteins together with their comparative loads, circulation, posttranslational modifications, actions, and communications with various macromolecules, in a particular cell or organism within a given surroundings and at a definite phase in the cell series.[1]

Proteomics is a comparatively new 'post-genomic' knowledge with vigorous and full-blown potential. It is now accepted as the successful protocol during the research in the biological system. It comes just after the genomic study and the transcriptomics study.

It is considered as the most intricate and complicated procedure than the genomics. As we know proteomics is much more complicated than genomics mostly because the genome in an organism is quite and considerable and maintains the constant feature, whereas the proteomics keeps on fluctuating with time and with different types of cells. This shows that the basic protein sets produced by the cell requires an exact calculation.[2]

Proteomics and General Dentistry: The two key places where dental proteomics encompass revealed are 1. Salivary diagnostics and 2. Proteomics of bone and enamel. The saliva of the human being possesses proteins that can be useful for infection recognition and scrutiny of oral fitness. The broad chemical scrutiny

e-mail: rashmitanayak@soa.ac.in

and recognition of the proteomic particles in individual saliva is an essential initial footstep in the direction of the invention of saliva protein markers in oral diseases like Sjogren's syndrome. Particularly the proteomic biomarkers of the saliva have been recognizedfor three features, namely the process inflammation, degradation of the collagen, and turnover quality of the bone. Hence it ensures a diagnostic as well as a therapeutic approach with the help from the whole saliva content.[3]

Proteomics and Periodontics: Of late, with the help of the immunological method, the study of the fibroblast protein expression from periodontal ligament has been focused and studied extensively. Even though this system is restricted to earlier recognized proteins for which exact antibodies are obtainable. A sum of around 117 proteins been recognized out of the fibroblasts of the periodontal ligament. It can provide or present itself as a suggestion map for upcoming clinical studies and also at the same time for basic research.[4] Broad proteomic research is done on *P.gingivalis*. The chemicalanalysis of the complete proteomic cell have been carried out to explore the transformation from an extracellular to intracellular lifestyle for *P.gingivalis*.[4,5]

Salivary Proteomics for Periodontitis: Saliva is considered as an important periodontal diagnostic tool because of its various proteins present which acts as a potential biomarker in periodontitis. Young-Jin Choi et al studied the GCF in healthy individuals and periodontitis patients to study biomarkers. In GCF he spotted azurocidin known to be the upregulated protein in case of periodontitis case but never could spot the same in the saliva. This made him draw a conclusion saying that azurocidin can be a very significant and important biomarker for detecting early periodontal destruction in a prone patient. However, the protein detected azurocidin can also play as an inhibiting factor for the differentiation of osteoclasts and thereby can be a great boon for checking the alveolar loss in the early periodontitis stage.[6]

Customized Drugs: Proteomics and Genomics helps in discovering the new potential drugs for the disease treatment. To make the drug act successfully on the targeted disease, the information of the proteome and the genome data is mandatory for recognition of the particular protein which is causing the underlying disease. And once the protein is recognized, the help of the computer software is taken to find the chemical formula or the 3D structure to provide the data to design the customized drug, required for the deactivation of the particular protein which is the source of the disease. Once the molecule fits into the target and active site of the enzyme, and fails to get released anymore by the enzyme, the deactivation of the enzyme takes place. This is the standard protocol of new drug formation, and in turn it helps to locate the novel drugs to deactivate the involved protein in the disease. However, researchersutilize this procedure to procure personalized drugs effective for the person, as many genetic differences are found among individuals.[7]

Development of Biomarkers: The two most important research ground for implication of proteomicsin dentistry are salivary diagnostics, or oral fluid biomarkers, and proteomics of bone and enamel. As saliva is easily reached and simple collection procedure and also non-invasive, its appliance in clinical diagnostics is uncomplicated. "Oral Fluid Nano Sensor Test (OFNASET) is an advanced test for identifying the salivary proteins which are not easily detected. The consequence will be the capability to clinically identify oral malignancy ahead of its oral signs and symptoms.

Computational Method: There is a method attempted by a computer known as"Virtual Ligand Screening". This method has the property to adjust billions of very tiny molecules into the structure which is the three-dimensional structure of a protein. The computer efforts its caliber or the standard to meet the required purpose of the targeted protein sites. The main goal is to either intensify or to deactivate the meaning of the protein,checking on its position in the cell. An excellent exemplar of this is the recognition of novel drugs to aim and deactivate the HIV-1 protease. The HIV-1 protease is aboon enzyme that splita very bulky HIV protein into slighter, purposeful proteins. The above virus can neversustain without this enzyme; hence this protein aims at killing HIV.[8,9]

Limitation: As protein expression and post-translational modificationsare vibrant processes, particularly in the periodontium, recognition and frequency analysis of proteins only are notenough to appreciateits functional changes. The latest development in science will be essential to permit combinations of metabolic grouping and recognition and the frequency analysis of the rate of synthesis. Also Proteomicshypothesis conducted in a particular laboratory may notbe able to get reproduced in another laboratory.[4]

Future Directions of Genomics And Proteomics:

Single-Nucleotide Polymorphism: At present, several investigators are seriously focusing on the genetic single-nucleotide polymorphisms in the dental field. Right now, there seems to be the availability of a genetic vulnerability test for the diagnosis of severe chronic periodontitis shortly. Also, it helps in forecasting the salivary IL-8 levels to recognize if by chance the individual is vulnerable to squamous cell carcinoma.[9]

Nucleic Acid Probes: DNA probes were invented to recognize the sequences of nucleotide for a particular species of bacteria, hoping to be a fantastic diagnostic value. And both DNA and RNA probes are easily procured today for the research and daily practice. It is very much expected shortly, the laboratories for the mini molecules will come up, and the mini molecular kit will be obtainable for chair-side DNA probe.However, the guidance of a microbiologist might still at times be essential to keep away from trouble that may happen in the diagnostic procedure.[5]

Infrared Spectroscopy: Infrared spectroscopy (IRS) describes in detail the intricate biologic systems by captivating the fully IR spectrum which represents the summation of all the biomolecules present. The IR spectrum of the sulcular fluid is a loaded supply of fantastic data relatingto inflammation. IR analysis of GCF, counts the entire possession of the GCF and may provide evidence as a commanding diagnostic and prognostic means for periodontal diseases.[5]

Near-Infrared Spectroscopy: Near-Infrared Spectroscopy (NIR) is capable of keeping an eye on hemodynamic and edema-based markers of soft tissues like gingival inflammation.(5)

Molecular Biologic Technique: It uses the bacterial genome as a way of spotting the particular bacteria. DNA obtained from the dental plaque, are here critically analyzed during nucleic acid probes technique or polymerase chain reaction (PCR). Bacteria can be recognized when DNA obtained from dental plaque is send for the hybridization process, with group definite probes that are branded to permit visualization. Checkerboard hybridization is a method that utilizesthe probes at the same time for testing up to 43 bacterial variety. PCR implicates a DNA replicating enzyme (polymerase) to magnify the targeted DNA sequencing. The usage of standard PCR is not encouraged much as it is only limited to quantitative evaluation of recognized bacteria, although a technique called real-time PCR goes for the recognization of a particular species.[2]Now is the time for nanomaterials and microelectronics for the realistic operation with miniaturized sensors, appropriate for a range of significant applications. The latest Nano-Biochip technology processes fluids to supply a digital fingerprint that can be linked with the local chemical situation, detecting pH, electrolytes, metal cations, sugars, toxins, proteins, and antibodies.

Progress of Rapid Point-Of-Caree and Nano-Biochip: The progress of rapid point-of-care (POC) chair side diagnostics has the caliber for the before time recognition of periodontal illness and development and to diagnose it in the embryonic phase and lessen health concern expenditure.(identification pathogen).[6]

Circulating Micro RNA's As Biomarkers: Micro RNAs are post-transcriptional regulatorsto recognize disease-specific expression patterns. It can diagnose both the malignancy as well as the benign diseases.[8]

Tandem Mass Spectrometry: To carry the huge-scale proteomic analysis of GCF, utilizing gel electrophoresis for protein separation or "shotgun" approaches.It is taught that the knowledge of the crevicular fluid is mandatory to spot the healthy along with the important risk potential biomarkers.[1, 6]

Microfluidic Immunoassays: It is a fast saliva-based clinical method to diagnose the risk proteins which may cause the disease.It is carried by the saliva analysis by integrating sample pre-treatment with electrophoretic immunoassays.[3]

Salivary Proteome Project: This is by using the proteomic method, a standard proteome plot of the individual whole salivapermits for the resolution of bigger than 200 protein spots in a single two-dimensionalpolyacrylamide gel is carried out, which says it will spot the vulnerable candidates for carrying the particular disease. It is of great diagnostic and therapeutic significance.[3,10]

Conclusion

The utilization of proteomics and gene expression will move ahead of the identification and dealing of different dental pathological circumstances. There seems to be a huge opportunities therapeutically for the genomic therapy, tissue engineering, local drug delivery, and simultaneously biopharmaceutical and definitely

will flourish. However, but not impossible, its entry into the area of the dental field depends on how finest dental doctors will fit this into their tradition as it demands meticulous information of individual genetics and implement of novel analytic and remedial technologies.

Periodontal Compromised Cases: The Patience and Perseverance That Bears the Fruit

Smruti Bhusan Nanda

Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, India

Abstract

Orthodontic treatment in periodontally compromised cases is quite challenging as it involves a thorough understanding of the periodontium keeping given the compromising factors. Bone health plays a pivotal role in patients opting for orthodontic treatment. Here, we are presenting a case series of periodontally compromised patients being treated Orthodontically.

Keywords: *Orthodontics, periodontics, compromised.*

Introduction

Case-1: A 28 years old female patient came to our dental office with a chief complaint of large gaps between teeth and bad smile. She had a very shy and conscious smile due to obvious reasons. Reasons for Orthodontic treatment was primarily esthetics. She was found to have Angle's Class I malocclusion on skeletal class I jaw bases, with anterior spacing, severe periodontal destruction in maxillary and mandibular jaws.

Treatment plan: The patient had undergone a non-extraction line of treatment, leveling and alignment, maxillary space closure, followed by bijaw, lifetime bonded lingual retainers in the anterior region (4 to 4) creating anesthetic smile. Figure. 1 depicts the patient's pre and post-treatment extraoral comparisons and Figure. 2 shows the intraoral changes before and post Orthodontic treatment.

Figure 1: Pre and post-treatment comparison (extraoral)

e-mail: smrutibhusannanda@soa.ac.in

Figure 2. Pre And Post Treatment Comparison (Intraoral)

Case-2: A 58yrs old female patient met us in the Orthodontic set up with the chief complaint of gaps between front teeth, which was making her smile uncomfortable. Reasons for Orthodontic treatment was primarily esthetics. Her doctor son's marriage was scheduled after 1 yr. she wanted to have good confident smiling photographs in the marriage album. She had Angle's Class I malocclusion on skeletal class I jaw bases, with anterior spacing, with grave periodontal destruction in maxillary and mandibular jaws.

Treatment Plan: It was planned to do non-extraction treatment, leveling and alignment, maxillary and mandibular space closure, followed by long term bonded lingual retainers in anterior region (4 to 4) of both the jaws, creating an confident photogenic smile. The pretreatment, mid-treatment, and post-treatment pictures are presented in Figure 3.

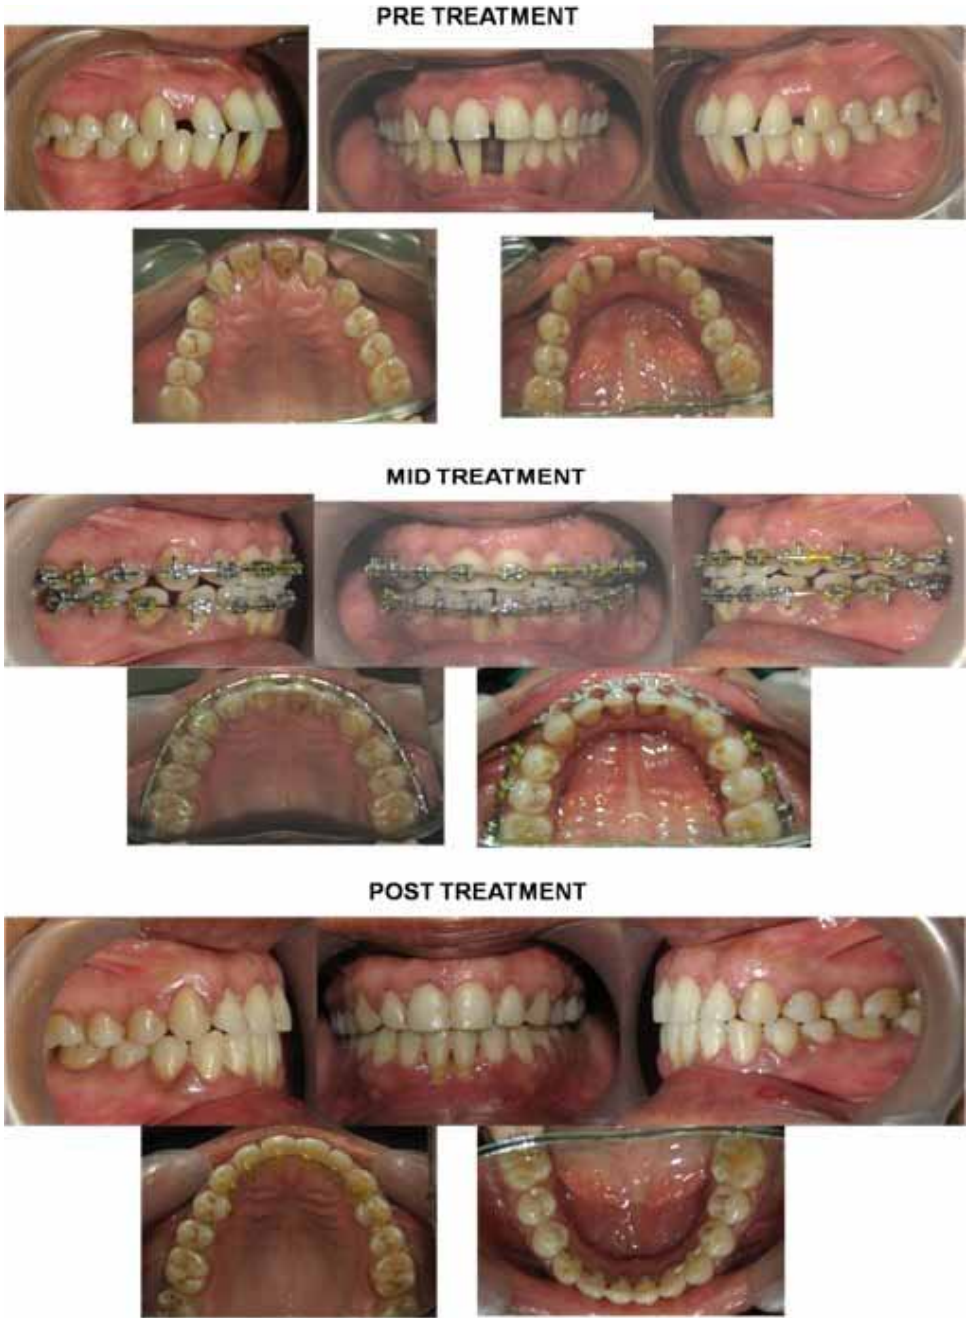

Figure 3. Pretreatment, Midtreatment, Posttreatment Comparisons

Case-3: A 35-year-old female patient had chief complaints of forwardly placed upper front teeth with gaps in between. The patient wanted a better smile as she was pursuing marriage. She had a convex profile, acute nasolabial angle, Liptrap, deep mentolabialsulcus, and Orthognathic face. She had Class- II malocclusion on a Class-I skeletal jaw base with increased overjet, overbite, Trauma from occlusion, spacing in upper anterior, crowding in lower anterior, increased curve of spee and harsh periodontal condition in both the jaws.

Treatment Plan: It was planned to do the upper first premolar (14, 24 extraction), leveling, alignment, maxillary retraction with maximum anchorage, finishing in good overjet, overbite, Class-II molars & Class-I canines bilaterally, resulting a pleasant noteworthy smile. Retainers planned were long term bonded lingual retainers for both the jaws. The pretreatment pictures are depicted in Figure 4. The post-treatment pictures are presented subsequently in Figure.5.

Figure 4. Pretreatment View

Figure 5. Post-treatment view

Conclusion

All these above three cases were adults with a primary concern of esthetics.[1,2] The patients were not worried about the underlying periodontal destruction. The key to our success in these cases are: the first and foremost objective was to make the patients aware of periodontal issue and a change in their attitude. It was of paramount importance to improve their oral hygiene habit to a more acceptable level by positive motivation and periodic oral prophylaxis. This was inevitable for a successful treatment and avoidance of relapse in the long term.[3,4] Repeated reminders to behavioral change and periodic periodontal evaluation was continued throughout the treatment as well as post-treatment. The non-extraction cases were treated with moving the teeth towards the midline so that the tongue space won't be impinged, which shall be detrimental with the already compromised periodontium, during the retention phase. Light forces with longer periods (6wks) of activation interval.[5] Self motivation of all the patients. Without their contribution in the form of persistent oral hygiene maintenance the results were unfeasible.

Conflict of Interests: The authors declare they have no conflicts of interest.

Knowledge and Attitudes of Dental Students in Prescribing Antibiotics for Pediatric Dental Patients in Bhubaneswar City, Odisha: A Cross-Sectional Study

Ankita Sinha[1], Susant Mohanty[2], Sonu Acharya[3]

[1]Postgraduate Trainee, [2]Professor & Head, [3]Professor, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Background: Antibiotics are the most widely prescribed therapeutic agents in dentistry, hence it represents an important aspect of dental practice. The inept use of antibiotics for the treatment of dental infections in children is a leading cause of developing microbial resistance.

Objective: The objective of this study is to investigate the knowledge & attitudes of a group of dental students when prescribing antibiotics during the treatment of pediatric dental patients.

Method: This is a questionnaire-based cross-sectional study conducted in a group of 300 dental students from various dental colleges of Bhubaneswar city, Odisha. The questionnaire consisted of close-ended questions, structured under three main headings. Data collected were analyzed using SPSS statistics version 24.

Results: The prime findings were that amoxicillin is the most commonly prescribed antibiotic, most students had not received training on antibiotic prescribing and had treated more than 10 child patients per week & their concordance with guidelines on antibiotic prescribing was generally low.

Conclusion: This cross-sectional study shows there is a need to improve the knowledge on antibiotic prescribing for children.

Keywords: *Dental education, dental students. pediatric antibiotics, antibiotic prophylaxis, antibiotic resistance.*

Introduction

Antibiotics are the most extensively prescribed 'therapeutic & prophylactic' agents in dentistry, hence it represent an important aspect of dental practice.[1,2,3] Prophylactic antibiotics are used for the prevention of diseases caused by a number of the oral microflora, mostly in the case of endocarditis prevention.[4] Therapeutic antibiotics are used for the hard & soft tissue diseases in the oral cavity when local debridement is unsuccessful.[5] Antibiotics in dentistry are generally prescribed for surgical,endodontic & periodontal manifestations. The inept use of antibiotic in treating children has been observed in the treatment of dental infections, is a leading cause in developing microbial resistance.[6-9] "Dr. Thomas J. Pallasch, stated in his study that antibiotic misuse in dentistry mainly involves prescribing them in 'inappropriate situations' or for too long, which includes-giving antibiotics after a dental procedure is complete in an otherwise healthy patient

to 'prevent' an infection, which in all likelihood will not occur".[10] So to avoid any unwanted complications, dental practitioners often prescribe the antibiotics.[11] This has led to developing microbial resistance, which is a serious health issue concern.

And this is a growing major health problem that contributes to treatment failure and development of antibiotic resistance by an individual.[12-15]

Method

This is a questionnaire-based study conducted in a group of 300 dental students from various dental colleges of Bhubaneswar city, Odisha to know the knowledge & attitudes of dental students in prescribing antibiotics for pediatric dental patients. A structured pre-prepared questionnaire was distributed to all participants via email (using google forms). The questionnaire consisted of close-ended questions & open-ended questions, structured under 3main headings are as follows:

1. Details about dental student participants based on their gender & qualification.
2. General knowledge about antibiotics prescription in pediatric dentistry.
3. Knowledge of dental student participants on prescribing antibiotics for various clinical situations.

Statistical Analysis: Data collected under the study was scrutinized, codified and entered into the IBM SPSS Statistics, 24.0 software, for analysis. The following statistics procedure was used for the analysis of data. There were 10 different questions canvassed to the respondents. The association of response with gender, qualification and training was studied using the Chi-square test of independence. The significant p-value was <0.05.

Results

In this cross-sectional study of knowledge and attitude of 300 dental final year and interns for prescribing antibiotic during the treatment of pediatric dental patients, 148 (49.3%) were BDS final year students and 152 (50.7%) BDS interns, of which 110 (36.6%) were males and 190 (63.4%) females. Besides the sample has 36 (12%) students who have taken any course/training in antibiotics in the past 2 years. The response of the sample students have been analyzed for association with gender, qualification (interns or final year students) and training on antibiotics.

Table 1 revealed that 117 (39.0%) update their knowledge about antibiotics through textbooks, only 44 (14.7%) through online resources and a maximum of 139 (46.3%) through both textbooks & online resources. The majority of the sample students i.e. 182 (60.7%) practiced more than or equal to 10 therapeutic antibiotic prescriptions per week and the remaining 39.3% practiced less than 10 prescriptions per week. The most commonly prescribed antibiotic for the treatment of pediatric dental patients was a combination of Amoxycillin + Clavulanic acid as stated by 82.3% of the students followed by Amoxycillin (7.0%). About 81% of students stated that the most common number of daily dose prescribed was BID while 16.7% of students stated that to be TID. About 2/3rd students said that the duration of antibiotics should be for 5 days, while 17.3 stated it to be 3 days and 16.7% said it to be for more than 5 days. Little above 2/3rd of sample students (68.7%) viewed that the most favourable antibiotic for penicillin-sensitive patients was Erythromycin while 31.3% preferred to Clindamycin. All the sample students preferred that the most common route of antibiotic administration was "Oral". About 77% of students preferred to see the patients before prescribing antibiotics for dental pain. About 3/4th students opined that they would prefer to prescribe antibiotics in carious primary tooth for pain, localized swelling after evidence of radiographic pathology. In the case of deep caries in primary teeth half of the students (50%) prefer antibiotics for pain, draining fistula, localized swelling only after the radiographic evidence confirmation($p=0.001$).

Table 1 further revealed that the source of updating the knowledge has a significantly higher proportion of male students who are using both the sources to update the knowledge of antibiotics ($p= 0.010$). As regards most commonly prescribed antibiotic- 9.1% male stated three-drug therapy & 3.1% female stated so, a number of daily doses – TID Male 25.5% and female 11.6%, duration in days- 5 days 57.3% males & 71.1% females., most favorable penicillin-sensitive antibiotic- male: erythromycin- 60% & clindamycin- 40% for female the proportions were 73.7% & 26.3% respectively, preferring to see patients before prescribing antibiotics for dental pain- male 62.7% & female 85.3% and preferring to prescribe an antibiotic in the carious primary tooth for pain, localized swelling with evidence of radiographic pathology- male 60% & female 84.2% have a significant association with gender ($p<0.05$).

Table 2 revealed that the source of updating the knowledge- interns have significantly higher proportion who are using both the sources to update the knowledge of antibiotic (p= 0.000). As regards number of daily dose – Interns: BID-94.7%,TID-3.9%, BDS final year student: BID-66.9%,TID-29.7%, duration in days- BDS final year - 5 days 54.1%, 3 days 21.6%, the corresponding proportion for interns were 77.6% & 13.2% respectively, and most favourable penicillin-sensitive antibiotic- BDS final year: erythromycin 60.8% & clindamycin 39.2% for Interns the proportions were 76.3% & 23.7% respectively, have significant association with qualification (p<0.05).

Table 3 revealed that the students who have received training in antibiotics in the past 2 years mostly refer to the textbook (66.7%) while students without training refer to both textbooks and online resources for updating the knowledge about the use of antibiotics (p=0.000). Students with training prescribed single drugs like Amoxicillin (44.4%) and a combination of drugs Amoxicillin+Clavulanic acid (50.0%) but students without training mostly prescribed combination drugs Amoxicillin+Clavulanic acid (86.7%) (p=0.000). Students with training never have prescribed TID while (18.9%) students without training have prescribed TID (p=0.000). Students with training usually prescribed antibiotics either for 3 days (58.3%) or 5 days (41.7%) and none prescribed for more than 5 days. However (18.9%) students without training prescribed antibioticsfor more than 5 days (p=0.000). All the students with training prescribed Erythromycin while (64.4%) students without training prescribed Erythromycin while (35.6%) prescribed Clindamycin (p=0.000). All the students with training prefer to see patients before prescribing antibiotics for dental pain while (26.1%) students without training did not prefer to see before prescribing antibiotics (p=0.000). All the students with training prefer to prescribe antibiotics in carious primary tooth for pain, localized swelling with evidence of radiographic pathology while (72.0%) of students without training prefer to do so (p=0.000).In the absence of fever, 41.7 % of students with training prefer to prescribe antibiotics in deep carious primary tooth for pain, draining fistula, localized swelling without confirming with a radiograph (p=0.000).

Discussion

"Amoxicillin is the preferred 1st choice antibiotic for treatment of dental infections in children".[16,17] Combination of amoxicillin-clavulanic acid can also be used, as it has activity against the beta-lactamase.[18] But in this study, the majority of participants preferred amoxicillin-clavulanic acid followed by amoxicillin. Also a significant proportion of prescribes combination antibiotics like amoxicillin/clavulanic acid with metronidazole. Combined drug prescription is becoming more significant in the case of mixed infections. Most participants would prefer to prescribe for 5 days. "The ideal duration of antibiotic treatment is the shortest cycle capable of preventing both clinical & microbiological relapse. Most acute infections are resolved within three to seven days". Short courses are chosen mostly when treating children due to their poor cooperation.

The prime findings were that most students had not received training on antibiotic prescribing and had treated more than 10 child patients per week & their concordance with guidelines on antibiotic prescribing was generally low.Those who had received training and those with more clinical experience are more likely to be knowledgeable.

A similar studywas conducted,showing a similar result highlighting the need to improve education in antibiotic prescription among dental students.[19,20] Up-gradation of antibiotic prescribing guidelines among dental students is also important for the treatment of dental infections in children.Antibiotic prescribing education may be done through lectures, workshops, informal education in clinical practice & self-directed learning.

Such education will instill greater self-confidence in reducing antibiotic prescribing unnecessarily & will lead to a change in antibiotic prescribing behaviour.

Conclusion

This cross-sectional study indicates the necessity to improve the "knowledge on antibiotic prescribing for children".Besides, the study states that there is a requisite for short programs to update knowledge of dental practitioners on the antibiotics, which are currently used in pediatric dentistry.

Stem Cells in Regenerative Dentistry: An Overview

Sushmita Paul

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The study of stem cells in regenerative dentistry is the most precious in-progress research. Stem cells are the cells that have the self-renewal capacity and can differentiate to mature cells. Stemcells also have the prospective to form dentin matrix, bone and neuronal cellsrapidly. Stem cell-based therapeutic approaches provide a better and attractive alternative that the classical dental treatments because of their questionable efficacy and durability. The most promising alternative for tooth loss is the utilization of stem cells and induced pluripotent for the regeneration of the whole tooth. Therefore helping with the progress in inducing bone rejuvenation, treating damaged teeth, stem cell-based therapy plays a vital role. So, this article will highlight the role and importance of stem cells in regeneration in Dentistry.

Keywords: *Stem Cells; Regenerative Dentistry; Therapeutics; Future Prospects.*

Introduction

Stem cells are defined as clonogenic cells capable of both self-renewal and multi-lineage differentiation since they are thought to be undifferentiated cells with varying degrees of potency and plasticity.[1] In all multi-cellular organisms, these primitive types of cells i.e. presence of stem cellsalong with the properties of self-renewal in addition to the potential to change into mature cell types. They show an impressive capacity for regeneration and perhaps could be utilized for the treatment of diseases like cancer, Parkinson's, Alzheimer and many more, with its ability to replace or repair of the damaged cells.[2] The stem cells can be classified as,[3]

Classification of stem cells:

The classification of stem cells are the following:

1. Embryonic stem cells (ESCs)
2. Adult stem cells (ASCs)
    a. Hematopoietic stem cells (HSCs)
    b. Mesenchymal stem cells (MSCs)
3. Induced pluripotent stem cells (IPSCs)

The identification of orofacial tissues as a foundation and therapeutic objective with clinical curiosity in dentistry for stem cells. The main properties of stem cells were first defined by Ernest McCulloh and James till in the 1960s.[4] The capabilities of the stem cells are mainly; produce cells having the same characteristics (daughter cells) and produce cells that have different properties. Mesenchymal stem cells are interpreted as multipotent because they tended to display the capacity for segregation into cells of a different variety, even as the mesenchymal stem cells are clonally isolated cells. They have the skill to differentiate along the other particular mesenchymal ancestry, and also can stay in an inactive undifferentiated state until offered the indication to segregate asymmetrically.[5]

Dental stem cells, which are derived from postnatal stem cells, are one of the most recent types of stem cells found in the mesenchymal stem cells (MSC) list. It shows capabilities based on development, differentiation, regeneration, and immunoregulatory/ immunomodulatoryproperties.[6]Afterthediscovery,study and progress towards medicalapplications of stem cells had made so much progress. For bone and dental regeneration, cell sources from dental pulp stem cells (DPSCs), periodontal ligament stem cells (PLSCs), stem cells from human exfoliated deciduous teeth (SHED), stem cells from apical papilla (SCAP)and dental follicle cells are taken due to their accessibility and abundance.[7]

Dental stem cells in India are still at the budding

stage, and there seems to be limited awareness regarding dental stem cells. SHED is obtained from baby teeth, the multipotent stem cells population are easily collected as the characteristics are either shed naturally or are removed physically for the suitable growth of permanent teeth, of the deciduous teeth.

The different diseases and trauma causes bone and dental loss and defects which has become a worldwide distress of elevated frequency. This affects the physical condition and wellbeing of a very big population and also put down a grave economic load on the public.[1,2] The present therapies done for dental diseases can only provide an improvement based on parameters of clinical diagnosis and arrest development of disease, although regeneration of missing tissue is not able to be done. Therefore, there is a high demand for new technologies that can help to accomplish the regeneration of bone and dental tissues.[8,9]

Table 1. History of Stem Cell[10]

1868	German biologist, Haeckel mentioned the term "Stem Cells" in his research works.
1908	Russian histologist, Alexander Maksimov hypothesized the subsistence of Hematopoietic stem cells
1932	G. L. Feldman demonstrated proof of regeneration of pulp in favorable conditions.
1985	Yamamura reports that pulp tissues contain stem cells.
2000	Gronthos et al separate dental pulp stem cells from human dental pulp of an adult thatcan regenerate complexes like dentin pulp.
2003	Miura et al reports the isolation of population of stem cells from the living pulp remnants of exfoliated tooth.
2004	Seo et al discovered the periodontal ligament stem cells from human periodontal ligament.
2005	Morsczeck et al and kemoun et al each of them discovered exclusive lineage-committed cells that cant be differentiated with the possession of features of progenitor mesenchymal in dental follicles of human.
2006	Sonoyama et al identified and characterized stem cells from dental apical papilla of human permanent immature teeth.
2009	Zhang et al informed the separation of a stem cell from the human gingiva's spinous layer.

Applications in dentistry:

The isolation and characterization of human dental stem cells are:[7]

1. Stem cells from human exfoliated deciduous teeth
2. Dental Pulp Stem Cells
3. Periodontal ligament stem cells
4. Stem cells from apical papilla

The different separation, culturing and differentiation procedures have highly developed over the decade for the various MSCs. The first isolation of mesenchymal stem cells was done from bone marrow, they appeared like cells similar to fibroblast and were capable of sticking to plastic dishes, and the single cells form colonies which divide to form mature cells of the mesenchymal pedigree which are osteoblasts and chondrocytes. The most familiar resource of Dental mesenchymal stem cells (DMSCs) is dental pulp stem cells (DPSCs), which were first isolated from human teeth in the year 2000.[4] These organs are the vital pool of adult stem cell populations as they have a parallel purpose to mesenchymal stem cells. Hence, DMSCs can be utilized in favor of rejuvenation of teeth or other organs that have essential restore possibility. The dental pulp stem cells are considered a rich source of mesenchymal stem cells due to the number of potential stem cells isolated from the human tissue samples, adding to its advantages apart from the cell number, is that lesser time consumption in the process of enzymaticabsorption from the dental tissues by extracting stem cells when compared with the other mesenchymal stem cell sources. These features make the dental stem cells less vulnerable to potential enzymatic stress and help to expand rapidly than other cells. Hence, even if from a tiny amount of dental tissue, they are extracted, yet latently adequate quantity of cells for a different type of clinical applications can be generated.[5]

The dental pulp stem cells are an amazing source of stem cells believing their multipotent differentiation potential. Under in vitro culture conditions, they are differentiated into odontogenic cell types, but apart from that, it has been also reported to distinguish into osteoblasts, chondrocytes, myocytes, neurons, melanocytes, hepatocyte-like cells and adipocytes.[5] The DMSCs in the dental pulp are situated normally in two slots, they are

1. Apical niche
2. Perivascular niche

These two types of niche hasa separate role for themselves, but in a way, their role is exchangeable at times.[4]

Mesenchymal stem cells have the perspective in support of the revival of dental tissues. Deciduous teeth contain residents of added undeveloped multipotent stem cells, that are competent in forming dentin like structures although not an entire dentin-pulp complex. Teeth contain well-defined pulp chambers, odontoblasts, pre dentin and dentin, and also enamel organ consisting of dental enamel, ameloblasts, stratum reticulum, stratum intermedium. The DPSCs are skilled in forming a reparative dentine like structure which is present straight on the surface of dentin.[11]

The lost regenerative ability within the PDL space to be domesticated is the foremost goal of the gene-enhanced regeneration of periodontal ligament. This technique has the maximum capability if it can be tailored for use with entirely adult cells, despite gene enhanced tissue engineering exercised within concurrence with stem cells.[9]

The different ways on how the regenerative procedures can take place are:

1. **Pulpal regeneration:** Pulpal tissue regeneration is done mainly by postnatal stem cells. To reduce the chances of immune response allogeneicstem cells can be used. Gene therapy and 3d printing are the newer modalities for perfectly placing the cells in their proper place which may also lead to the formation of new dentin.[8,12]
2. **Periodontium Regeneration:** Periodontal tissue surgeries are quite complex as it requires various factors to facilitate the production of a sufficient amount of tissues. Alveolar bone, periodontal ligament and cementum can be derived from bone marrow stem cells. Periodontal stem cells are started with biocompatible scaffolding helps to generate a 3D matrix which incorporated with various growth factors that are reported to the area which necessitates regeneration.[8,13]
3. **Facial tissue Regeneration:** After the treatment of a large oral lesion involving facial tissues, reconstruction will play an important role. Collagen along with myoblasts can be engineered along with various growth factors for reconstruction. For the correction of large defects, bone marrow-derived stem cells can be used.[8,14]
4. **Tooth Regeneration**- Epithelial and mesenchymal cells and the cells capable to differentiate to from tooth buds. The use of prenatal stem cells is more popular for regeneration because of their propensity. After tooth loss, the most ideal therapeutic approach would be the rejuvenation of the whole tooth. The different kinds of approaches that can be taken is, the formation of tooth germs which is prepared by the union of DMSCs, and DESCs in the alveolar bone is transplanted where the process of development, eruption and finally becoming functional tooth of germs is seen. An additional approach is implantation into the jaw of tooth-shaped polymeric biodegradable scaffolds packed with DESCs and DMSCs to rejuvenate a new tooth. Well, the experiments have been done only in mice, as the results have not been obtained in human cells.[4,15-17]
5. **Bone Regeneration:** Periosteal stem cells can be used for this. For closure of various bony defects, inorganic bone along with plasma rich platelets can be used. Mesenchymal stem cells along with autogenic stem cells can be used for TMJ reconstruction. The production of bioengineered TMJ is done by the adult mesenchymal cell in a biomimetic scaffold. The scaffolds which are strengthened with the mi-RNA showed improved osteoinductive properties and functionality.[8,18]

Tooth Stem Cell Banking: It is an unpopular trend around the world currently, but most of the developed countries have started the acceptance of stem cell banking. The different types of stem cell banking companies around the world are Stem Save (Stemsave Inc, New York) and Store-A-Tooth (Provia Laboratories, Littleton, Massachusetts, USA). The first tooth bank in Japan was instituted in Hiroshima University and was

named 'Three Brackets' company in 2005. Recently the thought of dental stem cell deposition was launched in Delhi and Mumbai in our country.[7]

The dentists would have immense prospect to make their patients attentive of the potential of the regenerative uses of stem cells, only if the stem cell banking system is matured and confirmed to be effective and safe, and can encourage the patients to store their dental mesenchymal stem cells for further medical usage during any kind of treatment. The different boons of dental stem cell deposition are that it can be stored in second chance if the first chance is failed to spot, unlike blood stem cells from the umbilical cord. The isolation procedure is painless and simple; also banking of stem cells can provide an ideal source of iPS banking. It also provides for future therapeutic uses, an autologous cell source. Adding to its numerous advantages, it is also not focused on any ethical concerns like the embryonic stem cells.[5]

Future Research and Prospects: The MSC-based regeneration researches have shown tremendous results in theremedy bone and dental loss and defects, both by exogenous transplantation and endogenous restoration. But as mentioned by Chengxi Zhang et al[1], the MSC-mediated regeneration is under tight charge of the micro environment based on its remedial efficiency, with the capability of controlling inhabitant MSCs under pathological and physical conditions and also adapt MSCs that are transplanted in tissue engineering and cytotherapy. As a result, the biggest challenge remains the accomplishment of MSC based dental and bone regeneration in an unhealthy microenvironment.[16]

T. C. Srijaya et al[5] mentioned about the huge amount of curiosity of dental stem cells in medical research because of their budding function in regenerative medicine. They have elevated capability of regenerating which has given higher expectations for therapeutics in the future. However, to achieve the complete therapeutic capability of dental stem cells much more work and research is to be done. In the future, for the research of dental stem cells, the biomaterials used and the diseases associated with teeth many more efforts and advances are very essential.

The environment in addition to conditions under which the stem cell research takes place and how it would effectively help in dental procedures are still a bigger problem to solve. The different clinical trials and researches have been going on stem cells and have not been fully studied. Moreover, in tooth regeneration the greater challenge is time; it acquires 7 years in humans for the whole process of odontogenesis. The individuals with missing teeth may find this long term physiological process discouraging and will look forward to instantaneous treatment outcomes.[18]

Bringing light to the topic of regeneration of periodontal ligament, Electron microscope radio-autography was utilized in an attempt to recognize if there is any connection among the site and degree of differentiation of cells in PDL. The existence of an undifferentiated perivascular population of progenitor cells was concluded and also that cytodifferentiation was seen in the progenitor cells, which is present in PDL. Narang et al. demonstrated that from solid-frozen human PDL, the postnatal stem cells can be recovered.[9]

Conclusion

While much progress has been achieved in the department of regenerative procedures through stem cells in dentistry, we still have a long way to go. The basic and pre-clinical stem research is very slow in the dental clinics, as the very obvious safety, regulatory, technical and ethical concerns exist. The depth of scope present in stem cells is enormous which would take the dental regeneration procedure to another level, bringing more success in the field of Dentistry. The various approaches started now are just the beginning, but it is very well known how much potential it carries in the future to help patients all over the world. The various new promising technologies such as imaging systems, mathematical modeling and nanotechnology would help to speed the stem cell researches all over the world to provide more qualitative and dependable results in the dental clinics.

Ortho-Perio Continuum: An Interdisciplinary Approach

Swati Punyatoya[1], Saurav Panda[2], Rinkee Mohanty[3], Rashmita Nayak[4], Anurag Satpathy[4], Abhaya Chandra Das[2], Manoj Kumar[2]

[1]Intern, [2]Reader, [3]Professor & Head, [4]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Orthodontic therapy is a combination of process which is related to move the malalligned teeth by correcting its position. There have been many dental cases where orthodontic tooth movement is assisted by periodontal therapy and also the periodontal condition is improved by orthodontic therapy. This interdisciplinary approach is a symbiotic relation between the two. This review highlights the various orthodontic therapies requiring periodontal therapy for better outcome and vice-versa. Harmonious cooperation between the periodontist and orthodontist would provide satisfactory outcome for the combined orthodontic periodontal problems. The knowledge of this approach in the field of dentistry would help clinicians' decide a better outcome in patient's favour.

Keywords: *Orthodontic Therapy; Malalligned Teeth; Periodontal Therapy; Interdisciplinary Approach.*

Introduction

In the different branches of dentistry, co-ordination and co-operation among them is very important. It will not only help to get a spectacular idea about the diagnostic procedures but also make the treatments easier. This type of interrelated relationship exists between Orthodontics and Periodontics. Basically, this is a symbiosis type of relationship where the treatment procedures of both the branches are interrelated. There have been many dental cases where orthodontic tooth movement is assisted by periodontal therapy and also the periodontal condition is improved by orthodontic therapy. Orthodontic therapy is a combination of process which are related to move the malalligned teeth by correcting its position. It is shown that patients who are under orthodontic treatment are more susceptible to develop plaque on their teeth surfaces. It is due to several orthodontic appliances, brackets, wires and elements which are present on the teeth surfaces. Because of the such elements, the oral hygiene procedures might be more difficult. It may also cause several compilations liketooth decalcification, tooth discoloration, tooth devitalization, rootresorption, gingival recession, pain, TMJ dysfunction, periodontal problems, loss of enamel, dental caries, many types of psychological compilations and allergic reactions also. Out of all above complication, periodontal problems are the most common in nature and also need proper consideration. Despite all these, orthodontic treatment sometimes is very helpful in increasing the periodontal status. So,the periodontal conditions in which orthodontic treatment is necessary should be given some special importance at the time of interdisciplinary approach in both the ways.

Adverse effectsof orthodontic therapy on periodontium

Orthodontic therapy may hinder the complete procedure of oral hygiene. So, improper oral hygiene creates feasibility of change of the subgingival plaque to a much more aggressive periopathogenic flora. But it can be reduced by appropriate plaque control method. So, patients having healthy periodontium can undergo for orthodontic treatments without infuriating the periodontal condition.

Orthodontic therapy produces several periodontal complications which includes; gingivitis, periodontitis, alveolar bone loss, gingival recession, tooth mobility, black triangles, periodontal pocket fenestration and dehiscence[1,2].

There are many ortho-dental cases which show the presence of various types of bacteria in the dental plaques of the patients who are undergoing orthodontic therapy. Some of such bacteria are spirochetes, intermedius, motile rods, *B. forsythus T.denticola, P.nigrescens, C.rectus* and fusiform bacteria.[3] Most of the cases show the development of gingival recession during or after the orthodontic treatment. This type of development of gingival recession coursesmany clinical problems. Most of the gingival recessions which develop during the orthodontic treatment had been shown to occur in the upper and lower anterior teeth regions. According to a study made by Steiner and his colleagues, the gingival recessions occurring after the orthodontic treatment are moretends to occur in the areas with thin underlying bony structure and thin keratinized gingiva.[4]

Periodontal conditions which require orthodontic treatment includes: Gummy smile, Midline diastema & correction of black triangles,Pathological migration with infrabony defects, Tilted molars, and Gingival margin discrepancies etc.

Orthodontic treatment as an adjunct to periodontal therapy: There is a strong correlation between the periodontal disorder and malposed teeth in the dental arch. The correction of the malposed teeth can eliminate any harmful occlusal interference which may prevent plaque accumulation and provide a better oral hygiene procedure. It may offer a great opportunity for the development of a good periodontal health.

Generally, during orthodontic tooth movement, the entire periodontal attachment apparatus, including the bony structure, periodontal ligament, and soft tissue components move along with the tooth. Brown made a study on the influence of uprighting of molars on the periodontium in four patients. After 7 months of treatment, the associated pocketing at uprighted molars had 2.5mm more pocket depth reduction than the control tooth.[5]

A clinical study was done on orthodontically treated patients having intact periodontium. It concluded that extrusion of mandibular incisors resulted in displacement of the mucogingival junction and the gingival margin by 52.5% and 80%,respectively, of the total amount of extrusion.[6] There are some cases where movement of attachment and margin of bone along with the tooth is not advisable as in crown-root fractures. In such cases, periodical circumferential supracrestalfiberotomy is needed. It should be done at the start and every 2 weeks during orthodontic extrusion. It has been suggested that orthodontic tooth movement into infrabony defects can result in healing and regeneration of the tooth attachment apparatus.

Periodontal therapy as an adjunct to orthodontic therapy: The aim of orthodontic treatment is to achieve a good occlusal relation, maintain a healthy periodontal status and to improve dental and facial aesthetics and also function. For the success of any orthodontic treatment, health of the periodontium is an important factor. So good periodontal health should be maintained not only before but also during and after the orthodontic treatment. Appropriate orthodontic forces do not produce any damage to the periodontium. There is different periodontal treatment which are used as adjuncts to orthodontic therapy.

Pre-orthodontic gingival surgery: It is seen that insufficient width of attached gingiva prevents plaque control and develops gingival recession. The denuded area extending through the marginal bone is known as 'dehiscence' which is a risk factor for the development of gingival recession. So, it is necessary to maintain the adequate width of attached gingiva. An attached gingiva with 2mm of width, is appropriate in maintaining a proper gingival health.[7] There are different mucogingival surgeries such as free gingival autograft, connective tissue gingival graft, apically repositioned graft and modified apically repositioned flap can be utilized for augmenting the width of attached gingiva. Among these techniques 'Modified apically repositioned flap (MARF) is a simple and less time-consuming procedure.

Fiberotomy: Elastic fibers,collagen fibers and the periodontal ligament are re-organized by several orthodontic tooth movements inorder to accommodate the re-established tooth positions. The teeth must be retained in the new positions to prevent orthodontic relapse and to achieve proper rearrangement of the supporting tissues. Supracrestal fiberotomy is usually performed to correct the relapse of tooth rotation corrected by orthodontic treatment. It is done before the removal of orthodontic appliances i.e. towards the end of the active orthodontic therapy.

Frenectomy and frenotomy: Abnormal frenum attachment is a potent aetiological factor for the development of midline diastema. By frenectomy incision and relocation of frenal attachment is done. Frenectomy is the complete excision of the frenum along with its attachments to the underlying bone. It can be done by either conventional scalpel technique, electrosurgery or by using lasers.[8]

Crown lengthening: It is a surgical procedure which is used to extend the supragingival tooth structure for aesthetic or restorative purposes either by the method of positioning the gingival margin apically, removing the supportive bones or by both of these.[9] It is necessary if there is not enough of clinical crown height. It reduces gum tissue and shaves bone down when required. The procedure usually performed by gingivectomy or an apically repositioned flap in combination with gingivectomy prior to orthodontic bonding procedures.[3] It can be done to prevent gummy smile in which gums are visible above the teeth while smiling.

Preorthodontic osseous surgery: It is mainly indicated for different types of defects such as; hemiseptal defect, three-walled defect,osseous crater and furcation involvement etc.

Missing interdental papilla are usually known as gingival "black holes". It may be due to a number of factors such as over-divergence of adjacent roots and advanced periodontal disease with loss interdental alveolar crest. An orthodontic periodontic interdisciplinary approach is usually advised to manage these problems.

Periodontally accelerated osteogenic orthodontics: This technique was developed by Dr Thomas Wilcko and Dr William Wilcko.[10] It is also known as alveolar osteogenic orthodontics or Wilkodontics. This procedure can be used as an adjunct to conventional approaches to accelerate orthodontic tooth movement. Basically this is a clinical procedure that combines alveolar augmentation and selective decortication facilitated orthodontic technique.[10] Theoretically it is a procedure which is based on the bone healing pattern in corticotomy regions known as the "Regional Acceleratory Phenomenon (RAP)". RAP was first described by Frost in 1993.[10] Regional acceleratory phenomenon is a localized tissue reaction to noxious stimulus. It accelerates the healing efficiencies of the affected tissues 2-10 times faster than normal physiologic healing process.[11,12] This is usually seen in osteotomy sites, fracture sites or bone grafting areas but mainly seen in fracture sites.[13] The two main features of RAP in bone healing which are believed to improve orthodontic treatment are; decreased regional bone density, accelerated bone turnover.[10] It mainly focuses on enhancing the manner in which the periodontium responds to applied forces and on providing for more intact periodontium and increased alveolar volume to support the teeth and overlying soft tissues during retention. The procedure for the PAOO technique is portrayed in Figure 1-6.

Advantages:

- Increases alveolar bone width
- Reduced treatment time to $1/3^{rd}$ to $1/4^{th}$ of conventional procedure
- Less root resorption
- Improved periodontal support
- Less chance of relapse
- Alveolar grafting also benefits patients by repairing bony dehiscence and fenestrations.

Disadvantages:

- Not applicable to all cases
- Costly procedure
- Post-surgical crestal bone loss and recession may occur
- Sometimes there is occurrence of pain and swelling
- Not suitable for patient who take NSAIDS o regular basis or patient having other chronic health problems

Applications:

- Resolve crowding
- Accelerate canine retraction after premolar extraction
- Facilitate slow orthodontic expansion
- Manipulation of anchorage
- Molar intrusion and open bite correction

Different studies on orthodontic periodontal interrelationship: Generally, the main reasons routinely cited to justify the provision of orthodontic treatment are important of dental and facial aesthetic and of dental function and health. Following are some of the studies regarding orthodontic periodontal interrelationship.

A research on correlation between periodontal health and malocclusion was conducted by Ngom and co-workers.[14] According to them malocclusions are the risk factors for periodontal diseases. But in this study the real conclusion about the cause or effect relationship between periodontal condition and malocclusion was not possible.

Van Gastel[15] conducted a review of literature which showed contradictory findings on the effect of malocclusion and orthodontic appliances on the periodontal health. Dental plaque is the primary cause of gingival inflammation and periodontitis. There are some studies reported loss of attachment during orthodontic therapy.

Two systemic reviews were conducted by Bollen[16] to know whether the malocclusion and orthodontic treatment affect the periodontal health or not. The first one suggested that person having greater malocclusion will have more periodontal problem. It may depend on oral health status. The second one showed that there is no reliable evidence on the effect of the orthodontic treatment on the periodontal health.

A systemic literature review was conducted by Gray and McIntyre[17] to determine the effect of Oral Health Promotion (OHP) upon gingival health. They concluded that an OHP for patients undergoing fixed appliances

orthodontic treatment produces a short–term reduction (up to 5 months) in plaque and improvement in gingival health. There are no specific oral health promotion method that can produce a greater short-term benefit to periodontal health during fixed orthodontic treatment.

Conclusion

Healthy periodontium is required for all types of dental treatment, mostly for orthodontic treatment. Orthodontic therapy has both beneficial and harmful effects on periodontium. For adult patients, combined orthodontic and periodontal treatment is required,who are seeking orthodontic treatment for aesthetic correction. Orthodontic treatment cannot be performed on periodontally compromised conditions. In such conditions regular follow up is required to check the periodontal status. Harmonious cooperation between the periodontist and orthodontist provides a satisfactory outcome for the combined orthodontic periodontal problems.

Abstract

Tobacco use is a global menace and leading cause of cancers and death. Tobacco cessation strategies are being formulated world over to curb this problem. Nicotine replacement therapy (NRT) such as chewing gum, patches and inhaler and drugs like Bupropion have shown some success in smoking cessation rates in the short and long terms.

Keywords: *Tobacco cessation, Pharmacotherapy, NRT, Nicotine, Nicotine Patch, Bupropion.*

Introduction

Nicotine is responsible for pathophysiological changes in smokers and also tolerance[(1)]. Despite the awareness and the determined protective efforts at both national and state level, tobacco still threatens the health and well being. Oral cavity and general health are affected due to smoking and chewing tobacco. Currently, tobacco intake is one of the major etiology of oral cancer, a severe and increasing worldwide problem[(2,3)].

Consumption of tobacco cause periodontal destruction with reduction in inflammation and gingival bleeding which ultimately results in delayed wound healing. It also leads to halitosis and other oral conditions[(4-6)]. Smoking causes oral cancer. Cardiovascular disease, chronic obstructive lung disease emphysema and chronic bronchitis are main cause of smoking. Smokeless tobacco is known to cause oral cancer.

Oral cavity being the entry point for tobacco smoker, it is the first to get exposed. Therefore, it is associated with tooth stains, abrasions and condition like smoker's melanosis, nicotinic stomatitis, keratotic patches, black hairy tongue and oral carcinoma. Oral keratosis and gingival recession are due to consumption of smokeless tobacco. The prognosis for periodontal treatment is affected adversely on consumption of tobacco[(2,7)]. Cigarette smoking has a dramatic effect on inhalation since more than 90 percent of the nicotine present in inhaled smoke is absorbed. Absorption instantly results in an increase in arterial nicotine level[(8)].

Pharmacotherapy in Tobacco Cessation: The objective of a pharmacological approach for tobacco cessation should ideally to blockage of positive reinforcing effect of nicotine and prevention of withdrawal symptoms. Pharmacotherapeutic treatment is mainly classified into: Nicotine replacement therapy (NRT) and non-Nicotine Replacement Therapy (n-NRT)[(9)]. NRT is not suitable in patients with history of cardiovascular conditions such as myocardial infarction, cardiac arrhythmias and angina pectoris. It is also contra indicated in pregnancy and for lactating mother. Action of NRT is by replacing nicotine component from cigarettes

which helps in preventing withdrawal symptoms caused by nicotine component. Non-NRT also helps in reducing withdrawal symptoms as well.

Nicotine qualifies to be a highly addictive drug[10]. Regular smokers develop a dependence on tobacco smoking and not simply an addiction to nicotine[11]. Dependence develops due to the temporal association of the habit and sensory inputs with the recurring stimulation and relief of withdrawal symptoms. This is the reason for minimal addictive potential of nicotine replacement therapy (NRT) products,that deliver nicotine slowly and do not produce high plasma nicotine

Types of NRTs are: Nicotine gum, Nicotine patch, Nicotine nasal spray and Nicotine inhaler

NRTs:

Nicotine gum[12]: This is an alternative agent which helps in cessation of smoking. It acts by principle of neuroadapation followed by abstinence as a daily cycle. Nicotine levels fall during overnight sleep or when gum not chewed. It works best with other NRTs or bupropion hydrochloride[13].Nicotine gum chewing facilitates absorption of nicotine through oral mucosa when gum placed between cheek and gum. Chewing of gum cause needle like sensation then park between cheek and gum. This chewing and parking process repeat alternately for about 30 min.

For smoker who smokes within 25 cigarettes per day, a dose of 2mg is advised and 4 mg dosage is advised for smokers smoking more than 25 cigarettes per day[13]. Patients should be instructed to chew the gum in a fixed schedule 1 piece every 1 to 2 hours. Hencearound 10 to 15 pieces per day may used initially[14]. They have to avoid eating or drinking anything before to and during chewing gum. An acidic beverage hinders nicotine mucosal absorption. This treatment should be continued for 6 weeks followed by 6 weeks tapering[15].

Advantages of chewing gum is that it acts by changing the behavior of urge to which control nicotine mood changes[14]. Common side effect includes nausea, sore throat, mouth and jaw, dysgeusia, dyspepsia, gastrointestinal discomfort etc[14-16].

Nicotine Patch[17]: Nicotine patchesare preferred over chewing gum because drug delivery is for long duration with high concentration than chewing gum. Patches are available in different formulation as per strength and concentration[2]. Patches may be used 16 hours to 24 hours in a day. One day patch has advantage of controlling the morning smoking urge by increasing blood nicotine level upon awakening. 24 hour patches may cause sleep disturbances unlikely by 16 hours patch.

The patch may be put on in the morning on a hairless area between neck and waist. The initial dose is tapered after 4 to 6 weeks up to 14 mg/24 hours then to lowest dose 7 mg/24 hours in the following 2 to 4 weeks. There may be differential recommendation of dosage for the patch depending upon amount smoked, amount of nicotine dependence [14,15,18].

A nicotine patch is easy to use with minimal side effect and more efficacy than chewing[14].However,some side effect may be due to constant nicotine level in the body. Side effects are mainly due to localized irritation of skin causing redness, itching and burning like sensation, which may lead to discontinuation of therapy in 5% cases[15]. Most of the above side effects are self-limiting, such as redness of skin by 1 to 2 days of therapy, rashes by applying steroid creams topically. Other minor side effects are generalized skin rash, headache, nausea, vertigo and gastric discomfort [14, 15].

Nicotine Nasal Spray[17]: Nicotine nasal spray is another type of NRT which helps in reducing nicotine crave in patients. Nicotine levels in plasma peaks within 10 minutes after intake. This is about two-thirds of the dose of nicotine in cigarettes[14,15,19]. Application of 0.5 mg equally in each nostril not more than 5 doses per hour or 40 doses per day and gradual reduction of the dose is recommended. Nasal spray may be avoided on lower nasal mucosa[14].Sniffing, swallowing and inhalation should be avoided. Uses of one to two canisters per week don't need any follow-up. Use of more than two canisters per week should be used with caution. It is mainly used for nasal spray up to 12 weeks, then it should betapered gradually[14, 15].

Side effects may include headache, burning like sensation, rhinitis, increased lacrimation, pain in nose and throat, sneezing and coughing. It occurs after initiation of therapy which gradually decreases within first week[15].

Nicotine Inhaler[20]: Each puff of inhaler delivers around 13ng of nicotine. Nicotine levels due to most cigarettes is approximately 2 mg, which is about 80 puff inhaler over 20 minutes. Absorption of drug mainly occurs through mucosal membrane of oralcavity,

pharyngeal mucosa and gastrointestinal tract. It may affect throat irritation and coughing; it should not give in bronchospastic disease[14].

NON-NRTs[21]: Even though the cessation of tobacco is achieved by NRT but the outcome rate is not more than 20% per year. Outcome of smoking cessation rate increases by NRT in comparison to placebo but not more than 20% per year. To increase these rates, non-nicotine agents came into consideration, which acts bynoradrenergic neurotransmission (Bupropion, Nortriptyline). These drugs have more efficacy are than those affecting serotonin (selective Serotonin reuptake inhibitors, Bupropione, Ondansetron etc.)[1].

Bupropion Hydrochloride[22]: Bupropion hydrochloride (Zyban) which is an aminoketone antidepressant group of drug that acts by weakly obstructing both noradrenergic and dopaminergic uptake, helps in cessation of smoking. It also helps in weight loss[14] in obese individual. It is also indicated in patient not willing to take NRT, relapse after taking NRT or failure of NRT. Starting dose of bupropion for smokers is one week prior to their cessation date. All the patients are allowed to continue smoking only for first week followed by cessation in end of 2nd week[1]. The starting dose is 150 mg once a day for 3 days followed by 150 mg twice every day for 2 to 3 months[1]. Minimum interval between two doses should be 8 hours. Second dose normally is advised in the late afternoon or in the evening to avoid sleeplessness. Bupropion can be used as mono therapy or in combination with other NRT (e.g., nicotine patch)[1,23].

It can decreased sleep and cause dryness of mouth, and seizure in 0.1% of patients as it decreases seizure threshold[24]. So always ask patients about seizures history and rule out other cause of seizures like cerebro-vascular accident, surgical intervention or significant history of loss of consciousness due to head injury. Drug which decreases seizure threshold (e.g., alcohol, neuroleptics, patient taking monoamino oxidase inhibitor)[14].

Clonidine[25]: Clonidine is a centrally acting drug that inhibits α2 receptor of sympathetic nervous system(primarily used as antihypertensive drug). Very few study have stated that Clonidine may help in cessation of smoking, but side effect due to Clonidine may limit its usefulness[1,14,26].

Antidepressants and Anxiolytics: Antidepressant like Nortriptyline which blocks the reuptake of nortryptyline and serotonin may have some role in smoking cessation, which is yet to be approved by U.S. Food and Drug Administration[27]. As smoking is mostly associated with depression and anxiety, a variety of other antidepressants and anxiolytics like (Buspirone, Doxepin and Fluoxetine) shown to have some promising effect[1,14, 28].

Varenicline[29]: To avoid addiction due to nicotine,non-nicotine containing drug came into consideration. Varenicline is a non-nicotine type drug which is recommended 1-2 weeks before quit date. Dose schedule starts with 0.5 mg daily dose for the first 3 days, then from fourth day the 1mg twice daily up to 7th day, from 8th day 2 mg twice daily up to the end of 12 weeks. To prevent relapse further 1 mg twice daily is recommended for another 12 weeks. The main side effects are nausea, headache, vomiting, gastric upset, lack of sleep and abnormal dreams which are mild in nature and decrease over time. Varenicline is found to be an effective drug in long-term relapse prevention.

Enhancing Pharmacotherapeutic Effectiveness: Safety and efficacy can be enhanced by appropriate use of drug, dose schedule and treatment duration. All patients should be monitored frequently in follow-up period and dose can be adjusted as per patient response. All patient should be instructed properly about the use of drugs[14,30]. A follow up in every 1 to 2 weeks interval should be scheduled for all patients[30]. If there are no signs of improvement within[31] two weeks, medications and motivations should be repeated. If the condition remains at the original level, discontinue treatment after 4 weeks or change to combination therapy

Method of Validation: Patient's smoking status can be assessed by carbon monoxide concentration in breath which is a non-invasive way and rapid method. Urine tests for Cotininare available to assess NRT adherence[32]. However, this test fails to distinguish between sources. Anabasine and anatabine like tobacco alkaloids may also be assessed in urine to confirm abstinence[33].

Future Approaches: A vaccine is being developed which is helpful to avoid nicotine from crossing the blood-brain barrier. Some drugs are being developed to modify the metabolism of nicotine. The discovery of gamma-vinyl GABA (GVG) is quite promising[34]. Although it is yet to be tested, it acts by three chief

mechanism: Drug addiction direct neurochemical effects, Behavioral effects and Neurochemical changes.

Nicotine toxicity: Acute toxicity at high doses (40 -60 mg) and very high dosage up to 500mg may cause sudden death due to respiratory blockade. Usual symptoms of nicotine toxicity may varies as Nausea, salivation, abdominal pain, sweating, headache, diarrhea, dizziness, delayed wound healing etc[35].

Conclusion

Tobacco is a major risk factor for most of the cancer deaths worldwide. Tobacco addicts can greatly be benefited by pharmacological approach.

Cryotherapy: An Alternative to Surgical Adjunct

Sushmita Paul

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The application of low controlled temperatures had advanced in recent years in many branches of surgery. Cryotherapy has opted as an option to destroy cancerous cells in mostly the head and neck region. In many cutaneous conditions, it has been productively used. It is a therapeutical process in which tissue inflammatory and destructive response is done by freezing. Hence, it deliberately destroys tissue by using severe cold. Mouth is reasonably accessible due to oral mucosa's moist surface that is well suitable for the application of cryoprobe. We will discuss how cryotherapy can be used instead of surgical procedures.

Keywords: *Cryotherapy; Applications; Surgical Procedures.*

Introduction

From generation to generation, many different techniques are used for tissue destruction other than the surgeon's knife, some of which can be summed up as high-frequency electric current, chemicals, irradiation by X-rays. And the advantages that are being looked upon them instead of using scalpel are painless and cause minimum destruction of surrounding tissues, and encourage speedy and uneventful healing. In 1845, James Arnott reported the use of low temperature to destroy cancerous cells and came the term Cryotherapy. It is derived from a Greek word 'Kryos' which means frost, thus meaning frost therapy.[2]

According to the medical definition, it is defined as a procedure used to destroy the tissue of both benign and malignant lesions by the freezing and re-thawing process. It is done with the use of cold, which is applied locally or generally various methodto lower the temperature of tissue that is affected.[3] Over 30 years, it has been used in Oral Medicine and Pathology as the oral lesions are normally warm and moist, therefore the procedure is preferably suited for treatment. A cryoprobe is used to attack the oral lesion constantly, which requires minimal preparation of the patient and operation field. It is considered as a simple procedure.[4]

Earlier it was used for the treatment of cancer of oral cavity and lip, but now as the technology has expanded and advanced in the head and neck region. This procedure is also advised after numerous surgical procedures.[4]

The different cryogens used in the procedure are:[6]

1. Liquid nitrogen (-196ºC)
2. Nitrous oxide (-89ºC)
3. Solidified CO2 (-78ºC)
4. Chlorodifluoromethane (-41ºC)
5. Dimethyl ether (-24ºC), Propane (-42ºC)(1)

The combination of these cryogens had also been proved to be used for the treatment of jaw lesions, and had shown a therapeutic effect.[7] In this process the tissue is not excised, rather the lesion is frozen and the ensuing necrotic tissue is allowed to slough instinctively. The main mechanism of the destruction of tissue is through intra and extra-cellular ice crystal formation, leading to cell dehydration, protein denaturation and disruption of the cell membrane and ultimately death of the cell, irrespective of the cryogen used or its temperature.[8] All biological tissues subjected to a temperature of -20ºC or below does undergo necrosis for a minute or more virtually.[9] In cryotherapy, the tissue which is close to the probe freezes quickly, but ice, in this case, acts as an insulator so the further freezing continues slowly. As the spread of freezing is delayed with the help of ice, the probability of unintentional damage to the underlying tissue is reduced. The neighboring tissues are unharmed due to the gradient of heat loss.[10]

The basic attitude of the procedure is: Rapid cooling -> slow thawing -> freezing process is done repeatedly -> maximize tissue destruction. The two method used for the process are:

a. Use of probes and nitrous oxide in a closed system.

b. Use of nitrogen and cotton tip in an open system.

According to Joule Thompson expansion, a substance undergoes a drop in temperature when moved from a high-pressure area to low pressure area. This principle is followed by the probe in cryotherapy, for example when from high pressure inside the cryoprobe nitrous oxide is released to the cryotip which is low in pressure, there is a drop in temperature which causes freezing of tissues to happen.[1,7,11]

History[2]:

1. Theuse of cold for inflammation and trauma was first done by the Egyptians.
2. In the 17th century- Robert Boyle bring into beingthat by freezing cells would be killed.
3. In the 19th century- In cryosurgery, the use of nitrogen and nitrous oxide was started.
4. In the 20th century- Baron Lorreyobserved its efficacy in sedation and anesthesia in the amputation of soldiers.
5. In 1845- The first report on the therapeutic use of low down temperatures in malignant diseaseutilizing salt/ice mixture applied to breast neoplasms was by James Arnott.
6. In 1877- Louis Callitet and Raul Pictetoffered liquefaction of oxygen and carbon monoxide experimental papers, and this was considered by Zacharian as the birth of modern cryogenics.
7. In 1899- The first cryosurgeon to use it for medical purposes was Campbell White.
8. In 1977- After freezing there was local tissue necrosis and vascular stasis, and that excellent healing of tissues was witnessed by John Hunter.
9. In the early 1960s- Amaral et al. made use of liquid nitrogen on swabs to treat cases of palatal inflammatory papillary hyperplasia.
10. In 1981- Mac Donald et al. suggested for treatingangiomas, hyperplasia of palate, leukoplakia and lichen planus, cryosurgery can be done.
11. In 1981- Barnard illustrated that cryotherapy produces an extended and reversible nerve block in the management of chronic pain and postoperative pain.
12. In 1988- Goss made use of cryoneurotomy for treating patients with intractable neuralgic pain in the preauricular region.

Role of Cryotherapy in Oral Lesions: It has shown tremendous effects in treating oral lesions in all these years with its rapid and uneventful healing. Patients have been seen accepting the treatment as it is less painful and damage to surrounding tissues is very less. The oral precancerous lesions are treated and eradicated with different other modalities like surgical excision, photodynamic therapy, laser surgery and many more, but the different advantages that make cryotherapy as an effective and alternative modality for treatment are very low incidence of secondary infections, lack of scarring and pain and most importantly bloodless treatment. The different oral lesions in which cryotherapy as a mode of treatment can be used are hyperplastic, keratotic, vascular, granulomatous pigmented lesions, and also lesions of gingiva and salivary glands. As given by Hocut et al in 1982, the different stages of cryotherapy are:[12]

Stage 1: sensation of cold 1-3 min.

Stage 2: aching or burning 2-7 min

Stage 3: local numbness 5-12 min

Stage 4: deep dilation >12 min

It has been suggested that after an injury >12 min should be used to attain stage 3.

The dependency of cryolesion dimensions is based upon three variables, which are:

a. Temperature of cryotip

b. The period of contact

c. Area of contact between the tip and the tissue

The determination of the velocity of freezing within the cells and the size of the freezing ball is a contribution by the temperature of the cryotip. A high velocity of freezing desired since rapid freezing can cause lethal effects to the tissues. The duration of freezing is directly proportional to the size of the lesion in the starting 1-7 minutes, according to the growth pattern of cryolesion

in vitro.[1,6] Taking an example of freezing a bony tissue, in that case multiple freeze sites are necessitated as the freezing of tissues is a difficult job. But in most of the soft oral lesions, the freezing time is limited to 20-30 seconds.

Mechanism of tissue damage in Cryotherapy: It has been determined with the help of several reports that most tissues freeze at a temperature of -2.2ºC, and for cell death to occur the temperature must fall below -20ºC. According to dermatological guidelines, it was suggested that small cancers should be treated at a temperature of 30ºC which is said to be effective. On the other hand, in aggressive cancers of the oral cavity, the treatment is done by repetitive freeze cycles of at least -50ºC or more temperature for the necrosis of tissue to occur.[1,6,10] Normally following the treatment, cryolesions are impossible to differentiate from original tissue, though as repetitive freeze and thaw cycles are undergone by the lesion, an accretion of damage takes place. And in the following days of the treatment, latent damage is created, which changes to progressive damage leading to consequent tissue necrosis.[7] Therefore, after cryotherapy tissue destruction is a multifactorial process, which combines both direct and indirect effects.[2]

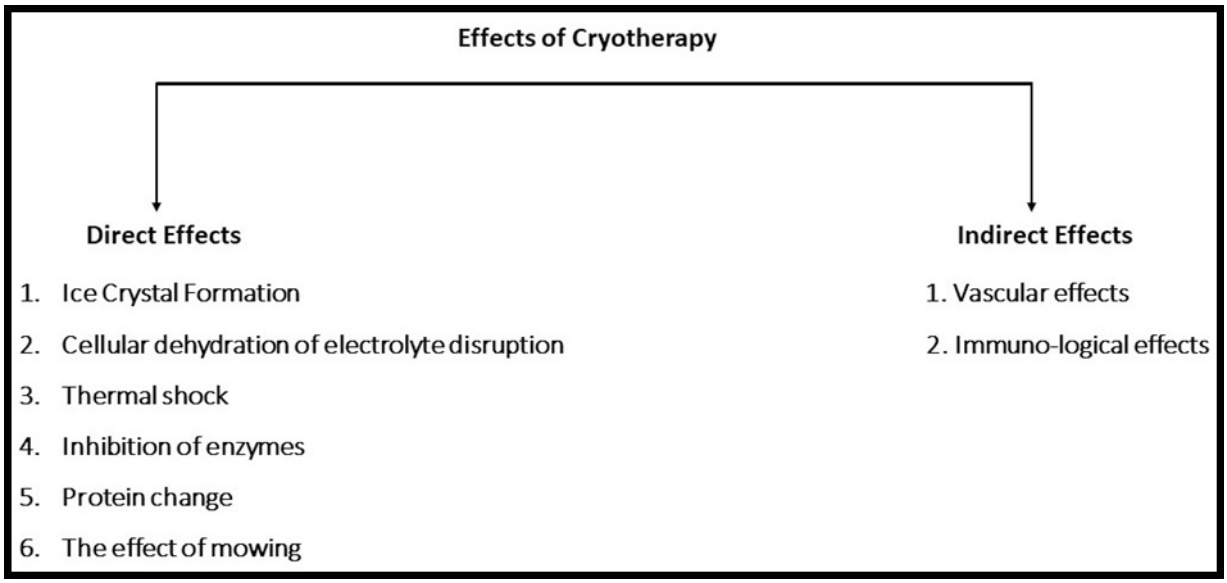

Figure 1. Effects of Cryotherapy

The description of the effects is given the following:

1. Direct effects

a. Ice crystal formation: Larger ice crystals are formed when the cooling rate is more rapid, therefore the degree of adhesion of the tissues to the probe is greater. The disruption of cell membranes is produced due to large ice crystals.

b. Cellular dehydration and electrolyte disruption: The cell membrane acts as a barrier to the propagation of ice crystals as the freezing occurs only in the extracellular space only within the outer zone. The extracellular molecules are captured by the slowed-down freezing, so in the extracellular space the ionic concentration of electrolytes is increased. Intracellular water is passed from the cell, but is then trapped in the ice front, leading to the cells to become dehydrated and undergo physical shrinkage. And the concentration of electrolytes both inside and outside of the cell is amplified, which becomes irrevocably toxic to cellular function.

c. Thermal shock: This is related to the rapid freezing rate which causes cell damage, systems recording temperature in order of 1000ºC/minute.

d. Inhibition of enzymes: Sudden cooling acts as an inhibitor, as each cellular enzyme operates optimally over a narrow temperature range. This makes the cell more susceptible to metabolic changes.

e. Protein changes: Protein is denatured in both the

cell membrane and mitochondria due to the fall in temperature, and cellular metabolism shows subsequent damage.

f. **The effects of thawing:** The tissues are allowed to re-warm when the process of freezing stops which causes damaging effects. Like, due to increased concentrations of intracellular electrolyte, the cells show water intake which is then vacuolated, bulged and burst.[13]

2. Indirect Effects:

a. Vascular effects: Vascular stasis and microthrombus formation causes ischaemic necrosis, which plays a significant role in cryodestructive process.[14]

b. Immunological effects: These effects could be seen due to the massive release of pathological cell antigens, which makes them vulnerable to host surveillance mechanisms. These also add to the damage of affected tissues treated by cryosurgery.[2]

Changes of tissue after cryotherapy: The clinical observations done in oral soft tissue include necrosis, sub epithelial hemorrhage, tissue edema, blister formation, sloughing and repair. In general cases, within a few hours of cryotherapy, edema, hyperemia or erythema is seen immediately. After 1-2 days, local swelling is seen which increases with time, followed by superficial necrosis and ulceration that is enclosed by a coating of yellowish or whitish necrotic pseudomembrane. After the 1st week, this yellowish or whitish slough is detached from the underlying tissue, leaving a granulating clean surface that is covered by epithelium partially. After 1-4 weeks, the completion of epithelialization is witnessed with no or very small scar formation.[6,9]

Cold therapy after intraoral surgical procedure: It has been observed that patients are always advised to apply ice after physical injuries and a variety of surgical procedures for therapeutic use. This therapeutic use of cold through various method is applied locally or generally to lower the temperature of the skin and subcutaneous tissue.[12,15] Many scientific studies are being done based on the physiological and clinical effects of cryotherapy but still there is a scarcity of information based on what should be the optimal time interval for therapy, the finest method of application and the entire time length for cryotherapy.

The five cardinal signs of inflammation pain, swelling, heat, redness and loss of function were identified long ago, but they are not the inflammatory response. The overlapping stages that can impair tissue function or structure are referred to as inflammatory response. The physical objectives that can be obtained when cold therapy is applied after an injury to cool tissues are edema (inhibit swelling), decrease inflammation, vasoconstriction (diminish blood supply), stopped the increase of temperature, reduced hemorrhage, decreased metabolic alterations leading to reduction of secondary infection due to lack of oxygen, cold reduces nerve conduction speed and eventually hurry up the revival process of the patient to resume normal function.[16]

Advantages: Cryotherapy is the most effective and best method of treatment when surgery is contraindicated in the patient. It causes very minimal general disturbance to the patient, especially the elderly age group. The volume of tissue destruction is reasonable and predictable. It is best suited for extensive superficial lesions, with a very low complication rate. It can be used as an adjunct to surgery and also radiotherapy in case of analgesic tumor control. It also helps in the preservation of the inorganic structure of bone, with minimal to no visible scarring. It also has a very low incidence of secondary infection. It is said to be safe, easy to perform, with no permanent side effects and more localized in action. It is a relatively inexpensive technique in an outpatient clinic for various oral lesions.[7,10,12,17]

Drawbacks: The technique is very safe and useful in treating oral lesions, but has got a few limitations also. Like, it is highly dependent on the operator skill and experience. The freezing capacity of the available instrument doesn't always reach the volume of the lesion which leads to multiple cryosurgery procedures or an alternative mode of treatment that has to be planned. Sometimes there is trouble in evaluating the extent of the lesion, which leads to an insufficient amount of tissue involvement which results in persistence of the pathologically changed epithelium and recurrence of the lesion. The healing process is slow in cryotherapy, which can also mean the persistence of lesion, especially if the case is neoplastic. Extensive procedures can lead to considerable scarring. It is contraindicated in patients with cold intolerance, cryoglobulinemia, cold urticaria, collagen diseases, and patients undergoing hemodialysis or immunosuppressive therapy.[3,7,18-21]

Conclusion

In comparison to conventional surgical procedures, it is an atraumatic form of therapy. Therefore it can be the choice of treatment in case of anxious patients, children,

and patients for whom surgery or other procedure is contraindicated. It is an effective mode of treatment for the head and neck region. By careful selection of patients, cryotherapy is a simple, safe, conservative and acceptable treatment for certain benign oral lesions and oral pre-cancers. The ice therapy canprovide several benefits that can be said after a lot of reviews on the physiological effects of the cold application, still many clinical trials are required to prove the therapeutic efficiency of cryotherapy.

Nursing Bottle Syndrome: An Overview

Ayesh Das

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Nowadays people face several dental issues among them one of the major issues is Nursing Bottle Syndrome. It affects preschool children and infants worldwide. It is one of the common childhood diseases. Driven by a dysbiosis state of oral micro-organism mainly caused by a sugar-rich diet. Little one less than 36 months of period if any indication of tooth decay seen than its a sign of acute Nursing Bottle Syndrome. Existence of single or many blights, lost or restored milk teeth in children aged 5 years or smaller starts with milk or fresh snow spot along the free gingival margin on the surface near the lip of upper central and lateral eyetooth which often goes undetected by folks and caregivers, spreading later to the (deciduous) maxillary and mandibular first molars,maxillary and mandibular canine followed by maxillary and mandibular 2nd molar whereas the mandibular molars are not affected (the teeth are affected in the order they erupt). Dental care acts as a major part of dental function and is required for phonetic and all-round self-development of individuals.

Keywords: *Cariogenic Microorganisms, Streptococcus Mutans, Streptococcus Sorinus, Blight, Fluoride.*

Introduction

The term Nursing Bottle Syndrome was introduced in the 1990s. In many countries Nursing Bottle Caries is a significant problem especially in association with disadvantaged communities in which malnutrition is a major problem. It is considered a chronic dental issue that harms young children's health and also considered a major dental issue. Nursing Bottle Caries is defined as a multi-factorial disease, that results in single or many blight (carious or non-carious areas), filled or mislaid tooth surface due to blight in any milk tooth, in children (5 years or younger). Nursing Bottle Syndrome has many distinct features in the medical aspect similarly as swift initiation of cavitation that affects the teeth that erupt from the gums.[1] Various parlance pre-owned to look into a similar situation, rampant tooth decay, milk tooth cavity, milk bottle syndrome, prolonged nursing habit caries. Nursing Bottle Syndrome is connected with other systemic issues of an individual body,ranging from local pain infection, pus accumulation, leading to difficulty in eating grinding the food and famine toddlers enteric upset,stomach flu and difficulties during night insomnia. Diet and nourishing for practices act a significant part in developing teeth cavitation also in causing rotted teeth. Multiple causes can be stated which are responsible for this chronic disease.[2]

Classification:

Type I (mild and moderate): Molaris Dens associated in decay tooth gasp. That are found in between 2 to 5 age group toddlers. Affect is generally tooth decay; gelatinous,spongy, paste-like food and absence of dental care and maintenance and lack of dental check-up. Numeral of infected tooth generally raises by the raise in pathologic flora of micro-organism by challenging their persistence.[3]

Type II (moderate to severe): Labio-lingual tooth decay area that infects the upper front tooth i.e. dens incisive, may or may not infect molaris dens according to the eruption time of an individual. It generally takes place as soon as the earliest tooth comes in the jaw. Unaffected lower front tooth i.e. dens incisive. Causes are generally inappropriate use of bottle milk suckling, mother milk suckling, or mash-up of the pair of habits that result in inadequate dental practices. Unless controlled it may proceed to advanced stage.[3]

Figure 1. Diagrammatic representation of Early Childhood Caries

Type III (severe): Dental Decay lesion occupies almost all the teeth,together with lower dens incisivus. It generally takes place in 3 to 5 years of age. Root is like a union of aspects and inefficient dental habits. Uncontrolled and affect several teeth and affect a number of the teeth surface.[3]

Sequence of Teeth Involved Due To Nursing Bottle Syndrome[4]:

Effect of the deciduous teeth in the following sequence:

- **Dens Incisivus:** Facial surface, lingual surface, mesial surface, distal surface,
- **Maxillary Lateral Dens Incisivus:** facial surface, lingual surface, mesial surface, distal surface, Maxillary First Molar: facial surface, lingual surface, occlusal surface, proximal surface,
- **Maxillary Canine and Second Molar:** Facial surface lingual surface, proximal mandibular molars are usually spared.
- Anterior teeth are usually spared since they have protection by the tongue and cleaning action of spittle due to the existence of the opening of the duct i.e. the submandibular glands very near to lower dens incisivus.
- **Lesion Progression:** De-mineralized dull lesion followed by white areas along gum lines (labial aspect) which causes white lesion and it become cavities that involve neck of the tooth in a ring-like lesion. Finally the whole crown of the incisors is destroyed leaving behind brown-black root stumps.
- **Unequal severity: Distinct pattern of the site:** Site of milk teeth eruption. Continuation of adverse activities of nurturing. Sinewy form of the toddler feeding practices Early Childhood Caries clinically present as a spectrum ranging from 1 to 2 isolated caries lesions to severe and rampant forms where many teeth are affected.

Epidemiology of early childhood caries: Frequency of Nursing Bottle Caries can be depicted in the following countries and society invovlement[10] in these respective years with the help of percentage: India (Kerela), 2003, 12%, Saudi Arabia, 2001, 27.1%, Manchester, 2001, 19%, Canada, 2004, 54%, Australia, 1985, 5.4%. Despite the frequency of Dental Caries has turned down in developed countries over previous years, Nursing Bottle Syndrome is still a major issue in toddlers. Various information or data can be used to ameliorate the dental health condition among the public.[5]

Pathogenic micro-organism: *Streptococcus mutans* & *Streptococcus sorinus* is one of the principal organisms which colonize the tooth once it comes in the dental space of the mouth. It is passed on into the toddler's mouth by the progenitress. It colonizes in the mouth produces a large number of extracellular polysaccharides that favors the growth of plaque development. *Lactobacilli* also plays a part in the development of the decay site and plays a significant role in lesion progression, but not in its initiation. Milgrom et al (2000), said that toddlers having increased streptococcus mutans level are 5 times prone to have dental caries.[6]

Etiology: Children who need special health care, Malnutrition children, Crowed home children, Children in families of low socioeconomic status, Low-birth weight infants (<2500grms) & premature, Late order offspring, Lack of routine oral hygiene, Prolonged sweetened bottle feeding, Frequent breastfeeding. If exposure to fluoride is insufficient, Iron deficiency, Excess of lead exposure, Remote and Rural area children.[7]

Consequences of early childhood caries: Infection and pain, Behaviour alteration,Eating difficulties and sleeping, Growth delay and poor nutrition, Distraction from normal activities, Emergency room visits and hospitalization, High treatment cost and time, Poor self-confidence, Speech difficulties and many more according to the place some variation can be seen.[8]

American academy of pediatric dentistry (AAPD) recommendation for nursing bottle syndrome: Sleeping with a bottle should be stopped for toddlers. Nighttime suckling should abstain. Parents and caretakers should be educated to have toddlers drink from a cup. Dental care steps majors should be planned out during the duration period of first milk tooth flare-up. A dental health check-up is mandatory to educate the parents caretaker for controlling the Nursing Bottle Syndrome.[9]

Preventive Measures:

- **Home Care:** Dietary habits, Oral hygiene, Fluoride dentifrices, Fluoride supplement, Transmission of bacteria.
- **Professional:** Early detection of caries, Diet counseling, Fluoride application, Pit and fissure sealants.
- **Community:** Health education, Community development, Water fluoridation.

The motto of Nursing Bottle Syndrome control is to properly develop the idea of that all factors responsible and toddlers at risk and try to control the recurrence of nursing bottle syndrome. Alot of factors are responsible for nursing bottle caries multiple approaches should be taken to control. Educate the people for dental checkup within 180 days of a flare-up of the first tooth and no later than 365 days period education program can be done to aware of the people and educate the parents and caretakers about causes and factors responsible for Nursing Bottle Syndrome. Dental supplements like dentifrices in the form of toothpaste with fluoride contain of 1000ppm and above are efficient in preventing nursing bottle caries. Fluoride Varnish should be used in toddlers with nursing bottle syndrome, at an interval of 3 months or 6 months.[10-14]

Summary: Nursing Bottle Syndrome is a high dental issue in evolving and evolved areas. Nursing Bottle Syndrome can occur untimely in individuals,develop fast in those who have more possibility, and usually unattended.[15] Its outcome ends in pain and potentially threatening infection, influence kid development and reduces the standard of living. It can be specifically vitriolic type of tooth decay, starts soon after dental eruption, blooming on a smooth surface, advancing fast and having an immutable detrimental impact on the dentition.[16] Infants or toddlers undergoing tooth decay have more chances of subsequent tooth decay in permanent dentition. Nursing Bottle Syndrome can be controlled and taken care with proper knowledge,data guidance and ability dentist can assist to refine and enhance dental health and lifestyle of young individuals through spreading awareness, enhance about home care practices and appreciate frequent dental visits to enhance the parental knowledge and perception about the Nursing Bottle Syndrome and its sources adding awareness, accompanied with the treatment plan of children with sign and symptoms of tooth decay.[17-22] Implementation of dental care steps no later than the time of the flare-up of the first milk tooth. Tooth-brushing habit must be taught to toddlers by parents or caretakers and taken care of and monitored that they are doing it 2 times a day regularly, using a soft-bristle toothbrush of age-appropriate size with a smear of fluoridated toothpastes must be applied. Every toddler of age 24 months to 60 months of age period, a pea-sized amount of toothpaste should be used. In toddlers who are reviewed to be at a scale of moderate to high risk of tooth decay under the age of 2 years should be taken a much-considered amount of care.[23-25]

Conclusion

While winding up I need to request and encourage every individual to take special care of there oral and dental hygiene and go for a regular check-up to the dentist every 6 months. Parents and caretakers should take special care of there offspring oral and dental hygiene since the mouth is the mirror that reflects the whole body activities. Well said prevention is better than cure so take care of your teeth before losing your pretty smile.

Introduction

Background: Presence of intact interdental papilla is considered as an essential component of health and esthetics. Interdental papilla loss or "black triangles" results in food retention, phonetic problems and unaesthetic appearance especially in maxillary anterior regions but there are very few studies reporting the prevalence of this condition.

Aim: To assess the prevalence of anterior interdental papillary loss among young adults in Bhubaneswar.

Materials and Method: A total of 483 patients were screened and 157 patients met the inclusion and were assessed for papilla loss parameters (Norland & Tarnow and Jemt Classification).All these patients underwent oral prophylaxis and then clinical photographs were taken.

Results: High frequency of papillary loss was seen in males (62.4%) compared to females (37.6%). Papillary loss was commonly seen in midline (51.0%) than in laterals(49.0%). Jemt Grade 2 (43.3%)and Nordland and Tarnow Class I(43.3%) papillary recession was more commonly seen.

Conclusion: There is higher prevalence of papilla loss in the midline region of maxillary anteriors presenting half or more of the height of the papilla

Keywords: *Interdental papilla, black triangle, classification, prevalence.*

Introduction

A smile reflects the happiness that one has in life[1]. The consonance of the smile is determined by the shape, the position and the color of the teeth but the existence of interdental papillae and healthy gingiva is also one of the important esthetic aspects that need to be considered[2]. Loss of interdental papilla (IDP) results in papillary recession, an un-esthetic gap known as "the blacktriangle"that draws an unpleasant individual attention.

Often the loss of papilla is either an outcome of periodontal disease or trauma. Loss of papilla may also be a result of post-surgical recession due to soft tissue contraction seen in the healing period[3,4]. The development and severity of the interdental papilla recession presents considerable differences in the population at large and young adults in particular[5]. There is no reported study on prevalence of papillary recession. Such information is necessary to gauge the burden of this type of condition in the public at large[6]. Hence, the aim of the present study was to assess the prevalence of anterior interdental papillary loss among young adults.

Materials and Method

Study design and study population: A cross-sectional epidemiological survey was conducted from January 2019 – October 2019 among the young adults aged 18–30 years visiting in department of Periodontics at Institute of Dental Sciences, Bhubaneswar, Odisha. The study was approved by the Institutional Review Board. All willing subjects were included in the study after obtaining a written consent. Subjects with absence of anterior interdental contact point, presence of restoration and prosthesis in the maxillary anterior region were excluded. Data was collected by carrying out dental examination. Each subject was examined in a dental chair by a single, trained and calibrated examiner using dental chair light, mouth mirror, and explorer. They were checked for papilla loss parameters as per classification put forth by Norland & Tarnow et al[7] and Jemt et al [8]. All subjects underwent oral prophylaxis and clinical photographs of the selected site (black triangle) were taken. These photographs were standardized, by setting a grid over the camera screen, while clicking them. The photographs are taken such that the black triangle, adjacent teeth, and the papilla between them was clearly visible. Magnification of the photographs was standardized to 25%.

Statistical Analysis: Data analysis was done with SPSS Statistics version 20. Summary and test of significance was done with Chi-squared test. A value of P of ≤ 0.05 was considered to be statistically significant.

Results

A total of 483 patients of both genders were screened out of which 157 met the selection criteria. In age group upto 35 years, the papillary recession was 32.5% ($n = 51$); age group 35–50 years, it was 41.4% ($n = 65$); age group above 50 years, it was 26.1% ($n = 41$). The frequency of interdental papillary loss was found to be highest among adults within age group of 36-50 years. It was revealed that there was higher prevalence of papillary loss with higher age. Males were mostly affected by papillary recession 62.4% (n=98) compared to females 37.6% (n=59) which was of statistical significance. Papillary loss was commonly seen in midline 51.0%(n=80) than in laterals 49.0% (n=77). The most commonly seen was Nordland & Tarnow et al class I type of papillary recession 43.3% (n=68) followed by class II 33.8%(n=53), class III 22.9%(n=36) and according to Jemt et al classification,the most common was grade 2 type of papillary recession 43.3% (n=68) followed by grade 1 33.8%(n=53),grade 0 22.9%(n=36),grade 3 0.0%(n=0). (Table 1).

Table 2 and Table 3 shows distribution of anterior papillary recession as per Jemt et al and Nordland et al classification, in which there was no statistically significant difference between the males and females (p=0.19) as well as no significant difference were found when age groups were compared(p =0.07) but there was statistically significant more papillary recession in midline as compared to laterals (p=0.00) as per both the classification system.

Table 1. Distribution of anterior papillary recession as per Gender, age group, Papilla Location, Jemt et al and Norland & Tarnow et al classification (N= 157)

Discussion

Anterior papillary recession is an unpleasant and unwanted condition, concerning mostly individuals of middle age groups throughout the world. Presence of a visible black triangle on smiling is often disturbing since it poses an esthetic, psychological and functional malady. However, according to the literature few studies have investigated the epidemiology of gingival recession, but no studies have been carried out was to assess the prevalence of anterior interdental papillary loss among young adults in India.

The present study showed that the prevalence of papillary recession was overall 62.4% in males and 37.6% in females, findings that were in agreement with studies that reported gingival recession prevalence ranged from 50.0% to higher percentages[9-11]. Kozlowska et al[12] reported 31.7% of females and 24.3% of males showed gingival recession. Our results were in contrast to these findings probably due to the fact that factors concerning papillary recession may are not similar to that of gingival recession[13].

The frequency of papillary recession was found to be more in middle aged group (36-50 years). This observation appears to be in usual and on expected

lines due to longer period of exposure to factors that are associated with periodontal disease and gingival recession exhibiting a cumulative effect. In our study, maxillary central incisors (n=80) had the highest prevalence of papillary loss when compared to lateral incisors due to the presence of midline raphe, midline frenum and developmental fusion of plates. These findings were in corroboration with the previous studies[14-20] as gingival biotype is thin in teeth that are prominently positioned.

To the best of our knowledge, this is the first of its kind survey that assesses the prevalence of anterior papillary loss in young adults. Prevalence studies are important for public health as they reflect the burden of disease in a specific population and help in the formulation of treatment strategies and policies[21]. A cross-sectional study has an inherent limitation of being specified to a single point which applies to the current study as well[22,23]. Nevertheless, within the limitations of our study, it may be concluded that there exists a high prevalence of anterior papillary loss among young adults and is significantly associated with age and location. Future studies may be carried out to understand the distribution of this condition better.

Recent Advancements in Pediatric Dental Caries Prevention

Lipsa Behera

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

In childhood dental caries is commonly affecting diseases. According to the World Health Organization 60% to 90% of school children and adults are affected by this disease. It is a disease that can be prevented and if diagnosed in early-stage tooth decay can be stopped by applying various preventive materials. The primary prevention of dental caries mainly focused on young children. Fluoride has been widely used as a preventive measure against caries development. Fluoride is found in topical and systemic form, the topical form is good, has a high life span. Recent advancements suggest that asymptomatic regimen of caries lesion has the inherent of re-mineralization. In the field of dentistry, nanotechnology has been introduced which has developed substances ranging from 100nm or smaller in size. Nanotechnology replicates the natural dental enamel by the process of bio-mineralization. Leading an integral part of bone and teeth is the hydroxyapatite. Since, nano-hydroxyapatite can provide preventive and therapeutic loom to caries in children worldwide, therefore various researches are performed to improve its capacity in clinics.

Keywords: *Dental Caries; Children, Dental Management, Host-defense system.*

Introduction

Oral health is an integral part of general health and well being. It is important to know about the factors which have a bearing on oral health on oral health so that preventive measures can be taken. In childhood dental caries is commonly affecting diseases. According to the World Health Organization 60% to 90% of school children and adults are affected by this disease. It is a disease that can be prevented and if diagnosed in early-stage tooth decay can be stopped by applying various preventive materials. The primary prevention of dental caries mainly focused on young children.[1,2]

Etiology: Numerous factors are associated with caries formation i.e; environmental, biological factor, and socioeconomic status and behavioral. It is dependent on the complex interrelationships between the five critical parameters such as: 1- Biofilm, 2- Tooth habitat, 3- Diet, 4- salvia, 5- Oral hygiene. If the person has higher risk factors, then the caries experience chances also increase. Dental caries is a condition that takes position when pathogens, primarily streptococcus mutans, overrun the tooth aspect and anabolism digestible carbohydrate to fabricate lactic and other acetous, prompting in demineralization of teeth. In children age 12 to 30 months, caries consistently begin with influence the maxillary primary cuspids and first primary bicuspids, through back the ornamentation of emission. Dental caries first noticeable as colorless fleck contusion, which are small-scale domain of demineralization underneath the enamel aspect.[3] At this phase, the caries contusion is conventionally unpredictable. If oral state forgoes ameliorate, demineralization advancement and in due course termination in irreparable cavities, with a deprivation of the accustomed tooth configuration and appearance. Uninterrupted continuance of the caries procedure guide to pulpitis and tooth dropping, and could be correlated along with impediment for instance facial fervouring and congenital inflammation.[4]

Streptococcus Mutans: Most of the organisms present in the human body consists near about 10^{14} cells and the majority are resident of microflora, and the progression to the growth of s.mutans instigate the dental caries. The ability of the s.mutans to bind to the tooth structure is highly assembled through dental plaque, and the set of bacteria are specially ordered and metabolically desegregated. Complex form of matrix and glucan isthe

main configuration of plaque accumulation.[5] *S.mutans* can survive at high ph and is the originator of enamel demineralization. Sucrose which is a sweetening agent naturally materialize carbohydrate and boosts critically with *S.mutans*, other acidolysis agents and acid indulging species. It can begin and maintain microbial growth and to carry on with acid production at low ph values. When there is a decrease in saliva flow, the ph of the plaque drops, allowing the acid-tolerant bacteria like s.mutans to proliferate. It forms dextran and causes a sticky plaque, trapping bacteria, calcium and phosphate ions.[6]

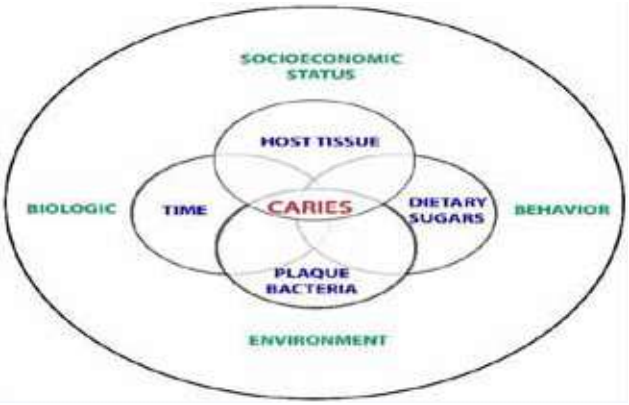

Figure 1

Host Factors:

Saliva: It consists of approximately 99% water along with 1% solid, the viscosity nature of saliva is due to electrolytes and proteins. It is the main defense against caries protection, and it also buffers the acid formed by Streptococcus mutans which is formed by oversaturation with calcium and phosphate ions. It configured a protecting mucoid coating on the mucous integument which reacts as a barricade to plague and intercept desiccation. Its flowaid to clear-out mouth of food and cancellated and bacterial detritus and accordingly slow down plaque establishment. The film with glycoprotein formed over the tooth surface by saliva also protects the tooth by wear due to erosion and abrasion.[7,8]

Remineralizing Agent: Minerals that are delivered onto carious lesion predominantly calcium and phosphate apprehend caries evolution. If the alignment of tooth and vulnerability to acidulated ambush then it is slighter to demineralization. Since the demineralization procedure persists, the ph of the mouth flatters further acidulated which encourages the evolution of cavities. Disintegrated deposits then dispense out of the tooth configuration and into the saliva abutting the tooth.[9] The shielding amplitude of saliva considerably smashes the ph of plaque neighboring the enamel, thereby restricting caries development. Plaque extent and the integer of bacteria attending regulate the efficacy of salivary shields. The elevated salivary centralization of calcium and phosphate which are retained by salivary proteins may register for the evolution and demineralization of enamel. The occupancy of fluoride in saliva pips up crystal drizzles establishing a fluorapatite–like plating which will be more impenetrable to caries.[8-11]

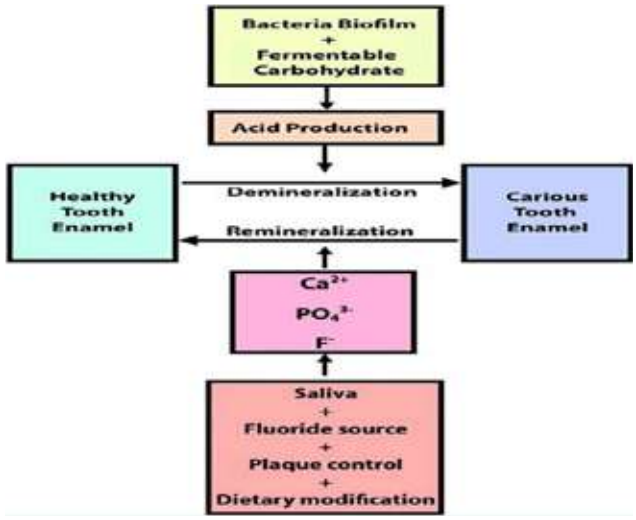

Figure 2

Fluoride: To reverse the tooth structure in early lesion, fluoride is the chief aspect of remineralization. It can minimize caries by counteract demineralization and developing remineralization of tooth surface and can impede plaque, acid fabrication. Considerable engrossment of fluoride liberate from the deliquesce enamel or previously available on the plaque, the more will remineralization be advocated and carious action is slowed down. Utilization of topical fluoride elevates the fluoride extent of tooth surface and fundamental tissues to anextent anticipated to defend in opposition to caries.[12]

CPP-ACP: It is Anti cariogenic potential and enhances remineralization. It is mainly used in the biomedical field because of extremely good bioactivity, adaptable biodegradable rate, High cell adhesion, and great osteoconductivity. For the treatment of tooth sensitivity it is the most recognizable abrasive cement. CPP-ACP holds together to plaque and it imparts immense calcium reservoir and diffuse unbound calcium steadily.

Tricalcium Phosphate (TCP): Fluoride and TCP are the attribute consigned to the tooth during brushing

and dispense intensify remineralization and put on preservation in opposition to demineralization. Calcium complex gets triggered when TCP extends to the tooth surface, and it is shifted by TCP and is guarded by fluoride ion. And remineralization gets boost up when the calcium and fluoride ion level gets down to lesion when delivered tooth surface.[7] Since the configuration of TCP is indistinguishable to hydroxyapatite, once the functionalized calcium ions are liberated, they voluntarily interrelate with the tooth surface and below the grounded structure. Since added calcium phosphate accompaniment may need an acidic ph, which credible restricts the prerequisite to the tooth, functionalized TCP can provide the most favorable advantage when distributed in a neutral ph environment.[13,14]

Silver Dynamin fluoride (SDF): is used in young children to restore carious teeth by conventional method. The excessive application of SDF Stains the tooth surface black, which results in the formation of an impermeable layer over the tooth structure.

Recently it was established that SDF does not inimically influence the bond strength of resin composite to non-carious dentin, contradictory to this an additional in vitro study from Japan establish that SDF intensifies the bond strength of GIC to bovine dentin. [3]

SDF can be applied to proximal caries lesion using spongy floss. A small section next to the contact is then saturated with SDF and pulled under the contact area. Secure the area by brushing fluoride varnish or petroleum jelly over SDF treated Surfaces. The application of varnish will not 'seal in' the SDF; in this protocol, the varnish is used to create a minuscule barricade in the middle of the treated surface and saliva.[4-7]

Nano - Hydroxyapatite: Enamel is considered as the main inorganic component of hydroxyapatite. Enamel is generally made up of HA of size 20 o 40nm particle. S. mutans which produces glucan is absorbed by hydroxyapatite along with salivary proteins which inhibit plaque formation. HA is an organically appropriate medium, and is appraised as ananalytical amalgamation replacement for the natural mineral component of dentin. Its appositeness in biomaterials by the introduction of HA powders to restorative dental materials for remineralization results and enhancement of mechanical belongings has been explored due to its magnificent biocompatibility and bioactivity nature.[5-8]

Mechanism of Action: HA perhaps reconstruct and intercept commencing contusion in enamel due to its immensity and high-level possibility of calcium and phosphate anion particles that take part in a lead character in demineralization and remineralization procedure. The absorption of calcium is perceived to have appreciable termination than the phosphate absorption in obstructing demineralization. The stunted portion of calcium in plaque is established to be a characteristic of caries prevalence while not a bit for the phosphate anion. The ph intensity transforms the absorption of calcium and phosphate in nano- HA ph cramming where high-rise degradation of remineralization is perceived at ph 4.0 apart from at ph 7.0, and as ph the practically diminishes,the absorption of calcium and phosphate intensifies.[7,8,14]

Conclusions

Although current research and technologies have enabled early detection of caries, no current diagnostic method fulfill all the criteria for optimal caries diagnosis. Recent advances have great potential to improve oral health, in the field of pediatric dentistry advancement can be carried out by the application of nanotechnology, by providing effective preventive, diagnostic and therapeutic measures. So, it is indispensable that we, as dentists should be distinct on managing not only those who are afflicted, but also handle those who are further probable to get sick.. we have a diversification of latest negotiator which can be handed-down to intercept dental caries but solicitation of this representative in clinical inquiry is stock-still restricted in the evolving countries. Furthermore dental caries are complex and all preventative estimates should be assessed appropriately in human litigation so that they can be established at the grading strength for the anticipation of dental caries.

Apexification: A Comprehensive Review

Nikita Samal,

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha-751003, India

Abstract

Necrotic pulp in permanent teeth with incompletely formed or wide-open apices results in the death of cells that are effective in the improvement of root. This slows down the possibility of apical closure as well as improvement of root. Endodontic management consisting of diseased or dead pulp with adolescent permanent teeth along with an open expanded root apex is a challenging concern. During obturation in that tooth,it is unimaginable to obtain a proper seal at the tip. There are various techniques to treat an immature tooth with open apex which involve the application of (1) a custom-made cone(blunt end); (2) a short fill technique; (3) periapical surgery; (4) apexification; and (5) one-visit apexification. Mostly recommended treatment of choice is ***'apexification'*** which is a method to induce root apex development of an immature nonvital tooth by formation of osteocementum or bone-like tissue. The most recommended medicament is *calcium hydroxide* that facilitates the development of a calcific barrier found in the root apex. According to the survey of the clinical involvement and information of journalists, management of an incomplete nonvital tooth can bring noticeable outcomes from the disinfectant and ossification promoting activity of $Ca(OH)_2$.

Keywords: *Apexification, immature non-vital tooth, apexogeneis, calcium hydroxide, root end closure, apical barrier.*

Introduction

Apexification is a method to prompt calcific blockade in an immature non-vital permanent teeth by removing the necrotic pulp just short of root end and placing a suitable biocompatible agent to close root apex[1]. Its purpose is to allow the formation of an apical barrier in immature teeth where advancement, as well as the progression of root, terminate by cause of pulpal death. The mineralized tissue can be consists of osteocementum, osteodentin or bone or combination of the three[2]. Apical closure may be complete or a few millimeters short from the root end. It may be either at the root tip or an uneven solidifying mass over the one-third of the apical part. Most of the cases have apical closure in an irregular and abnormal anatomy[2]. As compared to others; apexogenesis[3,4] (*root end closure in vital tooth*) gives rise to proper apical closure along with normal-appearing root development. Previously several attempts made for the treatment of an immature non-vital tooth with wide-open root apex by a custom made cone (employing a blunt-ended gutta-percha cone which is large and performing conventional root canal obturation); a short fill technique (keeping the obturation short of apex); periapical surgery and retrograde filling; *one visit apexification*[5] (restoration of the root apex by the use of a biocompatible substance like dentinal chips or tricalcium phosphate) and lastly apexification. Among them apexification[1] is the most popular method which may involve one or many monthly appointments for placing suitable medicament to achieve elimination of intracanal infection that stimulates calcification and produces the apical closure. To carry out apexification, calcium hydroxide is being replaced by MTA[6] as a single visit technique.

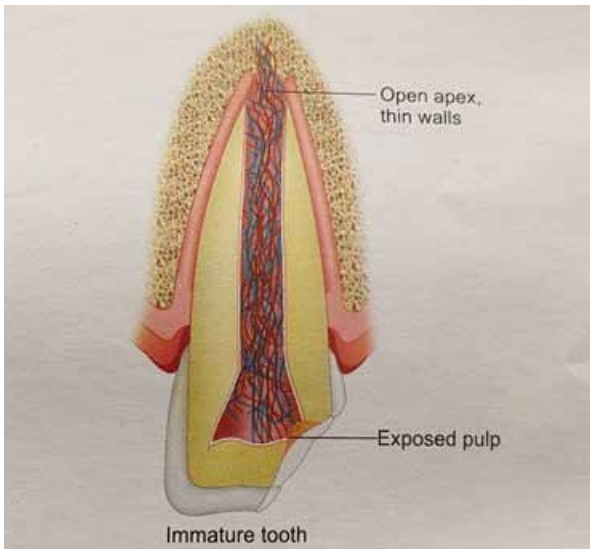

Figure 1. Diagrammatic representation on open apex

Indication Apexificationis indicated in Non-vital permanent teeth with wide-open apex

Aim: The purpose of the apexification technique is: the previously mentioned method should prompt apical closure in a non- vital adolescent permanent tooth root based on intermittent radiographic estimation. There should be no history of postoperative unfavorable indication and expressions like sensation for a lengthy period; ache or discomfort as well as inflammation. There should be an absence of irregular canal ossification; inner or outer constriction of the root; disorder at the lateral root; disintegration to periapical or peri-radicular prompting structures at the time of the procedure or after the procedure.

Materials Used: The most commonly used materials to induce root apex closure are: Calcium hydroxide +sterile water; Calcium hydroxide +CMCP; zinc oxide eugenol; resorbable tricalcium phosphate; Corticosteroid paste; Calcium hydroxide + methylcellulose; Chlormycetin paste;Calcium hydroxide + cresatin; tricalcium phosphate[7]. Various newer materials are suggested for single visit apexification. They are Mineral trioxide aggregate (MTA); Osteogenic protein I & II; and Collagen -calcium phosphate gel.

Procedure: The following measures are involved in the procedure:

Isolate the concerned tooth precisely with the use of rubber dam and gain access to the pulp canal using Gates-Glidden bur. Then keep a file inside the pulp cavity, after that radiograph is taken to build an exact working length of the root. Remember that no instrument should be kept inside apex which may lead to laceration of the tissues. In the first appointment extirpate the fragments of pulp by the help of barbed broaches and files. Next apply hydrogen peroxide for eradicate remnants and canal is flooded via sodium hypochlorite (NaOCl) solution followed by sterile saline solution without applying pressure[8]. The needle should loose within the root canal. By using absorbent points together with cotton pellets the cavity is dehydrated. To avoid destruction of small dentinal walls minimal instrumentation is considered.

A thick cement of calcium hydroxide along with camphorated mono-parachlorophenol (CMCP) or calcium hydroxide with methyl cellulose paste is conveyed to the canal by the use of lentulo spiral seated in a low-velocity engine with specially arranged syringes or with files followed by compression using endodontic plugger due to absence of apical stop. The operator must be careful in the case of rotary instruments as they cause breakage of instruments.

The patient is recalled after 2 to 3 weeks. The main purpose of the second appointment to complete debridement and eradicate tissue fragments distorted by calcium hydroxide dressing which might not be eliminated technically in the first appointment. Radiographically the root length should be established as electronic apex locators are not safe in such teeth. On the second appointment calcium hydroxide paste will be inserted within the canal with the help of endodontic pluggers[9].

Using an endodontic plugger the paste or cement is forced into the edge of the apex (apical tip), however material that overflows must never be pushed behind apex. Cotton pellet is established above calcium hydroxide [$Ca(OH)_2$]. Then close the tooth surface with a temporary filling like *zinc oxide eugenol* paste.

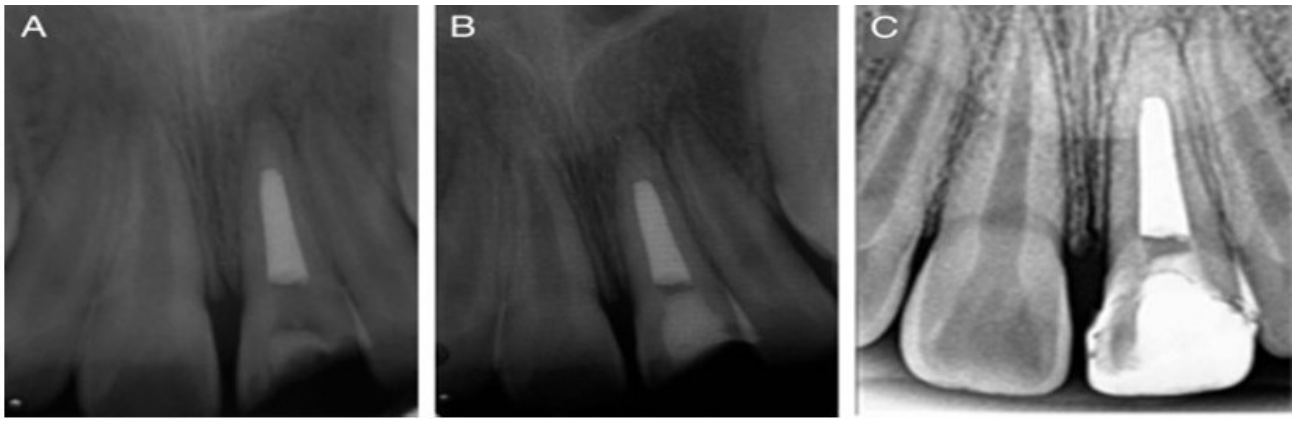

Figure 2. Procedure of apexification

Treatment and Follow up: Signs and symptoms are evaluated regularly. The follow-up assessment is repeated every 3 months up to the successful occurrence of calcified barrier. Then tooth is observed clinically and radiographically[10]. While a calcified barrier seen radiographically, then the tooth is re-established followed by flooding with sodium hypochlorite solution (NaOCl). To verify the integrity of the apical barrier, the apical zone should be investigated using a file to get the length of the root. Generally the cement is permitted to stay about 6 months. Then the pulp chamber or pulp cavity is re-established that one may resolve if the tooth is prepared toward traditional gutta-percha restoration being resolved via the existence of a "positive step" while the apical zone is explored using the instrument. Confirmation about radiographic findings for root-end closure is required too[10].

According to Frank, there are some criteria for apexification treatment: (A.) progressed apical closure of the pulp cavity as in normal tooth, (B.) a dome-shaped apex closure maintaining a blunderbuss manifestation, (C.) radiographically appearing calcified or ossified barrier at the apex, along with (D.) an apical stop with radiographic indication of a barricade coronal to root apex. If barrier or closure of root end is found insufficient within 24 weeks and the patient feels the touch of the file, then the procedure is repeated with calcium hydroxide paste till a complete barrier is developed[11]. While an ossified barrier constructed coronal to the apex, it should not be penetrated to pack the tooth till the apical end.[12] The apical barrier formed by the tissue considered as healthy tissue. It has been believed that the use of calcium hydroxide can consequentially enhance the chance of root fracture after long-term use. So it is essential to reduce the time required for apexification.[13,14]

At 3 to 6 months interval re-establishment of the canal for the lengthy-time period resembles justified as the patient stays relieved from unfavorable signs and symptoms as apex closure is likely to develop ultimately. As seen in normal tooth continuity of apical growth and closure expressed by postoperative radiographs. As apical closure takes place,the canal filled with gutta-perchaa and sealer.

Figure 3. Follow up evaluation of apexification; a, open apex before treatment; b. 3 months follow up; c. 9 months follow up

Types of root apex closure seen after apexification technique:

- Usual root end advancement
- Radiographic closure along with hard tissue stop conspicuous clinically
- Clinically noticeable hard stop with no evidence of radiographic bridge formation
- Development of calcific bridge just coronal to apex

Complications

Following the apexification procedure, crown-root proportion is unfavorable since the length of the root is short as compared to the normal tooth, therefore the diagnosis of tooth can be inconvenienced. In the case of post-induction (whenever required) is complicated because of the diameter of the root canal as well as induction of permanent crown may be prolonged because of the continued progression of the patient.

Summary & Conclusion

Apexification using calcium hydroxide Ca(OH)2 remains the most broadly applied method[1,16] Management of an immature non-vital tooth can bring noticeable outcomes from the disinfectant and calcification promoting activity of calcium hydroxide $Ca(OH)_2$ which cleanse the canal and encourage apical closure [17]. High PH as well as low solubility of calcium hydroxide maintain the antimicrobial action for a lengthy time period[18]. Either Calcium hydroxide alone or calcium hydroxide along with sodium hypochlorite enhance disintegration of fatal tissues for which it aids for removal of debris and remnants from pulp cavity.[19]

To perform an apexification, using calcium hydroxide is a valid therapy for many years. It may require several appointments and might require ages to carry out to form a barrier at the apex,which permits the pulp cavity restoring substance by gutta-percha along with sealer.[20] The time required for this procedure depends upon the condition of root development as well as the state of periapical tissue[21- 23]. Though the use of calcium hydroxide brings about favorable outcomes and percentage of auspicious apical barrier development is huge, deep-rooted follow up is mandatory. Tooth which managed by apexification is sensitive to break due to frailty arising from non-vitality as well as from thin dentinal walls of root[24-26]. Another demerit includesa period of treatment.

After all MTA barrier is a technique used as a substitution to calcium hydroxide[27]. This procedure doe not require several appointments and there is no need for an external factor for the development of barrier as well as in pulp regeneration.[29-33]

Chairside Diagnostic Aids in Periodontics: A Review

Srishti Shankar[1], Rashmita Nayak[2], Rinkee Mohanty[3], Gatha Mohanty[4], Sourav Panda[5], Abhaya Das[5]

[1]Post Graduate Trainee, [2]Professor, [3]Professor & Head, [4]Senior Lecturer, [5]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan, (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The need of the hour is an accurate and timely diagnosis for an effective treatment plan to cure or eliminate the disease. Clinical measurements, traditionally available, have their limitations in helping diagnose an "active" disease. Hence, novel chairside diagnostic kits are essential to detect active disease, predict its progression and help in the evaluation of response, of a patient, to therapy, thereby aiding in the management of periodontal patients. This review article, therefore, discusses the various chairside diagnostic aids available to aid Periodontists, in diagnosing and treating periodontal patients.

Keywords: *Diagnosis, Periodontal disease, Chairside, Diagnostic aids.*

Introduction

Periodontitis is an inflammatory disease of the periodontium, that is, the supporting structures of the tooth, resulting in a gradual loss of it. This gradual degradation of the periodontium leads to exposure of tooth root causing sensitivity, esthetic concerns, gradual mobility and eventually loss of the tooth. Accumulation of dental plaque, due to various factors, leads to an increase in the microbial load in the oral cavity, which eventually, in combination to host's immune response, leads to gingivitis, which if not treated, turns into periodontitis. A diagnosis hence is achieved by clinical inspection of the gingiva surrounding the tooth with the help of instruments, such as the William's Probe or the UNC-15 Probe, examination of the radiographs, such as the IOPAs and OPG and other investigations if required. [1] The traditional clinical parameters and methodusually predict previous periodontal disease than active disease. Therefore, diagnostic kits which can detect active disease and predict its progression are the need of the hour. [2,3]

The available 'Point of Care' diagnostics, are designed to measure microbiological, immunologic and genetic constituents in oral diagnostic media namely: saliva, gingival crevicular fluid (GCF) and plaque, indicative of health or disease. The main aim behind developing such kits is to diagnose active disease so that the following achievement:

- Less invasive treatment
- Reduced chair time
- Reduced expense
- Long term prognosis

Armitage GC 1996, listed out the following purposes served by periodontal diagnostic aids: [4]

- Screening of active disease
- Diagnosis
- Determining sites and/or subjects at a higher risk of disease progression
- Treatment planning
- Therapy monitoring

Chairside diagnostic aids:

Corresponding Author:
Prof. Rashmita Nayak

e-mail: rashmitanayak@soa.ac.in

The ideal diagnostic test should be (Chapple 1997)[5]:

1. Non-invasive
2. Cost-effective
3. Adaptable to sample collection, storage and transportation.
4. Simple to perform at the chairside
5. Rapid, with 1-stage or 2-stage procedure
6. Highly specific, sensitive, reproducible and quantitative.

Hence, keeping these goals in mind, the following are the available or in the making, chairside diagnostic aids.

Microbiological test kit: The main bacteria associated with periodontal disease are Aggregatibacteractinomycetemcomitans, Prevotella intermedia, Porphyromonasgingivalis and Tannerella forsythia.[6]

Presence, elevated levels or absence of these microorganisms may predict, indicate or monitor:

- "Active" disease
- Loss in Clinical attachment level
- Disease initiation and progression
- Sites at higher risk for active destruction and;
- Response to periodontal therapy

Evalusite (KODAK): Evalusite is a diagnostic kit based on the principle of ELISA, which involves the linkage between the antigen and a membrane-bound antibody to form an immune complex that is assessed through a colorimetric reaction. It is mainly used for the detection of three principal microorganisms: Aa, Pi and Pg.[7]

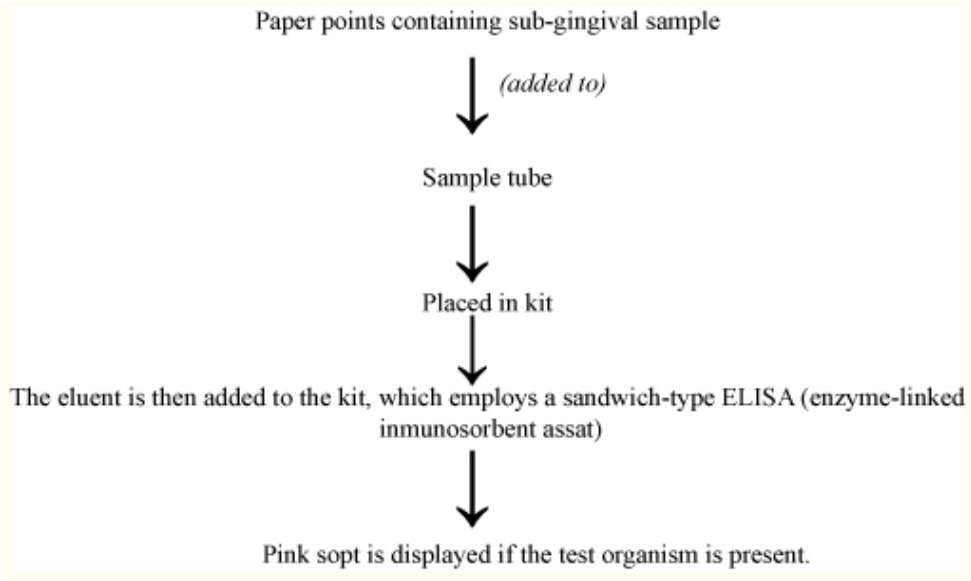

Figure 1: Evalusite (KODAK)

Omnigene: Omni Gene Diagnostics, Inc. has produced a set of DNA probe systems, by applying the principle of genetic engineering. These are species-specific probes which tests for 8 periodontopathogens:

- Actinobacillusactinomycetemcomitans (Aa)
- Treponema denticola (Td)
- Porphyromonasgingivalis (Pg)
- Fusobacterium nucleatum (Fn)
- Prevotella intermedia (Pi)
- Eikenellacorrodens (Ec)
- Campylobacter rectus (Cr)
- Bacteroidesforsythus (Bf)

Subgingival plaque samples, collected from patients for analysis, are sent through the mail to OmniGene Diagnostics. Practitioners may receive the results through phone,fax, or mail. [8]

BANA Test: A trypsin-like enzyme is produced by only 3 specific anaerobic bacteria amongst the various species present in subgingival microbiota. Those are Porphyromonasgingivalis (Pg), Treponema denticola (Td) and Bacteroidesforsythus (Bf). The test works by detecting the presence of these bacterias, as their enzyme hydrolyzes the synthetic peptide Benzoyl-DL-arginine-2-naphthylamide or BANA, present in the test. The test may also be used to assess oral halitosis, by detecting the presence of 2 BANA positive species on the surface of the tongue:[9]

- Stomatococcusmucinlagenous
- Rothiadentocariosa

It is a highly sensitive test, detecting the smallest quantity of pathogens. Studies have been performed, showing no significant difference in the sensitivity of DNA probes, immunological reagents and the BANA test, in the detection of these bacterias in dental plaque, of periodontally compromised patients.[10-12]

Principle:

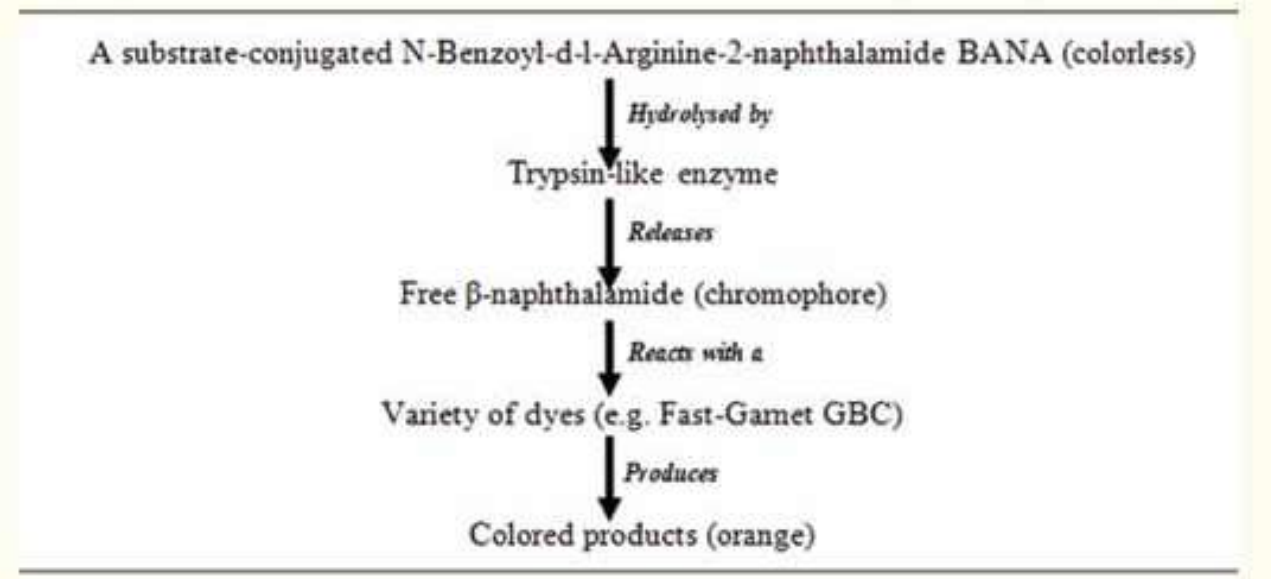

Figure 2: BANA Test

Directions for use: The test consists of a strip (plastic), to which two separate reagent matrices are attached. The upper matrix is a buff reagent, containing chromogenic diazo reagent. The lower matrix is impregnated with BANA. The subgingival plaque samples are applied to the lower matrix. A permanent blue colour is produced as a result of the reaction between the chromogenic agent and hydrolytic product produced by the enzyme. It may be interpreted as a positive or weak reaction depending on the intensity of the colour.

Perioscan: Perioscan diagnostic kit, utilizes the same principle as the BANA test. At Least 4 teeth should be sampled in each subject.

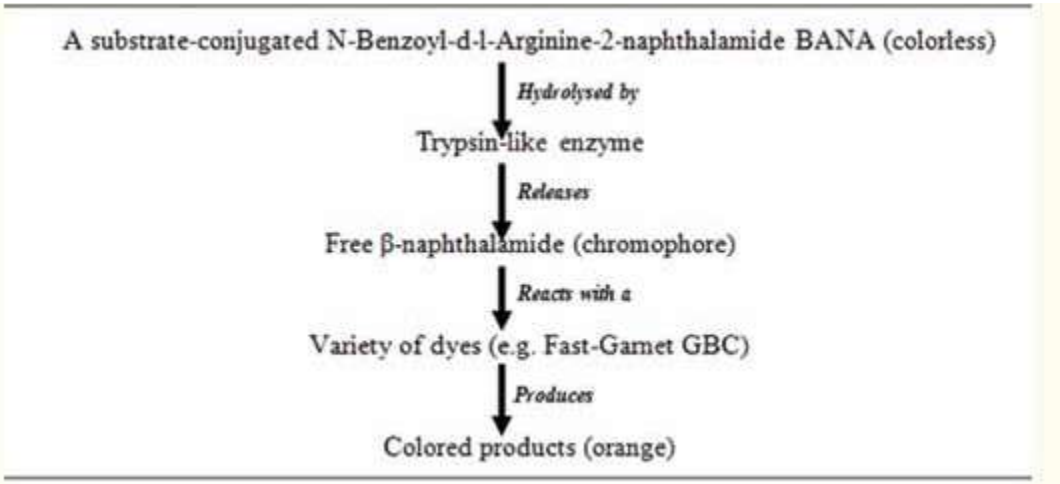

Figure 3: Perioscan

Perio 2000: This chairside diagnostic test is a combination of standard "Michigan O" style probe and advanced ion-selective electrode technology.[13]

It is designed to:

- Assess probing depths
- Assess bleeding on probing (present/absent)
- Assess periodontal pockets for sulfides

The system consists of:

- One time use sulfide containing sensor tips, which can be disposed
- Electronic control unit
- Probe handle, handpiece cable, foot-controlled pedal
- Solution provided to clean the equipment
- A stand
- System check

It can be used for:

- Assessment of patient's oral health status as an adjunct to other measurements
- Supportive periodontal therapy
- At maintenance intervals
- Patient education and motivation.

Biochemical test kits

To monitor health status, disease onset, treatment response or outcome, the molecules which can be most efficiently assessed are the 'biomarkers'.[14]

Biomarkers, present in the saliva or gingival crevicular fluid, can be measured, to monitor periodontal activity, under the following categories:[15]

- Biomarkers to determine the presence or absence of periodontal pathogens.
- Biomarkers for determining gingival and periodontal inflammation
- Biomarkers to determine the host's immune-inflammatory response to certain pathogenic microorganisms; and
- Biomarkers to determine host tissue destruction

Biomarkers may be tested from saliva and gingival crevicular fluid. GCF is the choice of oral fluid for testing as :

- Can be noninvasively collected
- Allows site-specific fic analyses
- Convenient measuring of destructive MMPs, by distinct immunoassays.

Saliva too can be used as it possesses certain advantages[16] :

- Easily accessible
- Noninvasive sampling
- Quick and reliable outcomes
- Consists of diagnostic biomarker molecules in abundance

Biomarkers in gingival crevicular fluid.

Inflammatory and immune products	Bacterial proteases	Host derived enzymes	Tissue breakdown products	Bone specific proteins
Prostaglandin E2 (PGE2)	Alkaline phosphatase	Alkaline phosphatase	Glycosamin oglycan	Pyridinium crosslink urine pyridinoline
Cytokines	Aminopepti dases	β-Glucuroni dase	Hyaluronic acid	Pyridinium cross-link collagen peptide fragment
Antibacterial antibodies	Chondroitin sulphatase	Elastase	Chondroitin-4-sulfate	Tartrate-resistant acid phosphatase
Acute phase proteins	Collagenase	Cathepsins	Chondroitin-6-sulfate	Hydroxyproline
Complement	Fibrinolysin	Serine prote nase (G)	Dermatan sulfate	Galactosyl hydroxylysine
Vasoactive intestinal	Glucosidases	Nonspecific neutral	Hydroxyp roline	Glycosaminog lycans
Peptide		proteinases		
Neurokinin a	Hemolysin	Matrix metalloproteinase-1,3,8,13	Fibronectin fragments	Osteonectin and bone phosphoprotein
Neopterin	Hyaluronidase	Aspartate amino transferase	Connective tissue and bone proteins	osteocalcin
Platelet -activating factor	Phospholipase	Myeloperoxidases	Type I collagen peptides	
	Hydroxyproline	Lactate dehydrogenase	Polypeptide growth factor	

Figure 4: Biomarkers in gingival crevicular fluid

Table Demonstrating the biomarkers present in saliva.

Markers of periodontal soft tissue inflammation	Markers of alveolar bone loss	Collagen breakdown products
Prostaglandin E2	Alkaline phosphatase	Aspartate aminotransferase
β-glucuronidase	Osteoprotegerin	Alanine aminotransferase
IL-1β	Osteocalcin	TIMPs
IL-6	Collagen telopeptidase	MMPs
Tumor necrosis factor-α	Pyridinoline cross-links of type I collagen	α2-macroglobulin
Matrix Metalloproteinase (MMP-8,9 and 13)	RANKL	
	Osteonectin	

Figure 5 Demonstrating the biomarkers present in saliva

Prognos-Stik: It determines increased levels of elastases in GCF. The elevated levels may, hence, indicate the presence of underlying disease.[17]

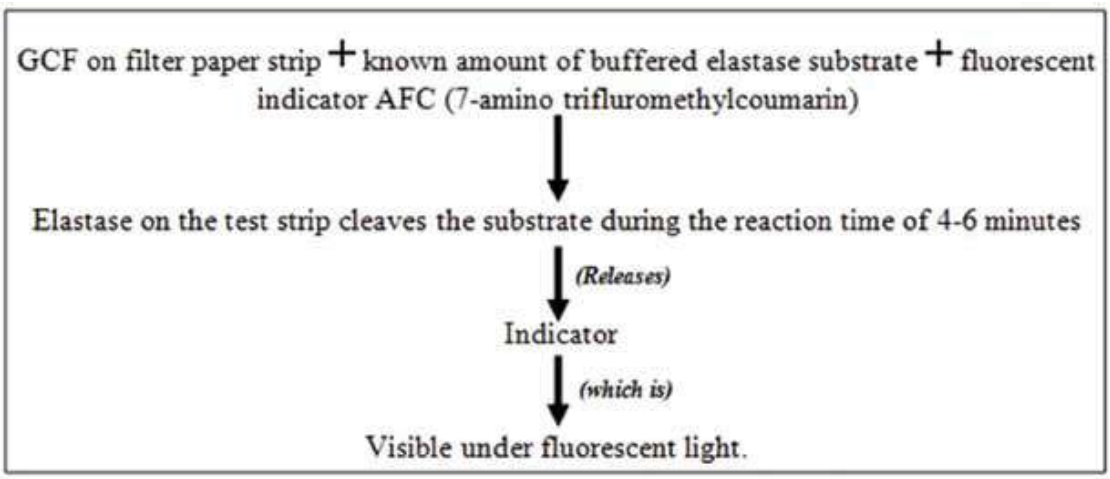

Figure 6: GCF

Periocheck: Periocheck is a chairside diagnostic test to evaluate the presence of neutral proteases. The elevated levels of these enzymes can be correlated to collagen destruction, implying the presence of periodontal disease.[18]

Biolise: Hermann et al. Developed a new test (SLT-Lab Instruments, Crailsheim, Germany) which is used to detect the elastase activity in GCF.[19]

TOPAS (Toxicity Pre Screening Assay): TOPAS is a diagnostic test kit for evaluating the presence of gingival infection, by indirect assessment of bacterial toxins and proteins. The principle for this test is the detection of the metabolic action of these pathogens, in the GCF. The color intensity scale of the test helps to differentiate between an inactive and active periodontal disease, as the degree of color change signifies the level of metabolic activity thereby determining levels of toxins.[20]

Periogard: Aspartate aminotransferase (AST), is a soluble intracellular cytoplasmic enzyme, present in the GCF, which is released as a result of cell death. Periodontal tissue destruction causes cell death. Hence AST becomes a potential marker for the presence of periodontal disease. Periogard is a chairside test to detect this enzyme, and its levels, in the GCF. [21,22]

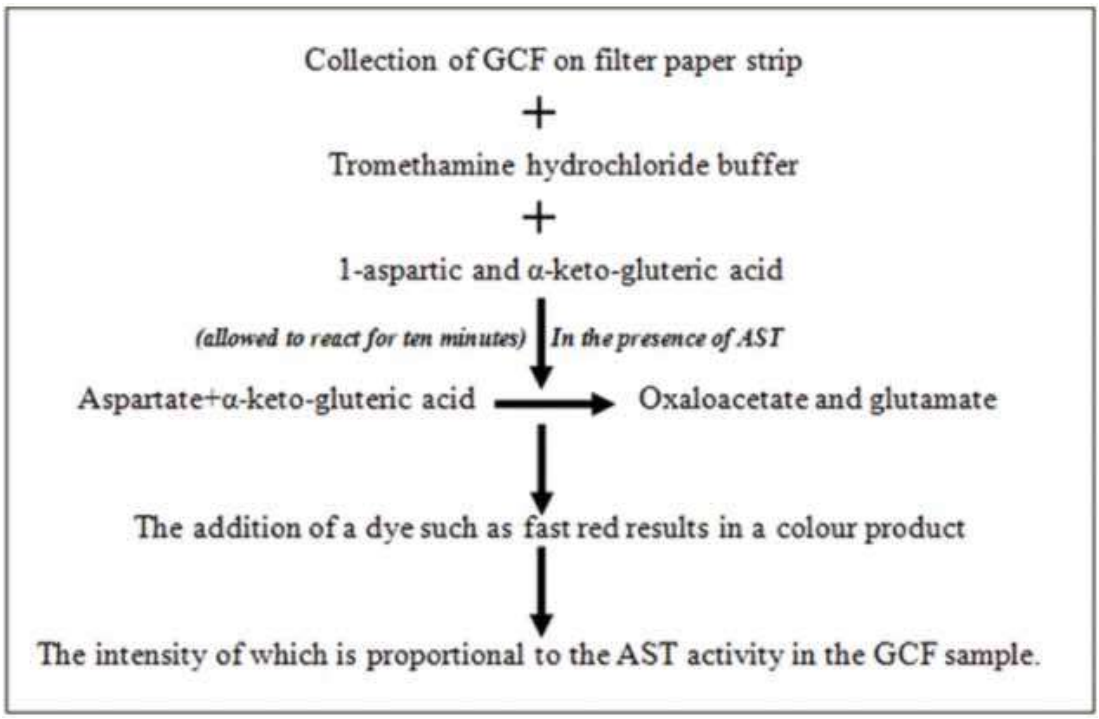

Figure 7: Periogard

Periowatch: The Perio Watch also analyzes aspartate aminotransferase (AST) at the chairside. It is an indicator of cell death, thus implying the severity of periodontal tissue destruction.

Principle: The conversion of cysteine sulfuric acid, belonging to an amino group, to alpha keto-glutaric acid to beta sulfinyl pyruvate, is accelerated by AST in the presence of pyridoxal phosphate. As a result of the instant degradation of β-sulfinyl pyruvate, inorganic sulfite is produced. It reacts with malachite green, thereby producing pink-colored rhodamine B dye. The amount of conversion of malachite green determines the levels of AST.

Oral Fluid Nanosensor Test (OFNASET):

A chairside diagnostic device developed by Dr. David Wong has been developed to detect oral cancer

by assessing the presence of certain biomarkers in the saliva.[23] It detects the following biomarkers (mRNA):

- SAT
- ODZ
- Interleukin 8
- Interleukin 1b

Also detects the following salivary proteomics:

- Thioredoxin
- Interleukin 8

Electronic Taste Chips

A chip-based chairside test which will have the capability to distinguish healthy individuals from the periodontally compromised, based on levels of C-Reactive Protein, is under development. The microspheres containing a sensor-rich platform, present on the interior of this microchip system, will measure analytes, through chemical and immunological reactions.[24]

Oraquick: The first FDA approved the oral swab 'in-home' test which facilitates accurate screening and diagnosis of human immunodeficiency virus infection. It provides results within 20 minutes and is an easy to use stick-like device. On its one end is a fabric swab, which is used to collect the oral fluid and then inserted in the testing liquid to produce results on the device.[3]

Integrated Microfluidic Platform for Oral Diagnostics (IMPOD): It is a rapid chairside device to evaluate the levels of salivary biomarkers as indicators of oral disease. Salivary samples, in small amounts (10ml), can be rapidly analyzed, hands-free, for analyte concentrations and other salivary biomarkers, through electrophoretic immunoassays.[24]

MMP Dipstick Test: It is a chairside diagnostic kit, to detect MMPs, which are host-derived proteinases, to help differentiate between healthy and periodontally compromised individuals.[23]

Genetic Test Kits: Identification of genetic polymorphism, to detect periodontal disease, is now possible due to the availability of certain chairside diagnostic kits. The initiation and progression of periodontal disease is controlled by various genes, whose polymorphism is present as a risk factor for the disease. In 1997, Kornman et al., "found an association between the polymorphism in the genes encoding for interleukin-1α and interleukin-1β and increased severity of periodontitis."

Periodontitis Susceptibility Trait (PST) test: It is the first of its kind chairside diagnostic kit to analyze 2 interleukin genes, IL-1 alpha and IL-1 beta, for mutations. It is highly useful in terms of early diagnosis of periodontal disease as it can differentiate between IL-1 genotypes, which are largely associated with various inflammatory responses.[25]

Principle:

IL-1 gene cluster, according to studies, consists of 2 polymorphisms which possess a close relation to periodontitis. These are:

- IL-1A gene, position -889
- IL-2B, position +3953

They both consist of alleles 1 and 2. Allele 1 carries cytidine and allele 2 carries thymidine at the respective positions. In cases where both genes (IL-1A and IL-2B) carry allele 2, IL-1 inflammatory mediator is released in abundance. The test hence, detects this mutation of allele sequence thereby granting early intervention and prevention of periodontal disease.[20]

Clinically, it is used for the following:

- New periodontal subjects
- To determine prognosis
- As an incentive for smoking cessation.
- Patients on maintenance.
- Specialist referral after detection.

Nucleic Acid Probe: It is a nucleic acid probe assay, developed by Microprobe corporation, to semi-quantitatively detect periodontal pathogens. The plaque samples are collected to test the bacterial load. The lysis of bacterial cells takes place by heating, in the presence of a detergent, to extract their DNA. The DNA thus obtained, is placed into a multi-well cassette, which is then placed in a machine with a programmable robotic arm. Finally, results are obtained digitally.[20]

Conclusion

To plan and treat any disease effectively, an accurate diagnosis is essential. The chairside diagnostic

tests, not only provides rapid, non-invasive and specific prediction of the disease, but also helps in early detection of the disease. As the saying goes, 'Prevention is better than cure', these tests help predict and detect an "active" disease thereby allowing early intervention, better prognosis and more effective treatment plan for the disease. The already available chairside tests help achieve these goals, despite having their limitations. Soon, better, more sensitive test kits shall be available to help diagnose and treat periodontal patients better.

Conflict of Interests: The authors declare they have no conflicts of interest.

A Simplified and Cost-Effective Treatment Approach for Combination Syndrome: A Case Report

M. Krishna[1], Abhijita Mohapatra[2], Gopal Krishna Choudhury[3]

[1]Postgraduate Trainee, [2]Professor, [3]Professor & Head, Department of Prosthodontics, Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Combination syndrome is a dental condition, mostly observed in patients with a completely maxillary edentulous arch and a partially edentulous mandibular arch persisting only the anterior teeth. Specific oral destructive changes are often seen in patients. The manifestation of this syndrome consists of resorption in the anterior maxillary ridge, overgrowth of tuberosities, and supra eruption of mandibular anterior and reduced alveolar ridge height in combination with hypertrophic and atrophic changes in the maxilla and mandible. Complications involved in chewing and mastication are of special apprehension in such a patient. Predictable prognosis can be offered by overdentures. This article attempts to provide a simplified and cost-effective approach to this type of treatment modality by a case report.

Keywords: *Combination syndrome; Cost-effective approach; removable partial dentures.*

Introduction:

The statement by Dr. Muller DeVan "Perpetual preservation of what remains is more important than the meticulous replacement of what is missing" still sounds factual.[3] Overdenture is onesuch preventive treatment modality that helps in delaying the process of resorption thereby improving the denture foundation area, as well as enhancing the masticatory efficiency of the patient. In certain casesof Kennedy's classI and class II rehabilitation of the edentulous space can be challenging where providing a fixed prosthesisis may not be possible due to lack of sufficient amount of bone or cost-effectiveness. The removable partial denture retained with attachments is one of the treatment modalities that can facilitate both functional and aesthetic requirements. Various types of attachment systems are available for tooth-supported overdenture treatment modality. Among various attachments, the Dolder bar and the Hader bar system are the most commonly used attachments for overdentures and implant-retained restorations.[1,2]

All the attachment systems intent to provide better retention and support for the overdentures. In the case of mandibular overdenture the retention can be profoundly achieved by thesupport of natural tooth retained with bar or stud provided in the anterior region. But the disadvantage of these extracoronal attachments bar systems is that they are expensive. The concept of conventional tooth-retained overdenture is proved to be one of the simple and cost-effective treatment modality in comparison to the complex implant-supported overdentures. Bar attachments are more advantageous over other types owing to its splinting effect on the abutment teeth while eliminating the need for parallel abutments and guiding the prosthesis in place. So, bar-retained overdentures are the choices of treatment for most of the clinicians, but the only obstacle is its cost, leading to the constant need for technical innovations to better the existing modalities in terms of their availability and expense.

In the past, custom made header bars using plastic straws and custom made clips using gold alloys have been tried in an endeavor to avoid the costlier.

The present article demarcates some of the necessary considerations in the treatment planning of a typical case of combination syndrome. Along with which the clinical report describes the complete treatment procedure for the patient, in which the mandibular tooth-borne overdenture is fabricated with a customized hader bar, customized clip and a metal base maxillary complete denture for better durability and proprioception. In consideration of periodontal health of remaining teeth and ridge form, overdenture with the hader bar attachment was planned. Customized hader bar and clip attachment was attempted owing to his financial constraints.

Case report: A 54-year-old male reported to the Department of Prosthodontics, Institute of dental sciences, Bhubaneswar, complaining of missing teeth and inability in mastication. Themedical history of the patient was evaluated which was found to be of non-contributory. On intraoral examination it was observed that he had a completely edentulous maxilla with enlarged tuberosities with to some extent a resorbed anterior maxillary arch and a partially edentulous mandible with Kennedy's type II modification 1 comprising of supraerrupted existing teeth i.e. 33,34,43,44 are presentbilaterally. (Figure.1) The patientreported the extraction of lateral incisors bilaterally 3weeks back. The patient gave ahistory of teeth loss since 5years due to multiple caries and periodontal problems. On radiographical examination of abutment teeth were found periodontally compromised.Onthe evaluation of the patient's existing clinical condition, it was planned to construct maxillary metal base complete denture and mandibular tooth retained overdenture with an extracoronal attachment. The patient was unwilling for the options of implants because of the need for economic constraints, additional surgery and the unacceptable duration of treatment phase.

Technique: After oral examination the impressions were made and the casts were retrieved which were used for the assessment of the inter-arch distance. A tentative jaw relation was recorded and the casts were mounted on an articulator.[1] In the present case, a sufficient space was found to be there to accommodate bar supported overdenture,which facilitated to fabricate a customized metal-based complete denture for maxilla along with the bar attachment overdenture for the mandibular arch.

The metal palate was customized in such a way that the metal loops were fabricated in a specific orientation and positioned upon the crest of the ridgeproviding an interlocking mechanism for the acrylic, without creating any interference for the arrangement of artificial teeth. The primary impression of the maxilla was made with impression-compound, custom tray was made with auto polymerizing resin. Border molding was done followed by a secondary impression with zinc oxide eugenol which was poured with dental stone (typeIII). The final cast was retrieved from the impression and was duplicated to make a refractory cast (Figure 2a). The customization of this metal palate was carried out on this refractory cast.

Spacerwax was adapted over the palate that extends 2-3 mm beyond the crest of the ridge. 2-3 mm long loops were made up of wax were attached to the margins of the adapted palatal wax. It was made sure that all the loops should be 3-4 mm short from the sulcus area.[4] The main function of these loops is to enhance the mechanical interlocking of acrylic to the metal base. This holds an importance that the loops should not be interfering with the acrylic border of the denture that extends to the sulcus. Towards the palatal side tiny loops were made palatal to the crest of the ridge. The loops were placed in such a way that it would not impede with the artificial teeth arrangement, and help in the flow of acrylic resin (Figure 2b). After the designing of the palate, wax sprues were attached,invested followed by casting. Following the casting and finishing of the metal base(Figure 2c), it was incorporated into the heat cure acrylic denture base. Later the occlusal rims were fabricated upon it.

For the mandibular arch, Root canal treatment was performed and post space was prepared in 33,34,43 & 44, keeping both the preparations parallel to each other so that a common path of insertion could be accomplished. Tooth preparation was carried out on both mandibular canines and right mandibular 1st premolar with a heavy chamfer finish line, which resulted in the optimal crown–root ratio and adequate clearance for overdenture prosthesis.[3] An impression was made and poured with dental stone type II, upon which a custom tray was fabricated. Border molding was carried out using a green stick compound in the custom tray. Impression of post space and the mandibular ridge was made with polyvinyl siloxane as illustrated mandibular final impression that was made with polyvinyl siloxane impression material and it was poured into dental die stone. On the master cast, the pattern for the post was prepared using pattern resin and the coping was made over it using pattern wax.[5]

The wax pattern for the copings was made and a toothpick was shaped and was attached to the wax

patterns splinting the right and left abutment teeth to obtain more stability.[5]Bar framework with metal housing mold was invested, burned-out and cast according to the manufacturer's instructions.[7]

The whole assembly was invested, burnout and cast in cobalt-chromium alloy, finished and polished. The casting was checked for a passive fit inside the patient's mouth.[2] After the metal try-in, the bars, with their respective copings, were again placed intraorally and checked. After this step, the bar, along with the metal copings, were luted onto the respective preparations and the respective tooth preparations with the help of glass ionomer cement and the undersurface of the barwas blocked (Figure 2d). The whole assembly was duplicated with the elastomeric impression material and was poured (Figure 2e). The remainder of the procedures up to try-in was carried out as the conventional method for complete denture (Figure 2f). After the fabrication of the mandibular overdenture, the inner surface at the site of the bar was trimmed about 1mm to make space for the custom clip (Figure 2g).

Later, the custom made plastic clip was placed on the cast bar in the patient's mouth and a pickup of the clip with soft relining material was done with the processed denture. The self-cure acrylic resin was replaced only on the crest of the clip and relining material didn't cover the intaglio surface of the clip.

Following the maxillomandibular relations, records were obtained from the patient, the cast was mounted on the articulator, teeth arrangement was done for both maxillary metallic denture and the mandibular bar-retained over denture and the try-in was performed, followed by acrylization (Figure 2h, 3, 4). The patient was instructed with the method of wearing and removing the dentures. Post insertion followup was done within an interval of 1 to 2 weeks. After a follow-up of about 6 months, the patient reported better improvements in symptoms which he had previously mentioned (Figure 5).

Discussion

Various extracoronal attachment systems that are easily available in the market are used for the fabrication of overdenture. Among all, dolder and hader bars are the most commonly used extraoral attachment systems for the overdentures.[7] Overdenture with attachments can redirect the occlusal forces away from the weak supporting abutment teeth and onto a soft tissue or redirect them toward stronger abutments thereby resulting in superior retention. Bar exhibits more cross-arch involvement and allows occlusal forces to be shared between the abutments.[3] The bar attachment provides a slight amount of vertical as well as rotational movement of the denture which almost acts as a stress breaker.[7]

This case involved the preservation of two canines and one premolar for mandibular overdenture in providing support, retention, stability and comfort superior to that of a conventional complete mandibular denture. In this clinical case, the mandibular anterior ridge allowed an easy fabrication of the bar joint. In this case metal bar was used as a male component splinting the abutments with a female component that has been embedded in the tissue surface of the denture base by following the indirect technique.[4]The splinting somehow reduces the torquing of the remaining root structure. There are several advantages to this procedure – ease of incorporation of clip attached to the metal superstructure helps in providing accurate fit and thus minimizing the damage to the definitive prosthesis, thereby providing adequate strength.[8] The retention clips can be easily replaced, further relining and repairing would not compromise or risk the fracture of the dentures.[3] The only disadvantage of the technique includes the extra steps during fabrication and limited applicability in patients with reduced interarch space. It is the most acceptable treatment for those who cannot afford the high implant cost and also those who are medically unfit to undergo surgery. The tooth-supported overdenture forefront the preventive prosthodontic modalities; this requires more innovation to make it the most beneficial and economical regular clinical practice.

For the maxilla, metal-based dentures were fabricated as a treatment option as it has advantages such as its adequate strength, better adaptation to the supporting tissues, enhanced plaque control, good thermal conductivity, minimal dimensional changes, and absence of interference to phonetics due to light-weight. Whereas only disadvantage associated with these dentures is difficulty in fabrication. Nevertheless; they may be indicated when polymer-based systems fail to provide acceptable physical properties.[9, 10]

Summary: To overcome the sequential destructive changes of the combination syndrome the prosthodontist

try certain treatment planning which may require a multidisciplinary approach, keeping in mind the functional, esthetic and economic requirement of the patients.In underdeveloped or developing economies, where the patient's willingness to pay is very low, the clinicians must utilize their knowledge to make sophisticated systems more economical.[10]

Conclusion

Therefore, this article presents a case report for a patient with combination syndrome that was treated with a significant treatment planning in a cost-effective method. The objective of these removable partial dentures is retention, stability, support and esthetics. The above-described method is a cost-effective technique and fulfills all the objectives.

Platelet Rich Fibrin in Socket Preservation

Monalisha Mohapatra

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

With the advancement in dentistry, there are different ways of treatment such as restoration, surgical procedures as well as aesthetic treatments socket healing after extraction comprises of hard tissue as well as soft tissue reconstruction with changes which is maximum dimensionally during the initial three months. One of the major challenges in clinical science is the development of bioactive surgical additives to improve the pace of the process of healing and inflammation control. Platelet-rich fibrin (PRF) exists in this context as a safe and adequate substitute with less risk and favourable outcomes. The methodology of use of PRF, concentration on its planning advantages and drawbacks of use in clinical applications are summarized in the following review. Platelet-rich fibrin (PRF) was developed in France first as a beneficial substitute to platelet-rich plasma to overcome its limitations.

Keywords: *Platelet-rich fibrin, socket healing, dentistry*

Introduction

There are diverse types of restorative, aesthetic and surgical procedures in today's world of advanced dentistry. Tooth extraction is a common dental procedure in the manner of decay, complicated fractures, infections and development of orthodontic spaces. Physiological healing of the post-extraction socket requires a complex pro -stop migration and maturation of bone cells leading to selective bone resorption and application. The most important factor is the preservation during routine extraction process of the residual ridge failure of which frequently leads to the compromise of potential implant placement and future recovery.[1] Post extraction cases results in the residual alveolar ridge having a dimensionally less in both vertical as well as horizontal axis. Several techniques are used to avoid loss of bone post-extraction and repetitive post-extraction placement of implant which includes preservation of socket with grafts and placement of implants immediately.[2]

Clinical practitioners have a range of graft materials to select from. Some of which need a longer period to heal when introduced even a little amount of new bone into the site of the graft. Biomaterial socket preservation was suggested and platelet-rich plasma with growth factors and platelet-rich fibrin (PRF) is used. A second generation of autologous growth factors that is PRF promotes healing and id suggested to be correlated with an efficient and early formation of the percentage of bone substance and volume of bone. A Leukocyte platelet concentrate thick fibrin matrix called PRF can be easily made with autogenous and non-coagulated blood when centrifuged.[3]

History: In 1970s platelets regenerative capacity was discovered. It stated that they produce growth factors culpable for raising the development of collagen, improvement of blood vessels, mitosis of a cell, mobilization of certain cells to the injury site and cell division activation. For in vivo tissue engineering utilization some of the new advances in the usage of concentrates of platelet in oral surgery are:

PRP - Platelet-rich plasma

PRF – Platelet-rich fibrin

As bioactive surgical agents used locally to promote healing of wound are a combined suspension of growth factor present in platelet called platelet concentrates. The usage of platelet-rich plasma in oral surgery was first promoted by Whitman et al [3] in 1997 with important benefits as osteoprogenitor cells in bone graft and host bone was stimulated by it. But, the development of antibodies to factor V, XI and thrombin was a possibility though, as bovine thrombin was used to treat PRP which may induce coagulopathies that may hazard life. On the other side, by Choukroun et al [4] primarily in oral and maxillofacial surgery,PRF was used in 2001 and is generally known to be a modern type of platelet concentrate. It has many benefits over PRP as it consists of an autologous fibrin matrix [5] including simplex processing and doesnot involve chemical stimulation of the blood so, it is purely autologous.[1-5]

Drawbacks of PRP: Several drawbacks of PRP was reported soon after its success in the initial years of its use. The procedure of preparation was very lengthy and hence to prevent clotting anticoagulants such as $CaCl_2$ or bovine thrombin was used. these materials are known for the inhibition of wound healing. Due to lengthy procedures, the oral and maxillofacial surgeons started avoiding the use of PRP. Another limitation was that it was liquid. So bone grafts of various origin were required to be combined with PRP. In 2006 Choukroun and his fellow workers tried to develop a PRP preparation simplifying method and elimination of xenofactors which lead to the development of second-generation platelet-derived material called platelet-rich fibrin (PRF).[6]

Types of PRF: Recently to get different ratios within the fibrin matrix different types of techniques using blood concentrates have been developed. According to a recent study, particular cell types are differently distributed based on the centrifugal force.

A. A modification was done in PRF by Choukroun to get – A –PRF (leucocyte enriched, advance type) and I – PRF (injectable type)

B. Pure platelet-rich fibrin (P-PRF) – It is a solid material and has no leukocyte

C. Titanium PRF(T-PRF) – It has a superiorly organised fibrin network with continuous integrity

PRFand its different uses in dentistry

- Sinus lift
- Socket preservation
- Guided bone and tissue regeneration
- Regeneration of periodontium
- Regenerative endodontics

Disadvantage of PRF: Proper handling of blood while its collection and its transfer to the centrifuge is the important factor for the success of PRF. Some patient might refuse to the procedure as it requires an invasive procedure to collect the blood sample. The resultant amount is very less as it is autologous blood.[7]

Advantages of PRF: PRF helps in soft tissue repair that protects the surgical site and accelerates wound healing, when bone graft is mixed to PRF it acts as a biological connector. Osteoprogenitor cells and stem cells are attracted to the centre of the graft. In the elderly patients where regeneration of bine is required PRF helps in implant rehabilitation. Tissue regeneration is stimulated by PRF as it contains the framework of natural fibrins containing growth factors. It is easy and simple in technique for preparation with the help of centrifugation and is easy for all clinicians to access. [8]

Preparation of PRF: The appropriate blood quantity is drawn from the patient into the test tube from the antecubital vein by venous puncture which is held without an anticoagulant. The centrifugal machine is used to centrifuge the blood at 3000rpm for 10minutes. There is a development of fibrin clot of platelets situated in the middle of the channel. It is mainly concentrated between the bottom red layer of the blood cells and top layer of the acellular plasma with the help of a sterilised tweezer the formed clot is separated from the test tube, then the placement of the PRF clot is done on the PRF box grid and with the compressor and lid, it is covered. This leads to the formation of autogenous fibrin membrane.[9]

Role of prf in healing of wound

(1) Ambushment of blood cells circulating in the blood.

(2) Neoangiogenesis

(3) At the site of wound healing, there is a continuous release of growth factor.

(4) Osteoblast and Fibroblast generation.

(5) Promotes collagen production.

(6) Accompanies wound analysis.

(7) Adherence of fibrin mechanically.

(8) Supervision of immunity.

Clinical Procedure: Buccal and lingual/palatal infiltration of anaesthesia of Lidocaine Hcl 2% with epinephrine 1:100000 is given. Extraction is done with least injury and avoiding the raising of flap. The dilation of the socket is done by the help of the periotomesby placing them aroundthe root. The removal of the tooth is done using the forcepswith the placement of PRF the extraction site is treated immediately followed by application of pressure and suturing with figure 8 . Post extraction instruction is given. [10]

Discussion

Number of Histological studies and experiments have been carried out on tooth socket healing but radiological studies are very less . A platelet concentrate assembled on a single fibrin membrane containing all the desirable healing elements is called as PRF. Platelet act as a source of many growth factors which play an important role in healing of hard tissue and soft tissue thus platelet preparations are done. Neoangiogenesis is promoted by human osteoblasts which is due to PRF.[7]PRF acts as a matrix to promote the healing of wound edges when used as a fibrin bandage in a membrane shape. The preparation of the chairside is quite inexpensive, easy and the process is simplified and fast. When the socket is filled with PRF. Neovasculization occurs and epithelial covering forms. Healing processes of extraction socket occurs concurrently with an amount of latency that contains both hard and soft tissue. The clot retracts and breaks down towards the end of the 1st week and is replaced by granulation tissue. The higher part of the alveolar bone ridge is covered by granulation tissue and the soft tissue cut edges are covered by epithelium. PRF which is formed naturally has a complex and dense structure that has both leukocytes and platelets.[8-10]

Conclusion

The amount of bone regeneration which is seen with the use of PRF is more appreciable as compared to the cases treated without PRF use. For the preservation of socket and rehabilitation,PRF is an inexpensive material and can be easily used. Minimal invasion, patient discomfort as well as expertise of the operator is required to conduct this procedure when compared to other processes that include bone grafting.

Soft Tissue Calcifications in the Orofacial Region

Monalisa Muduli,

Intern, Institute of Dental Science, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003,Odisha, India

Abstract

The main purpose of this article is to present a review of soft tissue calcification in Orofacial region. It can be systemically evaluated by using a simple algorithm based on the detailed clinical information and distribution pattern of these calcified lesions. The calcification of soft tissues belongs to a large group of lesions. Radiologists often detect calcifications in their daily work. For dental practitioners, this review should be of interest in encountering the soft tissue calcification in the orofacial region.

Keywords: *Soft tissue, Calcification, Orofacial, lesions.*

Introduction

Calcification of soft tissues in the orofacial area is unusual and is typically asymptomatic. Deposition of calcium salts in tissues other than osteoid or enamel is called pathologic or heterotrophic calcification. It occurs in an unorganized fashion in soft tissue. Three distinct types of heterotrophic calcification are recognized. They are dystrophic calcification, idiopathic calcification and metastatic calcification.[1]

Dystrophic calcification is the deposition of calcium salts, given normal calcium and phosphate levels, into the chief sites of long-standing inflammation and dying tissues. Examples are pulp stone, calcified lymphnodes, cysticercosis, arterial calcification. Idiopathic calcification results from calcium accumulation in human tissue given the regular calcium and phosphate levels in the serum. Examples are sialoliths, phleboliths, laryngeal cartilage calcification, antrolith/rhinolith. Metastatic calcification occurs when minerals accumulate, higher than usual serum levels of calcium and phosphate into the normal tissue. Examples are ossification of the styloid ligament, osteoma cutis and myositis ossificans.[2]

Pulp stone: Foci of calcification within the pulp chamberor root canalor reaching from pulp chamber into root canals without regularstructure or number. Asymptomatic in nature. Can occur as a result of increase in age or specific pathology. Often arises once the development of the tooth has been finished. Its histological types are true pulp stone, false pulp stone, free pulp stone, free pulp stone, attached pulp stone, embedded pulp stone. True pulp stone is composed of dentinal tubules. False pulp stones contain concentricalcalcified circles. Free pulp stones are freely placed inside the pulp tissue.Theattached pulp stone adheres to the surface of the dentin. Embedded pulp stone are covered by secondary dentin.[3]

Calcified lymphnodes: Calcification occurs in lymphnodes that have been chronically inflamed with often granulomatous disorders due to numerous diseases. Hydroxyapatite-like calcium salts takes the place of the lymphoid tissue,nearly obliterating all the nodal construction. The common disease that cause calcified lymphnodes are scrofula, sarcoidosis, catscratch disease, rheumatoid arthritis, lymphoma dealt with radiation treatment beforehand, systemic, sclerosis,infection by fungus, metastasis from specific neoplasm calcification.[4]

Calcified lymphnodes are asymptomatic, rigid, flabby, mobile and round to oval-shaped masses when

palpated. Submandibular and cervical nodes (superficial and deep) are the most frequently affected nodes and less frequently the pre-auricular and submental nodes. The most frequent location is the submandibular area,between the posterior border of the ramus and cervical spine, and at or under the lower border of the mandible at just the angle. The node calcification may be single or a series of nodes called lymphnode chaining. The periphery may be well-defined, irregular and sometimes may even have a lobulated shape identical to the external cauliflower form, radiographically. The inner core can differ in the level of radiopacity, creating the appearance of rounded or uneven mass collection called eggshell calcification.[5]

Tonsillolith: Typically,they are rigid, circular, yellow or white structures projected from the tonsillar crypts. Prevalent in the older age group. The small calculi may not produce any signs or symptoms. In the case of larger calcifications, pain, swelling, fetor orisswallowing disorders and a foreign object discomfort on swallowing has been identified. In rare cases, they may be giant tonsilloliths, which stretch the lymphoid tissue, resulting in ulcerations and extrusions. They show on the panoramic view as single or multiple radiopacities which cross the middle section of the mandibular ramus.[6]

Cysticercosis: If pork tapeworm eggs are consumed by humans their coating is digested in the stomach and the larvae are hatched. Such larvae cross the mucous membrane,enter the blood and lymph vessels and are circulated in the tissues all around the body, but selectively associate to the skin, heart, muscle and brain. These are also present in oral and perioral tissue, particularly the muscles of mastication. When the larvae die, they are regarded as foreign bodies producing granuloma growth, bruising and calcification, this takes on average three months. Such sites in the tissueare termed cysticerci. Examination of the area of the head and neck may show palpable delicate fluctuating swelling, well-circumscribed. Symptoms usually seen are gastrointestinal discomfort, epigastric pain, extreme nausea, vomiting, seizures, headache, visual disturbances and irritability. They appear as multiple, well-defined elliptical, homogenous radiopacities which resemble grains of rice.[7]

Arterial calcification: Monckerberg's medial calcinosis (arteriosclerosis) and calcified atherosclerotic plaque are two different patterns of arterial calcifications. Arteriosclerosis is characterized by the breakdown,degeneration and subsequent loss of elastic fibre accompanied by calcium accumulation inside the vessel's medial cover. Often patient is first symptomless,but eventually they may develop cutaneous gangrene, peripheral vascular disease and myositis due to vascular disease and myositis due to vascular insufficiency. Patientwith Sturge-weber syndrome alsoexperience intracranial calcification of the arteries. On panoramic radiographs, seen as involving the facial or the carotid artery. Tram track appearance is seen from the side, seem as a parallel pair of slender, radiopaque rows that can be straight or tortuous.[8]

Calcified atherosclerotic plaque is located in the extracranial carotid vascular system and is a main leading factor of cerebrovascular embolic and occlusive disease. This first occurs as a result of enhanced endothelium destruction at certain locations at the arterial bifurcation. On a panoramic radiograph, the calcificationis visible in the neck located close to the greater cornu of the hyoid bone and the cervical vertebrae C3, C4 or the intervertebral gap between them, which are numerous and irregular in shape.[9]

Sialolith: Sialolithiasisis the development of calcified blockagein the salivary duct that contributes to persistent retrograde infection because of a decreased salivary flow. This is usual in middle-aged person with mild predilection for men. The Wharton's duct and the submandibular gland are mostly involved followed by the parotid and sublingual glands. Discomfort may intensify at mealtimes, when the salivary flow is stimulated. Non-calcified stones are diagnosed with sialogram. On routine plain films, it shows laminated appearance because of multiple layers of calcification.[10]

Phleboliths: In the head and neck area, phlebolithsoften suggest the existence of ahemangioma, in which the calcified thrombi contained invenulae, veins or the sinusoidal vessels. The associated soft tissue could be swollen, throbbing or discoloured by the involvement of veins or a soft tissue hemangioma, that frequently vary in size, along with the changein body posture or during a Valsalva manoeuvre. On application of pressure change in colour or blanching is seen. A radiolucent centre with appearance of lamination around its pattern is seen, hence called a target or bull's eye appearance. [11]

Laryngeal cartilage calcification: Thyroid and tristichouscartilagecomprises of cartilage of hyalin,

that tends to calcify with age. The calcified tracheal cartilages usually present a homogenous radiopacity, with an occasional outer cortex and they are generally asymptomatic. [12]

Rhyolith/Antrolith: In case of rhinolith the nidus is normally a foreign exogenous body. Whereas the nidus for an antrolith is usually endogenous. Hard calcified bodies those appear in the nostrils are called rhinolithand when in the antrum is called antrolith. Initially, the patient may be asymptomatic. When increase in size it impinges the mucosa, producing pain, congestion and ulceration. The patient may develop facial pain, fever, fetor, anosmia, nasal obstruction, epistaxis, headache, sinusitis, purulent rhinorrhea. They may be homogenous or heterogeneousradiopacity, based on the formof the nidus and occasionally has laminations.[13]

Ossification of styloidligament: Styloid ligament ossification generally progresses downwards from the base of the skull and usually develops bilaterally. The associated conditions are eagle's syndrome, styloid syndrome and styloid chain ossification. Most common signs and symptoms seen are throat pain, fishbone stuck in the throat, pain on swallowing, referred pain to the ear of the affected side, tinnitus, pain in anterior cervical triangle, pain on turning head, headache in the orbital area and cervical pain. In the panoramic image, it is seen as a linear, elongated, tapering, slenderradiopaque process that is wider at the base, extending from the area of the mastoid process and passing into theposteroinferiorpart of ramus in direction of hyoid bone.[14]

Osteoma cutis: Those are regular bone-forming areas in unusual sites. In a scar or long-standing inflammatory dermatosis, it can grow secondary to long-term acne. Histologically, those are seen as regions in the dermis or subcutaneous tissue of compact viable bone. Extraorally it may occur on the face in the cheek and lip region and intraorally it may occur on the tongue, where it may be calledosseous choristoma or osteoma mucosae. This induces no noticeable changes in the overlying skin, except in some areas, where the colour may change to yellowish-white. It varies in size from 0.1mm to 5cm. The particular osteoma can be palpable. Normally when a needle is injected through one of the papules experiences rock like obstruction. It is seen as finely outlined, washer-shaped images and single or multiple radiopacities of various sizes. Radiographically, it appears as a homogenous radiopacity with a radiolucent core which reflects natural fatty marrow, making the lesion to resemble a doughnut. Trabeculae typically grow in the marrow cavity of a bigger osteoma. Calcified cystic acne lesionmimic a snowflake radiopaque view that relates to a scar's clinical position.[1, 3]

Myositis ossificans: In this case, the fibrous tissuesand heterotopicbones in the interstitial tissues of the muscles and relatedtendon and ligament. There is secondary damage and atrophy of muscles. It is of two types, localised myositisossificans and progressive myositis ossificans. Localised myositis ossificanshappens due to acute or long-terminjury, tough strain in muscle and muscle injury that can result in haemorrhageinthe muscles or related tendon or fascia. During the healing process, heterotopic bone and in some cases cartilage is formed. The commonly involved oral sites are the masseter, sternocleidomastoid and lateral pterygoid muscle. The location of the precipitating injury stays tender, painful and swollenfor a long time. Due to the inflammation, the skin appears red. If there is an involvement of muscles of mastication in the lesion then the opening of the mouth will be a discomfort. The region of ossification can become evident only after 2-3 weeks as a solid, intra-muscular palpable mass that gradually expands and finally stops increasing. The lesion might be fixed or on palpation could be easily moveable. Most frequently involved muscles of the neck and head region are masseter and sternocleidomastoid. Radiographically, a radiolucent band could typically be seen between the ossification region and correspondingbone and the heterotopic bone can lie along the muscle'slong axis. Masses generally measure less than 6cm in greatest dimension. Generally, the exterior is more radiopaque than that of the inner structure. Pseudotrabeculae can be seen from irregular oval to straight lines going in the same direction as normal muscle fibres because of the shape variability.[2]

Progressive myositis ossificansgenerally affects children younger than 6 years and occasionally as early in childhood. Progressive heterotopic bone developmenttakes place inside the interstitial tissue of ligament, tendon,fasciaand muscle atrophies. This condition may be inherited or maybe a spontaneous mutation affecting the mesenchyme. It begins in the neck and upper back muscleand passes to the extremities. It begins as a tender and painful soft tissue swelling which could cause redness and heat including the appearanceof inflammation. As the severe symptoms disappear that tissue remains strong in density. Later phases of the same disorder give the petrified man like look.

Radiographic appearance is similar to that of localised myositis ossificans. The boneset down will not possess natural bone structure.[1-4]

Conclusion

The calcification of soft tissues belongs to a large group of lesions. Radiologists often detect calcifications in their daily work. For dental practitioners, this review should be of interest in encountering the soft tissue calcification in the orofacial region.

Abstract

For a desired osseointegration to take place, implant stability plays an expository role. Hence to achieve a functional dental implant, successful osseointegration is a necessity. The two major factors affect the survival of implants that is the stability of the implant during placement and the event of osseointegration. Two separate phases determine the stability of implant: Primary implant stability as well as secondary implant stability. Mechanical grip withthe cortical bone determines the primary stability whereas Secondary stability is due to regeneration as well asremodelling of the surrounding bone and surrounding tissue around the implant after loading. Implant stability is a mechanical phenomenon which is in association with local factors such as quality of bone, type of placement technique used, quantity and the type of implant used. It is considered highly advisable for implementation of a user-friendly, non-invasive, clinically reliable method to assess the stability of the implant and the osseointegration process. Resonance frequency analysis (RFA) is one of the method thats how almost perfect consistency after statistical analysis. Therefore, the focus of this currentre view article is particularly on presently used RFA method which are highly followed in the current times to elicit oral implant stability.

Keywords: *Resonance Frequency Analysis, Implant stability, Implant survival, Osseointegration.*

Introduction

Osseointegration is defined as "the direct, functional, and structural contact between live bone and the surface of a functionally loaded implant. This was evinced by Branmarket al. in 1969. Modern dentistry aims at restoring the function, comfort, and aesthetics of the missing tooth. The success of a dental implant depends on its ability to osseointegrate with surrounding bone[1]. Within the clinical perspective, quantification of successful osseointegration is based on the implant stability.[1-3] Stability of implants is of 2 various types: Primary implant stability and secondary implant stability.[4] Primary implant stability is a component of quality of nearby bone and amount, the morphology of an implant (i.e. length, width and sort), and the installation technique utilized (connection between drill size and implant estimate, whether a pre-taped or self-tapped implant is utilized[5]. Secondary implant stability is the eventual result of regeneration as well as remodelling of the tissue and bone surrounding the implant. Primary stability determines the secondary stability, which dictates the time of functional loading. Condition of the surrounding tissues also influences the extent of implant stability. Hence, it is necessary to be able to evaluate implant stability at different time intervals to reckon a long term prognosis.

Method to assess oral implant stability: It is sometimes intricating to assess the stability of the implant because of the diverse nature of the implant's surrounding bone tissue and the phenomenon of osseointegration. In vivo, there are various method to gauge implant stability. However, for many surgeons, proprioception is the only thing they count on because of the difficulty to monitor in vivo healing of bone. To reduce the vulnerability of failure of the implant, precise quantitative measurements are needed to guide the operators.

Invasive/Destructive Method[4]

- Histologic/histomorphologic analysis
- Tensional test
- Push-out/pull-out test and
- Removal torque analysis

Non-invasive/non-destructive method[6]

- The surgeon's perception
- Radiographical analysis/imaging techniques
- Cutting torque resistance (for primary stability)
- Insertion torque measurement
- Reverse torque
- Seating torque test
- Modal analysis and Implatest
- Percussion test
- Pulsed oscillation waveform (POWF)
- Periotest
- Resonance frequency analysis (RFA): Electronic technology
- Magnetic technology

Resonance frequency analysis (RFA): Among all the method, RFA is one such method which is used most frequently. Meredith et al. in 1996 were the first to portray the RFA strategy, which is commercially available as Osstell, Implomates, and Penguin[4]. It is a diagnostic method which is nonintrusive while measuring bone density and implant stability at disparate time points using vibration and structural principle analysis[7].

To elicit implant stability two commercial devices have been generated. The original method i.e. electrical method utilizes direct wire connection betwixt the transducer as well as the resonance frequency analyzer. However, the second method used utilizes magnetic frequencies[7].

Within the electronic device, the transducer is anL shaped cantilever beam connecting like a screw attachment with the implant. The L beam has a vertical segment that posses a piezoelectrical crystal which lowers the implant/transducer complex. The opposite side, comparably has a piezoelectric crystal, similarly, on the opposite side of the beam second piezoelectric crystal discerns the beam's response.

Recently a new device with magnetic RFA has been introduced which has a metallic rod with a magnet on top, which is screwed onto an implant or abutment and a transducer. In this, magnetic pulse from a wireless probes stimulates the magnet. 1millisecond is the pulse duration. The peg vibrates unconfined after stimulation, and electric voltage present inthe probe coil is effectuated by the magnet. The voltage thus producedis the signal measured as well as sampled by the resonance frequency analyzer. Both the method that is electronic and magnetic method measure similar changes,but the magnetic device provides higher implant stability quotient (ISQ) value while measuring the stability of non-submerged dental implant[7].

Four generations of RFA have been introduced so far. The first-generation device was based on a measuring element transducer placed on implant/abutment and then connectedto a measuring unit with a wire. The second-generation device analyses frequency response utilizing the magnetic technology. The third-generation device was designed to overcome drawbacks of first- and second-generation. The third-generation system runs by a small battery system. This is helpful in swift as well as steady and chair side interpretation.[8, 9]

The first commercially available RFA equipment is Osstell™, followed by Osstell AB, then Osstell Mentor and Osstell ISQ, being the latest version, which utilizes a smart peg and a wireless probe attached to the device. A small magnet is attached at the top of the smart peg-top.To excite this, magnetic pulses are generated from a probe. The activated peg induces electric volt into a probe that is sampled by the magnetic RFA device[9]. Implant stability was determined under various surrounding bone conditions by Feng et al. and concluded that to elicit the implant stability during different healing phase,it can act as a non-invasive diagnostic tool.

For quantification of accuracy of prognosis of RFA measurements, clinical trials were carried out which determined the failure risk prediction's optimal threshold value. RFA value is just an indication that the implant inserted is stable clinically but may provide false assurance in considering immediate restoration of the implant. RFA as a prognostic tool, has a low sensitivity, before immediate loading,a combination of clinical parameters,radiographic evaluation should be taken into consideration.

Implant stability using Ostell: RFA evaluates the Stability of implant by quantifying the frequency of oscillations done by the implant on bone. Meredith et al. 1998 described the non-invasive method of assessing implant stability utilizing the RFA device OSSTELL. Sweden's Integration Diagnostics Ltd has been designing OSSTELL devices since the year 1999. These devices have developed with time with, improved generation of measuring the implant stability, these are, OSSTELL™, OSSTELL ISQ and OSSTELL Mentor[9].

This technique utilizes a piezoelectric transducer and is a diagnostic technique, which is non-invasive. It has sinusoidal signals which are projected in a limited frequency and the implant vibrates within this frequency. Resistance produced by the implant to this vibration is quantified and converted to ISQ values by this device. ISQis measured on a scale within 0–100, 100 being themaximum, and 0 lowest stability values[9].

OSSTELL ISQ is the recent generation of this device and was developed in the year 2009. It includes a newcontrol unit with a probe connected to it usinga cable. Its use is progressively extending to registerthe implant stability measurement due to the ability of

device to reproduce accurate values without intra andinter observer variability. The Osstell measurementsare highly reliable and are alone sufficient to assess the status of implant success[9].

When the ISQ is 47, Implant stability can be obtained. But, when the ISQ more than 49, it osseointegrated with healing period of 3 months. However, immediately loaded implants with an ISQ more than 54, osseointegrated easily. When ISQ value is low the implant stability depletes. In such cases, the operator should follow a tight recall schedule and should take point to point unloading measurements until implant stability is redeemed. When implants have high values of ISQ, the thing taken into consideration is the stability of the implant in the first twelve weeks of healing. This should not demand any changes in recall appointments. The downside of this system is that the measurement of the transducer is restricted to a set of 60, thus making the method much costlier. Implant has a fixed transducer in order execute RFA. This precludes observing the implants that support a cemented restoration[7].

Factors influencing resonance frequency analysis/ implant stability quotient values: It is revealed that ISQ is influenced by the diameter of the implant, form, surface, the ratio of contact to the bone,site where the implant is placed, system/type of implant used, the procedure of surgery, bone's height and bone quality. Stiffness of the interface affects the RFA along with 3 other aspects. At first healing of bone and remodelling of bone increases the stiffness of the interface of the surface of implant and bone. Secondly, bone stiffness and density along with cancellous and cortical bone ratioputs impact on RFA. Finally, interlocking parts of components of the implant can be a factor. Smaller drilldiameter final drill, varying surgical techniques e.g. self-tapping design implants, bone compaction technique, and wide tapered implants may also put impact on stiffness of the implant surface.

Application[10]

- It aids in making loading decisions.
- ISQ of 70 or more has reached–planning of the prosthetic phase can be done. Howbeit, since remodelling is always alternating, high Implant stability quotientdoes notalways state that there will be same the secondary stability will also be the same. Similarly, a when ISQ is low, it does not specify that there will beimplant failure because the contact between the bone and implant increases after the stand by interval of osseointegration.
- Alerts for hindering failure: An ISQ of 55 or progressive decline over period suggests of a hidden failure and notifies for necessary measures.
- Case documentation: Helps in maintaining records and hence communication is made easy as well as it is of great assistance in medico-legal cases.

Limitations[10]

- Comparatively expensive
- The smart pegs sum up the expense.
- Each implant system has a respective smart pegs.

- In case of single piece implant cannot record ISQ and requires an extra attachment.
- Cannot be utilized when the implant is placed subcrestally.

Conclusion

Clinically appurtenant information can be provided by resonance frequency analysis technique, regarding the state of the interface between bone and implant at any juncture of the treatment and follow-up. The inclemency of the interface of implant-bone is also based on implant stability and this particular technique quantifies it. Factors governing the above are such as the density of bone, time for healing of jawas well the implant that is exposed above the crest of alveolar bone. Research Studies specify that during recall examinations, successful osseointegration is elicited in implants with high values of ISQ. The opposite might signal in the direction of failure of implant or bone loss in the marginal area. To know clear specifications, for better implementation of the resonance frequency analysis technique, further clinical case reports are required.

Mesenchymal Stem Cells in Periodontal Regeneration: A Review

Nikita Samal[1], Gatha Mohanty[2], Rinkee Mohanty,[3] Rashmita Nayak[4], Anurag Satpathy[4], Abhaya Chandra Das[5], Manoj Kumar[5]

[1]Intern, [2]Senior Lecturer, [3]Professor and Head, [4]Professor, [5]Reader, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Periodontitis is most predominantly marked and plays a vital burden in dental health as well as in systemic health. It starts from a phase of swelling on supporting structures of tooth thereafter proceeds, destruction of tissues up till damage to tooth arises. Reconstruction of defective supporting tissues in periodontium inclusive of cementum, pdl and alveolar bone is a challenging objective in periodontal regeneration therapy that can adequately diminish periodontitis caused tooth loss. In the regeneration of tooth and their supporting structures that are gone or damaged due to periodontal disease, stem cells perform an essential character. Here we talk about the primary information based on periodontal tissue regeneration using mesenchymal mother cells.

Keywords: *Periodontitis, mesenchymal mother cells, periodontal regeneration, guided tissue regeneration (GTR).*

Introduction

Periodontium indicate to tissue which simultaneously supply and reinforce the teeth. Periodontal tissues comprise of soft tissues like gingiva, periodontal ligament along with hard tissues like alveolar bone and cementum. The construction and distribution are damaged due to miscellaneous acquired and genetic disorder, out of them periodontal disorder is most frequently seen. That leads to loss of periodontal tissue which brings about tooth damage whenever left untreated. The determined ambition about periodontal reconstruction or regeneration is to reconstruct numerous periodontal tissues inclusive of alveolar bone, cementum and periodontal ligament in impaired periodontium.[1]

The utilization of applied science like guided tissue regeneration (GTR) towards periodontal surgery may eccentrically rebuild periodontal tissue,but still, complete consequences are not significantly satisfying and present deficiency of clinical predictability.[2] As modern equipment along with growth factors have improved the procedures to govern periodontal injuries, scientific investigations have disclosed that their competence is, however, questionable and the fundamental, as well as occupational reconstruction of destroyed periodontal anatomy, stays demanding. Present-day the need of mother cells is acknowledged as a prevailing approach to periodontal therapy especially for a complete reconstruction of periodontal tissues which include both rehabilitation of alveolar bone and inducing cementogenesis along with root areas including oriented introduction of freshly developed periodontal tissues.[3,4] This manuscript presents the essential concept of periodontitis and mesenchymal stem cells; the role of mesenchymal stem cells (MSCs) in periodontal regeneration therapy; exogenous human mesenchymal stem cell therapy and lastly immuno-modulator properties of MSCs with tissue regeneration.

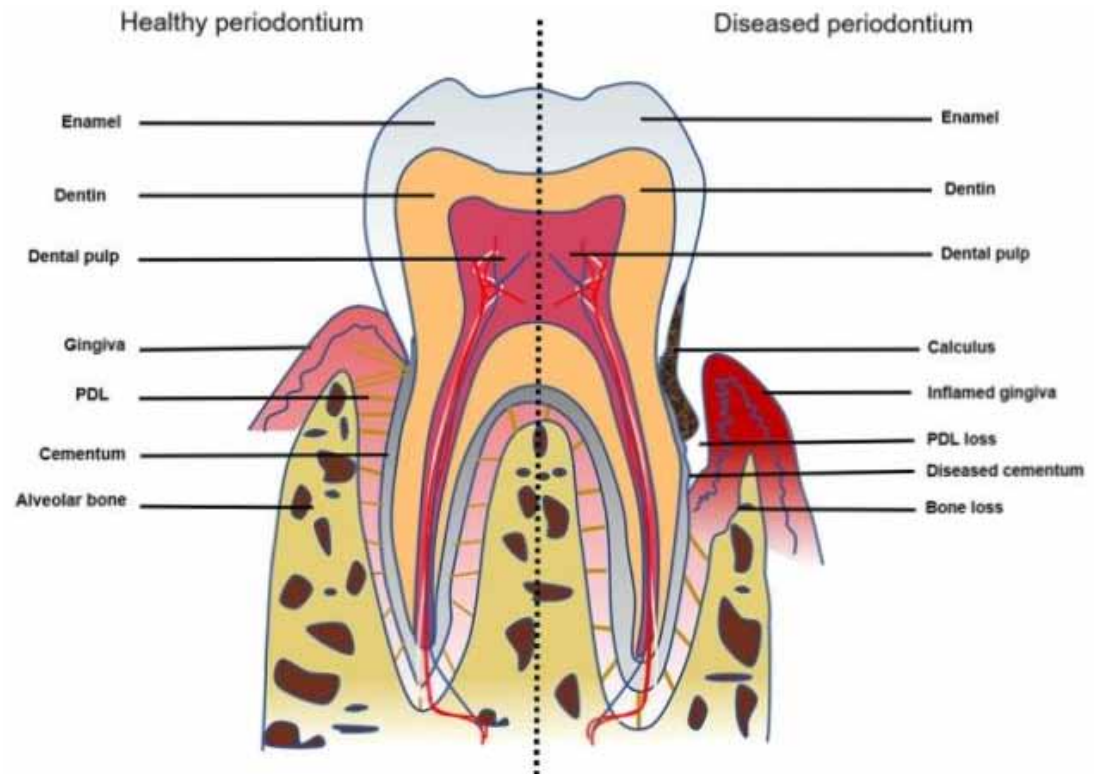

Figure 1. Healthy periodontium versus diseased periodontium

Periodontitis the condition: Periodontitis is a continuing incendiary disorder of periodontium. This disorder is induced due to various microbes that produce pharmaceutical disintegration of collagen fibers of the cementum; continuous damage to PDL as well as alveolar process including raised intensity of exploration establishment; receding gums; apical shifting of junctional epithelium[5]. It was a condition that damages the supportive tissues of the tooth that further leads to a lack of tooth from the socket and brings about numerous periodontal problems[6,7]. Disproportion between favorable and harmful microbes is the most crucial factor to cause periodontitis. Dysbacteriosis in primary period which mostly caused by low oral hygiene that provokes aggregation of various microbes like Aggregatibacter actinomycetemcomitans (A. actinomycetemcomitans), Porphyromonas gingivalis (P. gingivalis), Tannerella forsythia (T. forsythia), and Treponema denticola.

Periodontitis may occur at different age groups. In late adolescence gingivitis is seen which includes redness and inflammation of the gingiva. In adult age group aggressive periodontitis is most commonly seen which affects mostly incisors and first molars. Chronic periodontitis is mostly seen in the elder age group where attachment loss and destruction of periodontal tissue seen.

Mesenchymal Stem Cells: They are grown up connective tissue cells which originating at mesoderm. MSCs are undifferentiated cells capable of self-renewal and differentiating into specialized cells. Stem cells may be confined either in the beginning periods of embryogenesis (embryogenic mother cells) or within numerous Postnatal tissues (non-embryonic mother cells). As embryonic mother cells get great lifetime as well as the capability for huge differentiation, the virtuous features included in their construction put concentration on nonembryonic mother cells that are multipotent and present within almost all tissues, having the capacity for reconstruction of impaired tissues or else re-establish cell populations which are regularly getting interchangeable.[8,9]

MSCs are concerned with development, trauma healing, re-establishment of cells that are destroyed everyday either due to desquamation or in pharmaceutical circumstances. According to various research, it has been proven that they generate re-construction of neural, liver as well as skeletal muscle

following infusion in pre-clinical together with objective modes.[10-13] Those characteristic features of MSCs lead to feasible equipment during tissue engineering along with tissue reconstruction. MSCs may be acquired from different sources of developed tissues like bone marrow, skin, adipose tissues, and tissues of the orofacial zone. The initial cells obtained from the dental pulp of the third molar of the orofacial region[14,15]. They have been obtained from the periodontal ligament, deciduous teeth, apical papilla.[16,17]

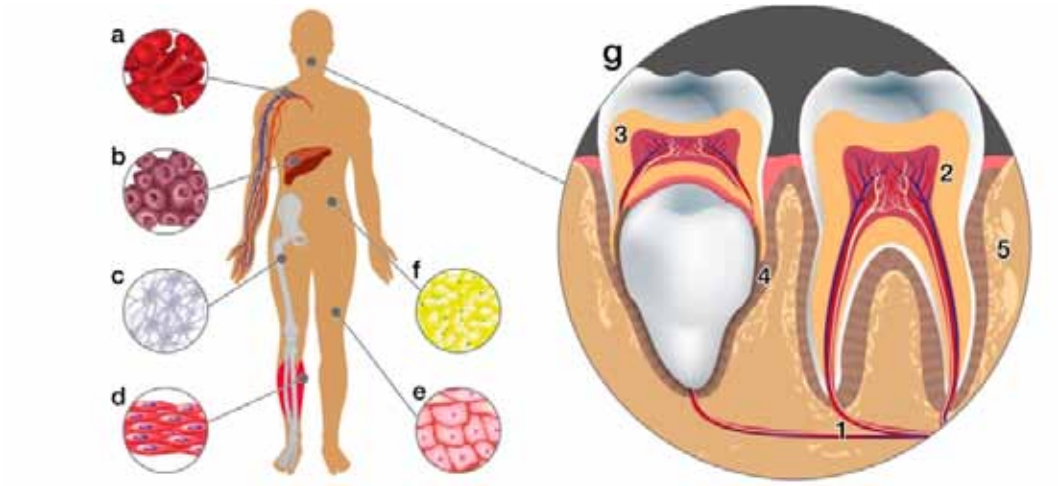

Figure 2: Sources of adult stem cells in human organisms; (a) Peripheral blood, (b) Liver, (c) Bone marrow, (d) Muscles, (e) Skin, (f) Adipose tissue, (g) Dental tissues: (1. Apical dental papilla, 2. Adult pulp, 3. The pulp of deciduous teeth, 4. Periodontal ligament, 5. Alveolar bone)

Human mesenchymal stem cells and periodontal regeneration therapy: Currently, according to methodical analysis about the potentiality of MSCs in periodontal regeneration therapy some authors confirmed that using MSCs,periodontal reconstruction might utilize the valuable responses somewhat in the pre-clinical aspect based on modern information. While other authors fail to determine the excellent combo about MSCs, bio-materials and biomolecules of different clinical conditions by the help of animal models which are an excellent representative of the etiopathogenesis of human periodontal disease. As there is no confirmation about the source that might be better products as well as scientifically achievable in human clinical conditions, depending entirely on xenotransplantation, we should recognize the beneficial effect of MSCs in the case of sick persons. The tissue engineering procedure needs MSCs, that are obtained from bone marrow, dental pulp of the patient along with developed in vitro. For generating an osteogenic constitute, MSCs are additionally cultivated with osteogenic factors as well as a scaffold (beta-tricalcium phosphate, hydroxyapatite/ tricalcium phosphate, etc.)[18]

Some scientific experiments have noted that the usage of human MSCs generates reconstruction of periodontal tissue. There are some experiments certified to periodontal reconstruction with the help of MSCs. Additionally, an inspection of the usage of MSCs to generate periodontal reconstruction, few investigations of gingival fibroblast-like cells, periosteum osteoblast-like cells, and periosteal cells are involved[19,20] even though they possibly don't perform the necessities of Universal Community of biological remedial treatment for human MSCs. There are investigations in individuals who have used homologous mesenchymal stem cells from bone marrow (BMSCs) along with established this is desirable for periodontal reconstruction.

On the other hand, even though they exhibit the potentiality of the cells to individualize former to the process of transplantation, nobody has considered the MSC immunophenotype. Based on these, Kaigler along with co-workers and Behnia along with co-workers used BMSCs to generate jaw bone restoration as well as rehabilitation of periodontal tissues, correspondingly, inducing excellent outcomes. On the other hand as both of them used BMSCs, they noted various

immunophenotypes also considered the individualization potentiality former the transplant with various specifications for the consideration. Based on clinical research d'aquino concluded that dental pulp stem cells (DPSCs) may generate a complete reconstruction of bone even though they are phonologically different from those proposed for periodontal tissue. Those cells show raised potentiality of self-expansion as well as differentiation in pre-osteoblasts. They also have a property of self- maintenance with renewal for a lengthy period. Other sources like infected pulp/adipose tissue, have been utilized in periodontal reconstruction along with appropriate outcomes.[21,22] Mesimaki and his co-workers utilize adiposestem cells to generate maxillary bone regeneration in elderly patients.

Exogenous human mesenchymal stem cell therapy: Exogenous MSCs may have the ability to manage the action of endogenous MSCs via paracrine components. Paracrine components have a great character during cell to cell communication or interplay which promote reconstruction of periodontal tissues. Based on research it is concluded that about 50 percent of cases showed analytical advancement and about 4.3 percent showed short-term reactions after MSCs infusion. But no one had harsh or dull reactions due to this therapy[23]. Exogenous MSCs therapy does not induce any type of crucial reactions and also there is no necessity of donor to recipient matching. In this therapy superficial or slight side effects may be seen for a short period. Utilizing human exogenous wharton's extract MSCs,survival as well as an assurance of myocardial reconstruction is an exclusive curative factor where no objective significant evidence is associated with it. It also found that epicardial or myocardial deterioration along with arrhythmias were not associated till 48 weeks which is a reason to treat with wharton's extract MSCs. As exogenous MSCs brought about noticeable advancement it is concluded that usage of exogenous MSCs therapy is desirable for reconstruction treatment of periodontal tissue.

Immunomodulatory properties of mesenchymal stem cells and tissue regeneration: According to various information, human MSCs may suppress in a close-dependent aspect, propagation together with cytokine reproduction of enough extrinsic immune cells like natural killer cells, T cells, B cells including dendritic cells. They discharge certain dissolved immunosuppressive components like interleukin-6,HLA-G5 together indoleamine 2,3-dioxygenase which are included in MSC interposed immunoregulation[24]. Depending upon potentiality that one may construct massive description about dissolved peptides as well as proteins. MSCs may trigger adjoining parenchymal cells to diminish apoptosis, decrease tissue loss, promote progenitor cell self-renewal, trigger angiogenesis aw well as promote repair. Numerous bioactive particles like enamel matrix derived growth factor; platelet-derived growth factor, plant extract (osthole, reveratol, quercitin) along with medicaments(aspirin, melatonin) are analyzed to improve results about tissue reconstruction of periodontium.[25]

Fu with his co-workers explained two techniques that negotiate the advantageous impacts of MSCs in periodontal tissue reconstruction. They are construction of extracellular vesicles together with the establishment of tunneling nanotubes (TNTs) which associate with various cells as well as deliver a variety of trophic components. Aliotta and his co-workers recommended that cells in the impaired tissue deliver information as mRNA to stem cells via extracellular vesicles that generate epigenetic revolution in stem cells. Sanchez together with his co-workers used MSCs of extract of Wharton along with exhibited tunneling nanotubes, that are elongate, narrow, F- actin positioned membranous mediums which associate cells along with havingthe potential to transfer their factors to associated cells. The utilization of those cells, even under hypothetically adverse situations will restore alveolar tissue and influence analytical advancement in patients with periodontitis.

Conclusion

As restoration of a destructed or injured Tooth is necessary, re-establishment towards operative or active and vital teeth is the biggest auspicious beneficial approach in the field of dentistry. Re-establishment towards operative or active and vital teeth is the biggest auspicious beneficial approach as the restoration of an injured or destructed tooth is much needed[26]. Depending upon the tissue engineering, value towards the microorganisms,biomaterials as well as growth factors recommended for advanced perception, considering treatment of periodontal disease.

According to various experiments, it is concluded that the capability of MSCs to induce periodontal tissue regeneration may give rise to the auspicious outcome even in unfavorable situations like in the

older age group. Periodontal tissue reconstruction is a complicated process that takes place from the interaction between stem cells and biomaterials. Utilizing MSCs for treatment of damaged periodontal tissue is one of the relevant alternatives, due to the interrelation of these cells with target tissue with miraculous convenience. This manuscript emphasized on application of stem cells that repair the tissue of periodontium and increase periodontal tissue restoration as well as reconstruction.

Abstract

Cranberry juice has been used in medical fields for the past decade because of its several health benefits. Due to its properties, cranberries and its molecular components have gained attention by the researchers. The chief bioactive component of cranberry is proanthocyanidins. Its improved health benefits are already being found in treating UTI and many systemic diseases. But only a few studies have shown its effect on oral health.

Keywords: *Cranberry juice, Periodontal Disease, Functional Food, Vaccinium macrocarpon, Proanthocyanidins.*

Introduction

The native North American fruit cranberryhas currently gained some interest in the medical field for its several health benefits. Widely grown in the peat bogs of the cooler northeastern part of North America, it is one of the three original fruits of the country, which grows as a vine or low trailing shrub, bears a red fruit and is acidic in taste.Cranberry itself is a unique, good source of several classes of bioactive flavonoids includingflavonols, anthocyanins, and proanthocyanidins which confer it the significant therapeutic potential. The cranberry fruit is commonly consumed via several foodproducts, including the fruit itself and also in powder form incorporated in capsules and tablets.[1]

Therapeutic applications of cranberries started during the17th century which includes the treatment of blood disorders, stomach ache, liver problems, vomiting, appetite loss, scurvy, and cancer. Recently, cranberry extract has gained enormous attention in various areas of health research, including infectious and non-infectious diseases.Cranberry (Vaccinium macrocarpon) is a berry bush found in North America as one of the original fruit of the country. It has a mild acidic taste. It is consumed via different ways like fresh and dried form, juices and sauces and also in capsules and tablets in granulated form. It is an exclusive source of bioactive flavonoids which includes anthocyanins,proanthocyanidins and flavanols. These components in cranberry are solely responsible for its distinct therapeutic properties.[2]

Structure of proanthocyanidins

The procedure of making it includes extensive dialization of cranberry juice along with some other modifications. This process results in a product which is devoid of sugar and acids, containing 0.35% anthocyanin and 65.1% proanthocyanidins[2].Prof. Jacques Masquelier is the first one to develop the distillation procedure for extracting the proanthocyanidins from pine bark and grape seeds. Proanthocyanidins are mainly of two types: type A and B. Type A can be found in apricot, cranberry and type B can be found in other berries. Proanthocyanidins are mainly composed of multiple epicatechin units along with a minimum of one A-type

linkage (O7 C2).[2] Other tannin-rich food contains B type linkage. The typical structure of cranberries is thought to be essential for the anti-adhesion property which can be used against the colonization of periodontopathogens in supragingival and subgingival regions.[3]

Nonetheless activation of the host immune system by bacteria and their products initiates a cascade of host-mediated noxious process which leads to the accumulation of inflammatory mediators. This reaction is succeeded by the inflammatory reaction normally caused by MMPs which will ultimately lead to tissue destruction. Degradation of tissue protein and invasion of periodontium occurs because of the bacteria secreted soluble and insoluble proteases.[4]

Periodontitis is a disease caused by chiefly the colonization of particular gram-negative bacteria. This ultimately leads to the impairment of soft and hard tissues of the periodontium and finally results in tooth loss. The pathogenesis of periodontitis is consisting of two major factors. First is microbial, which includes colonization of periodontal-pathogenic bacteria subgingivally, which destroys the soft tissue and junctional epithelium. The second is the host response of periodontopathogens which leads to increased production of inflammatory mediators and MMPs which are chiefly responsible for the initiation and progression of periodontitis. It was reported that cranberry has significant inhibitory effects on these two stages.[5]

Effects on periodontopathogens (adhesion and biofilm formation)

For the periodontal progression, the microbial colonization is an essential step. the ability of periopathogens to form biofilm and to generate adhesins which ultimately helps them to attach to the tooth surface, basement membrane or host cells. Thecranberry NDM fraction helps in inhibition of biofilm formation of but it does not affect the bacterial growth. This cranberry NDM fraction reduces the attachment of P. gingivalisto various proteins like Type I collagen and fibrinogen[3].

This fraction also inhibits the bacterial co-aggregation. They target those bacteria which are gram-negative anaerobes frequently responsible for periodontal diseases. These findings guides us to the decision that cranberry NDM fraction functions by preventing the bacterial adhesion rather than only by hindering the bacterial growth.

Proteolytic enzymes

Socransky et al. (1998) described that the members of the red complex which include P. gingivalis, T. forsythia, and T. denticola are the chief causative factors of periodontitis.[12] These periodontopathogens are closely related to periodontitis particularly in the destruction of junctional epithelium, increasing in pocket probing depth and bleeding on probing. The cranberry NDM fraction reacts with the period onto pathogens proteinases. It inhibits the action of gingipain (both Arg- and Lys-gingipain) depending on the dose. It also downregulates P. gingivalis activity, the trypsin-like activity of T. forsythia, and the chymotrypsin-like activity of T. denticola.[4] It also preventsP. gingivalis to denaturize proteins like collagen and transferrin. All these functional values of NDM fraction proposes that it can inhibit the production of red-complex bacteria in periodontal pockets.[6]

The destructive period onto pathogens produce proteinases. NDM fraction may reduce these tissue destruction mediators. Additional proof was given by Yamanaka et al. (2006) about the inhibitory efficacy of cranberry polyphenols action. Among the three fractions of cranberry polyphenols (anthocyanin, proanthocyanidin, and flavonol), the proanthocynidin fraction is highly effective and anthocyanin fraction is the least effective[5]. It has been suggested that these inhibitors can suppress bacterial pathogenicity and henceforth it can beassessed as a novel therapeutic agent for treating periodontitis.

Effect on periodontal bacteria and host mechanisms

Experiments performed by Labreque in 2006 and Yamanaka in 2008 revealed that the NDM fraction revealed that cranberry NDM fraction hinders the aggregation of Porphyromonas gingivalisand Fusobacterium nucleatum in the gingival crevicular fluid.[7]

Cranberries are reported to stop the protein denaturation occurred by the red-complex bacteria. It restrains the gingipain activity of P. gingivalis, the trypsin-like activity of Tanerella forsythia and the chymotrypsin-like activity of T. denticola, thus it leads to the conclusion that this fruit is having the capability to restrain the aggregation and multiplication of bacteria by restricting their growth resources like amino acids, peptides. It also inhibits the bacterial proteinases mediated tissue destruction.[8]

Inflammatory cytokines like (IL-1β, TNF-α) are produced by host macrophages. This process will lead to a cascade of inflammatory reactions like lipopolysaccharide production of A. actinomycetemcomitans, F. nucleatum, P. gingivalis, T. denticola and T. forsythia. A clinical experiment done by Bodet et al in 2006 found that the cranberry fraction helps in inhibiting these cytokines.[15] The NDM fraction acts by inhibiting the cell-signaling proteins and leads to the reduction in regular activator protein (AP-1). This AP-1 protein is an important transcription factor for pro-inflammatory mediators coding genes.[9]

Inflammatory cells chiefly macrophages and fibroblasts produce various enzymes like MMPs and elastase which is the primary cause of tissue destruction. In vitro ELIZA studies revealed that depending on the dose this cranberry NDM fraction has an inhibitory effect on the MMPs[6]. The lipopolysaccharide-induced interleukins and PGE-2 responses as well as Cyclooxygenase-2 expression are suppressed by the cranberry fraction[7].

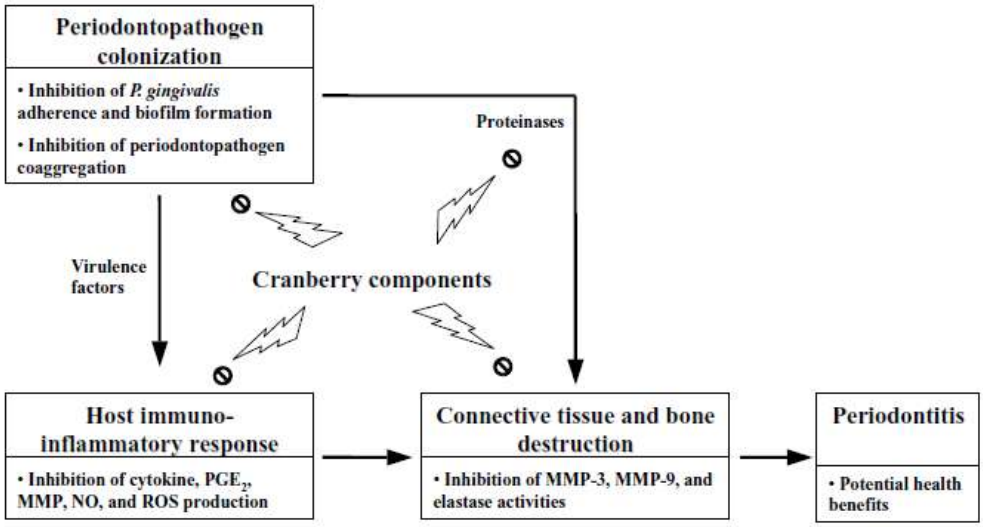

Figure 1. Pathophysiology of periodontal pathogens

Dosage: Various doses and formulations of cranberry are available in the market. This includes unsweetened or sweetened cranberry juice, cranberry extract tablets, pure cranberry extracts in a bottle etc. A recent randomized control trial performed showed that the one tablet of concentrated cranberry extract (300 to 400 mg) twice daily, or 8 oz. of pure unsweetened cranberry juice three times daily for 12 months is safe and effective as an daily systemic treatment doses for antimicrobial therapy.[10, 11]

Contra indications and adverse effects: Cranberry as a dietary supplement has shown a record of safety and it has not shown any particular drug interactions. Still, specific long term safety data is missing. A study found that patients who are under proton pump drug therapy, cranberry enhances the vitamin B12 in them which can ultimately lead to faster metabolization of weakly acidic drugs thereby reducing their effectiveness.[10] A study showed that it can be responsible for the significant rise of urinary oxalate levels and systematic daily use of cranberry may lead to a high risk of kidney stone formation in patients with a history of oxalate calculi.[8, 12-14]

Conclusion

Cranberry extract certainly helps in fighting oral diseases. However, due to high dextrose and fructose content and strong acidic flavour the cranberry juices which are available in the market are inappropriate for daily oral hygiene use. However, cranberry fractions included in the dietary supplements have shown some promising results as suggested by current research.

Remarkably, the cranberry fraction stops the pathologic mechanism of dental caries and periodontal infection. It can be included in various products like toothpastes and mouthrinses as well as gels and strips to arrest the progression or treat the oral diseases. Weiss et al in 2004 showed that NDM supplemented mouth wash reduces the salivary S. mutans levels in healthy adults. The study can lead to the conclusion that the anti-adhesion and anti-plaque therapy by the edible dietary components can be a sustainable way for treating oral diseases like dental caries and periodontal diseases.

Abstract

Chronic periodontitis has been the principal cause behind the irreparable destruction of the periodontium. In the field of surgical periodontal therapy, regeneration of damaged tissues by utilizing our body's naturally produced growth factors along with various other biomaterials either synthetically formulated or animally derived has piqued the attention of the dental practitioner. The human body has a natural capacity and potency of regenerating the lost tissue up to an extent; this characteristic is tapped in the regenerative therapy. Presently this therapy is bounded by the limited research and knowledge on the materials that can be used, instruments that are required for a successful procedure and method devised to gain desired outcomes presently available and the body's natural capability for regeneration. Tissue engineering use of stem cell, gene therapy and research on various aspects of regenerative therapy, has produced predicted results in exciting new treatment method for clinicians shortly. Traditional treatment modalities like mechanical instrumentation, curettage and open flap debridement result in keeping the inflammation in check and long junctional epithelium formation which leads to only periodontal repair and not regeneration. Many practitioners frequently use a combined method of putting both barrier membrane and bone grafts to curb the limitations posed by the down growth of epithelium and sagging of the non-rigid barrier used to maintain the grafts in place. This has led to enhanced interest in the Hence, there has been increased attention in the treatment of chronic diseases of the periodontium further elevating the quality of life of the patients. This review article aims to review diverse obtainable bio-materials, scaffolds, barriers and osseous grafts along with the plethora of procedures applied in periodontal regenerative therapy.

Keywords: *Periodontal regeneration, tissue engineering, cell sheet engineering; 3-D printing technology.*

Introduction

The principal aim of regenerative therapy is to fully restore the lost periodontium and other supporting soft and hard tissues that have been destroyed during the chronic inflammatory diseases. The foundation of the regenerative therapy is built on the formation of the new hard tissues and soft tissue i.e. the alveolar bone proper, the periodontal fibers, cementum along with its associated collagen fibers. It is often observed that traditional periodontal therapy such as scaling and root planing or open flap debridement commonly results in the gain in clinical parameters. It is evidenced by a reduction in the probing pocket depth and clinical attachment gain in the clinical attachment level, but the process of post-operative healing primarily occurs through the formation of long junctional epithelium which is considered as periodontal repair and not periodontal regeneration. The periodontal surgery is critically required for periodontal health and highly expected to regenerate tooth-supportive structures and restore periodontal functions such as pocket reduction procedures and regeneration

procedures (guided tissue regeneration;GTR or guided bone regeneration; GBR).[1,2] Adequate blood supply and wound stability, a source of bone and ligament forming cells, a supporting scaffold or matrix, and growth factors to regulate cell migration, proliferation and synthesis and angiogenesis for revascularization of the site are the basic elements required for periodontal regeneration and repair.

Cells in emerging regenerative therapy

Stem Cells:

Among the various types of stem cells found in the oral cavity are

DPSCs: dental pulp stem cells; SHED; PDLSCs: periodontal ligament stem cells; GMSCs: gingiva-derived MSCs, PSCs: periosteum-derived stem cells have reported for to regenerate periodontium. PDLSC differentiate into cells that inhabit and grow on the biocompatible scaffold, for bone tissue engineering in regenerative periodontics.[3,4] The verification of the osteogenic potential of differentiating PDLSC which is characterized by an increase of nitrous oxide and calcium represents a promising method for the management of periodontal defects. Human PDL has been reported to be a viable alternative source to be used in stem cell therapies.[5,6]

MSC niche:this concept is based on the fact that a specialized microenvironment is always desired for mesenchymal stem cells to preserve their 'stemness'. Under specific signaling conditions. It can differentiate into the endothelial, osteoblastic, adipocytic, odontoblastic, chondrocyte, and neural lineages. The major site of MSC niche in the body is the bone marrow microenvironment.[7]

Cellular Allograft: Novel allografts are cellular. They comprise the body's mesenchymal stem cells and cells having osteogenesis capacity. These have been successfully used for the management of demanding periodontal defects.[8]

Scaffolds/matrix in emerging regenerative technology: Cell sheet engineering: For enhanced and desirable treatment outcomes, the stem cells require an appropriate medium to reach the target site. This can be made possible by using the scaffolds which aids the stem cells in differentiating into the desired tissues. It also proves to be effective and maybe a promising source of periodontal regeneration.[9-11]

Zhao, et al. 2013 [86]	CSF of PDLSCs and PRF granules	Reimplantation of teeth in dogs	Better periodontal regeneration and reduced Ankylosis and inflammation
Dan, et al. 2014[88]	MLS composed of cells of gingival connective tissue, alveolar bone and Periodontal progenitors in a calcium phosphate- coated melt electrospun polycaprolactone scaffold	Athymic rats	Scaffold promoted bone formation in 4 weeks. Significant periodontal tissue formed by alveolar bone cells and periodontal progenitors

Shortcomings associated with the cell sheet engineering is that are multiple applications of multi-tiered cell sheets are needed to restore the damaged supporting tissues and make it resemble the original morphology. It is difficult to handle, transport and extremely fragile. Furthermore, this treatment plan is not at all cost-effective and hence only can be carried out in selective cases.

Growth factor-enhanced matrix 21S: It is a synthetic grafting system for bone and periodontal regeneration. It consists of the solution of unaltered recombinant human platelet-derived growth factor (rhPDGF-BB) in its concentrated form. It also has an osteoconductive scaffold (bone matrix). GEM 21S is supplied in a single-use kit. Each GEM 21S kit consists of the following: One cup containing 0.5cc of beta-tricalcium phosphate particles (0.25–1.0 mm). One syringe containing a solution of 0.5 mlrhPDGF-BB (0.3 mg/ml).[12]

PepGen P-15: It is an osseous graft material which has been tissue-engineered. It is composed of the HA bone matrix which is of bovine origin and inorganic in nature. It also consists of artificially formulated cell-binding peptide. This material has been proved to be useful in filling periodontal osseous defects. It has been shown that the P-15 helps in the binding of cells particularly fibroblasts and osteoblasts.[13] PepGen P-15 bone graft in conjunction with flap surgery was an effective periodontal regenerative potential in terms of linear bone growth and vertical bone growth for the management of three-wall bone defects.[14]

Nanomaterials: Nanomaterials available in the forms of nanopowders, nano gels, nano scaffolds are the materials with components less than 100 nm in at least one dimension. these materials can be organic (eg: chitosan, silk fibroin) or synthetic (eg: PGLA nanoparticles, dendrimers).[15] Silk fibroin derived from the cocoons of the silkworm which are processed into scaffolds integrated with bone morphogenetic protein-2 helps in osteogenic differentiation of human mesenchymal stem cells.[16,17] PLGA nanofibers are biocompatible but its role in bone regeneration can be hindered for its poor osteoconductive.[18]

Hydrogels: Fibrin, hyaluronic acid and Pluronic F127 are the hydrogels, which have effective delivery of growth factors. They are the scaffold system which lend a hand in bone repair. However, they are encountered with various drawbacks such as low physical properties such as mechanical strength, which further decreases their effectiveness as an osseous replacement. This problem can be triumphed over by designing composites which will comprise of an inorganic substance and a copolymer. One such combination is PLGA-g-PEG which has HA and a polyethylene glycol (PEG) as its inorganic substance and copolymer respectively. Its acidic pH environment is neutralized by hydroxyapatite.[19]

Titanium mesh: The nonresorbable barrier membranes used in periodontal regeneration are PTFE (expanded or high density) and titanium mesh. Titanium mesh (Ti-mesh) maintain the bone grafts under the barrier and has excellent mechanical properties. Its elasticity prevents mucosal compression. Its enhanced strength and resistance to deformation aids in maintaining the space and also prevent the contour of the tissues from collapsing. Graft displacement is prohibited by its stability. Furthermore, its plasticity allows bending, contouring, and adaptation to any unique bony defect.[20]

Amniotic Membrane: Amniotic membrane is the deepest lining of the placenta present in the most inner layer of it. It is usually discarded after parturition. It is lately being used in the regenerative and repair therapy both in the medical and dental fields to restore the lost tissues and speed up its repair. It is a novel tissue-engineered biomaterial that has numerous growth factors, proteins and stem cell reserves that help in regeneration of the lost tissues with the acceleration of wound healing. Many studies have also evidenced that this material can be effectively used in the management of intraosseous defects.[21]

Molecular mediators in emerging regenerative therapy: Teriparatide: Teriparatide, is nothing but the parathyroid hormone but in its commercially attainable formulation. It comprises the amino acids starting from 1 to 34 of the parathyroid hormones (PTH 1–34).They are subcutaneous injections, which can be administered by the patient himself in the muscles of the thigh or abdomen daily results into an increase in the number of active osteoblasts, a decrease in osteoblast apoptosis and probably, recruitment of bone lining cells as newly formed osteoblasts, thereby increasing bone strength and tissue integrity which finally leads to bone formation.[22]

rhFGF-2: The controlled release, local delivery of growth factors, such as FGF-2is another emerging approach to regeneration. Recombinant FGF-2 results in broad mitogenic and angiogenic actions that take place

by binding heparin. It helps in the differentiation of osteoprogenitor cells to induce bone formationand also be actively involved in periodontal tissue renewal.0.3% rhFGF-2 shows a greater capacity for periodontal regeneration than other concentrations.[23]

Platelet-derived growth factor: PDGF represents a family of growth factors consisting of 2 polypeptide chains (A & B) which form the dimer (protein pairs).

- PDGF-AA
- PDGF-AB
- PDGF-BB

PDGF-BB can activate any PDGF receptor; therefore its therapeutic application can activate any configurations of its receptors and when used in a synthetic scaffold matrix, promotes long-term stable clinical and radiographic improvements. The proliferation rate of wound fibroblasts is higher by PDGF- BB than PDGF-AB and -AA.PDGF-BB is a synthetic scaffold matrix.[24]

Concentrated Growth Factor: "Concentrated Growth Factors (GCF)" was introduced in 2006 by Sacco after the concept of PRF. It is a platelet concentrate that belongs to the second generation (advanced). It has many types of growth factors and fibrins. It is achieved by continuously centrifuging the blood and altering the time and the rotations per minute. It enhances the restoration of soft and hard tissues. It is prepared by accumulating 9 ml of patient's venous blood in the absence of anti coagulating agent in absolutely sterile tubes also referred to as vacuette blood collection tubes. The centrifugation takes place in the following order: first 30seconds acceleration, next 2minutes it is rotated at 2700 rpm, next 4minutes at 2400 rpm, then the following 4minutesat 2700 rpm, after which for 3min at 3000 rpm, followed by deceleration for 36 seconds and lastly stopping the centrifugation process. It stimulates the epithelialization process and also increases neo-vascularization making it an exemplary bioactive protein. It also accelerates the alveolar bone healing. In amalgamation with biomaterials and various promising graft materials it aids in the regeneration of the osseous tissues. Acceleration of osseointegration by increased differentiation of osteoblasts increases implant stability. It reduces periodontal intrabony defects depth and mixed with Bio-Oss and shows better results in the early period of healing.[25]

Biohybrid Interfaces: Modern dental implants lack the dissipation force, perception, and specialized receptors present in the periodontal ligament. In growing children or patients who are being orthodontically treated osseointegrated implants are not ideally placeddue to the absence of a periodontal ligament attachment.[26] Hence, a periodontal ligament-attached implant, or "ligaplant," could be a promising solution to practitioners. Furthermore, it can also provide a mechanism for allowing implant relocation orthodontically. Dental implants coated with HA surrounded with embryonic dental follicle tissues. It is a functional murine ligaplant model which was recently developed by Oshima et al that resulted in regenerated cementum, PDL, and alveolar bone.[27]

CAD-Based Compartmentalized Designs for Periodontal Complex Formations: In this process 3-D printing technology and computer-aided design (CAD) and is used to create a hybrid scaffold. Sectionalized articulation is present for the hard and soft tissues of the periodontium, including PDL-mimetic architecture which has perpendicular inclination for regeneration of periodontal complex.[28]

Gene Therapy: This therapy aims at injecting/ delivering various growth factors into the defects created due to inflammatory diseases of the periodontium. Numerous method of administering genes are accessible which offers great flexibility for tissue engineering. Tumor necrosis factor receptor 1 (TNFR1: Fc) is one such soluble protein that is used in gene delivery. It acts as host modulating agent as it curbs the destruction of alveolar bone by decreasing the activity of TNF (tumor necrosis factor). Direct in vivo gene transfer can also be carried out in this therapy. In large periodontal defects, platelet-derived growth factor-B enhance tissue regeneration as demonstrated,elsewhere.[29] For promising regeneration of osseous defects peripheral to dental implants direct gene transfer of adenovirus/bone morphogenetic protein-7in a collagen gel carrier has been effective.[30]

Conclusion

In the present era regenerative therapy continues to face multiple challenges both in research and clinical success. The emerging trends in regenerative therapy has become the turning point in the present-day theory of tissue engineering. However, cells, scaffolds and growth factors used recently have created new possibilities to envision the foresight and prognosis of present-day

surgical therapies. Future research should be carried out to uplift the development of novel treatment strategies. Proper selection of cases, the skill of the practitioner along with proper maintenance by the patient are of paramount importance for the success of regenerative therapy in periodontics.

Abstract

Periodontal disease isprevalent each in advanced and growing nations and affect about 20-50% of the world population. Several hazard factors inclusive of smoking,heredity,diabetes,bad oral hygiene,age,pressure and medication which is related to periodontal illness. The devaluation inside occurrence and popularity of periodontitis can decrease its correlated fundamental illness and diminish their economic impact on health care systems. Periodontitisis one of the most important diseases which is chronic and leads to death and disability worldwide. The speediest increase in the hardship of the chronic disease is acquiring in the growing nations.

Keywords: *Periodontal disease; Global burden;Risk Factors,Economic impact; Treatment policies*

Introduction

Periodontitis is a continuous intemperate disease and characterised through loss of periodontal ligament and elimination of neighbouring bone.[1] There are different analytic explanation of periodontal disease and it may be acute or chronic. Acute periodontitis are of limited period, quick onset and associated with pain. Early diagnosis and prompt treatment is necessary. Due to the deposition of dental plaque, chronic periodontitis occurs. Disintegration of the supporting tissues of the teeth occurs in periodontitis. Deepening of periodontal pockets and attachment loss is the sign of periodontal disease. A huge prevalence of periodontitis in adults and elder persons makes it a mutual well-being burden.

Prevalence of periodontal diseases: Periodontitis is the most accepted oral condition among human populations.[2] The frequency and popularity of periodontitis diverge due to preference, casemiscitation and sites and number of teeth investigated. The World Health Organisation (WHO) has managed overall oral health data bank by the help of the community periodontal index(CPI).[3] Community periodontal index varies from 0 to 4.[9]. Community periodontal index score 0 indicates an absence of periodontitis; score 1 indicates bleeding observed during or after probing; score 2 indicates during probing supra or subgingival calculus seen; score 3 indicates hollow pathological pocket of 4 or 5 mm (gingival margin within the black band of the probe);score 4 indicates pathological periodontal pocket of 6mm or more (the black band of the probe is not visible).[4] Among adolescents, widespread of calculus and bleeding problem is higher in developing nations than developed nations. The distribution of teenagers with calculus deposits varies from 35% to 70% in advancing nations and 4% to 34% in advanced nations. In advanced countries periodontal pockets of 4-5mm seen in a higher percentage of individuals. Correspondingly in grown-up, calculus deposits varies from 14-17% in advanced countries and 36-63% in advancing countries. Higher distribution of elder individuals (65-75 years) show pathological pockets of 6mmor more is seen in grown-up populations in both advanced and advancing nations.[5]

Factors related to periodontal diseases: A few risk factors raise the possibility of periodontal diseases which commit toward the scientific number implication of periodontal disease. The essential risk factors for serious periodontal disease are the adoption of tobacco, stress, malnourishment, extreme alcohol drink, diabetes mellitus and other systemic diseases.

Modifiable Risk Factors:

1. **Smoking:** The greater critical possibility causes for periodontal disease is smoking. The devaluation in periodontitis pervasiveness is associated with a decrease in the rate of smoking. In smokers, there might be increased in the loss of alveolar bone along with tooth loss than the people having no smoking habit and smokers have low results of patterns of periodontitis.[6]

2. **Bad oral hygiene:** Bad oral hygiene is connected with periodontitis, the need of legitimate brushing of teeth and different proportion of oral hygiene can support affidavit of bacteria and develop deposition of plaque on teeth and gums which can address an aspect for fiery changes in tissues which is present in the periodontal region.[7] There is an articulated relationship between bad oral hygiene and expanded aggregation of plaque, huge commonness and expanded seriousness of periodontitis.[8]

3. **Hormones:** Harmonization in females improve probability of periodontitis.[8] Ladies may encounter aggravation of gingiva previously period and at the time of ovulation because of a significant matched in progesterone which hinders fix of collagen strands and creates dilation of blood vessels. Pregnant ladies as often as possible display gingival changes,gum disease,now and again limited development of gingival tissues.[9] Luckily,these provocative changes vanish inside barely after conveyance beyond motivating tenacious harm to tissues present in periodontal region. Inadequacy of oestrogen diminishes the thickness of bone after the midlife crisis that can come full circle in alveoli misfortuneor the long run collapsing of teeth.[10]

4. **Diabetes:** People suffering from diabetes are more likely to develop periodontitis which can raise blood sugar level and various diabetic complications. Diabetesis the foundational ingredients for periodontitis which cause a significant job in commencement and movement of the disease.[11] Diabetes is related to tendon demolition which therefore prompt loss of tooth. Gingivalcrevicular fluid and salivation have higher convergence of fiery go-between including extraordinary sorts of cytokinesencompassed by diabetic patients with periodontal disease when contrasted with people not suffering from diabetes with periodontitis. Periodontitis is generally recognised a complexity of diabetes. People who don't control their diabetes, are especially at risk. Periodontitis can be a result of low diabetes management and associated with cardiovascular disease and strokes.

5. **Drugs:** Helplessness to contaminations and periodontitis increases lessened salivary stream because of medication powerlessness to contamination.[12] Periodontal sickness strengthens when there is reduced salivary stream because of certain limit the progression of salivation and produce Xerostomia, incorporates anti-depressants, anti-cholinergic,anti-histamines and beta receptor antagonists.[30] Some medications like nifedipine, cyclosporine and phenytoin can initiate the irregular development of gingival tissues which much of the time confounds the fitting expulsion of plaque beneath amplified gingival mass and in this manner bother currentperiodontitis.

6. **Weight:** It is obvious form proof that the pressure diminishes progression of slavery discharges that thusly upgrade formation of plaque. An additive relationship among weight scores and slavery pressure markers, calamity of tooth, attachment loss and pocket depth of 5-8mm. An investigation of 300 observational pieces shown that the rest of pressure is identified with a safe framework and diverse immunological changes happen in light of various upsetting events. The discouraged people have appeared to a greater focus of cortisol in gingival crevicularliquid and react inadequately to treat the periodontal structures. Scholastic pressure additionally brings about bad oral hygiene and gingival irritation with expanded grouping of interleukin-1beta.[13]

Static Risk Factors:

1. **Maturity:** Periodontal treatment increments with processing maturity which is the reason for the huge predominance of periodontitis which examines among overpopulation. Maturity is related toperiodontitis and attachment loss endure essentially huge among population matured 60 to

69yrs contrasted and gathering of grown-up 40-50yers.

2. **Heredity:** Heredity is one of the most important components which is related to periodontal disease which causes a few people further defenceless to infection than others. The mind-boggling interactions of hereditary variables among ecological or segment factors is speculated to exhibit broad varieties encompassed by various genetic and indigenous populations.

Relationship of periodontitis with other systemic conditions:

1. Ischemic heart disease: Reliable group of proof clarifies the connection between ischemic heart disease and periodontitis. A systematic survey recognised that the periodontal infection abidehazard element for congestive heart failure and affiliation autonomous of more hazard elements for example smoking, diabetes mellitus and financial condition. An examination of imminent and review considers, it has discovered that periodontitis probably going to purpose a 19% expansion in danger of coronary heart disease and expansion in relation hazard ranges directed toward 44% encompassed by people matures 65 years and over. An older survey and investigation of examinations discovered that periodontal malady with expanded degrees of foundational markers of bacteria was related toischemic heart disease. Periodontal ailment affiliation with stroke and fringe corridors infection is significantly more grounded than coronary illness. Correspondingly, an examination of 29 investigations revealed merged chances proportions of 2.35 and polled corresponding danger of 1.34 that recommended people with periodontitis has more noteworthy chance and higher chances of creating coronary illness than those without periodontal disease.[14]

2. **Metabolicailment:** There are bidirectional communication and teamwork among diabetes mellitus and periodontitis. An imminent associate examinations of 628 subjects along check out recognised that insulin-independent diabetes mellitus people among serious periodontitis had 3.2 occasions danger of fatality due to coronary illness contrasted with the people with no or on the other hand gentle periodontal sickness. An examination presumed that the periodontitis developed glycemic control for any event for non-insulin diabetesmellitus. Deliberate survey gave proof to help the job of periodontitis in improvement of adult-onset diabetes and also it's difficulties. Logical writing reliably underpins a bidirectional communication among periodontal disease and insulin obstruction. It has contended that periodontitis fuels insulin oppositions, constantquality embroiled in pathophysiology of catabolic sickness and adult-onset diabetes mellitus. It has additionally proposed that periodontal medication can lessen insulin opposition in diabetes. A few orderly audits have proposed a relationship between heftiness and periodontal ailment and recognised hazardfactors for improvement of periodontal diseases.Heftiness is appeared directed toward increment oxidated worry in periodontal tissues what's more motivated towards destructions. Predominance of heftiness has expanded drastically among globe51and affiliation with periodontal disease requires consideration among human service suppliers to forestall the general medical problems.[15-17]

3. **Unfavourable pregnancy result:** Periodontitis is identified with unfavourable pregnancy results which incorporate maternal disease,low birth weight, preterm birth, preeclampsia, mist biological and immunological factors are embroiled in hidden strictures. Below economic condition,smoking and other diseases are now known to be related with untimely birth; in any case,more as of late it was discovered that periodontal malady is likewise unequivocally connected with untimely birth episodes.[18]

4. **Rheumatoid joint pain (Rheumatoid Arthritis):** Periodontal malady is common along rheumatoid joint pain patients and malady remains start immune system reaction in rheumatoid joint pain patients. It is recommended that periodontal malady and rheumatoid arthritis accept comparable hidden pathophysiology of disease. People suffering from rheumatoid arthritis have huge pervasiveness of bone obliteration and misfortune of toothwhichever additionally sequelae of periodontitis.

5. **Respiratory illness:** The significance of keeping upideal oral consideration along individuals with incessant intrusive pneumonic ailment has underlined because of bidirectional relationship with periodontitis. Respiratory illness mainly includes asthma,pneumonia and lung cancer.

6. **Chronic Kidney Diseases:** There is a fractional connection between periodontitis and chronic kidney disease. Periodontal disease is ahazard factors for chronic kidney disease in an ideological investigation of 11,955 grown-ups precise audit of experimental and international examines found that patients along periodontal disease are expanded danger of chronic kidney disease and periodontitis brings about constructive appear in people with chronic kidney disease.[19-21]

7. **Diseases:** Hazard of oral cavity malignancy increments 5.23 occasion severe millimetre bone loss. Fitzpatrick saw that connection among periodontitis and vocal, abdominal,oesophageal,anorectic malignant growths have been accounted for all the more reliably in writing than with long and prostate malignant growths.

8. **Impedance of intellectual capacities:** More seasoned grown-up faces a decrease in their intellectual capacities which influence their practices including oral cleanliness habits. There is humble proof about a relationship between periodontal illness furthermore poor intellectual capacities as periodontal irritation has been appeared to influence discernment in old populations. Further, a late examination found that analytic attachment loss can advance beta gathering in mind whichcreate intellectual dysfunction.

Determent of periodontitis:

1. **Avoidance of periodontal disease:** WHO suggests utilising incorporated general well-being preventive techniques which ought to be founded on regular hazard factor approach. Hazard factors, for example,stress,smoking,below economic conditions are real etc with periodontitis along with alternative fundamental interminable sickness, in this manner consideration of oral illness anticipation procedures in interminable fundamental ailment preventive activities can diminish the weight of malady in the vicinity of aligned of population.[22]

2. **Cleanliness of mouthrehearses:** Appropriate cleaning of mouth, normal brushing of tooth and flossing are best among forestalling infection in mouth and periodontal disease. Despite most extreme importance of brushing of the tooth about the portion of populace brush two times a day. There are different diameter, configuration and sorts of brushes; be that as it may, two increasingly basic sorts incorporated controlled toothbrushes and manual toothbrushes. Controlled toothbrushes often more bite of leeway up standard toothbrushes in lessening plaque present in the tooth.[23]

3. **Starve:** Despite fact that the job of starving in anticipation of caries is increasingly huge contrasted and forestalling periodontal illness has been talked about in the writing. An eating regimen high in organic products, below in hefty and sugar is necessary for solid periodontal structures. Less calorie consumption is appeared directed toward lessening incendiary diversity and reduce the tissue harm in periodontitis.

4. **Fluoride utilisation:** Stannous fluoride has anti-plaque along with anti-gingivitis impacts what's more or lessen the extent of microscopic organisms and spirochetes in sub gingival zones, subsequently can assist with advancing gingival health.

5. **Utilization of antimicrobial specialist:** Chlorhexidine, triclosan,fundamental oils and mouthwashes and gels are utilised to prevent explicit microscopic organisms like plaque. Cholrhexidine diminishes dental plaque and gingival aggravation by bringing down provocation mediators. Gunsolley looked at the viability of anti-plaque and anti-gingivitis mouth rinses with oral cleanliness directions what's more grown-up prophylaxis and discovered extraordinary improvement in oral cleanliness.

6. **Smoking suspension:** Since smoking is a significant hazard factors for periodontal illness,in this way smoking end can forestall an extensive extend of periodontal cases. Smoking suspension not just further movement of periodontal ailment however can likewise decrease the periodontal tissue destruction. In light relationship among periodontitis and coronary heart infection,scaling has as of late appeared to lessen the frequency of intense cardiovascular infection localised necrosis also stroke.[24-26]

Conclusions

Whereas periodontitis is the common pervasive irresistible oral situation however it is stoppable and curable. Decreasein rate and pervasiveness of periodontal malady can bring about bringing down its related foundational ailments and confusions. Decreased periodontal ailment weight can limit treatment needs

and can lessen money related effect on wellbeing care frameworks. High commonness of periodontal ailment additionally requires the foundation of reconnaissance framework for oral ailments in the network. Preventive projects for periodontal ailment ought to use normal hazard way to deal with decrease the size of other incessant infections. Cost successful techniques would likewise improve interdisciplinary coordinated efforts among human service suppliers. Health care suppliers ought to be acquainted with Perio-fundamental connection and ought to have the option to analyse and allude patients to specific dental considerations to increase personal satisfaction of individuals. Research is expected to investigate fundamental instruments along with hazard variables of periodontitis and create imaginative preventive methodologies.

Abstract

Verruciform xanthoma can be described as a rare, benign lesion. It can be classified as a papillary, asymptomatic or sessile. it can be well-demarcated from the adjacent tissue and can be seen frequently in the alveolar mucosa and gingiva. The salient histopathological feature is the abundance of foam cells (xanthoma cells) along with macrophages present in the soft papillary tissue.[1] The exact etiopathogenesis is still unknown, but the causative agents can be local factors like viral infections or trauma that have been suggested by hypothesis. Therefore this case report aims to present a case of verruciform xanthoma located in the marginal gingiva (lingual aspect) and describe the clinical features and histopathological aspects.

Keywords: *Verruciform Xanthoma, Verrucous Lesions, Xanthoma Cells.*

Introduction

Verruciform Xanthoma (VX) can be described as a benign lesion that appears rarely in the oral mucosa. Shafer in 1971 described it for the first time. Typically VX has a papillary or verruciform appearance and presents features of hyperkeratosis, and lacks in having proper etiopathogenesis. It has equal sex predilection. The widely affected patients are about the age-range of fifty years. It involves bothupper and lower jaws equally and the gingiva near the premolar area is one of the main sites having a maximum occurrence of VX.[1] Predominantly, it can present itself as an asymptomatic, slow-growing lesion. The base is either sessile or pedunculated, colour varies from pink to white.[2] The size of the lesion varies in different cases.VX most frequently occurs in the palatal or gingival masticatory mucosa, nevertheless, other areas where it can appear are the lateral border of the tongue, buccal mucosa, and floor of the mouth.For its particular characteristics, several cases of VX can be diagnosed as papillomas, condylomas, ordinary (vulgar) warts, and leukoplakia and occasionally as verrucous or epidermoid carcinomas.[2,3]

Case Presentation: A 35-year-old female patient came with the chief complaint of a growth on the lingual aspect of lower front teeth region for 3 months followed by loosening of teeth in the same region for 2 years (Figure 1). The patient doesn't give any history of pain. On clinical examination a single swelling is present in the lingual aspect of 41, 42 of 0.8 cm in diameter,well-circumscribed with areas of erythema. On palpation it was firm in consistency,non-tender, pedunculated and was bleeding on probing (Figure 2). The Lymph nodes examination showed non-palpable lymph nodes. The patient didn't have any systemic disease andcan be considered as healthy. After considering the clinical features,a provisional diagnosis of pyogenic granuloma was concluded. An excisional biopsy was performed after the clinical evaluation to dismiss the probability of malignancy.

Histopathological examination was done. The hematoxylin andeosin (H & E) stained sections showed parakeratinization in the epithelium along with columns of parakeratin plugging present inside it. Uniform rete pegs with deep connective tissue papilla were seen. The papilla was extendedtill the overlying surface epithelium. There was the presence of few neutrophil cells in the upper spinous layer. The main histologic feature of VX, which is the lipid-laden foam cells were seen in the papillary zone of lamina propria. The presence of the foam cells in the papillary region of connective tissue itself confirmed the diagnosis as VX (Figure 3).Any signs of dysplasia or malignancy were not found in the histopathological analysis.

Figure 1. Clinical picture of the lesion present in the marginal gingiva (lingual aspect) i.r.t 41,42

Figure 2. Clinical picture of the lesion with probing depth located in the lingual aspect of 41, 42.

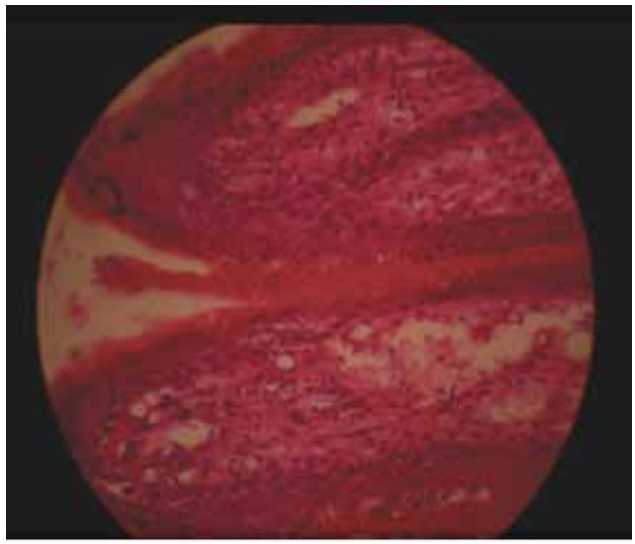

Figure 3. Presence of numerous lipid-laden foamy cells confined to the connective tissue papillae (H & E stain).

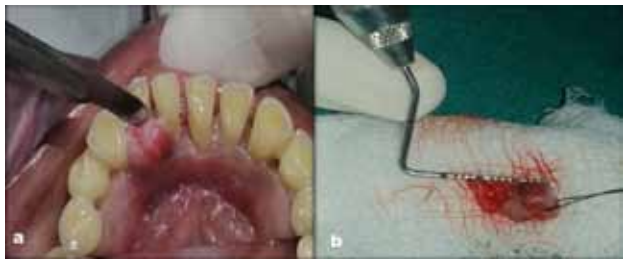

Figure 4a. Excision of the lesion using a scalpel; Figure 4b. Showing lesion after the excision.

Figure 5. Flap approximated and suture placed

Figure 6. Coe pack placed after the excision of the lesion

Surgical Intervention: The procedure was executed under 2% lignocaine. The lesion was excised asa whole during excisional biopsy (Figure 4). After the excision (Figure 5, Figure 6), the coe pack was placed (Figure 7) to avoid coming in contact with the external environment, and post-operative surgical instructions were given to the patient.

Discussion

Verruciform xanthoma is a benign lesionthat occurs rarely. Exclusively,two hundred and eighty-two cases had been reported up to 2001 and from the period of 2003 to 2007, only 3 cases of verruciform xanthoma were reported. Henceforth, it can be said that it's a rare lesion[3]. Reports have suggested that verruciform xanthoma is mostly seen in masticatory mucosa and mostly on the gingiva, followed by hard palate, tongue, buccal mucosa/ vestibule, floor of the mouth, alveolar mucosa, and soft palate.[4] Seen mostly in those patients having an age range of 40-70 years.[5] The clinical presentation shows isolated pink to white yellow papules or nodules, that are persistent, slow-growing and asymptomatic. The surface texture varies from papillary, granular, or verrucous.[5] They can have either a pedunculated or a sessile base.

VX is a quite uncommon lesion with an undiagnosed etiopathology. The probable reason can be due to the irritation in the squamous cells caused by infection, trauma which can ultimately lead to increased epithelial turnover rate. The epithelial breakdown results in a cascade of inflammatory response which further leads to the leakage of lipid materials from the degenerated cells.[6]

It appears similar to the HPV when seen histopathologically but any association between HPV and VX is not yet established. The main relevant clinical diagnosis can be papilloma or ordinary wart. Verrucous like solitary lesions in the oral cavity can be the differential diagnosis of VX. Due to its non-specific clinical features, there are several other differential diagnosis like squamous papilloma, condyloma accuminatum, focalepithelialhyperplasia, leukoplakia,verruca vulgaris or even epidermoid carcinoma in the initial stages.[6] Some previous case reports have shown the association between VX along with some other previous or concomitant lesions like lichen planus, carcinoma in situ or epidermoid carcinoma. These lesions are classified histologically based on several characteristics like surface texture, rete ridges proliferation etc. the rete pegs can be elongated, uniform and thin. They have keratinized clefts present in the central portion along with keratin plugging.[6] Nonetheless, the evidence of any metastatic features or dysplastic characteristics is not yet found.[7]

The main characteristics of VX are the abundant of the xanthoma cells in the connective tissue and the lipid-laden cells in the superficial layer of connective tissue. The accurate origin of these cells is controversial. It can be of the microphage or monocyte lineage. The treatment choice can be surgical excision of VX which is effective with almost no recurrence. In every case, after surgical excision histopathological examination of the biopsy samples should be done to rule out any possibilities of VX from any other verrucous lesions. [8-10]

Conclusion

VX can be described as a rare lesion encountered on the gingival mucosa. Its clinical features are not pathognomonic, so it should be considered as a differential diagnosis of Verrucous or papillary lesions. Furthermore, it needs proper treatment planning and management in time.

Abstract

Intraoperative or postoperative bleeding during any periodontal surgical procedure can to some serious complications. Difficulties related to bleeding can be seen in both healthy individuals as well as bleeding disorder patients, any systemic complications and patients under anticoagulant drug therapy. Having a clear perspective about the preventive measures to be taken to control the profuse bleeding is a must for a practitioner. The purpose of the literature review is to discuss the administration of different types of hemostatic agents available for controlling bleeding.

Keywords: *Hemostasis, hemostatic agents, bleeding control.*

Introduction

Bleeding is inevitable in case of any oral surgical procedures. The chief causative factor of bleeding is damage to the blood vessels during surgery. In this case, meticulous surgical procedures, availability of ideal hemostatic agents, proper postoperative care and follow up can reduce the complication to a greater degree. Profuse bleeding can to several complications like the formation of hematoma, delayed wound healing, persisting infection, wound dehiscence and necrosis. In this review, we discuss the preoperative, intraoperative and postoperative management of bleeding of patients undergoing periodontal or any kind of minor oral surgical procedures.

For evaluation and selection of ideal hemostatic agents for a particular case scenario, it is mandatory to understand the physiologic procedure of coagulation. The hemostasis occurs, vasoconstriction, platelet plug formation, platelet adhesion, activation, and aggregation. Whenever there is an injury, vascular spasm occurs and this will initiate vasoconstriction which will gradually lead to a stoppage of blood flow. Following the vasoconstriction, collagen which was exposed from the damaged blood vessel will influence the platelets to adhere, activate and aggregate to form a platelet plug. Platelet adhesion is mostly mediated by Von Willebrand's Factor. Platelets are activated by enhancing their shapes into a more of a pseudopodia form that the adhesion of platelets into the damaged tissue surface. Once the platelets become activated, it will help in the attachment of VWF and fibrin. The activation is further intensified by producing thrombin via the hemostasis mechanism.

This review article focuses on various measures to control intraoperative and postoperative measures to control bleeding.

Mechanical method to control bleeding: Application of pressure counteracts the hydrostatic pressure within the blood vessel. Applying pressure is usually able to control most of the hemorrhages. It should be applied directly over the bleeding site firmly over a gauze pack for at least five minutes. Hemostats are also called a hemostatic clamp, arterial forceps etc. Hemostat (mosquito, artery) forces are specially designed to catch

bleeding points in the surgical area. Also, prefabricated stents can be used after surgery to trauma to the surgical site also gives it adequate protection.

Embolization of the vessel: With the help of angiography, the exact bleeding point can be localized. Agents that can be used for embolization include steel coils, polyvinyl alcohol foam, gel foam, silicon spheres, and methyl methacrylate. These particles are placed precisely into the bleeding vessel via a catheter.

It has shown significant results in implant surgery to control bleeding immediately after the tear in the lingual artery[1]. Thus, it can be considered as a reliable method for hemostasis.

Thermal method to control bleeding:

Cautery: Hemostasis by using cautery is based on the principle of denaturation of proteins by heat. This proteins undergo precipitation and to coagulation of large areas of tissues. The heat produced by the cautery leads to protein denaturationwhich ultimately culminates into the coagulation of large areas in the tissue. In cauterization, heat is conducted directly into the target area (tissue) via the instrument.

Electrocautery: The fundamental of electrosurgery is based on the principle of using electrical energy which is directly transmitted to the tissue for inducing histological effects. Current range is 1.5 -7.5million per second or megahertz. Using two electrodes, an alternating current may be conducted through the body with almost no effects other than producing heat. The heat produced is solely the result of the resistance created by tissues to the current pathway. This results in a concentration of current at the smaller electrode and the effects are de, hydration, warming of the area, coagulation or tissue destruction by heat depending on the type, the size and the frequency of the active electrode and the duration of application.

The argon beam coagulator (ABC): It provides radio frequency electrical energy (coagulator monopolar current) to tissue by using a heavy stream of argon gas. It delivers noncontact, monopolar, electrothermal hemostasis. In cases of bleeding from small diameter vessels(size $\leq$ 3mm) where bleeding cannot be stopped using other hemostatic agents or ligatures, an argon coagulator is always a good option for these scenarios. This coagulator has also shown improved results in control of presacral bleeding[2].

Lasers: Lasers to perform surgeries with less or almost no blood, as these effectively coagulate the small blood vessels while tissue cutting or sectioning. It provides a clean, dry surgical field with improved visualization[3]. It was seen that it has enhanced the bactericidal effect when used in implant sites without extreme heat production[4]. An in vitro thromboelastographic study showed that after three and six seconds there is a decrease in coagulation time while using 10 W of continuous-wave laser irradiation of 10 ml of blood and resulted in increased clot formation rate[5]. In the present scenario, LASER is widely used because it aids in pain relief, improved healing and speeds up the tissue repair.

Chemical method to control bleeding:

Adrenaline: Adrenaline or epinephrine, applied topically induces vasoconstriction and thus helps in achieving hemostasis. However, adrenaline has a dual-action called a vasomotor reversal, at low doses it causes vasoconstriction but later it leads to vasodilation. Thus, extensive application or undiluted preparation can cause systemic effects therefore, care should be exercised while using adrenaline. It can also be injected with L.A in a concentration of 1: 80,000 to 1:2,00,000.

Astringent and stryptics: When astringent comes in touch with the injured tissue surface, a thin film is formed upon the surface and the superficial membranes and blood vessels are contracted to cause shrinkage of the tissue and thus resulting in protein precipitation[6]. Monsel's solution which is quite effective in controlling capillary bleeding contains Ferric sulfate and it acts by precipitating proteins. Tannic acid also has the same mechanism of action. A study showed that messaging astringent gels in the edentulous areas showed improved keratinization in the denture wearers.

Bone wax: The material is a combination of beeswax, salicylic acid, and almond oil. The mechanism of action of bone wax is mostly mechanical. It can be applied directly to a particular bleeding point in bone. It is normally non-absorbable in blood or saliva. It results in the formation of a soft and malleable mass when heated and manipulated. Commonly supplied in sterile sticks.

Another product BoneSeal® which is a composite of biodegradable polylactic acid with hydroxyapatite and having wax-like handling properties[7]. BoneSeal is designed to promote hemostasis and deliver improved

bone regeneration when compared to bone wax.

Thrombin: Thrombin agents are produced from either human or bovine plasma. It can also be derived from recombinant DNA techniques. The topical use of thrombin acts by converting fibrinogen into a fibrin clot[8]. It shouldn't be injected in the bloodstream or open, large blood vessels which can cause intravascular clotting. It was found in a study that a thrombin Arg-Gly-Asp complex helps in cell adhesion[9].

Gelfoam: It is an absorbable gelatin sponge containing fine, dry, heat-sterilized powder prepared by milling absorbable gelatin. It is insoluble in water, porous and pliable in nature. The mechanism it uses for hemostasis is more physical and it does not affect the blood clotting pathways. Gelfoam is absorbed completely, with little tissue reaction when used in less amount. Normally it is absorbed inside the wound area within 4-6 weeks. It doesn't in abundant scar tissue formation. It was reported that it can produce better results in clot formation than collagen[10]. It is contra indicated for skin closure because it might interfere with the healing of the incision lines.

Oxycel or surgicel (ORC): It is also known as Surgicel or Oxycel for commercial use. It is derived from plant-based alpha-cellulose. It is an absorbable hemostatic agent that has been used to control bleeding safely, simply and effectively. It soaks up the blood and transforms into a gel at the target area. It results in lowering the pH and also caused localized vasoconstriction. ORC also acts as a scaffold or matrix for platelet adhesion and also supports the newly formed platelet plug. It was used in the treatment of intrabony defects and it has shown a significant reduction of CAL and PPD[11].

Fibrin glue: Fibrin glue or Fibrin sealant is comprised of fibrinogen and thrombin that is used in the damaged tissue sites with the purpose of tissue adhesion. Some fibrin sealants also contain aprotinin, fibronectin and plasminogen. The thrombin(enzyme) leads to the conversion of fibrinogen into fibrin monomers incorporated 3-D gel-like structure within the period of 10-60 seconds.

Each fibrin sealant system is made up of two parts. The first part consists of: It is available as a two-component system: the first component contains fibrinogen, factor XIII, fibronectin, and traces of other plasma proteins. The second part contains thrombin, calcium chloride, and antifibrinolytic agents such as aprotinin. Combining the two parts initiates blood clotting mechanism along with the formation of fibrin.

Fibrin glue can be used in various surgical procedures like implant placement in the anterior tooth region. In a comparative study done in 2008 stated that the use of fibrin sealants is superior to using regular suture material because it is easy to handle, helps in induce hemostasis, proper adhesion of tissues and aids in wound healing[12].

Sealants must be used carefully because an excessive amount of sealant can to tissue necrosis[13].

Co-seal: It is made up of polyethylene glycols (PEGs) mixed with hydrogen chloride and sodium phosphate. It is a non-toxic, FDA approved material that is biocompatible and can be easily delivered[14]. When the solution is mixed, it transformed into a hydrogel which attaches itself to the damaged tissues. It is synthetic in nature and doesn't contain Glutaraldehyde. The mechanism of action is mostly physical as the gel swells up in volume (almost 4 times) and can undergo further swelling as it undergoes resorption.

Platelet-rich plasma gel: Platelets contain several growth factors such as platelet-derived growth factor, transforming growth factor, insulin-like growth factors I and II, and epithelial growth factor. Because of this property, autologous platelet concentrate(APC) is widely used to boost postoperative healing. The platelet concentrate can be prepared via centrifugation by using patients own blood. The thrombocyte count of PRP was 1,035,000/L (mean). It also bears mucosa-adhesive properties thus widely used in the field of dentistry.

Ethamsylate: The hemostatic mechanism of ethamsylate is due to the activation of thromboplastin formation on damaged vessel walls. It also decreases prostacyclin 2 synthesis and facilitates platelet aggregation. It acts by correcting abnormal platelet adhesion. It exerts antihyaluronidase action, improves capillary wall stability not (not an antifibrinolytic).

Tranexamic acid: Tranexamic acid 4.8% is commonly used as a mouthwash because it helps in clot stabilization. It also helps in down regulating plasminogen. Because of its antifibrinolytic activities, it can be used as a prophylactic in patients who are taking anticoagulant drugs. A study showed that the efficacy of tranexamic acid when combined with cetylpyridinium chloride, is significantly increased for treating periodontal diseases[15].

Botroclot: It is a form of concentrated enzyme sources extracted from the venom of South American viper, Bothropsatorox. Botroclot (Jaggat pharmaceuticals) is a topical preparation that contains extracted hemocoagulase. It aids in healing and also having procoagulant property. Botroxobin, a WHO-approved product, has been introduced to treat the site of injury. It has shown improved healing property when used in extraction sockets[16].

Protamine: A proteolytic enzyme from the venom of South American viper, Bothropsatorox. It also functions as a plasma clotting agent for fibrinogen. It is a protein molecule having a positive charge and it attaches with heparin which is negatively charged. The ultimate complex formed inside the body is removed by the reticuloendothelial system.

It was found that a combination of heparin and protamine has shown decreased postoperative bleeding[17].

Desmopressin: It is a synthetically manufactured vasopressin analogue which was actually originated for treating diabetes insipidus[18]. Nevertheless, it was used as a hemostatic agent when its ability to release of VWF and factor VIII from the endothelial cells was discovered[19]. It also aids in primary hemostasis.

Vitamin K: Vitamin K plays a massive role in the coagulation process. It also helps in the production of fibrinogen and prothrombin in the liver, thus it can be considered as a vital factor for bleeding control. It can even prevent the chances of bleeding in patients taking high doses of anticoagulant drugs.

Newer hemostatic agents:

Chitosan-based dressings: Chitosan is a biocompatible, complex carbohydrate acquired from chitin (a natural compound derived from zeolites): when the deacetylation of chitin is above 70% it is called chitosan. It is a type of acid salt which has mucoadhesive property. It has a positive charge and it attracts RBCs and Platelets which have a negative charge. It also offers sealing action and antibacterial property.QuikClot (inorganic hemostat) is a chitosan-based product currently available

Polysaccharide-based hemostats: Polysaccharide hemostats, like STARSIL® and HEMOSTAT, seems to be useful in bleeding control. It is widely used in cardiac surgery procedures[20]. Reduction of wound healing complications (mostly seen after using bone wax) can be considered as additional.

Conclusion

Hemostasis can always be considered as the main pillar for the success of any surgical treatment. Even with the judicious application of local hemostatic agents, minor to moderate invasive surgeries can be safely performed. Several other factors like the application of local pressure during surgery, post-operative mouth rinses also aids in bleeding control. However, detailed medical history of the patient, case selection and proper knowledge of surgical anatomy- these factors also have a major part in implementing a safe and successful surgical procedure without any postoperative complication.

Considerations in Questionnaire Development: A Review

Ipsita Mahapatra[1], Ramesh Nagarajappa[2], Dharmashree Satyarup[3], Sharmistha Mohanty[1]

[1]Postgraduate Trainee, [2]Professor and Head, [3]Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A fundamental part of good research is concerned with making sure that the design of the questionnaire addresses the needs of research. After a proper administration of the questionnaire, a questionnaire constantly measures what it intends to measure thereby giving us confident results of a study. It has been documented in several studies regarding Validity and Reliability, as an important source of measuring the accuracy and consistency of research instruments (especially questionnaires). But their measure is not observed to be practiced in developing countries among health plus social science researchers. This review article comprehensively explores and describes questionnaire design and measures to validate a questionnaire including its reliability testing.

Keywords: *Questionnaire, Reliability, Validity.*

Introduction

The questionnaire can be defined as "a tool for collecting and recording information about a particular issue of interest". It is a proficient means for estimating the "behavior, attitudes, sentiments, opinions and, intentions of generally large quantities of subjects" more economically and rapidly against different strategies. Questionnaires are a good research method because it can be accessible to a large number of people relatively easily and economically. They also provide quantifiable answers for a research topic, hence being easy for analysis.

A definite purpose of Questionnaires is to be related to the objectives of the research. They are prepared in various languages, expanding investigation into new measurements by leading examinations in various cultural groups. Validation of questionnaires in those individual languages lead to exact and strict data about the specific cluster.[1]

Design of the Questionnaire: Careful consideration must be given to the design of the questionnaire for gathering useful and relevant information. A lot of thought and effort is required for a well-designed questionnaire along with proper planning and development through various stages (Figure 1).

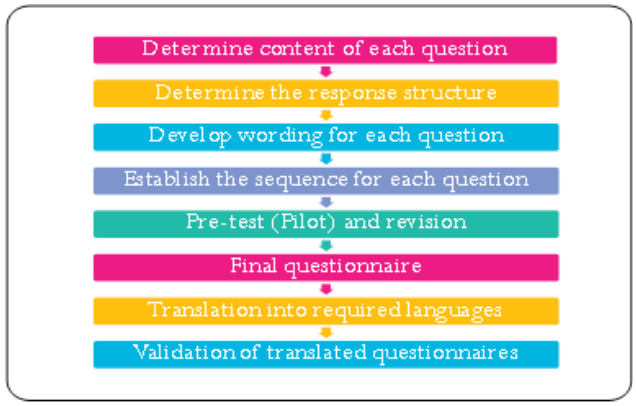

Figure 1: Questionnaire Design

Development of a Questionnaire: The numbering and order of the questions should be in a style that is reasonable in the participant's view. Usually "Funneling" method is utilized which starts from basic questions

Corresponding Author:

to comfort participants and afterward centers down to progressively more explicit questions.

Step 1: Determining the contents of the questionnaire: Determining what topics, the questionnaire will cover and how it will be administered is the first task. Based on the study objectives, the number of domains is decided. Posing a large number of questions that are not straight forwardly helpful or significant is the most frequent problem in questionnaire design. It can be organized as follows:

1. The prime objectives of the study should be outlined.
2. Questions relevant to the objectives must be asked and only necessary information should be recorded.
3. The lists should be rearranged and organized into distinguished sub-themes or sections of the questionnaire.
4. The decision for the process of filling up of questionnaire by participants themselves or by an interviewer should be taken.[2]

Step 2: Formulation of the questions: Once the sections of the questionnaire have been identified, individual questions must be formulated for gathering the particular pieces of information needed. To deliver significance and purpose of the question to the participants, a step called "wording questions" (selection of words or phrases) is practiced. This ensures that they are uniformly understood by the respondents. Below are the general rules on good question formulation:

i. **Each question must be clear, simple, and specific:** Questions must be indicated in simple, short and clear language. Such as the question can be broken into pieces to assist participants or they may be asked to reveal purposely the different measures taken by them since the beginning of the illness. The following questions may be involved: Did your child suffer from toothache within the past three weeks? (If yes): "Did you visit anyone for advice or treatment? Did you give the child any medicines?" (If participant mentioned medicine(s) were given): "Would you please list any medication(s) that the child has used since the toothache started?"

ii. **Each question must measure one thing at a time:** Measuring two or more dissimilar things in a question is incorrect. Such as questions like "How do you and your staff normally treat children who present with a toothache?", requires partition into numerous questions to permit participants for providing individual answers as there may be a favored method for treating toothache by different prescribers in the office.

When presumptions are made about the participants, Leading questions may also arise. For instance, the question: "What medication did you give your child when he got toothache?" is biased since the respondent would give the child medication, because of the presumption that the child had a toothache. An improved version may be: "Has your child had toothache within the last week?"

(If yes): "Did you take any action?"

(If yes): "What action did you take?"

iii. **Questions must be free from ambiguity:** It is advisable to exclude indistinctly defined or words having double meanings. The question: "What kind of patient was he?" Might generate responses like "poor" or "rich," "simple" or "complex," "cooperative" or "un-cooperative," etc.

"Double-barreled" questions like: "Do you think amoxicillin and paracetamol are effective for treating toothache?" can't be good questions as a participant could like any one of them. In such a situation, having a Yes/No reply would not truly mirror the participant's opinion. Instead it is worthy to divide it into two questions with individual thought.

Step 3: Sequence of the Questions:

The questions must be organized in a sequence after framing them. Following approach is helpful for participants:

(a) The topics should follow a logical order. A smooth flow of thoughts running from general questions within a topic to gradually more specific ones.

(b) Focus should be on interesting and relatively "non-controversial" questions, e.g., "How many years have you worked at this place?"

(c) Sensitive questions like personal information regarding age, education, occupation, and income may create unwillingness among the participants if asked early. Hence they should be placed at the end, after establishing a relationship of trust.

(d) Questions influencing answers to a different question should be separated.

(e) Clear indication of instructions for skipping one/ more questions

Step 4: Arrangement of the Questionnaire

The layout of the final draft questionnaire should be made both "consumer" and "user" friendly. It includes:

1. Required headings and spaces for labeling.
2. Identification of all questionnaires by recognizing information for participant, date and place of interview, and name of the interviewer.
3. Start each section of the questionnaire with necessary instructions.
4. Sufficient space between questions.
5. For pre-categorized answers, be constant with codes or boxes.
6. Enough Space to be provided for answers to open-ended questions

Step 5: Conducting Pilot tests:

Pilot testing of the questionnaire is done with the help of applied qualitative method. The developed questionnaire is tried in a group and a similar environment to that of the original study environment. This will provide an opportunity for interviewers to perform all the activities that are estimated to take place in the field.

Step 6: Translation of the Questionnaire: Most interviews are conducted in local languages. A thorough translation of Questionnaires is done before the fieldwork begins for ensuring consistency while using the words and meanings. Back translation of the questionnaire into the original language it was written is done by a different translator. A comparison of both the versions is then done to rule out any differences.

Step 7: Validation of the Questionnaire:

"Validity is the degree to which an assessment measures what it is supposed to measure". The different types of validity are mentioned below:

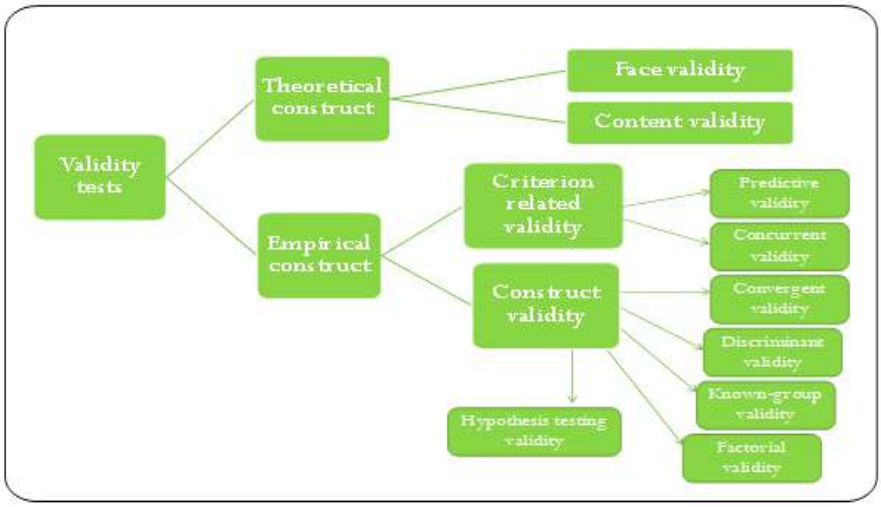

Figure 2. Validity test of the questionnaire

Face Validity: Face validity, "being a form of content validity is assessed by having 'experts' (clinicians/clients/researchers) review". The contents of the questionnaire are being reviewed by an expert on the research subject to see if the items seem appropriate.

Content Validity: "It pertains to the degree to which the instrument fully assesses or measures the construct of interest".[3-7] It is established by experts well-known with the research subject. The experts review the questionnaire items for "readability, clarity, and comprehensiveness" and get nearer to a certain level of agreement for including the required items in the final questionnaire. Based on the ratings of the items in the questionnaire, a significant level of inclusion of an item requires a CVI (Content Validity Index) of ≥ 0.78.[5]

Criterion-Related Validity: Criterion-related validity is "assessment of the relationship of scores on a test to a specific criterion".[8,9] It is a measurement of

"how well questionnaire findings pile up against another instrument".[9,10]

Concurrent Validity: Concurrent validity is "the ability of a test to predict an event in the present form". Here a highly rated existing standard (gold standard) is used for comparison against a newly developed questionnaire.[4] Concurrent validity comes into consideration when the criterion and the measure coincide at the same time.[9, 11-14]

Predictive Validity: It is the "ability of a test to measure some event or outcome in the future".[11,14]. Predictive validity deals with the capability of the questionnaire to predict future events, behavior, attitudes or outcomes. The correlation coefficient is used here.

Construct Validity: It is the "degree to which an instrument measures the trait or theoretical construct that it is intended to measure".[15] Instead of using a criterion for comparison,a hypothetical construct is utilized.[15] It measures how meaningful the scale or instrument is when it is in practical use. Depending on the research problem, four types of validity tests serves the function of construct validity:

Convergent Validity: In convergent validity we check the measures that should be related are related. For example, we construct "education" by asking people how much education they have completed. Then, this record can be compared with their institutional records and a test of school-level knowledge. Both the measures should converge or be similar for a good convergent validity.

Discriminant Validity: It proofs that one concept differs from other closely related concepts.[12] For instance, we have 10 items that measure good oral habits. People respond to all 10 in similar ways. But in the same questionnaire, we have also put 5 questions that measure bad oral habits. Our questionnaire holds good discriminant validity of the 10 good oral habits items stuck together as well as show a negative association with the 5 bad oral habit items.[4]

Known-group Validity: Here comparison between two groups is done within a known attribute. Such that a higher score is given to a group with related attributes while a lower score is given to the group with an unrelated attribute.[16,18-20] For instance, a questionnaire was used to investigate depression between two groups of patients with and without a clinical diagnosis of depression. As it is predictable in clinically diagnosed patients of depression, the score for the construct of depression in the questionnaire will be scored higher in comparison to those without the diagnosis.

Factorial Validity: Being an empirical extension of content validity, it "validates the contents of the construct employing the statistical model called factor analysis".[11] While analyzing factorial validity within a construct of interest, the several items which measure a particular dimension are meant to be highly associated with each other than those measuring other dimensions.[16] Such as there are eight dimensions in health-related quality of life questionnaire (HRQoL). Hence it is supposed that under the domain social function (one dimension from HRQoL) all items of the questionnaire measuring it must be highly associated than those items measuring another domain like mental health.[20]

Hypothesis-Testing Validity: It tests "the relationship between a measured concept (variable) or other concepts (variables), derived from a theory, thus providing evidence that a research hypothesis is supported".[17] Suppose in case of social learning theory revealing how observing physical violence in television leads to violent behavior, a hypothesis is derived from this theory stating a positive correlation between both variables. If the hypothesis is supported by the evidence collected, it is concluded that a higher degree of construct validity is observed in the measurements of physical aggression and viewing of televised physical violence. It is declared after measuring and examining the two theoretical concepts in the hypothesis-testing process.[4]

Reliability of a questionnaire: "Reliability is an extent to which a questionnaire, test, observation or any measurement procedure produces the same results on repeated trials". In short, it is the stability or consistency of scores over time or across raters.[3,4] A sign of lack of reliability exists due to divergences between observers or instruments. Usually carried out by a pilot test, it could be assessed in three major forms discussed below:

1. **Test-retest reliability:** "The ability of the questionnaire to provide similar results when delivered to the same participant on two separate occasions to see how stable the responses are". Generally, a correlation coefficient (r) value $\geq$ 0.70 is considered as good.[20] There is a scope for the memory of the last answer to affect test-retest practice as the participants become known with the terms from the previous test.

2. **Alternate-form reliability (or equivalence):** "It is referred to as the measure of agreement between two or more research instruments like two different questionnaires on a research construct that are delivered at nearly the same point in time".[3] Followed by a parallel form procedure, in which alternative forms of the same measure is delivered to either the same group or different group of participants. Questions or responses are reworded and rearranged to create two items that are related and un-identical. Delivery of the various forms can be at the same time or following some intervals. More similarity between the two forms indicates a higher degree of correlation between them.[4]

3. **Internal consistency:** "It is the degree to which the subjects answer similar questions similarly". Two equivalent forms of a questionnaire are administered at the same time to a subject and assessed for internal consistency. Other method include the "split-half reliability index" and "coefficient alpha index".[21] Sometimes, "Kuder–Richardson formula 20 (KR-20) index" can also be used.[3]

Intraclass Correlation (ICC): Intraclass correlation measures "the reliability of ratings or measurements for clusters- data that has been collected as groups or sorted into groups". It describes how strongly the units in the group resemble each other. The ICC ranges from 0 to 1. High similarity exists between values from the same group if the ICC value is close to 1. If the ICC value is close to zero, it indicates that values from the same group are not similar.[21]

Conclusion

Good questionnaire design is a key to obtaining good survey results. Based on validity and reliability testing, questions are re-written, removed or included, until the researcher feels the questionnaire met the standards set by him. In this article we have discussed the various ways of testing the validity and reliability of a questionnaire which will help the researcher to improve his knowledge and skills.

Recent Advancements in Imaging of Oral Cancer

Namrata Mishra[1], Abhishek Ranjan Pati[2]

[1]Postgraduate Trainee, [2]Reader, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In oral fissure, "squamous cell carcinoma (SCC) "is the commonest oral carcinomas which comprises (90-95%). After the 5th decade of age, male predilection is double as compared to females. (40%)of OSCC are confined to the dorsal or ventral surface of the tongue, (thirty percent)on the floor of the oral fissure. "OSCC" regularly distresses maxillary and mandibular attached gingiva, buccal mucosa, retro-molarand palatal region. In 5 years' survival percentage series from 20% {OSCC in the floor of the mouth} to 60% {OSCC in alveolus portion of jawbone} depicting poor prognosis. Although it is tough but it is required to do imaging studies to understand the results at the initialphases of the disease. Various modalities include {conventional plain film radiography, panoramic radiograph, cone beam computed tomography,Perfusion computed tomography,Magnetic resonance imaging–(diffusion-weighted MRI, dynamic contrast-enhanced MRI), ultrasonography, single-photon emission computed tomography}, fusion techniques such as (ECT/CT, CT/MRI, PET/CT, PET/MRI) along with nuclear medicines – (2-deoxy-2-[18F] fluoro-D-glucose), (18F-FDG), 18F-3-fluoroalpha-methyltyrosine, (18F-FAMT) and L-1-[11C]-tyrosine(C-tyrosine), radionuclide imaging. These various imaging diagnostic modalities support in the grading of the tumor, valuation of the vascular supply, resolution about metastasis combined with confined lymph nodes as well as detached organs. Furthermore, imaging lessons help to forecast the possibility of resection and advance management, graft establishment, and diversity amongst reactive and metastatic lymph nodes,and amongst diseases reappearance and marks or adversative reactions of post-operation or emission therapy.

Keywords: *Oral squamous cell carcinoma, imaging modalities, radionuclide imaging.*

Introduction

Ninety percent of oral cancers are the squamous cell carcinoma .75% of oral cancer occurs due to our lifestyle changes. Two decades ago there were 20% of HPV related cancer,now it has been a great hike to 50%. HPV related oral cancers are 6-7 times more likely to occur in men compared to women. Five persons die daily in every hour in India.[8] Oral cancer occurs due to various factors like tobacco consumption,human papillomavirus, genetic factors, etc. As it is adversely affecting the globe we should have a good diagnostic procedure for better treatment planning.[1]

Importance of Imaging of Oral Cancer:

- To know the extent of disease.
- Resectability
- Preservation of form and function
- To know distant or occult metastasis
- To know the dissemination and invasiveness of bone.[7]

Imaging modalities like (conventional plain film radiographs,panoramic radiographs,computed tomography, magnetic resonance imaging, ultrasonography, single-photon emission computed tomography,positron emitted tomography,fusion or hybrid imaging such as pet –ct,pet –MRI, etc).

Conventional Plain Film Radiographs: The distinctive structures of metastatic lesions in this radiograph depictcortical lamina degeneration, osteolytic weaknesses with solitary and multilocular with an initial osteosclerotic shell. In advanced phases, the crests of jawbone weaknesses becomes evere and teeth fail its bony maintenanceon the position of penetration ailment reappearance and marks or adversative responses afterward surgery or emission therapy.[1]

Panoramic Radiograph: In"panoramic radiographs", participation of the facial bony structures can"t be evaluated, because onceosseous tissues are damaged larger than 30%, the radiolucencies are suggestively amplified. Plain radiographs cannot assess soft tissues structures,reveals valuation of bone contribution on this radiographs have a 75% sensitive value 100% specific value .[1]

Positron Emitted Tomography: {F-Fluorodeoxyglucose positron emission tomography} (F-FDG PET) is a practical imaging technique that delivers data approximately tissue absorption and receipts been successfully functional to the estimation of head and neck carcinomas. PET is created on recognizing amplified glycolytic activity in menacing cells, in which radio labeled FDG is specially focussed due to rises in membrane glucose carriers and in hexokinase, an enzyme which phosphorylates glucose. Subsequently phosphorylation, radiolabeled FDG stays to gather in growth cells instead of glycolysis, permitting imaging by PET. (F-FDGPET) is extradelicate in comparison to CT or MRI to identify cervical node metastases.

It helps to identify metastatic nodes which are morphologically standard. It discovers distant and occult metastasis. It detects recurrences and used for treatment evaluation. It is used forplanning adjuvant for chemotherapy or radiotherapy. It is a prognostic indicator with CT or any fusion imaging.

PET alone cannot delineate the extent of the tumor. It has are duced anatomic resolution. [2]

Magnetic Resonance Imaging: It is the procedure that affords the maximum image value of soft tissues deprived of involving ionizing radiation,lacking any genetic risks. MRI is used to evaluate the degree of loco-regional tumor range, penetration of incursion and level of lymphadenopathy. The invasion of the floor of the oral cavity by the tumor is represented well in the coronal plane. Non-contrast T1W arrangements depicts cortical erosion and marrow invasion. Contrast-enhanced T1W images benefit evaluate marrow invasion, perineural spread, soft tissue extent, tumor depth and best demonstrate necrosis in nodes. The T2W images are sensitive to the presence of tumor tissue,which is usually hyperintense compared with the surrounding tissue. [3]It helps in surgical planning and assessment of problems that can occur during or after surgery. Limitation is the artifacts of ferromagnetic prosthesis of jaws.[11] DWI {DIFFUSION WEIGHTED MRI} can be accommodating in evaluating the initial answer of the tumor to chemotherapy. DCE-MRI {DYNAMIC CONTRAST ENHANCED MRI} helps in evaluation of micro vascularity and perfusion of tumor whichcan be estimated, which can help to forecast result.[1]

Ultrasonography: It is the imaging modality used for the evaluation of apparent diseases, lymph nodes as well as to guide needle aspiration biopsies. It is applied to know the microvascular changes, depicts the elevated vascularity within the tumor. It is used for the evaluation of the size and thickness of soft tissues. Intraoral USG along with colour Doppler helps in assessing the involvement of lymph nodes. USG guided FNAC gives a hint of nature and site of the primary tumor, helps in better assessment of pre and post-therapy. It also helps in confirmation of metastasis.[10,16]

Computed Tomography: This imaging modality helps in the detection of the primary tumor. It depicts the bony invasion of the lesions. It cannot appreciate the recurrence of the lesion,cannot differentiate the surgical scar as well as the adverse reaction of post-radiotherapy."Contrast-enhanced CT" able to precisely control lymph node metastases which can be originally appeared regular, despite the existence of micro metastasis identified in microscopic lessons. The sensitive value of CT in identifying tumors is (41–82%) (specific value 82–100%) and to determine bony infiltration (63–80%) (specific value 81–100%), respectively.[1,13]

Perfusion Computed Tomography: It is used to assess the participation of the surrounding tissues by assessing the perfusion of the tumor origin accurately,[12] tumor is categorized through amplified(blood volume) (BV) and (blood flow) (blood flow) in contrast with healthy tissues. This results from neoangiogenesis in the tumor. It is recommended that perfusion Computed Tomography is higher to Computed Tomography as favoursvaluation for mass engrossment.

Cone Beam Computed Tomography: High radioactivity dose, cost, availability, longer scanning time, poor determination and trouble in interpretation have led to restricted usage of CT which can be overwhelmed with CBCT, which delivers several potential benefits for Oral & Maxillofacial imaging, associated with conventional CT. The limitation of CBCT is the artifact impairs image value and boundary acceptable visualization of constructions in the dentoalveolar region. Artifacts can

be due to beam hardening (results in cupping artifact and stripes and dark bands), Patient-related artifacts (Patient movement resulting in unsharpness of reconstructed image), Scanner related artifacts (circular or ring-shaped) and cone-beam–related artifacts (partial volume averaging, under-sampling, and cone-beam effect. Image noises due tothe large volume being exposed during CBCT scanning causing in heavy communications with tissues creating scattered radiation, which in turn clues to nonlinear diminution by the detectors.[4]

Single Photo Emission Computed Tomography: This imaging modality helps in the mapping of metabolic activity. It helps to locate the sentinel lymph node. It helps to evaluate the distance of sentinel lymph node to skin. It detects the fluidity of lymph into the sentinel node. It accurately detects bony involvement as well as the relation to the surrounding structures.[9,15]

Radionuclide Imaging: "Radionuclide imaging" is the procedure which is a non-invasive functional imaging procedure, which providesdata of physiological as well as biochemical processes pathologically).[5]

Lymph Node Scintigraphy: Lymphoscintigraphy is used as a radioisotope procedure for the planning of sentinel lymph nodes. It takes the advantage of constant turnover of bone in response to metabolic or mechanical demands. Most diseases including bone end in amplified turnover or new development of bone. On scintigraphy, these areas perform as areas of amplified radio nuclide acceptance, called "hot spots."Lower acceptance is associated with metabolically inactive bone, deficient osteogenesis, or an absent vascular supply. It also designatesa lack of reparative response and suggests the presence of a violent lesion. Photon-deficient region or photopenic abnormalities are those areas where there is diminished or absence of uptake and are called "cold spots.[5]

Radio-Isotope Imaging in Oral Cancer:

{Carbon-11, Nitrogen-13, Oxygen-15, Fluorine -18}

It can be applied in positron emitted tomography images with the usage of (F-18) in FDG which helps for detecting, identify and distinguish the prediction of tumor.

{Cobalt-57}

It is used as a mode of (detector) of hypertrophy of cells, indirectly control the partition,advancement of cells growth to stimuli.

{Gallium -67}

It is applied for imaging the size of the tumour.

{Gallium -68}

It is applied in PET examination to distinguish metastatic action of the lesion.

Advantages of nuclear medicine:-

- Beneficial for initial analysis of diseases and assessment of management properties in the early post-therapeutic period.
- Permits simple demonstration of entire-body images and interactive display, which helps to notice metastatic action.
- It gives anatomical knowledge that is used for the diagnosis of diseases.
- Thorough investigations that can be accomplished at different sites as well as on multiple times afterward injection of a tracer isotope to illuminate conclusions deprived of growing radioactivity contact, distinct another simple procedure where there is the numeral of exposures.

Drawbacks of nuclear medicine:

- Though divergence of lesion against adjacent tissues is higher when radiotracers gather in the lesion, having a spatial resolution, generally, is poor with comparison to radiographs, Computed Tomography or Magnetic Resonance Imaging.
- The price of equipment which is applied is relatively expensive.
- The price of an individual investigation is dependent on the charge of radio drugs applied and the competency of the scanner.
- The Patients are unprotected of ionizing radioactivity managed to builds.6
- Emission contacts are very much unlike from radiographs and computed tomography, which includes peripheral as well as in generals imply partly body contact, radionuclide control patients cause internally entire body coverage in a non-uniform method firm by the bio circulation and permission kinetics of that tracer.

- Because of inevitable higher radiation from positron emitted tomography tracers to the staff people, interacting with radioactive patients, it is recommended that a 6 mm dense lead protective is not logical.

Inference: As the oral cancer progressing so rapidly we should prevent it by diagnosing accurately and doing treatment planning accordingly. For diagnosing carcinomas various imaging modalities are used like two-dimensional imaging like conventional plain film radiographs or panoramic radiographs are used to know the bony extension of the lesion,three dimensional like computed tomography, magnetic resonance imaging or any fusion imaging is used like PET-CT, PET-MRI these are used to know the asses the recurrence, evaluation of lymph node, peri-neural invasion, Lymphoscintigraphy is used to assess the sentinel lymph node. Nuclear medicine is used to know the initial phase of the lesion and post-operative action.

Diagnostic protocol for (detecting,staging and following up of patients with oralcarcinomas)

- To assess the primary tumor size-contrast-enhanced computed tomography, magnetic resonance imaging.
- To detect metastases in regional lymph nodes – ultrasonography, magnetic resonance imaging, computed tomography.
- To know response to radiation therapy and chemotherapy- perfusion computed tomography, magnetic resonance imaging with perfusion and diffusion.
- To locate the distant metastases-positron emitted tomography, single-photon emission computed tomography, fusion imaging modalities like {PET/ CT, PET/MRI}.
- To detect the recurrence-perfusion computed tomography (PCT), magnetic resonance imaging (MRI) with diffusion, magnetic resonance imaging (MRI), positron emitted tomography, fusion imaging modalities like {PET/CT.PET/MRI}14

Painless Anesthesia in Pediatric Dentistry: A Review

Sonali Bhuyan[1], Susant Mohanty[2], Sulagna Pradhan[1], Mrinali Shukla[1]

[1]Post Graduate Trainee, [2]Professor & Head, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Pain management is one of the most commonly faced problem for dentists while handling of pediatric patients. A positive dental attitude can be instilled in a child if pain is handled properly. In recent times, various advancements and research have been made in the field of local anesthesia. These techniques along with the conventional ones can be utilized for better handling of pain and to get better apprehension from patients. This review article is to discuss recent advancements in painless anesthetic techniques and to improve the quality of treatment regarding pain in pediatric dentistry. As management of pain is of paramount importance to instill a positive attitude about dentistry in children.

Keywords: *Local anesthesia, Painless dentistry, Eutectic mixtures, Jet injection,Pediatric dentistry.*

Introduction

Karl Koller discovered local anesthesia in the year 1884. Since then local anesthesia has been a boon to the medical and dental field as it allows to carry out various surgical processes painlessly. Pain control and pain management is greatly enhanced by the use of local anesthesia. The recent advancements in the field of anesthesia have made it possible to profession to make tremendous therapeutic advances which would not have been possible otherwise. For administration of local anesthesia one should have knowledge of anatomical structures, devices and method to be used, neuroanatomy, etc. A dental practitioner carries out various procedures like extraction, root canal treatment, scaling. In one or other procedures patients always have to overcome some amount of pain. To avoid that,local anesthesia is administered through syringes and needles via conventional techniques.[1]

This method in itself increase the fear and anxiety of the patient before even commencement of the procedures. Managing a child patient is in itself difficult. So, to avoid the above-mentioned procedures, it is essential to know the latest local anesthetic delivery techniques that will ensure painless treatment to the patient.[2]

Local Anesthesia Delivery Systems:

Various traditional method are available for the delivery of local anesthesia. But many newer advances have come to ensure painless dentistry via:

Computer-controlled local anesthesia delivery, vibrotactile systems,, jet injectors intraosseous anesthesia, etc.

Computer-controlled local anesthesia delivery (CCLAD) system: Computer-controlled local anesthesia delivery systems enable the rate of flow regulation of the local anesthetic using computers and hence reduces pain by slow delivering of anesthesia at a constant speed. The operator should look at the design of the system which includes parameters like infection management, weight, mode of drug injection, speed, possibility of aspiration, etc before choosing a suitable one to avoid infection. The first CCLAD used was the Wand system (introduced in 1997) and some subsequent versions around Plus and Compu Dent. Comfort Control Syringe (introduced in

2001) is different from the Wand system in a way that it does not possess a foot control.[3]

A. Wand System: This technique helps to deliver the local anesthesia by placing a needle at the site to be anesthetized with fingertip accuracy with better control. It administers local anesthesia at a constant rate and is controlled by a foot activator. For better tactile sensations held with a pen-type grasp and is lightweight so easy to handle

It is one of the most popular and commonly used CCLAD. Advantage of this being its operator friendliness and its circumference that is half the size of the conventionally used syringes. As the operator has to hold the device in the area to be anesthetized for a long period thus, lighter devices are preferred over the heavy ones as it helps prevent needle break injuries and muscle fatigue. The cartridges that are used in the Wand system are installed in the main unit and the assistant can change it whenever required but about 0.3 to 0.4 ml of solution may be wasted during the procedure. Initially aspiration time in wand system was 14 seconds which is now reduced to 5 seconds and plus. Feda et al13 and Mittal et at 14 reported that CCLAD proved to be advantageous while delivering the palatal anesthesia by reducing the pain.[4]

b. Computer comfort syringe (ccs) system: CCS differs from the wand systems it consists of a base unit, a syringe and no foot control. The syringe itself can be used to control injection and aspiration and the solution deposited to the desired tissues irrespective of the resistance offered. This makes it user friendly for those using conventional techniques. 5 programmed speeds and three buttons are present on the device. The injection can be controlled using these buttons namely start or stop, aspirate and double button to start or stop the anesthetic delivery, aspirate or double the rate of delivery. Digital feedback readouts are present in the base unit which displays the time elapsed, rate and volume of anesthetic injected. It is less desirable than a wand system because of its weight but is quite easier for those using conventional techniques.[5]

C. Jet Injectors: Mechanical energy is used for releasing the pressure, thereby allowing the liquid medication to make its way through a small orifice. A thin column of fluid formation is permitted to be created that will allow the anesthetic solution deposition into the subcutaneous tissue without using a needle. Merits of Jet injections are minimal tissue damage, fast drug delivery and absorption, and lesser pain. Patients having a fear of needle and apprehension can be best managed by jet injectors.Commonly used brands of jet injections are SyrijetMarkII, MED H JETIII etc.[6]

MED JET H III: This was introduced first in the year of 2011. The advantage of this being the anesthetic solution is deposited with a much smaller orifice that is seven times smaller than the needles with the smallest diameter. This system has almost great accuracy and the solution is delivered at a small pressure and does not compromise with patient comfort and user compliance.[7]

SYRIJET MARK II: This has been used for 4 decades and also have undergone various advancements. 1.8cc syringes are used, which deliver the local anesthetic solution from 0-0.2cc and can be autoclaved hence reusable. It uses a nozzle pressure of 2000 pounds psi and at this pressure the same effect is the same as that seen in a conventional needle piercing 1 cm deep in oral tissues. This can be used for various minor surgical procedures like removal of deciduous anterior teeth and permanent central and lateral incisors, soft tissue procedures, removal of bone spicules, application and removal of arch bars and ligature wires could be carried out with the use of Syrijet alone.[8]

Though it as its advantages,but certain disadvantages are also there. Bleeding from the punctured sites are seen if punctured twice or thrice, the unpleasant taste is also seen. Hence concluding that Syrijat Mark II can be used for certain dental procedures but some it requires adjunctive anesthetic measures.

D. Safety syringe needles: The safety needles provide the prevention of needlestick injuries to the health care provider. These special needles are covered by a sheath as soon as it is removed from the tissues. Some commonly used safety needles are Hyposafety syringe,Ultrasafety plus XL syringe, Ultrasafe syringe, SafetyWand syringe etc. However, these are no better than the conventional syringes and are of inadequate help in preventing needle-stick injuries.[9]

E. Topical anesthetics

1. Lidocaine patches: It consists of a mucoadhesive base and delivers the local anesthetic via the trans-oral delivery route. It

is commonly used before the needle is pricked into the tissue and for superficial mucosal and gingival procedures. Absorption is well into the tissue and effects are seen within 2 minutes and last for 30 minutes after removal of the patch. The demerits being high cost and poor adhesion to the oral mucosa.[10]

2. **EMLA Cream:** EMLA stands for the Eutectic mixture of local anesthetics. It is an emulsion of oil in water which consists of 2.5% prilocaine and 2.5% of lidocaine in the ratio 1:1. It is supplied in various forms like in a tube of 5 to 30g, in disc form or form of anesthetic patch. These are easily absorbed into the oral mucosa and can be used only for minor procedures. These are applied orally for 2 to 5 minutes to provide psychological and pharmacological effects before needle penetration. It shows good results for pediatric use of cream but yet its advantages are t be researched. However, it is contra indicated in patients with methemoglobinemia or those having allergy towards amide-type local anesthesia as can cause allergic dermatitis.[11]

3. **Intranasal sprays:** In this anesthetic solution is infiltrated in nostrils through a metered device to anesthetize the maxillary anterior teeth,canines and premolars.[12]

   These are a mixture of 3% tetracaine hydrochloride and 0.05% oxymetazoline. It constricts the vessels thereby reducing bleeding and making the operating field favorable for the same.

4. **Laser analgesia:** This acts by disrupting the sodium-potassium pump temporarily and by changing the behavior of neuronal cells. It thereby produces profound analgesia by blocking the impulses to reach the brain. However, it should be used along with other anesthetic measures to work properly.[13-16]

Conclusion

Management of pain is one of the primary concerns for pediatric dentist. Most of the patients usually have a fear of needle and the pain associated with it. To overcome that, the above-mentioned techniques can be far more useful for better patient apprehension. It will also improve the quality of treatment that the dentist can provide. These techniques can help to instill a positive attitude towards dental treatment in a child. Though some of the techniques are time-consuming,costly but are proven and successful ones. One has to use it according to the type of treatment, feasibility, and user-friendliness.

Genes Associated with Fibro-Osseous Lesion: A Review Article

Tariq Soyab

Post Graduate Trainee, Department of Oral Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

The Fibro osseous lesion is a group of diseases or lesions that are affecting the skeletal tissue which frequently includes maxilla and mandible. The disease can also be easily described as bone disorders. A lot of research and work has been done regarding this serious disease though due to similarities in its radiographical features or histopathology, it is been very complicating to diagnose and classify FOLs. The review article focuses on different diseases that come under the fibro-osseous lesion and the genes which have been associated with the respective one in an orderly manner with their Histopathological features. One to understand this lesion the clinical correlation with radiographic involvement is necessary to diagnose this kind of dysplasia. The article also throws light on that the mandible and maxilla also suffer from localized and generalized forms of skeletal dysplasia which results in disproportionate short stature. These dysplasias always remain in a confused manner for their nomenclature. Much classification has been proposed by the different authors in different years regarding the FOLs based on gene or protein defect in these disorders.

Keywords: *Fibro osseous lesion, Genes, Dysplasia, Skeletal.*

Introduction

The fibro-osseous lesions are very serious and complicated disease which can cause severity in the function of tissue including jaws and craniofacial bones. They consist of different type of pathological disorders which includes bone dysplasia, inflammatory lesion, neoplastic lesions, and metabolic disease. These maxillofacial lesions cannot be diagnosed by taking incisional or excisional biopsy alone but the correlation of clinical and radiological features is very crucial for detecting these serious disorders. As earlier mentioned many authors have proposed different classification and the article provides the latest classification which was given by ever sole et al in the 2008.[1]

Classification: In the year 2008 ever sole and their co fellows gives a classification of fibro-osseous lesion which was based on metabolic disorders, neoplastic lesions, inflammatory disorders, and reactive processes. Based on clinical features and radiographs with the adding of Histopathological diagnosis the behavior of this disorder can be judged and the final diagnose can be made, the ever sole et al have concluded in their classification or research.[2]

1. **Bone Dysplasia:**

a. Fibrous Dysplasia – This dysplasia includes its many types including monostotic,polyostotic,and polyostotic with endocrinopathy & osteofibrous dysplasia

b. Paget's disease

c. Pagetoid heritable bone dysplasia of childhood

d. Segmental odontomaxillary dysplasia

2. **Cemento osseous dysplasia:**

a. Focal Cemento osseous dysplasia

b. Florid cement dysplasia

3. **Inflammatory processes**

a. Focal sclerosing osteomyelitis

b. Diffuse sclerosing osteomyelitis

4. **Metabolic Disorder**

a. Hyperparathyroidism

5. **Neoplastic lesions**

a. ossifying fibroma

b. hyperparathyroidism jaw lesion syndrome

c. juvenile ossifying fibroma

d. gigantiform cementomas

Fibrous Dysplasia: This dysplasia compromises of bone-forming mesenchyme that manifests as a defect in osteoblastic differentiation and maturation which is skeletal developmental anomaly. The disorder is nonhereditary having unknown cause.[3]

Gene Associated for the Cause: Mutation in the GNAS1 (guanine nucleotide-binding protein, alpha stimulating activitypolypeptide) Gene. This gene encodes a G- protein which stimulates the production of c-AMP. The mutation results in the overproduction of cAMP due to the prolonged activation of G –protein. Due to this mutation hyperthyroidism, precocious puberty and overproduction of cortisol happens which results in hyperfunction of affected endocrine organs. Secondly large café au lait spots with irregular margins can be seen which is due to the increase in proliferation of melanocytes and at last fibrous dysplasia is caused as cAMP affects the differentiation of osteoblasts. Radiographic appearance is described as ground-glass appearance which appears radiolucent on radiographs which happens due to the fibrous tissue replacing medullary bone.[4]

Molecular Pathogenesis of Fibrous Dysplasia:

- The mutation of the GNAS1 gene activates the cyclic adenosine monophosphate(c-AMP),
- Which results in the elevation of c-AMP and stimulates the endocrine receptors
- In return which activates the c-fos (proto-oncogene)
- After which the impaired differentiation of osteoblasts results in bone lesion
- & the increased in the production of melanocytes results in cutaneous pigmentation
- & the hyperfunction of endocrine cells resulting in endocrine disturbances.
- The bone lesion giving rise to Fibrous dysplasia, cutaneous pigmentation concluding Mccune Albright syndrome & the endocrine disturbances lead to Jaffe Lichtensteinsyndrome.

Histologic Features:

- Fibrillar connective, woven immature bone, irregular in shape can be seen in the lesion.
- Large osteocytes and collagen fibers can be noticed extending out in the fibrous tissue.
- Stellate osteoblasts that form the bone can be observed.
- Osteoblastic riming can be seen.
- Wide osteoid seams can be observed in the trabeculae.
- Osteoclastic activity can be noticed in the histological slide.

Treatment & Prognosis: In the maxilla the lesion is been treated non surgically maximally.

No specific medical treatment is for bone diseases. Although the use of vitamin –D and bisphosphonates can be useful in relieving pain and possibly in reconstituting lesions with normal bone. The surgical procedure includes the curettage technique and replacing the bone with autograft or allograft.[5]

The malignant transformation for this lesion is very low which can be estimated 0.4%-1%.In most times the facial and skull bones went a malignant change in polyostotic disease. The fibrosarcoma and osteosarcoma are the most common tumors. The lesion size increases with an increase in pain can be noticed in the malignant transformation with enlarged soft tissue mass.

Paget's disorder: It can also be called as osteitis deformans. The disorder commonly affects the middle-aged and elderly ones. It is a disease which is non-malignant. Usually, this disorder is asymptomatic, but the patient may develop symptoms like pain in the affected bone, neurological, and cardio complication can also be seen in complicated cases. Almost 3-5% of people in the United States of America are been affected by this disease.[6,7]

Genes and other associated Factors for the cause: The etiology of this disease is still unknown but two main theories for its cause have been proposed which include Viral i.e. paramyxoviral infection & genetic.

Genes associated with it include: TNRSF(Tumor necrosis factor receptor superfamily member -11A), Sequestrome 1 (SQSTM1), and Valosin containing protein (VCP).

Different Phases includes:

This disorder occurs in 3 phases, which includes:

- **Initial Phase:** In this phase intense Osteoclastic activity and resorption of bone occurs.
- **Secondary Phase:** In this phase osteoblasts start to produce woven bone and the mineralization is ineffective.
- **Final Phase:** In the final phase trabecular and dense cortical bone dominates the deposition.

The bones which are commonly affected by this disorder include pelvis, femur, skull, humerus, cervical spine, and thoracic spine. This disease mostly affects the axial skeleton. Pelvis, which has a high percentage in its involvement.[9]

Radiologic Findings: In the affected person one can notice these findings as;

- In skull we can noticed osteoporosis circumscripta
- Sclerotic bone can be observed
- Banana or chalk pattern transverse fractures can be seen.
- Bowed limbs

Diagnosis: Imaging tests which include x-ray and bone scan & lab tests is been performed to diagnose the disorder. In the bone scan method, radioactive material is injected into the body, and the materials directly affect the areas which include the Pagets disease and thus they are light up in the scan. In laboratory testing elevated levels of Alkaline phosphatase can be observed in the blood. [10]

Histologic Features:

- Disordered areas of resorption with an increasing number of large osteoclasts is been noticed in the initial osteolytic phase.
- Jigsaw or mosaic pattern can be observed which is a result of continuous bone removal giving small bone fragments which are irregular in shape.
- The above-mentioned pattern can be considered as the hallmark for this disease.
- The pattern is mosaic with irregular cement lines joining the area of lamellar bone.

Treatment and Prognosis: In the present scenario no specific treatment is there for osteitis deformans but the use of radiation and hormone therapy, vitamins have been used to challenge this disorder. Very better and product results have been found nowadays by using the Calcitonin, which is a parathormone antagonist produced by the thyroid gland which suppresses bone resorption. Overall the complication of this disease is not so wide and less than 1% of osteosarcoma is noticed from Paget's disease.[11,12]

Ossifying Fibroma: It is a benign neoplasm that affects the jaw which has been enlarged. This fibro-osseous lesion is featured by substitution of normal bone by newly formed calcified products like bone, cementum, or both and fibrous tissue. It is commonly seen in teenagers and young adults. It is a rare and slow-growing tumor that is non-cancerous.[13]

Gene associated with it: HRPT2 gene mutation is found to be cause for this fibro-osseous lesion. The radiographic feature reveals a radiolucent area with an increase in calcification, displacement of adjacent tooth is common. The Histologic features include interlacing collagen fibers, proliferating fibroblasts and mitotic figures can be noticed. Small foci of irregular bony trabeculae can also be observed.[14]

The treatment includes excision of the tumor and the recurrence rate is very less.

Hyperparathyroidism–jaw tumor syndrome: It is a syndrome which is an autosomal dominant disorder. It is associated with fibro-osseous jaw tumors, renal lesions and featured by parathyroid tumors. The patient who suffers from hyperparathyroidism may develop symptoms of muscle weakness, pain in the joint or bone, fatigue, and may develop kidney stones with a decrease in the density of bone.

HPT-JT is a jaw tumor which is fibro-osseous lesions that consists both the maxilla and mandible and mostly affect in the 3rd decade of life. Ossifying fibromas generally slow-growing and benign tumors that arise from the periodontal ligament in molar or premolar areas are reported to be highly involved with HPT-JT.

Gene associating for its cause: The HRPT2 gene localizes to 1q24-32 which encodes a 531-amino acid long protein, which is called parafibromin, which exerts anti-proliferative activities via interacting with cyclin D1. Germline mutation and somatic inactivation of the HRPT2 gene which lead to hyperparathyroidism –jaw tumor syndrome. The treatment involves the management

of hypercalcemia. The focus of the treatment is to reduce the level of calcium to below 11.5mg/dl.[15]

Cherubism: It a skeletal dysplasia and an autosomal dominant fibro-osseous lesions of the jaw. It is a non-neoplastic hereditary bone lesion that has a similar type of histopathological features as central giant cell granuloma. It was first described by jones in 1993. It mostly affects the children. It is also known as disseminated juvenile fibrous dysplasia or familial multilocular cystic disease of jaws.[16]

Gene associated with its cause: The mutation in the SH3BP2 (SH3 domain-binding protein 2) gene is the most identifying cause for 70-80% cases in Cherubism. In the remaining cases, the etiology is unknown. The SH3BP2 gene gives instructions for producing a protein whose exact function is still not clear. This protein has an important role in transferring chemical signals within cells, especially involving in replacing the old bone tissue with a new one which is a bone remodeling procedure. Thus mutation in the SH3BP2 gene results in producing an overactive version of this protein which can lead to the disrupting of the critical signaling pathways among cells that maintain the bone tissue. This overactive protein leads to the inflamed jawbones and alters the osteoclasts production, which on return results in the breakage of the bone tissue during remodeling.[17]

Clinical and Radio graphical Features: The children who are been affected are normal at birth until 14 months to 3 years of age, after that clinical evidence can be seen which includes the symmetrical enlargement of the jaws. The symptom starts with deforming maxillary and mandibular overgrowth with a problem in respiration and defects in hearing and vision. Noonan's syndrome can be observed in some cases of Cherubism which involves obstructive sleep apnea, gingival fibromatosis with orbital involvement.

The radiograph is characterized by multilocular cystic expansion of the jaws. Numerous unerupted teeth with the destruction of alveolar bone will displace the teeth which results in floating tooth syndrome.

Histopathology: Multinucleated giant cells can be seen, fibroblasts are spindle-shaped present in the connective tissue stroma, water logged & granular. Numerous small vessels can be noticed.

The treatment is done by surgery to correct the deformities of the jaw and is very rarely indicated. The surgery is usually done after puberty when the remission phase reached.

Periapical Cemento–Osseous Dysplasia: This dysplasia is a kind of fibro-osseous lesion which is associated with the apex of a tooth. The disorder has a dominant autosomal inheritance pattern. The etiology of this fibro-osseous lesion is unknown. Usually the unifocal or multifocal dysplasia does not need any treatment but the larger lesion requires surgery to prevent further complication.[18]

Differential Diagnosis: The fibro-osseous lesion should be differentiated from the other lesion which can produce the same radiographic and histological features. Some of the important lesion which should be differentiated from fibro-osseous lesion are-

- Osteoblastoma
- Giant cell reparative granuloma
- Sclerosing osteomyelitis

Conclusion

The fibro-osseous lesion should not be diagnosed or classified only based on histological features as they all can show almost similar features. These craniofacial lesions should be judged by clinical correlation and radiographic involvement. The classification can only be done by radiographic appearance and their growth pattern. The genes which are involved in this type of lesion and their mutation provide a better idea of knowing the pathogenesis of these disorders. However, in this era, some of the cause of this lesion is found to be unknown. Research is been made for detecting the important causative factors which can further lead to the prevention and proper diagnosing of this lesion.

Special Stains Used in Histopathological Techniques: A Brief View

Tariq Soyab

Post Graduate Trainee, Department of Oral Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

The routine staining which is also called as H & E staining (Hematoxylin and eosin) is the most widely used stain in the laboratories or histopathology laboratory. In this procedure the nuclear protein stains purple and the cytoplasm and any other substances stains as red or orange. It plays a very crucial role in medical diagnosis or research where the specimen or tissue is been sent for processing. The staining procedure is performed by trained professionals and after which the role of highly trained pathologists and researchers come, which under the microscope view the specific structures, cells and even microorganisms to provide a diagnosis for the specific disease. The special stains are those which come under the special staining technique or alternative method for the H & E stains, where H & E staining does not provide the proper identification or appreciation of certain normal and abnormal tissue or structure which the pathologist or researchers needs. This article throws light on the Special stains which are been used in histopathological procedures in which these abnormal or normal tissues can be properly appreciated. The article also focuses on the procedure, principle and uses of these special stains in their respective field.

Keywords: *H & E stain, Special stain, Histopathology, Pathologist.*

Introduction

Special stains are those which come into the action where the given Hematoxylin and eosin staining does not provide much information regarding the tissue and structure of cells. Some of the particular tissue structure does not stain well with H & E stains like the reticular fibers in the liver which need a special staining technique, this special staining technique is performed for a better appreciation of normal and abnormal substance which is present in the cell and tissue.[1] These stains are used to identify specific microorganisms like bacteria or parasites, carbohydrates, lipids, mucosubstances which include both neutral and acidic, nucleic acid, and minerals along with connective tissues. The special stains include classification which makes it a convenient choice for different diagnosing procedures.[2]

Classification The classification includes:

I. Stains for amyloid

II. Stains for carbohydrates

III. Stains for microorganisms

IV. Lipid stains

V. Connective tissue stains

VI. Nucleic acid stains

VII. Stains for pigments and minerals

- Carbohydrate Staining- The carbohydrates are of two types of simple carbohydrates which include monosaccharides, oligosaccharides, and polysaccharides, whereas glycoconjugates consist of proteoglycans, mucins,and others glycoprotein.

A carbohydrate staining includes many techniques in which some of the most widely used method have been described:-

Periodic acid Schiff (PAS) stain- The dyes used in this technique involve 1%periodic acid and Schiff's reagent. The substance which shows positive result to PAS has purple magenta color and nuclei are seen blue. The substances which show positive PAS are

glycogen, neutral mucoprotein, glycoprotein, all fungi, cerebrosides, basement membrane, and phosphorylated sugar.[3]

This stain is used in the diagnosis of several medical conditions like mucins in adenocarcinoma of the large intestine, demonstration of fungi, glycogen storage disorder, Ewing's sarcoma, rhabdomyosarcoma, Whipple's disease, etc.

Alcian Blue Method: The reagents used are Alcian blue, aluminum sulfate, and nuclear fast red.

The results of this method show the blue color appearance of Hyaluronic acid, sialomucin, proteoglycans, and the nucleus is red. Neutral mucins are not reactive to Alcian blue.[4]

Combined Alcian blue-PAS method: The principle of this method is to differentiate the acid mucin from neutral mucin and demonstrate the presence of mucin. In this method only neutral mucin will be stained in magenta color appearance.

Mucicarmine Technique: The positively charged carmine and Mucicarmine bonds with negatively charged acid mucin in result acidic mucin stain strongly whereas neutral mucin does not stain. The reagents involved carmine, aluminum hydroxide, and 50% alcohol and aluminum chloride with Mayer's Hematoxylin. It is used in GIT disorders and to identify the acidic mucin also to identify fungi-Cryptococcus neoformans, etc.[5]

Nucleic Acids Staining: There are 2 nucleic acids which are DNA which is present in the nucleus & RNA that is present in the cytoplasm. They consist of deoxyribose or ribose, phosphate, and a nitrogenous base. The demonstration of nucleic acids depends upon the following factors which include the production of the aldehydes from sugar and reaction of dyes with the phosphate groups. There is no histochemical method to demonstrate the nitrogenous base. Several mostly used techniques to demonstrate the DNA includes-

- **Feulgen Stain:** In this staining procedure the solutions used are 1ml HCL acid, Schiff's reagent in which aldehydes are demonstrated, and bisulfate solution. The result of this staining gives Red-purple color to DNA & Green color to the cytoplasm. The standard control method for the Feulgen technique is the NAH method. (Naphthoic acid hydrazide). The blue thionin Feulgen technique is mostly used in the research for studying the nuclear morphology and ploidy of cancer cells. NOTE: The RNA can't be demonstrated by this stain as ribose purine bond is unaffected by hydrolysis 1M HCL.6,7
- **Methyl Green pyronin Method:** In this staining the reagents used is Methyl green in which the pure methyl green is specified for DNA and the impure dye contains methyl violet which can be removed by washing with chloroform. The NH2 of the dye reacts with the phosphate of DNA. The other reagent which is used is pyronin that binds to negatively charged constituent of tissue and also binds with mucins and cartilage, apart from RNA. The results show Green –Blue color to DNA whereas RNA shows Red color.

Staining of Lipids-3 forms of lipids is simple, compound, and derivative which includes such as fats, fatty acids, or cholesterol. The most widely used method for staining of lipids are Sudan black B stain and oil red o stain.[8]

Sudan Black B Method: This method is used for staining the lipoprotein,neutral triglycerides and it is very useful in hematological disorder. The result which it gives is fat is seen blue or black color and nuclei is seen red color.

Stains For Amyloid: Amyloid is an extracellular, amorphous, and eosinophilic material. It is composed of a protein in an anti-parallel beta-pleated sheet of configuration. Many times Hematoxylin and eosin is been confused with hyaline and fibrinoid substances. Earlier the stain which was used for amyloid was Iodine which was introduced by Virchow. The staining method widely used for amyloid is Congo red stain and Methyl crystal violet method.[9,10]

Congo red Stain: The mechanism principle is that the amyloidis extracellular, eosinophilic, and homogenous which can damage the surrounding tissue,hence when it is stained with Congo red the amyloid shows apple green color i.e. birefringence. The reagent includes 0.5%Congo red and 0.2% potassium hydroxide in 50% & 80% alcohol. It is used in renal amyloidosis, medullary carcinoma of thyroid, Alzheimer's disease, etc. The result gives nuclei blue color and amyloid, eosinophilic granules show red to pink in color.

Methyl/Crystal violet Method: The reagents used are 95% alcohol, crystal, 0.2% acetic acid, and 1% aqueous ammonium oxalate. The procedure includes

first the solution is prepared by using 2-gram crystal or methyl violet, alcohol, and 1% aqueous ammonium oxalate. After that the section is brought to water level then stain in crystal solution for five minutes after that washing and differentiating is done in 0.2% acetic acid and at last washes and mount in DPX. The result shows purple color is seen in amyloid whereas blue is seen in the background.[11,12]

Stains For Microorganisms: There are different types of staining method for different types of microorganisms which include bacteria, spirochetes, fungi. Different staining process includes Ziehl Nielsen stain, wade file Faraco stain, Warthin starry stain, Giemsa stain, and Gram staining. Among these widely used staining process is been described.

ZN stain process- In this method mycobacterium bacillus is stained. Mycobacteria cannot be demonstrated by gram's staining process as they possess a capsule that contains long-chain fatty acid i.e. Mycolic acid which makes it hydrophobic and it can be stained by carbol fuchsin. The Mycobacteria shows PAS-positive as their cell wall contains carbohydrates. The result of ZN stains shows red color to mycobacterium and background appears pale blue.[12]

Gram staining of bacteria- Includes:

Modified Brown- Brenn Method: This method includes the reagents like crystal violet stain, ethyl alcohol, gram's iodine solution, acetone-xylene solution, basic fuchsine, and picric acid, 0.1% in acetone. The result of this staining process gives Gram +ve bacteria shows blue color whereas Gram –ve bacteria shows red and the nuclei are also shows red color and yellow color presents other tissue elements.

Staining for spirochetes Warthin starry method is mostly used for spirochetes.

Warthin starry method: The reagents involved acetate buffer pH- 3.6 & 1% silver nitrate. This staining process gives the result as spirochetes-Black & Background – golden- yellow.[13]

Fungal stains Mostly used technique is GMS (Gomori methenamine silver nitrate): The reagents involves are 4%chromic acid, 1% sodium bisulfate, 5% sodium thiosulfate and 0.21% silver nitrate and light green solution and the results gives black color appearance of pneumocystis and fungi. The melanin also appears black. The dark grey appearance shows the presence of mucin and glycogen whereas pale green color appears in the background. [14]

The Giemsa stain is used for parasites:

Connective Tissue Stains: The connective tissues provide a matrix that connects and binds the cells and organs, which gives support to the body. Connective tissue consists of a proper one which includes loose and dense connective tissue like adipose, irregular, etc. The other one is the specialized connective tissue which includes bone, blood, and cartilage.

The Stains used for collagen fibers includes many techniques in which Masson's trichrome technique is mostly used.[15]

Masson's Trichrome Technique: The reagents used in this technique are Weigert's iron Hematoxylin, acid fuchsin, glacial acetic acid, methyl blue, and phosphomolybdic acid. The fixatives which are recommended are bruin's, Zenke's formal mercury, and zinc formalin.

The technique demonstrates the collagen and muscle in normal tissue, identifying the increase in collagenous tissue, to differentiate between collagen and muscle in tumors. It can indicate the fibrotic change in cirrhosis of the liver and also fibrotic changes in pyelonephritis. It gives blue or black color to nuclei, RBC, and muscle shows red color, and the cytoplasm appears in yellow.

Stains for pigments and minerals: There are different pigments including endogenous, exogenous, and artifact pigments. Different staining process includes:

Perl's Stain: This stain helps in identifying the ferric ions. When the ferric ions come in contact with ferrocyanide it gives Prussian blue which is a blue pigment. The result showsthe blue color of iron and nuclei appears in red whereas the background is pink in color.

Modified Fouchet's Technique-It is used for bile pigments. The reagents involved are Fouchet's reagent which includes 25% aq trichloracetic acid, 60% aq ferric chloride, distilled water, and Sirius red stain. The procedures follow to bring the sections to distilled water and oxidized in Fouchet's for five minutes then rinse well in distilled water and stain with citrus red for at least 30 minutes then dehydrate, clear and mount. The result

gives green color appearance to bile pigments, collagen shows red and background is yellow in this respective staining process.[16]

There are several staining tests for the demonstration of melanin which include Schmorl's ferrioferricyanide reduction test, enzyme method, IHC, and Masson Fontana silver method & Fluorescent method.

Masson Fontana Method: It is used for the identification of melanin and also argentaffin granules. In the diagnosis of malignant melanoma is also used. The principle of this process is as the melanin is insoluble in organic solvents and it is a non-lipid, non-hematogenous pigment that dissolves in 1M sodium hydroxide. The ammoniac silver nitrate solutions are reduced to black metallic silver by melanin and the result shows the black color appearance of melanin, and argentaffin granules whereas nuclei appear red.[17]

A note on IHC: The immunohistochemistry technique is the most useful and widely used staining process as it is used in the diagnosis of cancer or treatment of cancer, for differential diagnosis and has its application use in the research works. The method combines the immunological, histochemical and histological process foridentifying the specific tissue by using the definite antigen/antibody reaction which is a tag by an evident label. This process allows visualizing the specific cellular components which is been distributed and localized within a cell or tissues. The interaction of antigen-antibody is visualized by different types of markers like an enzyme, radioactive element, Fluorescent dye, or colloidal gold. The antibody is made up of two types of protein chain which includes heavy chain and light chain. Five types of immunoglobulin classes are found in serum which include IgG, IgM, IgE, IgD, & IgA. They all are distinguishing based onthe Heavy chain they contain. However every technique has its advantages and disadvantages & its disadvantages include such as the cost of the technique is high and it is not permanent, etc.[18]

Conclusion

Special stains are widely used in the different processes for the enhanced appreciation or detection of normal and abnormal substances, though the H & E stain is a routine test for histopathological diagnosis. The special stains give a more accurate result for the proper diagnosing of the respective disease and also it enhances the beneficiate in the research works. The pathologist and researchers should have a broad and clear cut idea regarding the special staining process for better outcomes. The use of special stains has revolutionized medical diagnosis in the Histopathological field and their application will surely lead the future.

Single Anterior Crossbite Correction in Mixed Dentition Using Z'spring Along with Posterior Bite Plane: A Case Report

Ankita Sinha[1], Susant Mohanty[2], Sonu Acharya[3]

[1]Postgraduate Trainee, [2]Professor & Head, [3]Professor, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Anterior cross bite is defined as "palatal positioning of the maxillary anterior teeth relative to the mandibular anterior teeth".Various treatment options available are removable & fixed appliances. This is a case report on treating a case of single anterior tooth crossbite during the mixed dentition using the "Hawley's appliance with posterior bite plane & Z'spring". The active treatment time was 3 months in total & the treatment outcomes were followed up consequently for the next 4 months successfully.

Keywords: *Anterior Tooth, Dentoalveolar Crossbite, Mixed Dentition, Malocclusion.*

Introduction

Crossbite is well defined as, "abnormal relationships of a tooth or teeth to the opposing teeth, in which normal buccolingual/labiolingual relationships are reversed".[1] Crossbites may be of the dental origin or the skeletal origin involving anterior teeth, or posterior teeth or both.[2] Anterior crossbite is defined as,"a malocclusion in which one or more of the maxillary anterior teeth occlude lingually to the mandibular incisors". Anteriorly located single tooth crossbite of dental origin is the commonly come across malocclusion in the course of the development of occlusion in kids.[3,4] In the case of dental crossbite the patient shows the deviations in the axial inclination of the involved tooth or teeth but with normal existing skeletal form. The management of anterior crossbite should be considered during deciduous & early mixed dentition irrespective of its dentoalveolar or skeletal basis.[5] Anterior dental crossbite generally becomes obvious during the early developing dentition. The anterior crossbite may result from various reasons like lingual erupting maxillary anterior incisors; cleft lip[6]; supernumerary teeth anteriorly; an over-retained deciduous tooth/root; crowding[7,8]; inadequacy in arch length; upper lip biting habit.[9-12] This developing abnormality necessitates immediate treatment to avoid anterior teeth fracture & mobility, periodontal inflammation & TMJ problem.[12-17] There are many method to treat the developing or developed anterior dental crossbite. The treatment method cited for the developing or developed anterior dental crossbite are such as using tongue blade therapy, lower inclined plane, crowns (either stainless steel or composite build-up), Hawley's retainer with double cantilever springs, labial and lingual archwires. Hence, a variety of approaches can be used to intercept anterior crossbite during the developing dentition period. This case report presents a simple & economical method to treat anterior dental crossbite using Hawley's appliance with posterior bite plane & double cantilever spring.

Case Report: An 11-year-old female patient came to the "Department of Pediatric and Preventive Dentistry", Institute of Dental Sciences, Bhubaneswar with the chief complaint of abnormal positioning of one upper front tooth with corresponding lower tooth. There was no relevant past medical & dental history found. Extraoral examination revealed a slightly convex profile

with potentially competent lips. On clinical examination it was found that 21 was in crossbite with 31 slightly proclined 11 & an angle's class I molar relation bilaterally. After careful intraoral examination, it was decided to treat the case with "Hawley's appliance with posterior bite plane to achieve a 2 mm incisal clearance and double cantilever spring (23 gauge wire) to push the palatally placed upper incisor labially".

The Treatment Objectives: To achieve the normal overbite & overjet, by aligning the inclination of the anterior tooth which further, improves the patient's facial & dental profile. The success & prognosis of this treatment is immensely dependent on children's cooperation & parental guidance.

Procedure: Immediate treatment: This includes educating patients & parents about the use of appliance planned to be given for the crossbite rectification. It also included thorough oral prophylaxis.

Definitive Treatment: Alginate impression was made for both the arches and immediately poured with dental stone. Hawley's appliance with posterior bite plane and double cantilever springto 21 was made for rectifying the crossbite. This appliance is known to deliver slow-lightcontinuous force.

The removable appliance was inserted in the patient's mouth and the patient was trained to insert & take out the appliance on her own under parental guidance. The patient was recalled after 24 hours to check the fitting of the appliance (Figure 1, 2). She was recalled after every week for the activation of double cantilever spring which was accomplished by opening each of two helices 2mm. She was instructed to wear it full time except during eating and the night while sleeping. In the 6th week, crossbite was found to be corrected with 21(Figure 3). After 2 months, the posterior bite plane was removed & Hawley's appliance with z spring sustained for another 2months to establish a normal overjet. Later exfoliating 53, 63 were extracted as a balancing extraction simultaneously to give an adequate space for the crossbite treatment to avoid anterior crowding and provide adequate space for anterior incisors alignment. At the end of the first 3 months of active treatment, the crossbite was successfully corrected. The use of Hawley's appliance was continued to achieve adequate overjet and overbite for another 2 months. The treatment outcome was followed up for further next two months.

Figure 1. Preoperative frontal view showing crossbite to maxillary left central incisor.

Figure 2. Intra-oral view with removable appliance.

Figure 3. Post-operative frontal view.

Discussion

Interceptive Approach: It incorporates all method initiated to decrease the complexity of malocclusion to progress normal occlusion in the future. The aim of using removable or fixed appliance primarily for the prevention purpose is to attain:

1. Good alignment of the permanent dentition.
2. To achieve harmony between dentition and aesthetic.
3. Stability between dental, muscular & skeletal components.
4. Dental arches with anoptimal intercuspation,

Interceptive procedures should be widely used in mixed dentition period to correct the developing abnormalities. Anterior crossbiterarely corrects by itself due to locking of the upper incisor behind the lower incisor & later it progresses to severe malalignment of teeth, therefore consideration of primary approach can re-establish the right muscle balance & a well-organized occlusal development.[18,19,20] Appliances used for rectification of 'anterior' crossbite are: "tongue blade, inclined plane, composite plane, reverse stainless steel crown, Hawley's appliance with 'z' spring and screws embedded in acrylic".[5]

Tongue blade therapy: It is suggested for a single tooth crossbitecase provided that incisors are still erupting stage. It is positioned at an angle between the teeth. After which the patient is directed to bite tightly for five seconds. This has to be redone twenty-five times in a day. In case after two days no changes observed then it is stopped. The main drawback is that it demands patient full co-operation.

Inclined plane: It is recommended when multiple teeth are to be treated. It is formed of acrylic & causes a 'forward sliding motion' on closure of upper teeth. Its usage is limited to four weeks because it may result in the supra-eruption of the posteriorly located teeth, opening the bite anteriorly.

Composite Plane: An inclined plane is made up of composite on the lower incisors.

Reverse stainless steel crown: It is also used in the case of a "single tooth" crossbite. This crown is used for the upper incisor which forces the upper tooth away that is towards the lip as the child bites down on the lower teeth. It takes two to four weeks for the correction.

Maxillary appliances with 'z' springs & posterior bite plane: It can be a choice when multiple teeth are in crossbite. The posterior bite plane used, put the anteriorly located teeth out of occlusion, allowing the incisors to escape the bite to provide incisal clearance and the 'z'spring used for the labialization of tooth.

Screws embedded in acrylic: Medium, mini or micro screws can be used that are activated daily to bring about correction of crossbite.

In the above case report the economical & acceptable method of choice for the crossbite correction was using a removable appliance with a posterior bite plane for incisor clearance & z spring for labialization was used. The removable orthodontic appliance used has three major advantages:[21,5] i) Reducing chair time; ii) They can be removed easily & iii) They are easy to clean thus, keeps in maintaining good oral hygiene.

Prakash Pet al in their study in 2011 reported that 8 to 11 years is an ideal time for anterior dental crossbite correction since it's the duration of root formation & the active stage of eruption of the tooth. Hence, a child's age plays an important role. But the motivation for treatment, how he or she co-operates during treatment is also being very important.[4]

Conclusion

It is essential to realize the need for early diagnosis and rectification.[22] During the early correction of simple and minor malocclusions, which is a part of interceptive orthodontic treatment, the anterior cross-bite was corrected more rapidly & it is achieved by removable appliances or fixed appliances. The primary treatment in such cases just not only restores aesthetics anteriorly but may also lessen the complexity & course of successive required treatment.[20] Hence, it may help to prevent the prospect of any adverse effects upon the growth and development of the child.[23]

Laser-assisted Operculectomy in an 8-Year-old Child Using Diode Laser: A Case Report

Sourav Bhattacharjee[1], Susant Mohanty[2]

[1]Postgraduate Trainee, [2]Professor & Head, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The past years in dentistry has seen the growth of the use of laser advance by leaps and bounds. Though soft-tissue laser was originally presented, but with the development of new-generations of laser technology, lasers are equally effective on hard tissues. Lasers have a plethora of uses in pediatric dentistry including prevention of caries, prompt diagnosis, restoration of cavities, managing cases of trauma to teeth along with various minor oral surgical procedures. Lasers are advantageous for being more rapid, more precise, sterile and providing a bloodless field of surgery and are also better accepted by pediatric patients and their parents. In the same light, treatment of a pediatric patient becomes easier it is less fear-inducing for the child thus increasing co-operative behavior. The soft tissue covering over a partially erupted tooth is known as pericoronal flap or gingival operculum. Surgical removal of the latter is termed as Operculectomy. The following text reports a case of Operculectomy performed using a diode laser in the pediatric operatory.

Keywords: *Laser, Operculectomy, Pediatric dentistry.*

Introduction

LASER is an acronym that expands as 'light amplification by stimulated emission of radiation'. Gordon Gould is credited with its first introduction in 1959 a graduate student at Columbia University.[1] Theodore Maiman at Hughes Research Laboratories created the first working laser in 1960.[2] Application of lasers in dentistry varies widely among both soft and hard tissues. Soft tissue applications may include procedures such as a frenectomy, exposure of unerupted teeth, disinfection of root canals among others. Hard tissue applications involve the detection and removal of caries and removal of old restorations.[3] Pediatric Dentistry involves close interaction with children is thus dissimilar from dentistry in adults. It is thus indispensable for the dentist to be thoroughly acquainted with the skills required in line with the child's age and level of development. The employment of various categories of laser devices facilitates the pediatric dentist to deliver dental care in a minimally invasive way with negligible distress, reduced bleeding, while also being painless both during and post-treatment. Pedodontists aim to fashion a pleasurable experience for the child during their dental visits by inculcating innovative, minimally invasive machinery to instill a positive dental attitude within the child.[4] An operculum may be defined as a flap originating from the gingival tissue usually present distally to a molar or covering the occlusal surface of the molar frequently presenting as a sequela of tooth eruption. In a few cases, an operculum may cause pain due to the masticatory forces from the opposite molar teeth in which case operculum may become ulcerated and inflamed either due to repeated trauma or due to local inflammatory reaction due to accumulation of food debris and plaque between the surface of the tooth and the opperculum.[5]

Case Report: An 8-year-old female patient reported to the Department of Paediatric and Preventive Dentistry at the Institute of Dental Sciences, Bhubaneswar with a chief complaint of pain on chewing food in her upper right back teeth region since the last 6 months. Patient-reported a history of dull aching pain along with food lodgement in the region of the chief complaint. Clinically the patient showed good general health with the absence of any relevant medical history.

The child displayed a Negative (-) behavior according to the Frankl behavior rating scale given by Frankl et al. in 1962. Intraoral examination revealed the presence of an operculum covering the occlusal surface of the upper right first permanent molar (Figure 1). The operculum was pinkish-brown in colour, firm, resilient and remained tightly adhered to the gingival tissue distal of the upper first molar tooth. No abnormalities were recorded on the radiographic examination of the affected tooth. The results of routine blood investigations were satisfactory.

Keeping into consideration the uncooperative and apprehensive behaviour of the child a treatment planning of surgical excision of the operculum with diode laser was made to reduce both treatment time and patient discomfort.Oral prophylactic procedures were carried outbefore the planned excision. Infiltration anesthesia was given in the region of the upper right first molar tooth to provide anesthesia to the surrounding soft tissue including the operculum tissue. 2% lidocaine with epinephrine [1:2,00,000] was used for the same. Appropriate eyewear was worn by the pediatric dentist, the child and also the dental assistant before the initiation of the surgical procedure (Figure 2). Excision of the operculum was started from the distal margin of attachment using a 940nm diode laser [iLASE^{TM} diode laser from BIOLASE Inc.] in continuous contact mode at 1.8 W of power rating in the presence of a high volume evacuation. The tip of the laser was cleaned regularly during the procedure to remove the adhered scorched tissues. A conscious effort was made to avoid contact between the enamel surface and the laser tip. Satisfactory hemostasis was obtained postoperatively (Figure 3). The surgical site was irrigated with saline and povidone-iodine to remove any unwanted or remaining debris. The total time required for completion of the procedure was below ten minutes and the patient tolerated the procedure well with minimal pain or discomfort. The patient was advised to use a topical anesthetic gel at the site of excision and was counseled on the maintenance of appropriate oral hygiene. A post-operative follow-up after 7 days revealed adequate and uneventful healing (Figure 4).

Figure 1 Pre-operative view of operculum about right upper first molar tooth

Figure 2 Protective eyewear in place during the procedure

Figure 3: Immediate post-operatively

Figure 4: 7 days post-operatively

Discussion

Operculectomy may be referred to as the surgical technique of eliminating the operculum, or the gingival flap that usually covers the occlusal surface of the tooth partially. Operculectomy is aimed to reduce the incidence of pericoronitis, a condition that is marked by pain and inflammation associated with the operculum. Pericoronitis is usually seen among young adults, mainly in the molar teeth that are beginning to erupt.[6] The patient in our case presented with pain and discomfort in the region of upper right first permanent molar due to the presence of an operculum associated with the tooth. Plaque build-up on the underside of the operculum along with the accumulation of food debris caused inflammation and enlargement of the gingiva. The latter was being easily traumatized at the time of mastication, subsequently causing pain and discomfort.

Operculectomy with diode laser was the chosen treatment plan as it presented with numerous advantages over the conventional scalpel surgical procedure.Its profits in soft tissue surgeries include enhanced accuracy, easily achieved hemostasis, less necrosis of tissue from heat in comparison to electrosurgery, the accelerated rate of wound healing, sutureless surgery, decreased post-operative pain, and discomfort with reduced need for analgesics. Most procedures using lasers may be operated with topical local anesthesia alone that results in enhanced patient co-operation along with abridged procedural time that is especially of significance in the pediatric scenario. Additionally, the bactericidal effect of lasers on the surgical site means reduced use of antibiotics postoperatively.[7]

Conclusion

Operculectomy is a minor surgical procedure aimed to eliminate the operculum or the gingival tissue flap present over a fully or partially erupted tooth, usually in molars that if left unchecked may lead to pericoronitis and symptoms associated with the latter. Operculectomy using soft tissue lasers may be considered as a more favorable option in pediatric dentistry in comparison to conventional method where patient co-operation and procedural time must be accounted for.

Autism: Where the Little Things are Never Little

Biswabandita Mohanty[1], Susant Mohanty[2], Antarmayee Panigrahi[3]

[1]Postgraduate Student, [2]Professor & Head, [3]Reader, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

The aim of this write up is to furnish nearly all elemental aspects on varied behavioral patterns along with different management strategies which may lead to an improvement in treatment planning and management by the dental practitioners, and comprehensive oral health care of the children suffering from Autism. Along with it, this article focuses on raising concerns among primary health care providers and parents of those children regarding there un-mate dental needs.

Keywords: *Autism, behavioral pattern, health care providers.*

Introduction

Autism, where the little things are never little and every milestone is a celebration. It is mostly spectrum associated with multiple disorders of neurodevelopmental origin called Autism spectrum disorders which comprises a class of neurodevelopmental dysfunctions with a set of determining measures that comprise impede social associations, communication, and restricted or monotonous behavioral standardization.[1] It comprises of 5 subtypes, which consists of Autism disorder (AD), Asperger's syndrome, childhood disintegrative disorder (CDD) and Pervasive developmental disorder not otherwise specified (PDD-NOS).[2]

The symptoms of Autism starts by 3 years of age and normally experiences a stable route without recovery as the age increases. Common features in an autistic child can be as follows: [1]

(a) Discernable impairment in the use of multiple non-verbal communications,

(b) Lacks in developing social connections and sharing incidents and fascinations,

(c) Retarded or completely lacking linguistic development,

(d) Existing with potential sensory disabilities, mental retardation or epilepsy.

Those children may display excessive anxiety while facing the dental setup, and can create problems for the operator for providing the normal pattern of dental care[3]. Therefore it has become very important to discover various method so that the practitioner can cater to individual needs to decrease their suffering and anguish and create a peaceful and pragmatic experience for the child and his/her family. Those strand points of care will be of prime importance in this article.[4]

Epidemiology: According to various reports incidence of autistic disorder extends from about 5 per 10,000 to 20 per 10,000. The IQ score vary among man and women that is 2:1 in the children who are handicapped severely and 4:1 in moderately handicapped children. Boys are 5 times more affected than girls. The occurrence in siblings is suspected to be from 3% -7% presenting 50-100th fold increase in risk. [2,5]

Autistic disorder vs autism spectrum disorder:

- **Autistic Disorder:** Early infantile autism or childhood autism are 2 different names of this spectrum of disorders. Those children have a

Corresponding Author:
Dr. Antarmayee Panigrahi
Reader, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India
e-mail: antarmayee.pani@gmail.com

moderate to severe range of communication, socialization and behavioral problems. Many children with autism also have mental retardation.[5]

- **Autism Spectrum Disorder:** Spectrum is a term that represents a class of disorders with symptoms that are seen on a continuation which can be mild to severe in expression. It can be any of the disorders included in pervasive developmental disorder that shares undistinguishable behavioral patterns that constitute social interaction, impaired communication, and limited schemes and interests. As each individual shows a different set of combination of those behaviors so it is considered as a spectrum of disorder.2,5

Oral Manifestations: Dental manifestation related to autism can be of various origins, stating from developmental to caries related or can be due to traumatic injuries. There can be developmental disorders such as anomalies of tooth morphology, macroglossia and drooling of oral fluids. There can be delayed tooth eruption due to drug-induced hyperplasia. A higher incidence of caries was reported in the primary dentition. However, some studies also suggest lower rates of caries among children suffering from ASD. Due to the behavioral challenges and lack of awareness and training of the caregiver/parents, leads to poor periodontal health among those children. Most of the children suffering from ASD have high arched palate which forms the major cause of malocclusion. Children with autism have a higher prevalence of bruxism, tongue thrusting, snoring, nail-biting, non-nutritive chewing as well as they are more prone to traumatic injuries. Certain cases of hyper gag reflex and xerostomia has also been reported.[6]

General Awareness:

Awareness among Health care providers: The major issue on which most of the health practitioners accord is the advice for early oral examination of those children.[7] Children diagnosed with ASD, first reach to a Health care professionals before visiting any dentist. Therefore it becomes a responsivity for those health care professionals to advise the parents of those children for regular oral examinations. According to a study conducted by Murshid, the medical and educational issues are always given an upper hand by the health care professionals and mostly they always neglected the dental aspect. Nearly half of the study population did not focus on the importance of oral hygiene, and did not advise tooth brushing or mouth rinsing. They did never make any efforts to refer the children to any dentist. According to most of the health care providers, the parents should be the one held responsible to cater for the oral hygiene needs of the children, no one ever thought about the teachers being involved with tooth brushing practice of the child which he is not being able to do properly even if the child spends most of the time of a day with them in the health care center.[8] Lewis et al[9] and Dela Cruz et al[10] described similar findings among health care professionals.

Awareness among dentists: Mostly, dental education is very much important for the professional functioning of the practitioners while doing treatment for children with autism. According to reports the treatment for autistic children is mostly refused by more than 60% of dentists[11] Special clinic setups, preconditioned classes are still not considered by many dental curriculum[12]. The discrepancies in undergraduate educational programs may be compensated by newly introduced undergraduate educational programs, as it has been specified that autism interventions has been increased among health professionals by using Internet-delivered programs.[1]

Parental Awareness: According to a survey among parents, the autistic child's approach towards oral examinations, expenses, and no dental coverage by any insurance company being recognized as the major problem for providing oral health care to those children with ASD[13]. Resistance to dental treatment, complications associated with the medical condition, and difficulties in locating a dental practitioner abled to provide care have also been reported by guardians of children with autism[14]. Adding to the above-mentioned problems is the limited availability of specialized dentists who are trained to serve those children adds further complications in delivering proper treatment for those children.

Most importantly the parents should be trained to deal with various stress-inducing variables. The health care provider or any dentist to whom the parents approach should have a responsibility to guide the parents to certified professionals. Hence, access to proper health care services will provide participation of parents in decision making for treatment and fortify their reliance in handling the attitude of their child.[1]

Dental Management: One of the associated

problems in the case of an autistic child is a failure to develop joint attention that means impairment in the supposition of stimulus uptake, which results in deviant behavior to various signals. Due to the many-fold symptoms of autistic disorder dentists needs to ascertain their treatment protocol according to a distinctive presentation of various characteristics in each child patient.

Behavior management strategy: A pre-clinical evaluation and behavioral preparation is most in case of autist children as no autistic child is same as the other, pre-clinical evaluation includes Personal details, medications, previous experiences and in pre-clinical behavioral preparation dentist must have a proper idea about verbal/non-verbal, interests, signs of behavioral change, parental inputs, rewards, etc. Depending on the behavioral pattern the dentists should set the stage according to the child's requirement there should be proper teaching tools, visual pedagogy, social learning stories and if possible then use the same staff and dental environment for all the appointments. The child should be given clear instruction one at a time, Short appointments with frequent breaks to minimize distractions. Behavior management strategies like tell shoe do and positive reinforcement can be applied depending upon the child.[6]

If at all, all the strategies fail then the child is needed to be taken under sedation or General anesthetic procedures.

Dental treatment under General Anesthesia:

Guidelines for treatment under General Anesthesia: (Solent NHS. Internal Guidelines for Extraction of Teeth under General Anesthesia, 2015)

- Major goal is to complete all the dental treatments at once to avoid recapitulation of general anesthesia procedures in the future.
- When the patient is decided to be taken under GA, then not only the current treatment needs are to be catered but all the necessary treatments should be completed.
- All the teeth that have a poor or questionable prognosis should be extracted and all the needed restorative care should be completed in one sort.

Considerations for pediatric general anesthesia for dental treatment (Royal College of Surgeons guidance, modified)

- The attitude, co-operation and perceived anxiety of child
- The procedural complexity.
- Medical status: ASA I and II, mostly of ASA III
- Age – minimum of 2years
- Weight - more than 10 kg.
- Treatment must be carried out under hospitalization.
- Time and expenses
- Carious extent.

Preliminary considerations :

Preliminary considerations that must be carefully considered before general anesthesia procedure like, BMI: More than 40, severe bariatric patient. Chronic severe respiratory condition, previous adverse reaction to anesthetics, Profopol cross-reactivity, sickle cell condition,poly addiction to drugs, cardiac dysfunction. Anti-epileptic drugs, cardiac drugs, bronchodilators, anti-hypertensive drugs should be continued without alteration. Anxiolytics and tranquilizers should be carefully monitored as they can interact with pre-anesthetic drugs. In case the patient is under diabetic or corticosteroid therapy then the patient's physician must be consulted before starting up with the procedure.[15] Pre-anesthetic clearance by an anesthesiologist is the must before taking any patient under general anesthesia

Pre-anesthetics:

Ketamine medication or combination of midazolam along with ketamine is usually considered to be effective.[16]

Procedural Management: Definitive source of oxygen, suction, resuscitation equipment and emergency drugs, monitoring equipment such as non-invasive blood pressure monitor, pulse oximeter, electrocardiography, stethoscope, and capnography must be available. In case of any life-threatening emergency, there needs to be immediate availability of advanced airway management tools, defibrillators. An anaesthesiologist need to be there while the procedure is being performed till the discharge of patient.[17]

Possible Complications: Approximately 20% of complications under general anesthesia are, airway obstruction, nausea and vomiting[18]. Other complications such as non-fatal ventricular arrhythmia, hypotension or

rise in blood pressure, laryngospasm, airway problem which can result in oxygen desaturation.[19]

Conclusion

In order to treat the children with ASD there is a requirement of in-depth knowledge about the autistic behavioral profile. As explained before every child is different and so are his/her requirements and basing on these behavioral profiles therapeutic approach should be individually designed for each child. There is an absolute need for continual education among dental and health care professionals, so, that they could address and cater to those children with specific and unique health care requirements.

Root Coverage Procedures: A Case Series

Prachi Khuntia[1], RashmitaNayak[2], Abhaya Chandra Das[3], Rinkee Mohanty[4], Saurav Panda[3], Sharmistha Das[1]

[1]Post-Graduate Trainee, [2]Professor, [3]Reader, [4]Professor & Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Gingival recession can be defined as the progressive loss of gingival soft tissues. Most of the recession cases can lead to root exposure, interdental bone loss, mobility of teeth. The defect can involve one or multiple teeth. Eventually it progresses towards the root hypersensitivity and tooth loss due to mobility. Recession can be treated via using different treatment modalities, by using gingival grafting and regeneration. Grafting procedure entails to harvesting the tissue from donor sites and suturing it back to the area of recession for root coverage. For regeneration purposes, various biomaterials are used with improved properties. Techniques involved in gingival grafts and regeneration involves free gingival grafts, coronally advanced flaps, guided tissue regeneration, etc. This case series reports the effectiveness of various techniques for vestibular deepening along with root coverage, removing the frenum pool along with increasing the width of the attached gingiva, etc.

Keywords: *Gingival recession, Bridge flap, subepithelial connective tissue graft, Coronally Advanced Flap, Attached gingiva, Mucogingival surgery*

Introduction

The chief purpose of periodontal care is to prolong the aesthetics and function of normal healthy gingival tissues. The treatment techniques for maintaining healthy gingival tissues also involves the treatment of gingival recession and its complication. Gingival recession can be defined as the displacement of gingival soft tissues apical to the CEJ. This will finally lead to alveolar bone loss and dehiscence. GR is mostly seen in older people but can also be seen in young patients because of several reasons like frenum pull and insufficient width of AG.[1]

The exposure of roots due to soft tissues and bone loss can progressively lead to several problems such as hypersensitivity, discomfort in the soft tissues, root caries, various aesthetic problems and problems regarding oral hygiene maintenance and adequate plaque control etc.

The current evidences showed various techniques with improved predictable success rate for treating Miller Class I and II single-tooth defects. Difficulties arise when there are case scenarios with Miller Class III and IV defects involving one or multiple teeth. Evidences gathered from various RCTs and systematic reviews showed the high success rate of subepithelial connective tissue graft (SCTG) for treating maxillary recession defects present labially or buccally.[3] Nevertheless, there are insufficient evidences and data available for the treatment of palatal and lingual recession sites. Therefore, this case series presents different techniques to treat the mucogingival problems.

Case Reports:

Case 1: A female patient of forty-two years of age visited inthe Institute Of Dental Sciences, Sum Hospital

Corresponding Author:
Dr. Prachi Khuntia
Post-Graduate Trainee, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha
e-mail: dr.prachikhuntia@gmail.com

with a chief complaint of lowering of gums in the lower front tooth region. Clinical features revealed shallow vestibule and insufficient width of attached gingiva.

The recession was Grade I, according to Miller's classification[5],in 31, 41, 42 teeth (Figure 1a). The recession was similar (4 mm) in all lower anterior and the width of the attached gingival was approximately 2 mm (Figure 1b). IOPAR shows inadequate bone support present I .r.t to 31, 41, 42. UNC-15 probe is used for the measurement of clinical parameters which includes Probing Pocket Depth, Gingival Recession, width of attached gingiva,and Clinical Attachment Level. The patient was clarified about the surgical procedure and an informed consent was signed beforehand. The patient is not medically compromised. Phase 1 therapy was done 2 weeks before the procedure.

Surgical Technique: After injecting local anesthesia (with epinephrine), an incision was given in the vestibule from 31 to 42 (Figure 1c) which also includes the periosteum. The incision was made till the bone which will induced scar formation. After the sulcular incision, a full-thickness flap was elevated which connects the whole flap with the first incision so that the whole bridgeflap can be raised and coronally advanced to cover the recession from 31, 32 and 42 (Figure 1d). There was no need for a vertical incision. This forms a bridge from the coronal aspect to the vestibule (Figure 1e). Afterward, tetracycline HCl as a root conditioning agent is applied[4] which is further proceeded by the placement of platelet-rich fibrin membrane (Figure 1f). Then, the flapwas coronally advanced by the interrupted sling suture (Figure 1g). Resorbable sutures were used in this case. After the suture, the periodontal pack is (Figure 1h). After giving all the postoperative instructions in both verbal and written format and also required medications for improved postoperative healing and to avoid complications, the patient was discharged from the clinic. The patient was recalled after 14 days for suture removal and also to check for the healing of the surgical site. No such postoperative complications were seen with satisfactory healing was satisfactory with a significant gain in attached gingiva and clinical attachment was 5 mm (Figure 1i). Postoperative recession at a 1-month follow-up was about 1 mm. The patient was further instructed to use a softbristle toothbrush in the treated area. The patient was also instructed to maintain good oral hygiene in the surgical sites. Even after 9 months follow up, there was no such recurrence of recession.

Figure 1a. Pre-operative view showing Millers Class I gingival recession (labial aspect) in the mandibular anterior region. Figure 1b. Pre-operative view showing gingival recession (clinical attachment level); Figure 1c. Sulcular incision given; Figure 1d. Incision given in the mucogingival junction.

Figure 1e. Full-thickness flap (Bridge Flap); Figure 1f. Platelet-rich fibrin placed; Figure 1g. Coronal repositioned flap and sutured; Figure 1h. Coe pack placed; Figure 1i. 3 weeks Post-operative.

Case 2: A 31-year male, having a chief complaint of dentinal hypersensitivity in relation to 23 and 24, reported to the Department Of Periodontics And Oral Implantology, Institute Of Dental Sciences, Sum Hospital, Bhubaneswar.On examination, there was Miller's Class I gingival

recession[5] was present in relation to 23 and 24 (Figure 2a). Intraoral periapical radiograph in relation to 23 and 24 showed a sufficient presence of interdental bone. Clinical parameters included ProbingPocket Depth, Gingival Recession, width of attached gingiva,and Clinical Attachment Level. The briefing of the surgical procedure was done to the patient and an informed consent was signed beforehand. The patient is not medically compromised.Phase 1 therapy was done 2 weeks before the procedure.

Surgical Technique: After administering local anesthesia inthe recipient site, an intrasulcular incision was given from the distal aspect of 22 to the mesial aspect of 24 aspect. After that, full-thickness (mucoperiosteal flap) (Figure 2b) was raised. The surgical site was thoroughly debrided and the presence of any subgingival calculus was meticulously cleaned. After the preparation of the recipientsite, the size of the required graft was measured by a pre-sized tin foil template. The graft was harvested from the left palatal area, from mesial to the first premolar till mesial to the first molar. By utilizing the trap door technique[6], sub-epithelial connective tissue graft wastaken out of approximately the size of the tin foil template from the donor site. Afterward, the harvested tissue is kept in a moist gauge piece. (Figure 2c). The graft is shaped according to the size and need and abundant connectivetissue and fat were scared off by usingCastroviejo scissor. Subsequently, the graft was secured properly in on the recipient site, and secured with the help of sutures. (Figure 2d, 2e). After the graft placement, the flap was coronally advanced with the help of continuous sling sutures. (Figure 2f). After suturing, the patient was recommended to use a retention plate which the patient was previously using.

After giving all the postoperative instructions in both verbal and written format and also required medications and povidone-iodine mouthwash for improved postoperative healing and to avoid complications, the patient was discharged from the clinic. The patient was recalled on the tenth day to investigate for the acceptance of graft acceptance. Sutures are removed from both the donor and recipient sites. The patient was again made aware of the oral hygiene instructions (Figure 2g). In the follow-up sessionsthroughout 3 months patient wasrecalled, in which were seen a good root coverage

and significant aesthetic improvement was seen. Clinical examination revealed complete acceptance of the graft resulting from coverage of the root surface with the graft tissue. (Figure 2h). Complete healing of the donor site was also noted.

Figure 2d. Placement of the connective tissue graft; Figure 2f. Coronally advanced the flap followed by suturing;Figure 2g. Periodontal dressing Figure 2h. 3 months post-operative

Case 3: A 31 year male, with the chief complaint of hypersensitivity in relation to 14, reported to the Department of Periodontics And Oral Implantology, Institute Of Dental Sciences, Sum Hospital, Bhubaneswar. Nothing significant reported in past dental history and medical history. Periodontal pockets were absent and there was no bone loss present in relation to 14 on intraoral examination (Figure 3a). There was Miller's Class I recession i.r.t 14 (Figure 3b) and no trauma from occlusion was present. The patient was recalled 4 weeks later after the scaling and root planing was performed. After the patient's consent it was decided to treat the case surgically by coronally advanced flap[7].

Surgical Technique: Local anesthesia 1:80,0000 was administered after the proper isolation of the surgical site. A 15 no. scalpel blade is used to make a sub papillary incision along the soft tissue margin of the surgical site (Figure 3c). After the incision, full-thickness flap was raised followed by undermining in order to advance the flap coronally (Figure 3d; 3e). Sling suture was placed once the flap was advanced coronally (Figure 3f).To prevent infective complications, antibiotics were prescribed to patients. Amoxycillin 500 mg thrice a day for 5 days and Analgesics (Ibuprofen) was prescribed thrice a day for 3 days and Chlorhexidinemouthwash was also prescribed twice daily for four weeks and advised to avoid vigorous brushing on the surgical site. The patient was recalled for follow-up after 2 weeks (Figure 3g). The sutures were removed and the site was irrigated with normal saline and Betadine. Healing was satisfactory. Recall was scheduled for 2 months. The recession coverage result showed morphologic and chromatic resemblance to adjacent gingiva. Thus patient satisfaction was perceived (Figure 3h).

Discussion

The favourable results of root coverage procedures depend on several factors, such as elimination and/ orcontrol of the etiology of gingival recession, evaluations of the interproximal bone level and decision making for the particular surgical based on the surgical site. Since the period of 1960s and 70s many surgical techniques to resolve mucogingival problems have come into limelight. Coronally advanced flap, laterally displaced flap, coronally positioned flap with free gingivalgraft are widely used as a chief treatment modalities of mucogingival problems. In the year 1985, Langer and Langerdescribed came up with a technique of harvesting the subepithelial conjunctive tissue graft for. This was considered ideal for treating single or multiple tooth recession. This SCTG is still considered as the gold standard in mucogingival surgical procedures because of its enhanced blood supply from the underlyingperiosteum and overlying flap.[8] The prime factor of the success of grafting depends on the proper placement of the flap and to maintain the position of the papilla. The bridge flap technique includes twosurgical techniques simultaneously. In this technique, the survival and the success of graft depends on the blood circulation from the adjacent tooth surface areas. The flap creates a practicalsurgical procedure with good aesthetic outcome with less or no recurrence.[1]

It is usually performed when a single surgical technique is required to cover the denuded root surfaces with insufficient width of attached gingiva. So basically this procedure both improves the width of the attached gingiva and also covers the root surface in a single step. Nevertheless, for the success of any surgical procedure, proper knowledge of the anatomy of CEJ and the bone should be mandatory. This knowledge will help out the clinicians for proper placement of flaps and giving incision. Lastly, the clinician should always check for the presence of the width of the attached gingiva which should be 2-3 mm for maintain good sulcus depth to perform daily oral hygiene habits. Subepithelial connective tissue graft technique was chosen for the root coverage procedure depending on several anatomic and socioeconomic factors of patients. Along with the improved blood supply, good colour matching is another perk of subepithelial connective tissue graft.[6]

However, all periodontal plastic surgery aims for the root coverage, but a proper and specific treatment strategy is required to determine the success rate of the mucogingival surgery e.g., patient-related factors (maintenance oforal hygiene, method of brushing and smoking, site-related factors like interdental periodontal support and extent of recession.

Allen and Miller in 1989 proposed another surgical technique named coronally advanced flap.[9] The coronally advanced flaps don't involve a donor site, considering this it has less morbidity than CTG and SCTG. It is the treatment of choice in cases where sufficient width of the attached gingiva is present. By using this technique, the colour, texture and thickness of the tissue can be maintained in the treated site (mostly in the buccal aspect).

Conclusion

The success rate of multiple recession defects is based on predictable periodontal plastic surgery (PPS) procedures.[10] Etiology of the multiple defects,proper diagnosis, and case selection in a careful manner increase the surgical success. Bridge flap technique along with vestibular deepening, Subepithelial connective tissue and Coronallyadvanced flap technique may be used for successful management of single tooth recession or multiple teeth recessions.[11]

Abstract

A major part of the world population is affected with carious teeth, among which the number of children affected is maximum. Carious lesions are more common in susceptible, uninsured and financially weak populations. Caries which are not treated for a very long period along with no utilization of available services in both developing and underdeveloped countries pose an essential public health question. Children have limited adaptive capacity which may also lead to difficulty in some treatment procedures. Hence, the need for an efficient and affordable approach for dental caries treatment was required in areas that have a finite access to oral health care services like the school children. Nowadays, Silver Diamine Fluoride (SDF) is very much in demand as it can control caries progression and is very less technique sensitive. This approach does not require caries excavation using instruments, in addition silver has many antimicrobial properties and fluoride helps in remineralization.

Keywords: *Silver Diamine Fluoride, Dental caries, Fluoride.*

Introduction

Early Childhood caries (ECC) present a high prevalence worldwide according to various research papers. Patient cooperation is very important for a desirable outcome that cannot be satisfied by conventional restorations available for the treatment of ECC.[1] After referring to the 2015 Global Burden of Disease Study, it is the most prevalent condition that affected 560 million children with primary dentition.[2] Caries which are not treated for a long time increases the risk of infection in other permanent and deciduous teeth, which leads to a decrease in school attendance, discomfort, expensive emergency treatments and the need for general anesthesia and limitation of growth and development.[3] Children have limited adaptive capacity which leads to difficulty in some treatment procedures.[4] The World Health Organization (WHO), the FDI World Dental Federation (FDI) and the International Association for Dental Research (IADR) jointly convened the Global Consultation on Dental Health through Fluoride, in Geneaon November 2006 declared that "prevention by using fluoride is the only realistic way of reducing this burden (of dental caries) in populations".[5] In 2007, at the 60th World Health Assembly, WHO proposed the governments "to promote oral health in schools, aimingat developing healthy lifestyles and self-care practices in children". In the Beijing conference in 2007, there was an announcement that was collectively summoned by the WHO, the FDI, the IADR and the Chinese Stomatological Association (CSA) that said "fluoride dentifrice remains the most widespread and significant form of fluoride used globally and the most rigorously evaluated vehicle for fluoride use".[6,7] In recent times,

SDF is used because it stops caries formation and its progression is arrested simultaneously. This approach does not require caries excavation using instruments, in addition silver has many antimicrobial properties and fluoride helps in remineralization. In 2014, the US Food and Drug Administration introduced SDF for the management of tooth hypersensitivity.[8] Many in vitro studies have proven SDF as caries arresting and antimicrobial agent that destroys the activities of S.mutans and dentinal biofilm.[4]

History: Since 1000 years silver has been used as tooth cosmetics to prevent dental caries in Japan.[9] Due to their caries inhibition properties in 1891, silver amalgam and nitrate were used.[10] It was directly applied on carious surfaces as silver niraefor caries prohibition and it was called as Howe's solution.[11] At school dental care services in Western Australia 40% silver fluoride (AgF) was used to treat dental caries of deciduous teeth.[12]

Other parts of the world did not have much idea about SDF use till the late 1960s and the 1970s as SDF use was restricted to Japan. The Central Pharmaceutical Council of the Ministry of Health and Welfare in Japan in the 1960s established it as a therapeutic agent for treating dental caries. Australia and China have also used SDF to prevent caries progression in the last few decades.[13,14] Argentina, Brazil and Spain have used SDF for various public health events in different concentrations; and public health events were planned for sub-Saharan Africa and for different parts of Africa.[15] In Southern California 1995 there were reports that children with early childhood caries were treated with SDF to inhibit caries process as published by an American Journal at that time.[16,17] The US Food and Drug Administration approved SDF for treatment of dentinal hypersensitivity in 2014, which had the molecular formula as Ag(NH3)2F which is Silver diamine fluoride (38%).[8] Since then it was used as a very efficient caries arresting agent in Japan. Different in vivo studies done by Chu et al., Llodra et al., and Yee et al., mentioned that SDF was reducing dental caries in primary teeth as well as effective in arresting caries and also as a treatment substitute for other technique sensitive restoration method.[18-20] In vitro trials done by Knight et al., found that dentinal discs treated with silver diamine fluoride (SDF) showed a reduction in Streptococcus mutans counts.[12]

Silver Diamine Fluoride and Glass Ionomer Compound (GIC): The dark colour of the arrested of caries surface is not one of the most pleasing outcomes of SDF use. For better aesthetics there is a requirement for another effective treatment. Glass ionomer has been used as a restorative material with benefits of releasing fluoride which helps in remineralization. The release of a high concentration of fluoride ion prevents new dental caries development. Moreover, for anterior teeth restorations the tooth color of GIC makes it an obvious choice.[21]

Silver Diamine Fluoride Compared with Atraumatic Restorative Treatment: For school children having finite reach to oral health services, it is necessary to look for an affordable and atraumatic restorative material. There is increased demand all over the world for conservative caries treatment options. So, Atraumatic Restorative Treatment (ART) was introduced first in Tanzania in the mid-1980s and this is a pain-free, minimal intervention approach that is not technique sensitive and where less skill is required along with only hand instruments used to remove carious tooth substance. The conventional, self-hardening Glass Ionomer Cement (GIC)is used to restore the tooth and then used to seal any adjacent enamel fissures.[22] This procedure is largely pain-free and is well preferred by children and GICs demonstrate sustained fluoride release, pulpal biocompatibility, and chemical adhesion to the tooth surface.

The action of SDF on the carious tooth surface:

These could be the available mechanisms of action of SDF in arresting caries:

1. The first step isthe occlusion of dentinal tubules with silver. When SDF is applied the dye permissibility of dentine is decreased and electric resistance strengthened. It is also said that the products formed by silver from SDF use to halt the diffusion of acid and entry of microbes into the dentinal tubules. Further growth of microorganisms is inhibited the by oligodynamic action of silver. The surface area of dentin is decreased by the obturation of the dentinal tubules. The use of 38% SDF preserves collagen from degradation in demineralized dentin and suppresses demineralization.
2. The protection of dentin towards the activity of acid which leads to decreased access of acid into deeper parts of dentin is accelerated by the presence of fluoride. The fluoride ions released goes to a depth of 50–100 μ. in vivo conditions when SDF is applied

to dentin. Also SDF (Ag(NH3)2F) reacts with hydroxylapatite (HA) of a tooth to release calcium fluoride (CaF2) and silver phosphate (Ag3PO4) resulting in hardening of affected dentine.

This is chemically interpreted as:

$Ca10(PO4)6(OH)2 + Ag(NH3)2 \rightarrow CaF2 + Ag3PO4 + NH4OH$

$CaF2 \rightarrow Ca^{++} + 2F^-$

$Ca10(PO4)6(OH)2 + 2F^- \rightarrow Ca10(PO4)6F2 + 2OH^-$

The Ag3PO4 that is formed on the tooth is insoluble to acid attacks. The CaF2 formed as a reaction product becomes a pool of fluoride ions for the formation of fluorapatite (Ca10(PO4)6F2. It has also been proved that fluoride ions enhance calcification of tooth, and restores lattice imperfection and improves the crystallinity of HA.

3. The anti-enzymatic actions of the reaction products between Ag(NH3)2F and organic component of the tooth can be the next mechanism of action for caries arrest. Its antibacterial properties arise from inhibition of the enzyme activities and dextran-induced agglutination of cariogenic strains of Streptococcus mutans. Resistance of dentin to trypsin increased when SDF is applied on the tooth surface. Also,a study reported resistance to collagenase and trypsin for dentin protein increased after treating the tooth with SDF.[4]

Principles of selecting tooth for Silver Diamine Fluoride applications include:

SDF can be used in:

- Patients having active cavitated caries lesions with high caries risk in anterioror posterior teeth.
- Patients diagnosed with medical and behavioral challenges.
- The ones with a greater number of carious lesions cannot be treated in a single sitting.
- Carious lesions with complicated treatment plans; and those withdifficulty in accessing oral health care.
- There should be no signs of spontaneous painor acute/chronic pulpal inflammation.
- The use of radiographs to assess the depth of infection
- The carious lesions should be checked for accessibility of the applicator brush.(To gain access in proximal lesions orthodontic separators can be used.)
- As part of caries control therapy, SDF can be used before restoration placement.[23]

Clinical Applications of SDF are:

- Xerostomic patients, who are more susceptible to dental caries.
- For the treatment of caries in mentally disturbed young children.
- Caries management of the anterior deciduous teeth.
- Children whose guardians do not have time for long operative procedures.
- This is a great atraumatic option along with minimal use of equipment.
- No anesthesia is required for the procedure.

Method of applying SDF:

- One drop of SDF is dispensed into a dappen dish.
- The affected tooth surface is isolated and dried.
- Petroleum jelly is applied then on all the adjacent mucosa of the affected tooth.
- It is then applied with a micro brush or an applicator tip.
- The excess is removed with cotton gauge and then left for 2 minutes.
- Rinse with water.
- The tooth can be restored with restorative material like GIC.
- The restoration is evaluated every six months.[21]

SDF is advantageous because:

- Control of pain and infection as the caries is arrested in its initial stage.
- The simplicity of its use as it is like painting/ applying on the affected surface with a microbrush.
- The material is quite affordable which is around 100 applications per 5ml bottle and is available in most parts of the world.

- The requirement of skill is less as it is not technique sensitive.
- It is non-invasive and atraumatic nature.
- Duration of treatment is shorter than other restorative procedures.

The available concentrations of SDF are 10%, 12%, 30%, and 38%. Review articles and original studies related to SDF have suggested the use of 38% SDF for dental caries(8,20). A review by Contreras et al.(24) proposed that SDF for arresting caries was more efficient at concentrations of 30% and 38%.

Disadvantages of SDF: Pulpal irritation, dental staining, and oral soft tissue irritation are the main adverse events associated with SDF applications. Skin pigmentation is for short duration as silver does not enter the dermis. When keratinocytes are shed over 14 days desquamation of the skin with pigmentation occurs. The dental pulp is at lesser risk by the use of SDF. One of its demerits is the blackish discoloration that appears after the SDF application.[4]

Public Health Significance: Silver diamine fluoride arrests more than 80% of the caries when used twice per year. It is a source of powerful indirect prevention of dental caries. Hence, it is a game-changer in the field of dental public health as it is affordable in comparison with other expensive dental procedures and saves a lot of time, requires a lesser amount of skill, not technique sensitive and can be used in field settings like a school-based programmes by both dental auxiliaries and dentists. The benefits of SDF far outweigh the risks. Hence emerging as an effective public health tool.[4,21]

Conclusion

The application of SDF once in every 6 months is preferred to other minimally invasive techniques. SDF as a primary preventive material is better and convincing than other materials for restorations, excluding dental sealants which are >10 times expensive and requires more skill and technique. If it is used as a preventive or curative procedure, it can prevent or postpone the requirement of caries treatment in both children and adults. The use of fluoride varnish for caries cessation can be replaced in patients with SDF. It is a potent public health tool especially in low-income countries in the fight against dental caries.

Over-Dentures and Attachments: A Review of Literature

Rasmita Kumari Samantaray[1], Krishna Nanda[1], Debashish Sahoo[1]

[1]Post Graduate Trainees, Department of Prosthodontics and Crown & Bridge, Institute Of Dental Sciences, Siksha O Anusandhan (Deemed to be Univerisity), Bhubaneswar, Odisha, India

Abstract

Tooth-retained overdentures are a simple and cost-effective treatment than the implant-supported overdentures. When few teeth are present which are periodontally strong can be used as abutments for overdenture fabrication. This helps in the retention and stability of the final prosthesis. The extraction of teeth results in bone resorption, so preserving them as an abutment can not only provide retention and stability to the denture but also prevents bone loss and provide proprioception. Above all, "it gives the patient the satisfaction of having prosthesis with his natural teeth still present".

Keywords: *Tooth Supported Denture,Implant Retained Denture,Overlay Prosthesis.*

Introduction

An Overdenture is a "dental prosthesis that covers the natural tooth and or is partially supported by natural teeth, natural tooth roots or dental implants". According to GPT 10, "overdenture is a partial or complete denture that covers and rests on one or more remaining natural teeth, roots and/or dental implants; a dental prosthesis that covers and is partially supported by natural teeth, tooth roots, and/or dental implants". It is also called as "overlay denture, overlay prosthesis and superimposed prosthesis.[16]

Preventive prosthodontics "emphasizes the importance of any procedure that can delay or eliminate future prosthodontic problems and overdenture is an important part of the preventive treatment modality". De-Van's golden statement: "Perpetual preservation of what remains is more important than the meticulous replacement of what is missing" still rings true[7].

Tooth supported overdentures have various advantages over conventional complete dentures such as maintenance of alveolar bone maintenance, periodontal proprioception is preserved, improves retention, stability and support,enhances psychological comfort and increased mastication efficacy.[4]

Chen et al. "observed that the patients treated with tooth-supported overdentures had significantly more comparative masticatory efficiency than those with conventional complete dentures, while there was an insignificant difference in comparative masticatory efficiency between tooth-supported overdentures and implant-supported overdentures"[2.]

Crown and Rooney 1975 in their study found that "retention of mandibular canine for overdenture led to preservation of alveolar bone"[2].

Indications for Overdentures:[1]

1. For better support in morphologically compromised dental arches.
2. Cleft palate cases and congenital anomaly cases like microdontia, amelogenesis imperfecta, dentinogenesis imperfecta, and partial anodontia.
3. Dentures patients with maxillofacial trauma.
4. Patients with worn-out dentition.
5. Patients with abnormal jaw size and position where orthognathic surgery is contraindicated.

General Considerations during Diagnosis and Treatment Planning for an Over-Denture[1,2,4]:

1. Maintenance of Periodontal Health: Once an overdenture is planned and constructed, the patient must maintain his teeth free from plaque. The dentist should check for pocket formation around the abutments periodically and failing may lead to the loss of abutment tooth.

2. Reduction in Crown-root Ratio: Reduction in crown size during preparation can be beneficial for the tooth, as it "reduces the crown-root ratio" and "decreases the leverage forces acting on the tooth".
3. Success of Endodontic Therapy: Endodontic therapy may be necessary for most abutment teeth because they need extensive crown reduction. A two-to-four week interval should be provided after completion of root canal therapy to determine the success.
4. Number of overdenture abutment teeth: "Two Abutments On Opposing Sides Of The Arch Particularly In The Canine Regions Will Provide Excellent Results". Four Widely separated Abutments Are Even Better.
5. Adaptation and Coverage of Denture-Bearing Area: The denture base should be well adapted to the soft tissues to prevent accumulation of food debris and to evenly distribute the force acting on the denture.
6. Design of the Denture: As the denture base for overdentures are thin, they have to be reinforced with metal. At the same time they should be easy to fabricate and maintain.
7. Ease of Use: The patient should be able to easily insert and remove the denture without any harm to the denture base or the abutment tooth.

Advantages of Overdentures:[3]

1. Maintains the integrity of the ridge.
2. Improves the "retention and stability" of the denture.
3. Improved proprioception leads to better neuromuscular control. This helps in regulating the biting force over the denture.
4. The psychological effect on the patient as extraction can be avoided.
5. If there is abutment failure, the abutments can be extracted and the overdenture can be relined and used as a conventional complete denture.

Disadvantages of Overdentures:[2]

1. Nutritional counseling, oral hygiene measures, and fluoride application should be carried out periodically.
2. "High incidence of caries and periodontal disease around the overdenture abutments".
3. Frequent reviews are needed to verify the health of the supporting tissues of the overdenture abutments and Improper maintenance of the overdenture may lead to periodontal breakdown of the overdenture abutments and the patient may lose all his remaining teeth.
4. More costly than conventional dentures because:
   (a) Root canal therapy and coronal restorations may be needed for certain overdenture abutments.
   (b) Most cases need a cast metal denture base, as acrylic is weaker.
5. Additional designing and laboratory work is needed.
6. Cannot be used in cases with reduced interarch space, bony undercuts adjacent to the abutments, etc.

Abutment Preparation[1]: The preparation of abutment teeth is one of the keys to the construction of overdenture. Assuming the periodontal status to be good, the operator has three choices:-

1. Preparation just above the mucosal level.
   - The bare root face approach.
   - The dome-shaped gold coping.
2. The use of attachments.
3. The thimble-shaped coping.

The Bare Root Face Approach[1]: The occlusal section is obturated with glass ionomer or silver amalgam. It is normally employed for immediate insertion prosthesis. On later stages coping can be given the crown of abutment is reduced to a height of 2-3 mm. the abutment tooth is endodontically treated the occlusal surface is to be contoured to smooth or polished dome-shaped surface. This will minimize lateral occlusal stress. It offers following advantages-

1. "It is the simplest,cheapest and least space-consuming".
2. "It is ideal during maturation of edentulous ridge"of a recently extracted case.
3. It should be replaced by an coping with precious or semi-precious metal otherwise there is a chance of vertical longitudinal root fracture.
4. Contraindications:
5. It should not be used for a long period where a natural tooth is opposing the overdenture.

6. Leaving it as such may lead to longitudinal root fracture.

The Dome Shaped Copings[1]: The Abutment Tooth Is root canal Treated And Reduced To A Height Of 2-3mm and Post Space Is Created. Dome Shaped Cast Metal Copings 2-3 Mm In Height With Chamfer Finish Line And Post Are Fabricated And Cemented. Coping Should Be Atleast 1 Mm Thick To Withstand Occlusal Forces.

Thimble shaped coping[1]: These are 5-8mm in height and need considerable space. These copings can be used to support the telescopic crown to enhance retention. The chamfer finish line is given in the prepared abutment.

Basic Principles to be followed[1,5]: The abutment teeth must be surrounded with healthy periodontal tissue.

1. Maximum reduction of the crown to attain a better crown-root ratio and avoid interference during the placement of artificial teeth. Endodontic therapy may be done if needed. A simple tooth preparation without any internal attachments can be done in a single visit. This can be done for elderly patients and medically compromised patients. It is less expensive than copings.
2. Gold copings or crowns and sleeve coping retainers can be given for grossly destructed abutments after assessing the patient's susceptibility to caries. Gold or metal coping can be prepared with posts and retentive pins after evaluating the amount of tooth structure above the gingival attachment.
3. Attachments are added to the cast copings for additional retention. These attachments may be resilient or non-resilient types.
4. Regular reviews and periodontal evaluation of abutment teeth should be done.

Types of Overdenture:[1]

Two types:

Tooth supported overdenture

Implant-supported overdenture

Heartwell's classification for tooth-supported overdenture

Based on the method of abutment preparation:

1. Coping
2. Noncoping – with simple tooth modification
3. Attachments
4. Submerged vital roots: Effective in preserving alveolar bone

Based on length of coping:

1. "Short coping – 23 mm long and normally require endodontic therapy".
2. "Long coping – 58 mm long, an attempt is made to circumvent endodontic therapy by conservative reduction".

Abutment with attachment–"Most of the attachments are secured to the abutment by a cast coping. The objective of attachment is to improve the retention of denture".

Attachments Used In tooth/root/Implant supported Overdenture:

Definition: "A mechanical device for the fixation, retention and stabilization of a prosthesis,a retainer consisting of a metal receptacle and a closely fitting part; the former (the female matrix component) is usually contained within the normal or expanded contours of the crown of the abutment tooth and the latter (the male matrix component), is attached to a pontic or the denture framework".[16]

The attachments used for overdenture can be classified as[1,9]:

Stud attachment

Bar attachments

Magnetic attachments

Requirements of Attachments:

- Patients should have a low caries index.
- Sound periodontal health.
- The vertical space should be sufficient enough to accommodate the attachment and denture teeth.

Disadvantages of Attachments:

- Time-consuming and expensive.
- Difficulty in construction as well as repair is difficult.

- Require careful use by the Patient. So not recommended for mentally and physically handicapped patients.

Stud attachment[1,9,15]:

It is the simplest of all types of attachments.

Stud attachments can be divided into two groups:

1. **The Extra Radicular:** "The Stud" (Male part) usually attached to metal coping cemented over the prepared abutment and it projects from the root surface of the preparation. The female part is attached to the denture. Attachment of male component to female component provides retention. The male parts are available as:

a. Prefabricated Metal Posts-Cemented Directly To The Root.

b. Prefabricated Resin Patterns- Which Is Cast And Cemented To The Root.

The female component is also termed as retentive anchor and made in metal or plastic and is in the form of an o ring or matrix. Eg-CEKA, ORS-OD, DALBOS, SERIES, GERBER, LOCATOR ATTACHMENT AND ROTHERMAN.

Ceka Attachment:

The male part is round and composed of titanium.

The female part is replaceable plastic part that is flexible And compressible.

O Ring Series System: O-rings are "doughnut-shaped, synthetic polymer gaskets that possess the ability to bend with resistance and then return to their approximate original shape".

Parts of an O-Ring Attachment-metal encapsulator,o ring post, and o ring which is available in 3 different sizes.

Dalbos Series Attachment System:

- It is the most popular stud attachment with a long life.
- It is available in two designs- ball and socket dalbo & rigid dalbo.
- It is available in spherical and cylindrical forms.
- The ball and socket dalbo is the smallest of 4mm height and easy to clean and maintain.

Rotherman System-

- The male part consists of a groove.
- The female part is c shaped ring that fits in the deeper part of retaining groove.
- The attachment looks like a press button with a groove.
- The female unit is clip with open end.

Locator attachment-

- The locator attachment system is an attachment system with a self-aligning feature and has dual retention (inner and outer).
- Locator attachments come in different colors (white, pink and blue)
- "Extended range attachments, which can be used to correct implant angulation up to 20 degrees they are offered in green, which has standard retention, and red, which has extra-light retention".

Gerber Attachment: Readily replaced male or female attachment Which can be replaced if they are worn out.

The spring-clip of the female part engages in the peripheral groove in the male.

Other extraarticular attachment systems used are:

(a) The Ancro fix attachment

(b) The Introfix attachment

(c) Quinlivan attachment

(d) Schubiger Attachment

2. **The Intra Radicular Attachment:** "The Stud"(Male element) forms part of the denture base and engages a specially produced depression(housing or female part) within the root contour. This attachment is indicated in situations with reduced interocclusal space.

Eg-Logic,Zest attachment,ERA attachment

Zest Anchor System:

The female sleeve is cemented in the post space.

Male portion consists of nylon.

ERA system: Resilient attachment system with

color-coding resin unit providing various degrees of retention.

Universal hinge with vertical movement.

Metal jacket which holds the male attachments.

Bar Attachment: It consists of a bar spanning an edentulous area joining copings on the roots of the abutment teeth on either side of the arch.

Sleeves and clips placed in the denture attach to the bar when the denture is inserted,providing retention.

The bar splints the abutment teeth and thus distributes the forces.

This type of bar attachment requires vertical and buccolingual space.

Oral hygiene maintenance is very much essential otherwise may lead to abutment loss.

It can be a bar joint or bar unit.

Depending on the number it can be a single bar or multiple bars.

Depending on movement it can be a bar unit that provides no movement and is made up of solid rigid material or bar joint which permits rotational movement between bar and sleeve and thus made up of resilient material.

Hader Bar:

It is named after the swiss tool and die technician "Helmut hader".

It is a rigid bar connecting two or more attachments.

When viewed from the cross-section it appears a keyhole consisting of a rectangular bar with a rounded superior ridge that creates a retentive undercut for the female clip within the removable prosthesis.

The bar provides mechanical retention and the round part makes the bar resilient type and thus some amount of movement is seen in this attachment.

The sleeves which are available commercially in plastic form can be cast and converted to metal if extra retention is required.

Dolder Bar:

It is named after swiss prosthodontist Eugene j dolder.

The bar is straight and is rounded at the top. The Sleeves that fit over the bargain retention by friction only.

The bar is available in various sizes and when cross-sectionally viewed appears to be pear-shaped. The clip which is fitted in the denture base allows some rotational movement.

It is available in sizes in diameter of 1.6 and 2.2 mm.

Ackermann and CM bar

These bars are round when viewed in cross-section.

As they are round they offer some resiliency and can be bent in all directions.

A short extension of 5 mm is carried behind the most distal root and the sleeve is positioned on this section.

Sleeves or clips are made up of gold.

Available in 1.8 mm diameter in plastic and gold.

The CM bar is available in a 1.9 mm diameter and used in long-span cases.

Magnetic Attachments[1,3,8]

Magnetic attachment consists of keeper and denture retention element.

The keeper is made up of stainless steel and is cemented to the abutment teeth.

The "denture retention element" consists of" paired,cylindrical magnets" made of cobalt-samarium with opposite poles placed adjacent to each other.

One end in the denture with knurled housing which fits into the denture and other ends which is smooth fits on the keeper.

The retention principle is due to the mutual attraction of unlike poles.during dislodging forces, the magnetic forces reseat the denture.

Advantages of magnetic attachment: No path of insertion, No specialized casting or instruments required, No paralleling of abutment.

Automatic reseating, Ease of repair and relining, Minimum forces are transmitted to roots.

Disadvantages: Alloy and corrode and fracture leading to loss of magnetism with loss of retention and thus need for constant replacement.

Discussion

Tooth & implant-supported over-dentures are a "step in the direction of preventive prosthodontics". They Preserve the residual ridge, provide support and stabilization to the denture base, and thus gives the patient a sense of security in knowing that teeth aid in support of their prosthesis. The maxillary overlay denture is of great value when it opposes remaining mandibular anterior teeth because it aids in conserving the ridge against resorption from "masticatory stress"[4'].
The greatest difficulty is the use of attachmentsbecause of their "complex design". A thorough understanding of the case and knowledge about the various attachments and its applications and limitations is a must to apply clinically.

Conclusion

Overdenture helps reduce shrinkage of surrounding bone and reduces pressure on the alveolar ridge. In the case of an overdenture prosthesis, "proprioception is maintained" there is the presence of "directional sensitivity; dimensional discrimination; canine response and tactile sensitivity"[1,14].

Stress in Dentistry: A Review

Marlin Jena[1], Dharmashree Satyarup[2], Ramesh Nagarajappa[3], Upasana Dhar[1]

[1]Postgraduate Student, [2]Professor, [3]Professor & Head, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dentists are prone to have different kinds of mental, physical, psychological and financial complications related to stress. It is important for the dentists to de-stress themselves by a reduction in the number of stressors and increase the ability to deal with stressful situations. The practices like resisting stress as well as time management and choosing goals which are similar to real-life scenario should be encouraged. So that stress can be reduced to a tolerable level. Like any profession, the transition from academics to the workplace could be a challenging task. As it is known that dental care professionals have responsibility for the health status of general people. So,there is a need for stress management and reduction programs to be integrated into dental education, which can provide practical solutions for curtailing various types of stress. Here we will know how to promote and enhance the well-being of the dentists by understanding the value of life.

Keywords: *Stress, anxiety, depression, dentist, dentistry*

Introduction

It is frequently assumed that dental professionals have a soothing career but, the fact is that, various stressful situations can cause worry in dental professionals. Usually dentistry is perceived as monotonous and stressful[1]. It has been expressed by experienced dental professionals that, it increases stress level to a negative peak but also hampers daily activities which include personal relationships, leading to early retirement[2]. Psychological disorders such as depression, anxiety,narcotic abuse, and various health problems such as heart attacks, strokes, fluctuations in weight and professional burnout could be tied to stress points in dentistry[2,3].

In the dental profession the stress may set in from the beginning that is, while studying to qualify as a dentist. Various studies have been conducted which have concluded that dental student has more stress compared to any other professional education[4]. This stress keeps intensifying with each year of study[5]. Stress may come from various external factors such as physical, mental and psychological well-being. Hence stress must already set in even before qualifying as a dentist. Therefore, only a few perfectionists may seem to continue their career with an academic track record of excellence. After completing the qualification, the stress usually reduces in other professions but here it only increases due to the financial pressure of setting up and keeping the dental practice running. Post completion of graduation, a person is stressed to find an employer to settle any educational loans taken and it will keep on increasing along with various new debts which have an impact on psychological and emotional shades of life.[6]

While, restoring the clinical, functional, and structural aspects of a dental career, consequences could be due to as extreme stress levels leading to numerous complications like panic attacks, drug abuse, alcohol abuse, health disorders like cardiac problems,

early stroke, variations in weight and professional burnout. Dental professionals have a chance of having musculoskeletal issues because of less workings pace, continuously working in the same posture and impaired vision due to continue concentrating on the oral cavity. If a dentist has his/her dental clinic, then he/she is anxious about dealing with various expenses, like dealing with staff and co-workers, lab bills and payments for rent it time. Dentist is worried about their professional liability[7].

In the study conducted on dental professionals by Sumaya Basudan., et al (2017)[8], it was observed that 55.9% of the respondents had abnormal levels of depression, 66.8% had anxiety and 54.7% had stress,Severe and extremely severe scores for depression, anxiety, and stress were reported in 20.2%, 34.0% and 20.2% of respondents, respectively[8].

How to suppress stress: The impact of stress on an individual can be broadly divided into two parts. One is the usual meaning it carries which leads to depression by lack of motivation and the other one is in a good way. The latter one affects a person positively where he/she can concentrate his/her energies in a specific direction to simplify various problems or situations by uplifting career or achieving any goals. But the former one is the matter of concern that needs to be addressed by various stress management method, like constant motivation.

Physical Stress: Good health is the key to reducing stress in any field, however, a dental practitioner requires strength, flexibility, endurance and coordination. So, it is necessary to maintain a decent physical and mental health by eating healthy meals, getting a sound sleep, and doing adequate exercise. Exercise, enables your body to perform well, and also have psychological benefits. Exercises to help in stretching of the muscles that support the spine. Walking or swimming are also highly recommended[9]. These practices lessen the physical stress to a significant level and increase productivity in professional lives. For spinal problems, correcting postures in between time intervals, relaxation during work sessions, could be utilized[10].

Psychological stress: Students and faculty should be made aware of psychological stress associated with dentistry very early in their careers. Initial signs and symptoms of anxiety or depression would be identified and addressed at the earliest. A health professional should try to solve this issue on his/her own. As a doctor we should recognize the problem at the beginning and understand the necessity of mental health, besides being with friends and family can help to be emotionally stable and get moral support. Similarly, taking vacations is a boon for a dentist. To reduces tress, deep breathing and muscle relaxation should be practiced routinely. The dentist can also discuss with their peers regarding the improvement of the work environment at the clinic, dental practice and management processes, and expertise in method for effective control over patient anxiety. Health professionals should take leisurely breaks sensibly or holidays from busy work life, as it relaxes the brain as well as the body[11].

Financial Stress: A dentist may lack financial skills to manage all the monetary issues. Not receiving payments in time for their services can lead to anxiety about their future. It is recommended to hire a financial advisor, who can help you in various possible ways to manage your monetary aspect in exchange for a small management fee. It will be time-saving as well as convenient. A few steps to consider in refinancing your student loans at a different lender so that the money you need to provide every monthly payment interest will be lower. It could help you to reduce your financial stress and guide you for future loans. A person should not make dentistry, as their only source of income, he should invest generously in various investment programs. This can help to reduce the financial pressure to a great extent. In all these things one should also consider that time is equally important as the value of money and make the financial decision wisely to lead a balanced work life[7].

Stress coping mechanisms: In the study conducted on dental professionals by Sumaya Basudan., et al (2017)[8], the authors illustrate different mechanisms to cope with stress. The most common method for coping with stress was activities such as watching movies, studying novels, sound sleep and shopping with friends (71%), followed bye motional support from others (53%).Under other mechanisms, intake of food or drinks and going on a vacation was mentioned by some[8].

Coping with stress: When dentists are compared with doctors, they consider it as a personal insult. Working in their scheduled routine dental practices for long hours leads to a frustrating life[12]. It is known that stress is not good for health so it leads to many issues such as ulcer, colitis, back pain, eye strain, marital disharmony, and even suicide[13]. Significance of high-stress levels was evident in the survey conducted on

UK dentists, where responses showed that 17.6% of all respondents had seriously thought about committing suicide at some point in their lives, which was compared to a recent survey conducted on UK dentists by Dr. Vicki Collin,et al (2019)[14], which found that 20.6% of the normal population had reported suicidal thoughts came to their mind, moreover the researchers found that dentists showed higher levels of suicidal thought than the normal population, among them whomever said that they thought of attempting suicide is 57.7% last 12 months. The high levels of self-reported stress, burnout and psychological stress found are a serious concern for the dentists[14]. Stress is a well-known factor for mood swings, mental disorders, and suicide risk due to negative life events. Not every person can cope with the same pressure, and that leads to the risk of developing depression and suicidal thinking[15]. It can also cause absenteeism, personal anger, jealousy, low productivity, and increase complaints at work place[16]. Due to running behind schedule sometimes any kind of work-related comments by colleagues may lead to inferiority feelings, discouragement, self-doubt on abilities to work and lack of self-confidence can cause emotional fall out[17].

How to manage stress: Stress can be reduced by expressing feelings verbally, mainly the negative thoughts like anger and sadness, listening to music for relaxation of mind, as it helps to calm anger and spread positivity[18]. Good social network is equally important with family members, friends, any other contacts like doctors, colleagues, etc, as it will assist at the time of need. If someone will use his/her past experiences and knowledge, they can tackle problems easily in different situations. As a dentist, there may be many unpredictable situations and we have to tackle it by using self-management skills and problem-solving behaviour[19]. Always try to create innovative ways to deal with the current situation, boost self-confidence by developing personal growth, learning new things, or collecting new information regarding arts such as literature, music, and painting[18]. As health professionals, we have a duty towards society to meet their expectations because we are offering services to the community. Dentists should know how to improve the skill of communication, listening, and have financial and business management knowledge too[20]. For managing apprehensive patients, some stress releasing procedures such as relaxation, hypnosis, desensitization, coping therapy could be useful[21]. Awareness to understand emotions and means to cope with them by self-control is essential. Professional and patient relationship should be good enough to avoid stressful environments[19]. Minimize the impact of negative thinking and maximize the positive thinking.

To summarize the preventive measures that can be implemented are:

- Improvement in work environment
- Don't stay alone and discuss issues with colleagues
- Utilize time wisely and take breaks
- Learn how to manage patients fear and anxiety
- Attend programs in stress management
- Do one thing at a time, Create time for yourself
- Initiate outside interests
- Listen actively, Talk less and more slowly
- Regular physical exercises
- Relax mind and listen to music
- Say no to the unachievable
- Do breathe in and out technique repeatedly
- Less demand for efforts and be kind to yourself[22].

Don't try to become perfect, sometimes it is fine to be satisfied with whatever you have. Accept the fact that no one can have control over everything in life.

Conclusion

As the problem of anxiety and depression is faced by both students and professionals at some point in time, it is important to identify various symptoms to improve psychological well-being. These strategies may be implemented early in dental schools for improving student's lives, prevent premature dropout and the same can help a person in their profession at a later age. This ensures curtailing of all further kinds of complications that may set in after completion of the qualification,hence it can improve both quantity and quality of the work-life significantly[8].

So, overall,we can say everyone is susceptible to stress. Although the dental career is tremendously stressful, but if proper measures are taken in proper time one can reduce the stress to a bearable limit. Identifying the sources of your stress, then eliminating the problems to get solutions over your stressor is advisable. Remembering to be kind to yourself and try to

push your limits can help to reduce stress. Like any other profession dentistry can be considered as a marathon, where one should try to live with it instead of trying to escape from it. Dentists are susceptible to professional burnout, anxiety attacks and clinical misery. Stress can't be eradicated from dentistry but it can be minimized to some extent. Key to manage stress is finding out the root cause to know the problem properly and try to solve it. If the cause is identified then preventive measures or precautions can be taken[7].

Post and Core Treatment of Maxillary Right Central Incisor Using a Fibre Post: A Case Report

Jnana Ranjan Swain[1], Sushant Mohanty[2], Sonu Acharya[3], Bismay Singh[4]

[1]Senior Lecturer, [2]Professor and Head, [3]Professor, [4]Senior Lecturer, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Preserving a badly mutilated tooth has always been a challenge for the dentist. Patients usually approach to a dentist where there is significant loss in tooth structure. Post and core can be done in such a case for the restoration of the teeth. For success in such cases, proper post-selection is of utmost importance. This case report highlights the usage of post and core to save teeth with less crown structure using prefabricated fiber posts.

Keywords: *Mutilated tooth; Post and Core Treatment; Right Central Incisor; Fibre Post.*

Introduction

Dental caries being a common chronic disease worldwideis a cause of pain-related loss of function in patients. Patients with dental caries in the anterior part of the dental arch come with an added challenge of decreased self-esteem and confidence owing to loss of speech and aesthetics.[1] A case of dental caries with pulpal involvement may require endodontic intervention followed by prosthetic rehabilitation both functionally and aesthetically. The endodontic intervention may lead to significant loss of tooth structure in the crown owing to dental caries and/or the preparation of access. This makes the tooth susceptible to fracture even under the normal force of biting. In the absence of sufficient tooth structure for proper rehabilitation after endodontic treatment, the use of post and core may be taken into account to retain the crown.[2] Post and core is a widely used treatment protocol that helps in the preservation of grossly decayed teeth or teeth with less crown structure. It not only replaces the missing tooth structure but also provided resistive and retentive to the crown thus, restoring the tooth both in terms of function andaesthetics.[3] "Dowel (Post): The dowel is a metal post or other rigid restorative material placed in the radicular portion of a non-vital tooth. A dowel, usually made of metal, is fitted into a prepared canal of a natural tooth. When combined with an artificial crown or core, it provides retention and resistance for the restoration. (Glossary of Prosthodontics) .Core: Refers to properly shaped and well substructure, which replaces missing coronal structure and retains the final restoration. The core is designed to resemble or become the crown preparation or crown itself. (Glossary of Prosthodontics)."[4] The biological width is an important factor that has to be kept in mind in the treatment of any tooth. Post and core treatment helps in restoring the tooth by acting as a reinforcement for the tooth structure. Badly mutilated teeth are weak and susceptible to fracture. Root canal treatment alone can eliminate pain but will not strengthen the tooth structure. Hence, post and core is required in such cases. Indications for post and core are, when the crown length is less than 1 mm, root canal treated teeth with extensively damaged or lost, endodontically treated anterior teeth with susceptible

e-mail: gyana.happy@gmail.com

to fracture at the cervical area, etc. Contraindications including poor crown root ratio, fragile/weak root, teeth with heavy occlusal load, poor periodontal health, dilacerated root, persistent periapical lesion, patient with unusual habits, inadequate skills, etc.[5]

Posts are available in a variety of sizes and materials. They can be custom made or prefabricated. The ideal post should be such that it closely conforms with the root canal wall and has sufficient strength to withstand the forces directed along the long axis of the tooth. The length of the post should extend up to 4-5 mm short of the apex leaving the apical gutta-percha intact. The apical seal with gutta-percha is necessary as the maximum incidence of lateral canals is seen in the apical 3mm. The obturating material seals these canals reducing the chances of failure of treatment.[3-5]

Prefabricated posts are made from fiber. They are available in a variety of sizes that can be selected according to the width of the root canal. They are not technique sensitive and are easy to perform. The ease of procedure with these posts make them a widely accepted procedure among the dentists. However, they don't conform well to the root canal walls. This leads to the appearance of potential space between the prepared root canal walls and the post itself.[3-5]

This case report is based onthe management of adecayed maxillary right central incisor in a young permanent dentition. There was significant loss of crown structure and pre-fabricated post was used after the endodontic treatment.

Case Report: A 14-year-old male patient reported to the Department of pediatric and preventive dentistry with the chief complaint of pain in the upper front tooth region. The patient gave a history of sharp, shooting,and continuous pain that was aggravated on the intake of hot and cold beverages. On clinical examination, there was a presence of caries involving the pulp in the right central incisor(figure 1). There was also a loss of significant tooth structure due to long-standing decay and chipping of the tooth structure. Radiographic examination showed caries extending up to the pulp chamber. The patient was advised to post and core treatment.

After the administration of local anesthesia, the access cavity was prepared. Working length was established with electronic apex locator and a radiograph was taken for the same

The canals were cleaned and shaped upto 40k files. Irrigation was performed with 5.25% sodium hypochlorite and saline during each instrument change. Master cone radiograph was taken as depicted in. Obturation was done with mono cone technique using AH Plus sealer(figure 2). Following this, post space was prepared with peesoreamer upto size 3 leaving the apical 5mm gutta-percha technique (figure 3).

Figure 1. Pre-Operative

Figure 2. Obturation done

Figure 3. Post Space prepared

For the ease of preparation, it was decided to put a prefabricated fiber post in this tooth. Post space was prepared using peesoreamers up to size 3. The prefabricated post was selected according to the root canal width. The post was inserted and luted using resin cement. Following this, crown preparation was done was porcelain fused to metal crown was prefabricated and cemented using Type II glass ionomer cement. After 3 days crown was provided to the patient (figure 4).

Figure 4. Post-Operative

Discussion

It is often impossible to achieve sufficient support to a restoration when there is a loss of coronal tooth structure. Restoration of the endodontically treated tooth is very important as it has an impact on the long-term prognosis of tooth.[6]

Trauma and decay are mostly associated with an extensive loss of tooth structure, necessitating restoration of the tooth with a complete crown for esthetic and functional rehabilitation.[7] It is impossible to achieve sufficient anchorage of a restoration in the remaining dentin when a large portion of the crown has been lost to damage. In such situations, post and core restorations are required for additional retention.[8]

The resin fiber post is more similar in its characteristics to natural dentinal structure than any previously used post. It has excellent transverse strength and acts as a shock absorber dissipating much of the stress placed on the finished restoration, transmitting only a small fraction of these forces to the dentinal walls. The fiber post bonds to tooth structure, core materials, and resin cements. It is delivered to the patient in a single-appointment, chairside procedure.[9] Hence proper selection of post and meticulous clinical procedure is critical in the success of post endodontic restorations.[10]

Conclusion

The restoration of endodontically treated teeth with significant loss of tooth structure necessitates post and core treatment. Post and core treatment have a long term prognosis.This case report highlights the usage of cast metal post. There are certain limitations of every post hence, the clinician must make a proper decision regarding the choice of post. The proper selection of proper post design and material is necessary to ensure a successful treatment outcome.

Complex Odontoma: An Overview

Somalee Mahapatra[1], Priyanka Debta[2], Saswati Siddhartha[3], Anurag Dani[4]

[1]Tutor, [2]Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to University), Bhubaneswar, Odisha, India, [3]Lecturer, Department of Oral Pathology and Microbiology, Hitech Dental College and Hospitals, Bhubaneswar, Odisha, India, Professor, Department of Prosthodontia, C.D.C.R.I. Rajnandgaon, Chhattisgarh, India

Abstract

The dental tissues comprising of dentin, enamel,sometimes pulp, and cementum are the hamartomas which are known as odontoma. These have behavior not so aggressive. The common type of tumor of odontogenic origin about (35-76)% is the odontoma. It is a tumor of benign type arising from epithelial and mesenchymal differentiated alteration, odontogenic cells. These odontomas are of two types–complex and compound, the both are differentiated from each other by the organization of the tissue of dental origin in a ratio of 1:2. Although the etiology is not known till now but may be related to anomalies of hereditary origin, infection,also by trauma and by hyperactivity of odontoblast process. By the means of radiological view these odontomas can be recognized and these in very few case causes expansion of the cortical bone. These odontomas occur in the second decade in number and usually takes place in the mandibular second or third molar tooth. This particular article summarizes the complex composite odontoma.

Keywords: *Complex Odontoma; Prognosis; Differential Diagnosis; Treatment.*

Introduction

The tumor of odontogenic origin and benign is the odontoma. It was first put forward by Broca in the year 1866 as odontoma and he had mentioned this as a tumor by the tissues which are completely dental in origin with the excess growth.[1,2] The tissues of dental origin which are proliferated abnormally combinedly by the mesenchymal and epithelial components results in the form of odontoma. As these odontomas neither have any type of growth that is continuous nor to the tissues surrounding them, they infiltrate inside. So they can be considered as malformation of hamartomatous type. The lamina of dental origin from the bud of extraneous gives rise to the odontoma.[3,4,5] Usually, the odontoma is linked with retained or impacted teeth.

Odontoma etiological factors[6-10]:

(a) History from family

(b) Processes which is infectious and inflammatory.

(c) Hereditary factor leading to anomalies in conjunction with Gardner and Hermann's syndrome

(d) Alteration in genes giving rise to the aberrations in the pathways which gives signals for the development of tooth to be controlled.

(e) When the odontoblast activity is hyper.

(f)During dentition of primary type, under trauma.

Review of literature

Aspects, Epidemiologically: The tumors of odontogenic type are recorded worldwide which varies in the frequency range of 1-32%.[11,12] is the odontoma. They are as per various studies reported higher in females of age group 17 to 22 years in the other hand others reported higher in males of age group from 13 to 25 years,

Tutor, Department of Oral Pathology and Microbiology
Institute of Dental Science Siksha O Anusandhan
(Deemed to University), Bhubaneswar, Odisha, India
e-mail: msomalee@gmail.com

as per the meta-analysis conducted by Hidalgo O et al in the year 2008 odontomas, characteristics is sorted out epidemiologically. By a study of cases of 3,065 patients resulting in males about 50.6% and females to 49.4%.[13] To conclude with no difference significantly was present as per the gender is concerned.[14] Odontomas are identified by a wide range of age factors reported, predominantly in the life of 2nd decades.[15]

Characteristics–Clinically: There are three presentations found clinically in the literature scientifically that have been recognized in the case of odontoma: extra-osseous, intra-osseous and erupted. The commonest type of odontoma is intra-osseous.[14] The canine to incisor is the frequent location reported in the maxillary arch about 67% then is the anterior mandibular arch with that next region is the posterior mandibular arch about 33%.[15,16-18,19]The complex type of odontoma occurs frequently in the mandibular arch,posteriorly about 59% but the compound odontomas usually appear in the anterior- maxillary arch in the region over the crown in un-erupted, one or more teeth, in some cases appears between the teeth of erupted root region about 61%.[20,21]These tumors are not of aggressive nature which is symptomless, benign and are elicited radiologically in about many cases reported upto 57%. In isolated, unusual cases these odontomas are reported to be found in the nasal passage, antrum of Highmore, and the orbital floor. The odontoma commonly is intraosseousand from the cases reported never have they ever erupted towards the cavity of the orbit. As per Suenagaetal, the odontoma of complex type in a case was found to be located at the fossa of the nasal cavity of the right side leading to obstruction of the nasal region with bleeding.[22]

Characteristics- Radiologically: The odontoma of complex type exhibited with radiopacity that is unique. Accordingly, the degree of calcification of odontoma, 3 stages in the development are identified- 1st stage lesion is radiolucid by calcification lacking of tissues of dental origin, the stage of intermediate characterized which is calcified partially and the stage finally shows radiopacity which is surrounded with a halo of radiolucidity.[23]

Characteristics- Histologically: The odontoma of complex type characterized with presence of tissues of dental origin comprising of enamel that is demineralized,dentine, with cementum sometimes pulp included exhibitinga mass that is disorganized of dental hard tissue, peripherally the epithelial odontogenic strands are found, sometimes cementicles, cells of phantom and epithelium of the ameloblasts is detected. These odontomas can get associated with other tumors of odontogenic typeas Fibroodontoma, Ameloblastic fibroma, Ameloblastoma, Calcifying Epithelial Odontogenic Tumor, Odontoameloblastoma, Dentigerous Cyst and Odontoameloblastoma. For this reason histopathology report is needed in every case.[24]

Differential Diagnosis: The odontoma of complex type in the phase of intermediate resembles lesions like lesions of fibrooseous, origin, Fibrous Dysplasia,Calcifying Cystic Odontogenic Tumor and osteomyelitis of chronic type.[25] The most frequent type of odontogenic tumor associated with odontoma is Calcifying Cystic, found about 24% cases.[26] When surrounding the crown it could be differentiated with Adenomatoid Odontogenic Tumor, Ameloblastic Fibro-dentinoma/odontoameloblastoma, and Calcifying Epithelial Odontogenic Tumor.[16]

Prognosis: The odontomas may have complications as: teeth are impacted,obstruction of the nasal cavity, syndrome in the dental region.[24] The major cause of impacted incisors in the permanent dentition by which the eruption of the teeth is hinderedis due to the odontoma besides an extra number of teeth.[16]In rare cases may cause an inflammatory reaction of the adjacent (soft) tissues/infection along with suppuration when the odontomas erupt spontaneously into mouth. From the reported cases more often complex odontoma occurs rather than compound type of odontoma.[17] In cases with erupted type of odontomas, it exhibits the formation of abscess and caries.[27]

Treatment: The treatment of choice in these cases is by conservative enucleation surgically by removing the tissue of conjunctive capsule surrounding it and a sample is prepared for histopathological report which will make the diagnosis accurate.[24,25] In some cases treatment, orthodontically is required for the repositioning of the arch for the retained tooth.[28] The prognosis is favorable and the rate of relapse increases in the cases an enucleation has been conducted in the first stage of calcification.[16,23]

Conclusion

The review of literature revealed the view that is quite wide for the complex odontoma in descriptive means. The complex odontoma is frequently tumor of odontogenic type which could be detected by

radiographic routine examination,with that commonly seen in the patients at their 2nd decade. Hence it's advisable to diagnose the condition timely and it should be accurate to avoid complications. The analyses of histopathologically is recommended by which the association with another tumor of odontogenic type can be ruled out.

3-Dimensional Plating System in the Management of Mandibular Parasymphysis Fracture: A Case Report

Harsh Mohan Pathak[1], Satyabrata Pattnaik[1], Wasim Alam[2], Sanchari Sinha Roy[2], Soumyakanti Roy[3]

[1]Associate Professor, [2]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Introduction: The aim of treating mandibular fracture is to recover the anatomic structure and function with special caution in restoring the occlusion. Champy's miniplate fixation has been the most commonly usedprocedure amongst the various treatment modalities available. The 3-dimensional (3D) plating is fairly new for treating mandibular fractures.

Aim: This research was performed to equate the effectiveness, flexibility, and rigidity of 3-dimensional plates with that of 2 mm titanium miniplates in anterior mandibular fracture surgical management.

Material and Method: The study was conducted on a singlepatient with anterior mandibular fracture (Right parasymphysisregion).

The patient's preoperative, intraoperative, and postoperative clinical and radiological findings were recorded in a proforma.

Results: The timerequired to adapt and fix the miniplates were slightly more than3-D plates and results were significant. Skeletaland occlusal stability was maintained.

Conclusion: the 3-dimensional plate is as effective as conventional miniplates in the treatment of anterior mandibular fractures. Its the ease of use and reduced working hours that are advantages over traditional miniplates.

Keywords: *Anterior Mandibular Fractures, Champy's Miniplate, 3D Plate.*

Introduction

The mandible of an adult human being is made up of spongiosa in the center surrounded by compact cortical bone at the outer and inner aspects. Out of the two cortical plates, the buccal cortical plate is thicker than the lingual cortical plate and thickest in the symphysis region. On average the cortex is 5mm thick; in some cases, it may be less than 3mm thick. Maximum stress is distributed along the lines in spongiosa. A breakthrough was achieved, when Mostafa Farmand.et.al in the year 1992 has developed a new miniplate system, called a three-dimensional plating system. Titanium 3D miniplate is the most recent internal semi-rigid fixationdevice for maxillofacial fracture management. Shortcomings of rigid and semi-rigid fixations lead to developing the three dimensional (3D) mini plates. The 3D miniplate consists of 2mm 4-hole miniplate, which is joined by the 4 interconnecting cross struts. In combination with the unicortical screws, the 3D plate forms cuboids, which provides three-dimensional stability at the fracture

site. Although some of the studies on biomechanics confirmed sufficient stability at the fractured site, only a few studies previously reported clinical experiences of the mandibular symphysis and parasymphysis fracture treatment using 3D miniplates.

Case Report: A 30-year-old patient reported to the department of oral and maxillofacial surgery with the chief complaint of pain in the lower front tooth region for 7 days. The patient gave a history of a road traffic accident a week back and emergency treatment was given at a nearby hospital. The patient was conscious with a GCS score of 15 (E4V5M6). The patient gave a history of bleeding from the mouth immediately after the trauma but no history of unconsciousness & bleeding from the ear and nose as well and no intraoral laceration. Extra orally 2cm laceration was present near the chin region.

On intraoral examination, a step was felt at the incisor region which was tender on palpation, and hematoma (Coleman sign +ve) was seen on the floor of the mouth. There were no other injuries elsewhere in the body; all the teeth were clinically present. Based on the history and clinical features, a provisional diagnosis of mandible fracture involving the right parasymphysis region was made. The radiograph revealed a well-defined radiolucent line running between both the lower central incisors to the inferior border of the mandible. Exploratory surgery was explained to the patient and informed consent was taken. After all the basic hematological investigations and pre-anesthetic checkups, the patient was taken for open reduction and internal fixation under general anesthesia.

Treatment Done: Erich's arch bar fixation was achieved under local anesthesia preoperatively. Under the proper aseptic condition, the patient was painted intraorally and extraorally using 2 percent providone iodine, and draping was done after infiltration of 2 percent lignocaine (1: 80,000) at the surgical site. An extraoral incision was madefrom a pre-existing scar. The mentalis muscle was exposed and incised perpendicular and deep to the bone, leaving a flap of muscle attached to bone for closure. A full-thickness mucoperiosteal flap was carefully raised, keeping the neurovascular mental bundle intact and exposing the fracture site. The segments were manipulated and reduced to its anatomic position satisfactorily after obtaining adequate exposure of the fractured segments. After the fractured segments were reduced, temporary intermaxillary fixation was performed to ensure sufficient occlusion, and a 2 mm 3-D non-locking titanium miniplate was used to repair the fractured section. Betadine & saline was used to irrigate in the area, and adequate hemostasis was achieved. The wound 's deeper layers were closed with Vicryl 3-0, and the skin was closed with ethilon 5-0. Intermaxillary fixation was released, and extraoral adhesive pressure bandage was given. Postoperatively, a radiograph was taken to check the adequacy of the reduction and fixation. On 1st week, 1st month and 3rd-month follow-up was done after the of discharge the patient. However, the patient was also instructed to report post-operatively for any complaint. The occurrence of complications was checked at each appointment, apart from routine examination and wound care.

Discussion

Mandible fractures are the commonest fracture on the face usually caused by accidents and other possible etiologies may be interpersonal violence, falls, sports injuries, etc.[1]. The maximum mastication force in a healthy adult man with healthy teeth is measured as 600 N force at the molar region, which comes down to 290 N force at the incisor region.[9]

The recently developed 3D plating system offers significant benefits relative to traditional miniplates. Compared with conventional miniplates, the 3D plating system uses fewer plates and screws to stabilize the bone fragments. Thus it uses lesser foreign material, reduces the operation time and overall cost of the treatment as described by Zix J, Lieger O and Iizuka T(2007) and Farmand M (1995).[2,3,4] The principle of management of mandibular fracture has always been repositioning to its proper anatomical location and fracture site immobilization. For fifty years, the ease of which anesthetics are working for the pain management and newer techniques of radiographs for the diagnosis of the fracture, introduction of antimicrobials to manage infection, specific surgical armamentarium, and newly generated biomaterials in the market allows surgeons to minimize the surgical mistakes during surgery. [6] There is limited space available in the region of mental foramen for two miniplates. Because of the anatomical issues, sometimes it is difficult to avoid damage to the root apices and the mental nerve while putting two miniplates. Despite utmost care and the use of monocortical screws, injury to the root apices cannot be avoided always during drilling and placement of screws. The normal distribution of forces should be restored. So,

fixation elements have to be placed near the tension site (ideal osteosynthesis line)[8] or on the superior side as put forward by Champy.et.al.

3D miniplate is based on the principle that it obtains support byits geometrically stable and closed quadrangular structure. The quadrangular geometry of 3D miniplate assures greater stability and also offers good resistance against torsional forces at the fractured site. Ideal designs of the three-dimensional plates are square plate (1cm×1cm), rectangular plate (1cm×0.5cm), continuous square or double square plate (2cm×1cm), continuous rectangle or double rectangle plate (2cm×0.5cm), double rectangle plate with an intervening square (2cm×1cm). The thickness of the standard three-dimensional miniplate is 1mm and the diameter of the plate hole is 2mm.

The main advantages of semi-rigid fixation by using 3D miniplate are:

- Excellent profile design and space between the plate holes provide good revascularization.
- Excellent biocompatibility, pliability, no stress shielding effect.
- The operator may simultaneously observe anatomical reduction at the fracture site as well as the occlusal relationship of the patient.
- Instead of the bony curvature of the symphysis and parasymphysis region, 3D miniplates are easy to adapt rather than the compression and reconstruction plates.
- Blood supply not disturbed since only minimal dissection necessary.

Pre and post-operative mandibular occlusal radiographs were taken to evaluate lingual splay of the fractured mandible as was done by Claude Guimond. et.al[10]. Postoperative occlusal radiographs were taken on 3rd postoperative day. The postoperative infection was managed by antibiotics(Tab. Amoxicillin trihydrate 500mg + Potassium clavulanate 125mg and Tab Metronidazole 400mg, TID, 5 days). The masticatory difficulty was managed by intermaxillary fixation postoperatively for 3 weeks.Occlusal stability of the patients was recorded postoperatively for change and stability on first, second, fourth, and twelfth weeks respectively. No or minimal loss of the occlusal relationship of molars was seen.

Conclusion

From the results of this study, we can say that the 3D plate is effective for the management of anterior mandibular fractures. The 3D plate offers an edge in the treatment of symphysis and parasymphysis fracture with reduced operating time and less implant material, with clinical outcomes somewhat identical to those obtained with traditional miniplate osteosynthesis.3-Meets the treatment objectives of adequate reduction, fixation, and stabilization of mandible fractures.We conclude that the 3D titanium miniplate is a superior method for the management of anterior mandibular fracture as it provides better stability and approximation radiographically, helps in osteosynthesis, and can restore normal form and function easily. This 3D plate is made up of titanium which is a biocompatible material and is a desirable mode of treatment of anterior mandibular fractures.

Endodontic Therapy in Single Visits

Narottam Praharaj[1], Debasruti Naik[2]

[1]Tutor, Department of Endodontics & Conservative Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Endodontic success usually depends on the localization of canals along with the proper shaping as well as cleaning of the root canal system in addition to 3 D Obturation of the canal system. Root Canal (or endodontic) therapy in single visits can be defined as a non-surgical as well as conservative management of an endodontically associated tooth that consists of biomechanical preparation with obturation of the root canal system in a single visit. The purpose of endodontic therapy is thorough mechanical as well as element debridement of the total pulp cavity as well as its full obturation with static restorative material. There has been a subject for long eminence debate within the dental community regarding the advantages and disadvantages of single sitting root canal therapy versus the multiple visit root canal therapy. With modern advanced technologies and surfacing of new gadgets as well as evidence-based dentistry along with the concept of maximum dentistry in minimum visits has given an urge to a new venture in the treatment protocols in dentistry. This review article discusses the advantages and microbiological considerations of single-visit endodontic therapy.

Keywords: *Single visit, Endodontic therapy, Advantages.*

Introduction

The purpose of endodontic therapy is thorough mechanical as well as element debridement of the total pulp cavity as well as its full obturation with static restorative material. Endodontic success usually depends on the localization of canalsalong with the proper shaping as well as cleaning of root canal anatomy in addition to 3 D Obturation of the canal system. Root canal therapy in single visits can be defined as a non-surgical as well as conservative management of an endodontically occupied tooth that consists of biomechanical grounding with obturation of the root canal system duringa single visit. This review article discusses the advantages and microbiological considerations of single-visit endodontic therapy.[1]

Evolution of Single Visit Endodontics[2]:

(a) Dodge JS. The 1880s: Concept of single-visit root canal management Ferranti 1950s.

(b) Tosti 1970: Clinical study using a single-visit approach.

(c) Rudner and oliet: 1983 described a concept and clinical technique for treating teeth in a single visit.

(d) Ashkenaz. P.J. 1984 Defined and enumerated the indications and contra indications for single sitting endodontics.

Indications: Uncomplicated vital teeth. • Anteriors and fractured or bicuspid teeth anywhere aesthetics is the concern. • Indicated for endodontic surgery. • Nonvital teeth along with sinus tract. • Patients who are medically compromised and require antibiotic prophylaxis. • Patients who are physically compromised and are not able to visit the dental clinics frequently• Intentional root canal therapy. • Patients requiring full

mouth rehabilitation. • Some of the re-treatment cases. • Accidental/Mechanical pulp exposure. • Vital pulp exposures because of trauma with symptomatic pulpitis. • Vital pulp exposure because of caries with indicative pulpitis • Teeth in need of urgent post-placement, everywhere esthetics is the alarming thing.[3]

Contraindications:

• Developmental anomalies teeth like calcified as well as curved canals. • Teeth with periapical pathology as well as non-vital teeth without symptoms as well asno sinus tract. • Pus discharge with acute alveolar abscess cases. • Acute apical periodontitis along with severe pain on percussion. • Symptomatic non-vital teeth and no sinus tract. • Most of the re-treatment cases. • Allergies to medications or any kind of restorative material • Teeth having restricted access. • Patients who are not able to keep mouth unlock for a longer duration for example TMJ disorders.[4]

Clinical Advantages:

• Clinicians have the most intimate awareness of canal morphology, immediately the following instrumentation, and need not reorient themselves with the peculiarities of particular teeth.

• No risk of bacterial regrowth and leakage of the temporary seal.[6]

Single-Visit Versus Multiple-Visit Root Canal Treatment

The small chance of a life-threatening reaction is reduced by not repeating procedures such as local anesthetic injection. • For patients at threat of contracting bacterial endocarditic, the American Heart Association (AHA) had recommended completing as many procedures as possible during the antibiotic course. • Anxiety as well as post-operative discomfort of patients will be limited only to one episode. • If hemorrhageor else exudation occurs, it may be tricky to manage • Complicated cases utilizing extremely fine, calcified, multiple canals could not be treatable in one appointment without causing undue stress for both the patient and the clinician. • The clinician may be deficient in expertise correctly to manage a case in one visit. This could result in failures as well asflare-ups.[6]

Practice management advantages:

• Prosthetic work can begin without delay. • The risk of canceled appointments is reduced. • Increase in the number of teeth that patients can save. • Several types of equipment and restorative materials that are needed for another separate visit like suction tips, disposable bib, anesthetic as well as irrigation needles along with rubber dams can be saved. • Time is also not wasted as there is no requirement of giving reappoint to the patient and also nor reconfirm appointments • Medico-legal risk is reduced: AHA guidelines are followed, the likelihood of cross-contamination is minimized and invasive procedures are fewer.[1,5]

Patients Advantage Patient expediency–There will be no need for discomfort regarding repetitive local anesthesia, treatment procedure as well as no additional appointments for the patient. • Patient ease – decrease in the number of frequent visits and repetitive measures of injections can be avoided.[7]

Restorative consideration–Effective coronal seal, as well as esthetics, can be achieved by distinct visit or by urgentfixation of coronal restoration (post and core placements) • The total economy will get increase both for the patient and for the dentist by not wasting chair side time as well as using less restorative material. • Overall anxiety, as well as fear towards treatment, will decrease for some years.[8]

Disadvantages:

The access to the apical canal will not be an easy task if there is a flare-up. • Usually cliniciansget tiredness with long and repetitive working hours such as extended one -appointment operating time. • Patient fatigue - The longer single appointment may be tiring and uncomfortable for the patient.[9]

Adjuncts to provide resourceful plus quicker management during solo endodontic therapies:

1. Pain management and isolation access cavity preparation
2. Light as well as magnification use of irrigants
3. It relaxesthe concerned patient plus saves time
4. It is advisable to make use of a long-acting local anesthetic mediator.
5. It also helps tomanagepost-operative pain.
6. Now and then supplemental anesthesia is indicated. These include 1. Local Infiltration 2. Intrapulpal injection 3. Intraosseous injection[10]

The utilization of a rubber dam is compulsory in endodontic therapy. The rubber dam use in endodontics ensures the following:

1. The patient is confined from aspiration of required instruments, tooth debris, and medicaments along with irrigating solutions. 2. A surgically hygienic operating field is inaccessible from saliva, hemorrhage as well as other tissue fluids. 3. Soft tissues are extracted and also protected. 4. The visual site is improved. Isolation access cavity preparation before access cavity preparation, Caries usually is removed early, ahead of the pulp chamber entrance. The roof of the pulp chamber is best perforated with a round bur. A. No 2 bur - anterior and premolar teeth and a No.4 should be used in molar teeth. B. Once the roof is perforated, tapered, Flame shaped and round ended tapered diamonds are excellent for endodontic access.[11]

An uncovering receded or calcified root canal orifice is a challenge. • Use of low - speed smaller burs. • These burs have an extra-long, flexible shaft that allows in visualization by the operator as the bur advances into the deeper portions of the access preparation. • For identifying canal orifices as well as to determine canal angulation DG-16 endodontic explorer and CK-17 endodontic explorer can be used.[12]

Fiber-optic endoscope• A recent addition to the field of visualization is a fiber-optic endoscope designed for intraoral use. • The Orascope uses a fiber optic probe, xenon light source, and a medical-grade video monitor to provide a magnified image of the operating field.[13]

Use Of Irrigants: The theory of single visit root canal management is based on the entombing theory. • Even though instrumentation of the root canal is the principal method of canal debridement • Especially in the case of single visit endodontics, irrigation plays a critical role as there is no scope of taking advantage of intracanal medicaments. • Irrigation serves as a bodily flush to get rid of smear layer, debris plus serving as a bactericidal agent, tissue solvent as well as lubricant.[14]Of all the presently used substances, sodium hypochlorite appears to be the most ideal • NaOCl is efficient against endodontic germscounting those tricky to get rid of root canals, for example, Enterococcus, Actinomyces and Candida organisms. • NaOCl solutions are used in a concentration ranging from 0.5% to 5.25%.[15]

Sodium hypochlorite in combinations- • There is ever-increasing evidence that the efficiency of NaOCl, as an antiseptic agent is augmented when grouped with other solutions such as calcium hydroxide, EDTAC, or Chlorhexidine. • With Chlorhexidine- Kuruvilla and Kamath 1998 in a study combined alternating use of NaOCl and Chlorhexidine gluconate irrigants and results indicate a superiorfall of microbial flora (84.6%).[16] EDTA-Goldman et al showed that the residual layer is not disconnected by NaOCl irrigation alone but it is removed with EDTA. Ultrasonic activation of sodium hypochlorite has also been advocated, as this would "accelerate chemical reactions, create cavitational effects, and achieve a superior cleansing action".[17]

To illustrate the modern endodontic procedural sequence for single visit endodontics, an itemized sequence follows1. The diagnosisgives a positive indication for the need forendodontic treatment and therefore the tooth is anesthetized. 2. Subsequent placement of the rubber dam, then access is being made. 3. The pulp chamber is precisely prepared by thorough use of microscope at low to mid magnification size 2 for inspection. 4. The floor of the chamber is examined for additional canals under high magnification (16–24) because more than 50% of molar teeth have a fourth canal.[18, 19]

Conclusion

There has been a subject for long-standing debate within the dental fraternity regarding the advantages and disadvantages of single visit root canal management versus the multiple visit endodontic management. With modern advanced technologies and materialization of new gadgets as well as evidence-based dentistry along with the concept of maximum dentistry in minimum visits has given an urge to the new venture in the treatment protocols in dentistry. Careful case selection and proper and thorough adherence to standard endodontic principles, with no shortcuts, should result in successful one-appointment endodontics. Practitioners should attempt one-visit root canal treatment only after making an honest assessment of their endodontic skills, training, and ability.

Hemangioma and its Management

Sobhan Mishra[1], Subrat Padhiary[2], Bijayalaxmi Panigrahi[3], Shibasis Biswas[3]

[1]Professor & Head, [2]Professor, [3]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar

Abstract

The highest frequent benign vascular neoplasms that occur quite often in neonates & infants are haemangiomas. Haemangiomas usually occur on the surfaces of the head and neck regions. Management of haemangiomasincludes wait and watch, drug therapy, sclerotherapy, cryotherapy, radiotherapy, laser therapy and surgical excision.Size, location, hemodynamic of the lesion and age of the patient are the important conditionsthat need to consider while planning for treatment of haemangiomas.

Keywords: *Haemangiomas; Head and neck tumor; Management; Treatment.*

Introduction

Haemangiomas are commonest benign vascular neoplasms that occur often in neonates, infants, and children. Microscopically thereisa proliferation of endothelial cells, which comprise a space comprising blood that is covered with an endothelial layer. Haemangiomas are classified into two types according to development,they are infantile and congenital haemangiomas.[1] Infant haemangiomas (IHs) seems to be the most common childhood tumor that occurs in 5-10 percent of children. These are vascular tumors associated with abnormal propagation of endothelial cells and anomalous architecture of the blood vessels. They can be differentiated from vascular malformations, which are structural anomalies and inborn vascular morphogenesis errors. These include capillary anomalies (includes port-wine stains), venous anomalies, lymphatic anomalies (also known as lymphangiomas or cystichygromas).[12] Infantile haemangiomasare benign, self-limited vascular endothelial neoplasms which commonly affect the maxillofacial and cervical region.[2] These tumorshave 3 phases' i.e. apparent neonates and grow rapidly to its maximum dimension during the first year of life, preceded over several years by stabilization and spontaneous involution. Spontaneous resolution occurs in 49% of patients within 5 years and 7 years of age 72% of cases resolved spontaneously. But few lesions can take up to 10 years to resolve. These tumors don't typically pose any functional issues; but in approximately 10-20 percent of cases, where there will be facial disfigurement, airway compromise due to pressure, loss of vision or ulceration, active intervention is required.[3]

IH are classified based upon their depth of lesion.[4] It includes:

1. "Superficial IH": bright red, thin, frequently paved/ pebbled, vascular papules/plaques, formerly known as "strawberry haemangiomas"
2. "Deep IH": blue/violaceous or skin-colored, compressible, subcutaneous papule/nodules, formerly known as "cavernous haemangiomas"
3. "Combined IH": both superficial and deep components, oftenfound as superficial IH overlying a deep IH component

IH classified based upon anatomic configuration includes:

1. "Focal IH": a solitary, isolated IH, frequently a papule/plaque/nodule

Corresponding Author:
Dr. Bijaylaxmi Panigrahi
Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar
e-mail: missdentist.rosy@gmail.com

2. "Segmental IH": IH involving larger region or whole body (i.e., hand, lower leg, hemi-face) in a well-demarcated area
3. "IH indeterminate": IH those does not fall uniformly into either category or that doesn't proliferate fully/ evenly[4]
4. "Multifocal IH": multiple, discrete focal IH not occupying a specific area or territory.

"Congenital haemangiomas (CH)"can be classified as below:

1. "Rapidinvolution congenital haemangioma" (RICH),
2. "Partiallyinvolution congenital haemangioma" (PICH) and
3. "Non-involution congenital haemangioma" (NICH)[3]

Figure 1

Initial Evaluation & Management: Haemangioma's management must be planned based on the patient's age, the diameter & extent of the lesion, growth rate, complexity (superficial, deep or segmental),complications (like ulceration or vision loss, or vital organ dysfunction) and location. There is a 4% increase in the need for intervention for approximately every 10 cm rise in lesion diameter.[5] Two systems were proposed to help clinicians evaluate the lesion extension and the response to the therapy. Haemangioma Severity Scale (HSS), developed in 2012, was designed to classify patients based upon complications and help in guiding treatment needs. Patients scoring above 10 usually needed beta-blocker therapy with the HSS. Higher HSS scores were associated with a raised presence of an ulcer, structural abnormalities, and everlasting disfiguration. Hemangioma Activity Score (HAS) had been proposed in 2011, based in large measure on IH lesion color. One prospective study conducted by the HAS system's creators compared HSS to HAS and concluded that the HAS system was preferable in assessing the response of therapy.[2] Generally, lesions that are segmental, large in number, or peri-orbital should be considered complicated. Additionally, lesions larger than 5 cm in size may raise skeptical for extensive underlying defect.[6]

Phace Association: PHACE syndrome is a rare condition diagnosed in 1996 and with limited research data. Following conditions are associated with PHACE syndrome:

Malformations of posterior fossa of the brain: Haemangioma, Anomalies of the artery, Aortic coarctation/other cardiac problems, Malformation of the eye.

The white female neonates with massive haemangiomas of the face are at a risk for PHACE syndrome must always be screened for extreme aortic coarctation using echocardiography or cardiac magnetic resonance imaging. Systemic beta-blockers cannot be given to these patients as coarctation is a contraindication for b-blocker usage. Before treatment selection, MRI of the head and neck with angiography is suggested as vascular malformations involved with PHACE syndrome can lead patients to hypotension condition.[7-11]

Non-operative Management: Medical intervention usually not necessary for Small, uncomplicated, localized, superficial capillary haemangiomas. Management involves reassurance, teaching, and the setting of expectations with sequential followups.[2] Many IHs are operated by observation because 90 percent are minimal, localized, and do not include areas of aesthetic or functional significance. In the proliferative stage, infants are closely monitored regularly if a lesion has the potential to cause obstruction, damage, or ulceration that needs intervention. Once the IH has stabilized in growing, patients are followed annually during the involving process, if intervention in childhood may still be necessary.[12, 13]

B Adrenergic Blockers: Propranolol is a nonselective β-blocker commonly recognized as a first-line treatment for complexhaemangiomas. Following the serendipitous discovery of the dramatic action of propranolol on lesions in 2008 in patients having steroid-induced cardiomyopathy under treatment for haemangiomas.[14] The efficacy has been verified by several broader research and randomized clinical trials. B-blockers action on haemangiomas is not clear still. Propranolol is believed to limit the development of the lesion by blocking proangiogenic activation of the vascular endothelial growth factor and the essential fibroblast growth factor. Apoptosis is also believed to be aggravated in the late phase of therapy.[15]

Since 2014, the US Food and Drug Administration has approved Propranolol for the proliferation of infant haemangiomas requiring systemic treatment. Complete or near full resolution of the infantile haemangioma is normal after 3-6 months of therapy during the proliferative stage. Patients of cardiogenic shock, chronic sinus bradycardia, chronic hypotension, 2nd or 3rd-degree cardiac obstruction, heart failure, H/O reactive airway dysfunction, aortic coarctation, preemies under 5 weeks and PHACE syndrome-associated vascular anomalies (predisposing to stroke in hypotension setting), a systemic beta-blocker is contraindicated.[16]

Dose: It is advised to initial treatment with 0.5-1mg/kg/day oral propranolol in 2-3 divided dosages with feed. The dosage may be raised progressively by 0.5 mg/kg/day over 2 weeks to a target dose of 2 mg/kg/day, with 2-3 divided dosages. Considering the possible side effect of hypoglycemia, it is highly advised to medication with feed.

Topical β-Adrenergic Blockers: Topical b-blocking agents are usuallyused to managetiny, superficial, uncomplicated,and ulcerated haemangiomas. 92 percent and 77 percent of patients having uncomplicated haemangiomas reported a substantial recovery in the color and dimension of the lesions, respectively, after 6-9 months of topical timolol therapy in a study. All topical timolol and propranolol found to have similar efficacy.

Corticosteroids: Previous to the introduction of oral propranolol, systemic corticosteroids had been the mainstay for IH management. The usage of systemic corticosteroids in managing haemangiomas is currently restricted to patients contraindicated to systemic b-blockers. The mode of action of corticosteroids on haemangiomas is not known but it has been shown that corticosteroids impede vasculogenesis by inhibiting the factor-A expression of vascular endothelial development.

Dose- While steroid dose had been variable, oral prednisolone at 2-3 mg/kg/day is a normal starting dosage every morning. Depending on the lesion response,usually, the course of treatment lasts for 6-12 months. Once the treatment response is achieved, a steroid taper should commence. Oral corticosteroids could result in adrenal crisis or rebound generation of haemangiomas if discontinued abruptly.[17]

Intra-lesional and Topical corticosteroids: In resistant IHs with mild ulcerations, highefficacy topical corticosteroids, such as clobetasol cream are used. Intralesional triamcinolone acetonide injections are restricted for tiny, localized, deep haemangiomas that are resistant to treatment. Dosage ranges between 10 and 40 mg/mL and shouldn't more than 3 mg/kg/day. Clinical lesion reaction is usually noticed initially in the first 2 weeks of injection, with further improvements over the subsequent months.

Laser Therapy: In fewer cases, pulse-dye laser (PDL) can be used to treat IH. While its use has been limited to ulcerated IH in the superficial or very early lesions where Pulse Dye Laser therapy tends to promote re-epithelialization and analgesia. It is also used subsequently for residual telangiectasias in life after IH involution. In combination with other treatments, like topical timolol or systemic treatment (propranolol or corticosteroids), PDL is quite effective when used for treating ulcerated IH.

Surgical Management: Surgical excision of infantile haemangioma is reserved for fibro-fatty residues, post involution phase scars, or deformed zones for reconstruction. Surgery could frequently be considered in patients who are unresponsive to conservative management in the proliferative stage.[18]

Sclerotherapy: Sclerosing agents' intralesional injection, such as bleomycin, may be useful in small lesions and only 49 percent of thorough resolution is recorded in literature. Sclerotherapy has been extensively used in the management of minorextraoral lesions. However, after the injection of the sclerotic agent into intraoral lesions, the pressurized bandage cannot be applied, thereby restricting the efficacy for intraoral use. Cutaneous necrosis and neural impairment are the commonadverse effects of sclerotherapy. Systemic complications are uncommon and linked to alcohol's absorption into the systemic circulation. These can involve hemolysis and cardiac arrest with possible renal toxicity. There must beno extravasation during injection.[19]

Embolization: Vascular anomalies already in advanced stages are generally best managed by preoperative embolization followed by surgically, particularly if not responsive to medicines. The efficacy of embolizing vascular lesion in normalizing function and bleeding prevention with decent cosmetic outcomes as demonstrated by Churojana et al. Nonetheless, extended intubation or tracheostomy must be considered in the condition of involving the tongue, oropharynx and laryngotracheal region to protect the airway from extreme inflammation or significant postoperative bleeding as claimed by them. Besides, the embolization procedure can have some possible disadvantages. The risk of iatrogenic embolization through majorcarotid arteries has been identified on intracranial vessels. Therefore, this procedure needs to be performed by an experienced radiologist, and temporary flow blockage is required.[3]

Radiotherapy: Radiotherapy especially forintraosseoushaemangiomas, has been described as a beneficial option. Though, its negative effects, like damage to the regular development of adjacent tissues, residual scarring, and neoplasm, are known and unjustified for benign neoplasms such as haemangiomas and vascularmal formation.[3, 20]

Conclusion

Although most haemangiomas could be observed without treatment, medical or surgical intervention will benefit others. While surgical excision remains the favored treatment, it can be appropriate for curettage, sclerotherapy, embolization, or a combination of those method. Additionally, routine follow-ups should be carried out due to the possible risk of complications and recurrence. [12]Where complications are possible or management is unclear, it maybe advisable to refer to an expert or multidisciplinary vascular anomaly center.

COVID 19 Pandemic: Challenges in Healthcare System of India

Debasruti Naik[1], Motirmoy Giri[2], Ramesh Nagarajappa[3], Ipsita Mahapatra[4], Upasana Dhar[5]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Senior Resident, Fakir Mohan Medical College, Balasore, Odisha, India, [3]Professor and Head, [4]Postgraduate Trainee, Department of Public Health Dentistry, [5]Postgraduate Trainee, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The new coronavirus virulent disease is stretching the health organisations worldwide and because of this the growing demand for health services and health care workers rapidly increasing. This emergency has encouraged the researchers to get more serious about the deadly unknown virus. Gradually within 3 months, the virus kept spreading all over the world by direct or indirect contact with the affected people. "The best defence against any outbreak is a strong health system". Focusing on COVID 19 associated actions, as well as progressing to endow with necessary services, is significant not only to sustain people's belief in the health system to distribute essential health services but also to lessen an increase in morbidity and mortality from other health conditions. This review article discusses the existing healthcare resources of India and the impact on healthcare scenario of India during this outbreak.

Keywords: *Covid-19 Pandemic, Challenges, Health care system of India*

Background

It was reported that on 17th November 2019 in China, the first case of Coronavirus came in front but due to lack of evidence it went unrecognised. But after that incident within not many days, 8 more new cases appeared during December. This emergency has encouraged the researchers to get more serious about the deadly unknown virus. Gradually within 3 months, the virus kept spreading all over the world by direct or indirect contact with the affected people. Since we are now living in the modernised technological era of 20th century and are connected globally, travelling through air and migrants connecting all over the world with each other by the means of flights is now supposed to cover the globe by spreading the infection. Because of this, the infectious virus has spread rapidly by March 2020. It was documented that anoutbreak situation has aroused globally, therefore on 11th March 2020, WHO announced that this coronavirus causing COVID-19 was officially a pandemic that has affected 114 countries in 3 months plus affecting over 118,000 people. [1]

A newly discovered strain was found in humans called a coronavirus which is the causative organism for COVID-19. The patient affected with coronavirus will be having respiratory problems, cough as well as a fever that may progress to pneumonia and then death. This infectious disease gets contaminant from one infected person to another healthy person through sneezing droplets. Focusing on COVID 19 associated actions, as well as progressing to endow with necessary services, is significant not only to sustain people's belief in the health system to distribute essential health services but

e-mail: smilewithdebshruti@gmail.com

also to lessen an increase in morbidity and mortality from other health conditions.[2] "The best defence against any outbreak is a strong health system". This outbreak due to coronavirus has tensed themedical system providing treatments and medicines in almost all the urbanized countries and is also making the economic slumpbeyond compare in recent times. This review article discusses the existing healthcare resources of India and the impact on healthcare scenario of India during this outbreak.

The response towards the pandemic situation by the Indian Government: India has bagged rank of 100on the "Oxford COVID-19 Government Response Tracker (OxCGRT)" to keep a record of in addition to make a comparison of responses made by the government to the coronavirus disease constantly. The government of India wants to stick on to their strategy of 'prevention is better than cure' model.[3]

Steps were taken by the government:[4]

(a) Every person coming from the outside country was mandatory to undergone through a screening test and this screening was being initiated by the government with the help of health workers during the initial days of January 2020. But if an individual is asymptomatic then he will be tracked for progression for further two weeks constantly by the health workers.

(b) All the domestic, as well as international flights along with the Indian railways, are being cancelled from 21st March till date.

(c) The major historical step taken by the government is total lockdown of for three weeks from 24th March.

(d) Well-harmonized action strategy including quick establishments of quarantine facilities across the country as active health laboratories were established.

Decisions are taken by the Government to strengthen the health care system of India:

1. Protocols for controlling this outbreak in the country are enforced under Biological & Public Health Emergencies (BPHE) as well as under the National Disaster Management Plan (NDMP) are made. Under these plans, they have started acting upon as listed below such as "Stockpiling of essential medical supplies such as vaccines and antibiotics etc." "Establishing adequate decontamination systems, critical care ICUs and isolation wards with pressure control and lamellar flow systems", "Adequate PPE for all the health workers associated with the responding to biological emergencies","Upgradation of earmarked hospitals to cope with emergencies", "Mobile telehealth services & Mobile Hospitals", "Specialised healthcare and laboratory facilities to address biological emergencies/incidents", "Establishing and strengthening quarantine facilities"[5]
2. Government has spread awareness as much as possible to avoid the risk of transmission of coronavirus to one another. Therefore,special care has been taken to promote the importance of hand hygiene, social distancing, face mask and hygienic social habits and disinfection.
3. India is the largest supplies of generic medicines all around the globe. Now India is known as pharma hub all over the world in the last few decades with a 20 % share worldwide by volume as well as a 50% share in fulfilling the need forvaccines. During this outbreak of coronavirus, India has again given a major contribution to the pharma industry as an opened export of hydroxychloroquine that can help save thousands of lives. Several medical types of equipment have also risen now during this outbreak and have started manufacturing PPE(Personal Protective Equipments), ventilators, facemasks, gloves, and diagnostic kits for coronavirus testing. This medical equipment manufacturing has strengthened the health care delivery system in India.[1]
4. The Indian government has utilized the technology by the means of telemedicine and training of primary health care through online training sessions for all the medical and paramedical staff frequently during this emergency outbreak situation according to the requirement for protocols to be followed for prevention and management of communicating disease. The government is also ready with its plan to utilize the MBBS students during this pandemic if required. Because of the additional needs of immediate hospitals throughout the country, the government has already converted several railway trains into isolation wards which can be utilized as mobile hospitals according to the demand of the situation.[6]

Challenges in health care delivery systems:

1. Patients of chronic disease are now suffering pain

in movement because of the restriction made by the government. For this reason, delay in treatment of such cases may lead to long term sequel. All these will ultimately end up in possible complications as well as deterioration of illness towards the body. Unavailability of quite a lot ofmedical setups blocked due to the management of this coronavirus outbreak. All this has made the restriction towards the accessibility of emergency management of acute conditions for the general people suffering from other diseases.Everything at the end has only increased the burden of diseases of our country.

2. India ranks 145 among 195 countries in provisions of ease of access as well as the quality of healthcare globally.[3] No doubt progress is being made constantly in the past but still, lots need to be done to improve the health resources. This need is felt now during this outbreak throughout the country as the situation might go out of our hands in recent times. Truth to the fact that Indian health infrastructure is running out of its health budget to provide the world-class health facilities to its 133 crore population may be because of low public investment in quality healthcare. India's economic and manpower health infrastructure is repulsively not enough to endow with quality resources to its overpopulated citizens. It should be noted that if the coronavirus outbreak can causedisaster in western countries with far better quality health resources, then our country India is sitting on a time bomb now in the present scenario.

Access to quality health care services for the vast population of India: Quality healthcare service is of no use if doesn't reach the people in need. According to the Global Burden of Disease, it was reported that in Healthcare Access and Quality (HAQ) Index,India is at the number 145 among 195 countries. The score was 41.2 for the reason that of out-of-pocket expenditure (OOP)- which means the total sum of health expenses waged from the bag of persons was a fraction of the whole public healthcare disbursement of the respective country.[7]

Poor public investment in healthcare: According to the National Health Profile(NHP) 2019, released in October 2019, India's public expenses on health (centre plus state) is less than 1.3% of the GDP for several years.[4]

Government initiatives of private investors in health care:

(a) Initiation of Pradhan Mantri Jan Arogya Abhiyan (PM-JAY) or the Aayushman Bharat which promises to offer hospitalization cover (insurance) of up to Rs 5 lakh to 10 croresfor poor as well asunder privileged families (about 50 crore people).

(b) This yojanais funded by the Centre as well as states share funds at 60:40 which is considered as the tax payer's money.

(c) Initiation of setting up secret medical colleges along with useful district hospitals through PPP (Public Private Participation) by the government.

Scrutiny of growing COVID-19 patients as well as existing medical capability: The outbreak of coronavirus has paralyzed the health infrastructure if many countries globally mainly because of shortage in medical equipment and resources like manpower, finances, hospital beds, and other relevant medical equipment like ventilators, personal protective equipment). This lack of essential services to the people during this outbreak has forced the Indian Government to take the historical decision of lockdown of 21 days and again it was further increased to 19 days and also few states are still demanding of a further increase in the days of lockdown. This lockdown is a necessary step because this is the only way of achieving social distancing that will help in slowing down the spread of disease. And this decision will help our health system to deal with the rising number of patients with limited resources.[8,9] However, due to the lack of doctors as per the population ratio, India is still lacking in making a sufficient number of doctors. For this reason, three scenarios are being considered:

Scenario 1: 1% of doctors treat COVID 19 patients,

Scenario 2: 5% doctors treat COVID 19 patients,

Scenario 3: 10% of doctors treat COVID 19 patients

Medical Facilities provided during this outbreak are as follows:

(a) A cheap fast testing kit is now available in the market that will give us results in two and half hours and is capable of testing 100 samples and costs is between 1200 rupees to 4500 rupees.[1]

(b) At present, now more than 29 laboratories are present in our country which are accredited by the Indian Council of Medical Research (ICMR) for testing of novel coronavirus as instructed by the government. These testing research laboratories have approximately 16,000 collection centres across the country. Apart from private labs, there are also 280 government laboratories approved by ICMR, of which 104 are operational for testing Covid-19 and also more number of labs are in the process of getting functional as per data collected from the ICMR March 24th, 2020.[1]

(c) Till now the Indian Government has already made 14000 ventilators along with lakhs of PPE and N-95 masks available for the use of COVID 19 cases. Special Covid-19 hospitals are now being opened as well as isolation beds are being added.[6]

(d) Economicsin India concerning the health sector has made provision of Rs 15,000 crore. Healthcare professional workers were promised three months' worth of payments for medical insurance which was an estimated total sumof 5 million rupees, or $66,802.[10]

Conclusion

Government of India is taking all the necessary steps to strengthen the health sector. India is very well taking care of its highly populated citizens. The government is providing all the necessary medical equipment and is taking necessary measures to control this COVID 19 pandemic. No doubt India has fewer resources and financially weak as compared to developed countries but still, India is fighting back very strongly providing all kinds of facilities and protection to medical doctors and nurses and health care workers. India is very well coping up with the challenges faced everyday due to this COVID 19 pandemic and it is hoped that India will stand strong during this outbreak.

Ectodermal Dysplasia: A Case Report of Aesthetic and Functional Rehabilitation

Jnana Ranjan Swain[1], Sushant Mohanty[2], Sonu Acharya[3], Bismay Singh[4]

[1]Senior Lecturer, [2]Professor and Head, [3]Professor, [4]Senior Lecturer, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

During the development of embryo ectodermal dysplasia occurs as a consequence of disturbances of the endoderm. Clinical features include hypotrichosis and palmoplantar hyperkeratosis or alopecia,a triad of nail dystrophy,a partial or complete absence of primary and/or permanent dentition,and lack of sweat glands. In this study, the syndrome ectodermal dysplasia shows a severe case of anodontia. Since the oral rehabilitation of these cases is often difficult; particularly in pediatric patients, treatment should be administered by a multidisciplinary team involving pediatric dentistry, orthodontics, prosthodontics, and oral-maxillofacial surgery.

Keywords: *Ectodermal Dysplasia; Aesthetic & Functional Rehabilitation; Anodontia.*

Introduction

Ectodermal dysplasia is a heterogeneous group of inherited disorders, resulting from the abnormal development of two or more tissues at a time, derived from embryonic ectoderm.[1] Analyzing several ectodermal dysplasia cases reveals that the syndrome is an X-linked recessive trait. The first clinical cases of Ectodermal dysplasia were reported in early 1792 by Danz, who described the congenital absence of teeth and hair in two Jewish boys. The prevalence of the syndrome is more in the case of females than males. In some cases, the mother of the patient exhibited hypodontia/conical teeth. Syndrome ectodermal dysplasia is divided into two categories and among two categories anhidrotic type is more severe manifestation. Clinical features include palmoplantar hyperkeratosis, alopecia, and dystrophy of nails some may found with partial or complete absence of dentition.

Finn reviewed 82 cases of anhidrotic ectodermal dysplasia and found that 5.4% had more mandibular teeth than maxillary and 63.5% had more maxillary teeth than mandibular teeth. And many of the teeth are conical in shape.[3] There is always a lack of development of alveolar ridge in anodontia patients. The vertical dimension of the face is also reduced along with dryness of oral mucosa and malformation of existing teeth.

Histopathology: The epidermis of Ectodermal dysplasia is thin with effacement of rete ridges around it. Sebaceous glands, Apocrine glands are variably reduced and mucous glands of the upper respiratory tract may be sparse. Light and scanning electron microscope findings of hair shaft abnormalities are longitudinal clefts or grooves and transverse fissuring, the bulb of the hair shaft is dystrophic. Also, mandibular X-ray shows dental aplasia or hypoplasia. Other histopathology features including epidermal and follicular orthokeratotic hyperkeratosis, apocrine ducts enter follicles at abnormal locations, and comedo formation.

Dr. Jnana Ranjan Swain
Senior Lecturer, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India
e-mail: gyana.happy@gmail.com

Differential Diagnosis: Differential diagnosis including Alopecia Areata, Aplasia Cutis, Incontinentia Pigmenti, Congenital focal dermal hypoplasia syndrome, Pachyonychia Congenital, Naegeli-Franceschetti-Jadassohn Syndrome.

Case Report: An 8-year-old female patient visited the Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Bhubaneswar, India, with the chief complaint of the absence of teeth in her oral cavity since childhood and 7 primary teeth erupted in the oral cavity with dryness of the mouth. There was no history of birth complications during his delivery, and no other live family member presented a similar condition.

And other medical history was taken including vocal function, bleeding disorders, other syndromes associated with this. All the medical history examined were normal.

On clinical examination, the skin appears to be dry (Figure 1A)and there is a mild elevation of temperature. Hair examination showed thin and less hairs. On examination of eye dryness and reduced lubrication was seen. Brittle nails were observed on finger examination. Ears were large and gives an older look (Figure 1B) gives an older look as compared with those of his age with a normal intelligence and partial Anodontia (Figure 1C). Intraoral examination revealed dry mucous membranes and reduced vertical heights of both the arches were of considerable significance (Figure 1D & E). On radiographic examination, there is the presence of tooth buds of permanent molars. In this case, the treatment modalities include temporary prosthesis(Figure 2 A to D). After there is a proper growth of arch and face, implants and permanent restoration will be provided.

According to the history and investigation treatment modalities had planned and appointment for the patient was scheduled.

Appointment I- proper case history with intraoral and extraoral photographs of the patient and OPG had taken. Non-pharmacological behavior management had performed by demonstration of instruments and friendly communication with the patient. Preliminary impression had taken using alginate and perforated impression tray. The patient was recalled after 7 days.

Appointment II- Border molding procedure and secondary impression had taken using ZOE impression material. Other lab procedures including denture base, occlusal rim, and articulation had done.

Appointment III- Most important procedure for the removable prosthesis 'Jaw relation' including anteroposterior, horizontal, and vertical relation had performed. Lab work, teeth setting on occlusal rim had completed.

Appointment IV- In this appointment patient had recalled for teeth trying, masticatory movement of jaws, and speech analysis. After that, all the lab work as well as dearticulating, packing, dewaxing, curing, finishing, and polishing of the denture had done.

Appointment V- Adjustment of denture had done and the removable denture had delivered to the patient with the postoperative instructions.

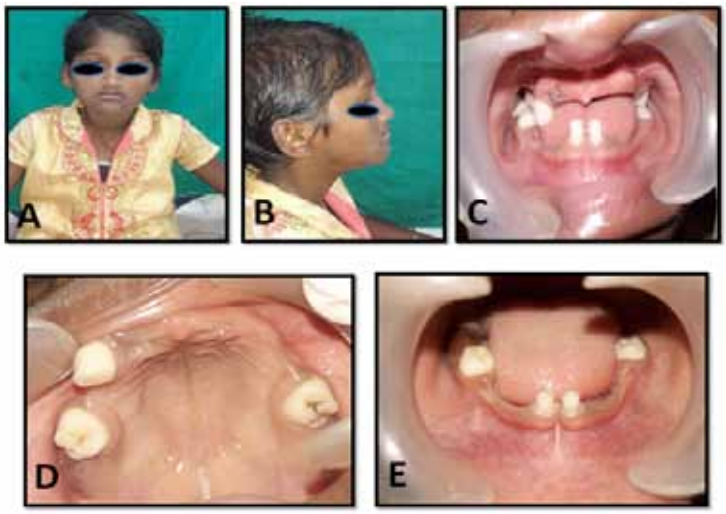

Figure 1A to E : (A) Dry skin, (B) Midface hypoplasia, (C) Partial Anodontia, (D and F) Upper and Lower Arch with a reduced vertical height of alveolar bone respectively.

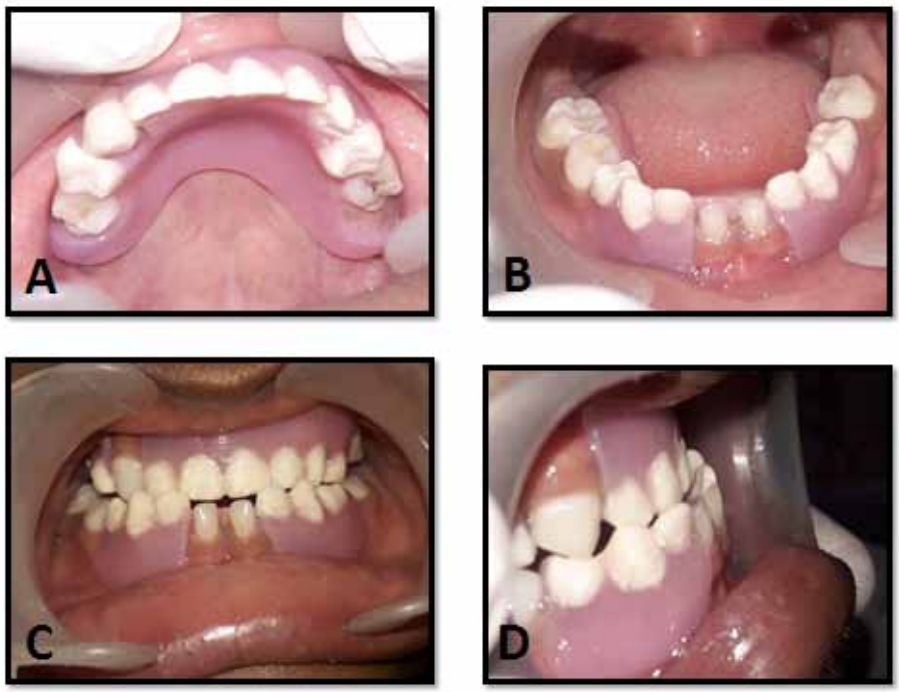

Figure 2A to D: Post-Operative Photographs

Discussion

Freire-Maia and Pinheiro proposed the first classification system of ectodermal dysplasia in 1982.[1] They classified ectodermal dysplasia into different subgroups according to the presence or absence of (1) anomalies of Hair(2) anomalies of Teeth (3) abnormalities of Nails (4) eccrine gland dysfunction.[6] As in the above-mentioned case report, all features of ectodermal dysplasia classification were present; like scanty hair, partial anodontia, thin-brittle nails, dry mouth as well as dry cornea.

Medical care of ectodermal dysplasia depends on which ectodermal structure is involved. In this case report, the temperature was raised,So it was advised for frequent intake of liquids to maintain hydration patient having dental issues are advised for early dental evaluation and treatment and encouragement for routine dental hygiene is done.[7] In the above case report, upper partial denture and lower complete denture was advised. After the construction of dentures, the patient was educated for adjustments and reconstruction of dentures at different stages of growth and advised that dental implants may eventually be required. Patients with xerostomia and reduced lacrimation may benefit from artificial saliva and tears respectively. The defect of the lip can be corrected by cheiloplasty to improve esthetics. The patient is advised to take consultation with a genetic counselor to find out the diagnosis and genetic analysis.[8]

Lip-Nose Reconstruction Post-Cancrum Oris Defect: A Case Report

Sobhan Mishra[1], Shelly Mishra[1], Shibasis Biswas[1], Pankaj Kumar Panda[1]

[1]Professor & Head, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Private Practioner, Bhubaneswar, Odisha, India, [3]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [4]Senior Research Officer, Apollo Proton Center, Chennai, Tamil Nadu, India

Abstract

Cancrumoris is a disease of great antiquity described by Hippocrates and Galen. The termnoma, a common synonym for the disease, is derived from the Greek verb 'to devour'.Tourdes(1948) definedcancrumoris that is still substantially correct. Hedescribed the condition as a gangrenous affection of the mouth that especially attacks children in whom the constitution is altered by bad hygiene and serious illnesses such asexanthematous fevers. According to him, the disease is manifested by an ulcer of the oralmucous membrane, edema of the face extending from within out, and rapid destruction of the soft tissues and bone with an outcome that is almost always fatal. Nowadays, cancrumoris still affects children predominantly. It occurs very rarely in the aged with decreased hostresistance. Noma sequelae comprise bony and soft-tissue losses that affect both aesthetics and function. Complex defects should be treated in a staged fashion with the most complex initial stages performed in better-equipped institutions and less complex stages done on home ground. Although complete correction may be planned to restore function and aesthetics, thenoma patient may eventually be satisfied with a functional but less aesthetic outcome.

Introduction

Cancrumoris is a disease of great antiquity described by Hippocrates and Galen. The term noma, a common synonym for the disease,is derived from the Greek verb 'to devour'. Tourdes (1948) definedcancrumoris that is still substantially correct. He described the condition as a gangrenous affection of the mouth that especially attacks children in whom the constitution is altered by badhygiene and serious illnesses such as exanthematous fevers. According to him, the disease is manifested by an ulcer of the oral mucous membrane, edema of the face extending from within out, and rapid destruction of the soft tissues and bone with an outcome that is almost always fatal. Nowadays, cancrumoris still affects children predominantly. It occurs very rarely in the aged with decreased host resistance.[1] Although a reconstructive surgeon may be keen to apply the principles of oncologic reconstruction to noma surgery, it must be noted that the 2 are dissimilar and a slightly different approach is necessary.[2] Craniofacial defects are rare, disfiguring facial anomalies, with an incidence of about to 4.9 cases per 100,000 live births. Craniofacial clefts may be caused by the failure of the maxillary processes to fuse, external pressure, amniotic bands, oligohydramnios, central disorganization of the neural crest, and hematomas.[3] In 1973, Tessier classified craniofacial clefts based on clinical, radiographic, and

e-mail: sobhan.surgeon@gmail.com

surgical findings. The median cleft of the upper lip, or Tessier 0 class, has a variety of presentations, ranging from a minimal notching of the lip, vermilion, and nose to a wide cleft that divides craniofacial structures.[4]

Although great improvements have been achieved in the primary correction of the bilateral cleft lip and nasal deformity, secondary lip and nasal deformities occur in a significant number of patients. Typical secondary deformities involve broad nasal tip projection, flared alar rims, fistulae of the nostril floor, a short columella with varying degrees, and a vertically short upper lip (whistle deformity), in which severe short columella complicated with marked philtrum deficiency poses a highly demanding challenge to plastic surgeons. The columella and philtrum serve as two functional and aesthetic subunits. In deformities, a short columellaoften includes a deficiency of skin, nasal mucosa, and supportive alar cartilages.[3] We present a case of an adult patient with noma sequelae managed by a staged approach. Although complete correction was initially planned, following the patient's requests, the last stage was abandoned and a functional but less aesthetic result accepted.

Case Report: A 55-year-old lady reported to our dept. of Oral & Maxillofacial Surgery, Institute of Dental Sciences & SUM Hospital, Bhubaneswar, Odisha, India with a large anterior maxillary facial defect involving the lips and the nose owing to cancrumoris about 10 years ago. The defect was large involving the upper lip in the midline, anterior hard palate, and columella of the nose (Figure 1). The surgical procedure was aimed to improve the aesthetic outcome and also increase the functional capacity of the mouth.

Defect Assessment: The defect in the present case can be compared similarly to a cleft nose and lip(Figure 2 & 3). The field of cleft surgery has seen major advances over the past 30 years. Normal function and normal to near normal appearance are a realistic goal and can be achieved.

Nasal Deformity: The abnormal anatomy of the cleft nose includes several components. The alar base, the medial and lateral crus of the alar cartilage, the nasal dome, the columella, and the nasal septum all are affected by the skeletal base, consisting of the alveolus, maxillary segments, and palate. The severity of the primary nasal deformity is intimately related to the degree of displacement, abnormality, and hypoplasia of the maxillary segments. Con- tinued hypoplasia and displacement of the maxillary segments, particularly the lesser segment, result in varying degrees of maxillary deficiency in the unilateral cleft lip and nose deformity. Subsequent growth and the final degree of deformity and outcome depend on the cleft dysmorphogenesis and the selection of surgical procedures and sequencing. Rehabilitation must address the three-dimensionality and growth over time to obtain the desiredresult.[10]

Lip Adhesion: A median cleft can also be called midline cleft or vertical cleft through the center of the upper lip, and is a rare anomaly, the exact developmental origin of which is not clear. Tessier 0 clefts occur during the third week of gestation due to the failure of the two medial nasal processes to close in the midline. It can occur in isolation or be a part of a syndrome such as orofacial-digital syndrome. In this case, the defect occurred due to previous aggressive infection of the anterior facial region. Various treatment options are present for mild deformities that do not involve the white roll. When developing the treatment plan, reconstruction of the cupid's bow, labialphiltrum, vermillion, and buccal mucosa should be kept in mind. Some articles described using a V-Y flap, in another article they used a diamond incision to repair these anomalies. Some authors described a mucosal Z transposition technique to treat mild cases. For moderate defects involving the philtrum, Millard and Williams reported using an inverted V excision. In this case report, we have addressed both the lip component and the nasal component as a different entity to achieve maximum outcome.[4]

Surgical Technique:

Nose: The operation was performed under general anesthesia. The incision design, which involved two small triangular flaps on the nasal floor, was made along with the scarred philtral columns and extended vertically along the medial nostril walls. The prolabial flap based on the nasal tip was harvested with underlying subcutaneous tissues to protect the subdermal vascular network. By adding the alar rim incisions, an open rhinoplasty was performed. Excess fibrofatty tissue between the medial crura of the lower lateral cartilages can displace the alar domes laterally and so be removed completely. Then, the lateral and middle portion of the lower lateral cartilages was dissected from the nasal mucosa and the overlying skin. Once the desirable tip projection was obtained, the whole prolabial flap was used to cover the nasal tip and reconstruct the columella. Two accompanying small triangular flaps were inserted

carefully into the defects created by the septal mucosal contracture release (Figure 4).

Lip: Lip repair was done using the triangular flap technique initially describe by Tennison and Randall. The approach to this flap is based purely on a mathematical approach and precise measurements. The repair technique is conceptually similar to rotation advancement flap with the primary difference is that the rotation back-cut in the non-cleft side is performed more inferiorly, closer to the vermilion border. Similarly, the advancement segment on the cleft side is designed to occur inferiorly near the vermillion cutaneous border (Figure 5).

Discussion

Noma or cancrumoris is gangrenous stomatitis affecting particularly children from developing countries. It has been known since the time of Hippocrates, Galen, and Celsus. In 1848, Tourdes used the term *cancrumoris or noma* for the first time and gave a clear description of the disease. In the earliest stages of the disease, a painful, red, or purple, indurated papule is present. It is most frequently seen in the posterior region of the alveolar margins. Ulceration follows rapidly and may extend into the mucosal surfaces of the cheek and the lips. Tissues appear swollen and tender to palpation. There is a profuse salivary flow accompanied by a foul-smelling and purulent discharge. Over several days, a blue-black area appears on the skin of the lips and cheeks. The gangrenous area may also involve the chin, the infraorbital region, the palate, the nose, and also the antrum. Sloughing of the tissues leaves deep, perforating wounds. The teeth are often exposed. Following the acute phase of gangrene, if the child survives, healing will proceed by contraction and fibrosis, leading to severe distortion of the mouth region.[5]

Surgery is targeted at restoring normal speech, oral competence, and acceptable cosmesis. The surgery differs from the reconstruction of defects following ablative oncologic resection in the following ways. In the adult noma patient, compound tissue losses (skin, soft tissue, bone) are commonplace. Remnant tissue is left scarred and distorted with loss of normal anatomical reference points. Because noma occurs in early childhood, the bony defect and soft-tissue scar affect facial skeleton and dental development, producing gross asymmetry. Nutritional deficiencies are commonplace. Preoperative optimization must include nutritional assessment and correction of these deficiencies.

Complications, including poor healing and infection, are common in the immediate postoperative period. Hence, a longer observation period is necessary before discharge and return to the country of origin. Noma sequelae comprise bony and soft-tissue losses that affect both aesthetics and function. Complex defects should be treated in a staged fashion with the most complex initial stages performed in better-equipped institutions and less complex stages done on home ground. Although complete correction may be planned to restore function and aesthetics, the noma patient may eventually be satisfied with a functional but less aesthetic outcome.[2]

Midline defects of the face are associated with a range of developmental brain defects, trauma, or severe infectious disease leading to gangrene. Many are incompatible with life but some patients may have a normal or near-normal mentality and a full life expectancy. Reconstruction and repair utilizing existing surgical method are applicable for this latter group of patients but the midline nature of the defects may require adaptation of these techniques.[8]

The columella is an important aesthetic entity in the mid-face and following its loss or congenital absence a severe aesthetic defect results. Over the years a variety of reconstructive techniques for the columella have been described in the literature including alar margin flaps, the internal nasal vestibular flap, nasolabial flaps, and nasomalar flaps.[8]

The basic principles of treatment of the established case of Cancrumoris have remained the same. These are to release the ankylosis and only then to carry out reconstruction of the facial defect. To undertake the latter before achieving the former is disastrous for the patient, who previously was able to feed through the hole in the cheek, but with the closure of the defect is prevented from taking anything but fluids.[7]

The first step of nasal reconstruction is a thoughtful analysis of the defect. The best surgical option will provide the patient with an excellent aesthetic result and nasal function. Depending upon the extent of the defect

as well as the anatomic site, a local flap, full-thickness skin graft, composite graft, or interpolated flap will provide the optimal result. The decision will depend on the surgeon's experience and expertise, as well as the expectations and desires of the patient. Many cutaneous defects will require not only reconstruction of the defect, but also cartilage grafts to provide nasal contour and support. Most large or complex defects will require a paramedian forehead flap for reconstruction along with cartilaginous and/or bony support, as well as a lining flap.[6]

One of the most distinct problems of secondary bilateral cleft nose deformity is a short columella with a flattened nasal tip. There have been many attempts to perform columella lengthening and nasal-tip elevation. Various techniques, such as a central V–Y advancement flap from the upper lip, and bilateral forked flaps, have been commonly used to lengthen the columella. Meanwhile, different bone or cartilage grafts can be used to elevate the nasal tip and stabilize the columella. However, the most important procedures that contribute to the long-term stability of columella length and nasal tip projection are the full release of nasal mucosa contracture and sufficient soft tissue coverage at the nasal tip.

In our approach, the total height of the prolabium was used to lengthen the columella and provide adequate skin coverage for the nasal tip. Furthermore, any contracting forces induced by inadequate mucosa were fully released and the resultant defects were repaired by the two accompanying triangle flaps in the prolabial flap.[3]

Conclusion

Noma sequelae comprise bony and soft-tissue losses that affect both aesthetics and function. Complex defects should be treated in a staged fashion with the most complex initial stages performed in better-equipped institutions and less complex stages done on home ground. Although complete correction may be planned to restore function and aesthetics, the noma patient may eventually be satisfied with a functional but less aesthetic outcome.

Abstract

Violence is one of the primary sources of facial injury. It forms a big part of emergency care and trauma and differs from each because of the physical, psychosocial and economic relations. Trauma from pointed arms happens less frequently affecting the head and neck region, most commonly affecting males. Facial injury: 83 percent comprises of bone fracture, 66 percent of lacerations & 53 percent comprises of hematomas.

Keywords: *Assault using sharp weapon, le fort osteotomy.*

Introduction

The form of injuries witnessed associated with the suspected weapon used, but only hematomas or fractures suffered by 20 percent of victims who reported attacks with sharp weapons. The most casualties are caused by punching (72% of assaults), or kicking (an attack of 42 percent). Only6% of victims registered with sharp weapon accidents & 11 percent of those wounded with drinking glasses. All injuries were classified as hematomas, lacerations, or fractures. It included intra-oral lacerations linked to the underlying fractures of the jaw including the surrounding alveolar mucosa of the hard palate. Weapons were classified as blunt, sharp, broken glass, fist, feet, firearm or 'other'. The level of seriousness of injuries was developed and were classified as:

Category I: Single laceration or single hematoma.

Category II: Multiple soft tissue injuries.

Category III: Single fracture.

Category IV: Single fracture and soft tissue injury elsewhere.

Category V: Multiple fractures.

Case Report: A patient aged 28 years, male, reported the emergency department of SUM hospital with a history of assault using a sharp billhook due to interpersonal violence. On examination, the patient had a laceration about 10cm long extending from the nasal floor to the zygomatic buttress bilaterallyand a depth of about 2cm. The entire maxilla was mobile. There was a derangement of occlusion on both the left and right sides. In a pre-operative 3-dimensional computed tomography (CT) scan we see a linear fracture line seen passing from the right pterygomaxillary region crossing the floor of the nose to the left pterygomaxillary region fracturing a part of the left piriform aperture thus making the maxilla floating. The patient had difficulty in breathing so tracheostomy was done & initially the wound was cleaned, bleeding was arrested sutures were placed using 4-0 prolene and fluid transfusion was done.

Treatment Done: The patient was intubated through a preexisting tracheostomy tube. Local anesthetic agent 2% lignocaine with adrenaline (1:100000) was injected into the surgical area. The patient was subjected to

maxillomandibular fixation using the ivy-eyelet wiring technique. The fracture site was exposed via a pre-existing scar. The fracture site was reduced and fixed with one 1.5mm L-plate using four 6mm screws on the right side & using two 1.5mm L-plate and ten 6mm screws on the left side. Occlusion was achieved intraoperatively. The surgical site was irrigated thoroughly and hemostasis was achieved. Sutures were placed in the muscle layer using 3-0 vicryl and on the skin using 5-0 ethilone. A tight dressing was given in the incised area.

Discussion

A rise in the cases of maxillofacial injuries due to assaults may be attributed to the country's low socio-economic circumstances, contributing to tension/stress and criminal propensity. The job rate for university students has generally increased from 4 percent in the early 1970s to 45 percent today.[1,2] The face is the first point of touch in the various people-to-people encounters, and the goal for maxillofacial injuries is often chosen especially in assaulted cases. The peak age rate for assault was observed to be 20-29 years.[3-7] The higher frequency recorded by males[3,4] is in support of other related research, this may be because males are more likely to participate in interpersonal altercations, probably due to the use of alcohol or psychoactive drugs in males compared with females.

Blunt objects were reported as the most common assault mechanism for maxillofacial injuries. Shepherd et al.[8] related the assault mechanism to the form of injury, indicating that assaults with blunt objects may produce sufficient force to cause fractures, leading in particular to dento-alveolar fractures/facial skeleton fractures.[8] The Olasoji et al study identified attack as the major cause of facial injury, as 48 percent of their patients had facial damage due to assault-related injuries.[9] This discovery is counter to the pattern identified in the past hence assault is suggested as a recent phenomenon and should not be underestimated as the most popular etiology of maxillofacial injury. During this research, the injuries suffered as a result of an attack ranged from abrasion to soft tissues to facial bone fractures. Laceration of the soft tissues of the nose and subsequent invasion of the middle third of the face. Bite wounds are mostly seen on the face and women tend to be more affected in their third decade of life, with the lips and ears being the most common target.[2]

Barde et al found that injuries suffered in car collisions are normally very different from those incurred in personal disturbance; while victims of automobile and motorcycle collisions tend to have multiple mandibular injuries, those patients struck by a fist typically have single non-displaced fractures. Victims in violent

offenses like assault and gunshot injuries are most likely to sustain fractures in the mandibular body and angle. Barde et al also recorded fractures of the mandibular angle to be the most frequent in their study, whereas symphyseal and condylar fractures were rare.[10] Any of the soft tissue lesions are treated with antiseptic fluid washing and dressing. Gentle violet solution has in some cases been applied to avulsed areas to aid with wound healing.[2] Lacerated wounds were sutured in layers, while the case of extreme avulsion on the lower lip due to human bite was healed with good results. The fragments of the broken jaw were sufficiently limited, strengthened by intraosseous wiring and immobilized by intermaxillary fixation. The damaged teeth were either removed or endodontically treated in fracture rows.

Drugs such as analgesics, antibiotics, anti-inflammatory medicines, and anti-tetanus medicines were prescribed as necessary. In this situation, recovery was uneventful, with strong results.[2]Biomechanical injury research uses mechanical principles to investigate and explain the physical and physiological reactions to impact injury resulting from that.[6]Both penetrating and nonpenetratinginjuries may be addressed, but the latter are morecomplex, less well understood, and offer greater opportunities formitigation through technological advances. The risk of injury isrelated to the energy delivered to the body by the impacting objectas well as to the object's shape. Penetrating injuries are caused by high-speed missiles, such as bullets, or by sharp objects traveling at very low speeds, such as blades, axes, and daggers in this type of injury, impact energy is concentrated in a small region of the body, there is no chance of dissipating this force, and the structural risk processes are relatively clear. ContradictoryHowever, injuries occur when the body is struck by a blunt object, such as a vehicle instrument panel, at a moderate velocity but the impact force is distributed over a wide area".In this case, padding or other crushable materials may absorb impact energy, which makes the impact and impact surfaces to bend and thereby increase impact length and its frequency rising.[6] After studying the various classifications and biomechanics of facial skeletal fractures, the present case may be classified as bilateral maxillary alveolar process fracture or unfinished Le Fort I fracture due to high penetrating injury.

Conclusion

Sharpened facial traumas have a tremendous aesthetic & functional loss. However, with proper diagnosis, adequate planning, and immediate surgical treatment, the maxillofacial surgeon can minimize sequelae and ensure patient rehabilitation as well as reduced risk of infection.

Nosocomial Infections: A Long-Lasting Challenge in Public Health

Shakti Rath[1], Naushaba Akhtar[2]

[1]Associate Professor (Microbiology & Research), Faculty of Dental Sciences and Nursing, Central Research Laboratory, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Post Graduate Student, School of Public Health, Asian Institute of Public Health, Bhubaneswar, Odisha, India

Abstract

Nosocomial or hospital-borne infections are one of the most difficult challenges faced by health care professionals, as these infections are arises in hospital settings. Both human and non-human contaminations are responsible for these infections inpatients during their hospital stay. This article helps to understand the epidemiology of nosocomial infections and to overcome major public health challenges. It also identifies the factors responsible and the mode of transmission of these infections to overcome some major public health challenges.

Keywords: *Nosocomial infections; Antibiotic resistance; Multidrug-resistant bacteria; Public health challenges*

Introduction

The word nosocomial has been adopted from the Greek words 'nosos', meaning "disease" and 'komein', means "to care for". Nosocomial infection or "hospital-acquired" or "hospital-borne infection"occurs in the hospital settings, which means it is an infection picked up by a patient in the hospital who has been admitted to the hospital for an ailment other than any disease caused by microorganisms. These microorganisms are present in the hospital settings, devices or among hospital staff and get transferred to a newly admitted patient with no infection history (Figure 1). These infections can be defined based on a period within the hospital stay, like among those occurring within 48-hours of hospital admission, in the last few days of discharge or within 30 days of surgery. Nosocomial infections are always associated with large numbers of co-morbidities, initiating new illness and are the common cause of mortality among hospitalized patients.[1,2]

Nosocomial infections majorly occur orspread through respiratory tract infections, surgical abrasions, and urinary tract infections (UTI). Areport from the World Health Organization (WHO) suggests the nosocomial infections are highly prevalent in Intensive Care Units (ICU) and hospital wards. They are most prevalent among patients with comorbidities, older groups of people, children (especially below <5 years), and among chemotherapy patients.[3] The major factors responsible for acquiring these infections include patient's immunity, increasing variation of medical and invasive techniques, exposure to infected health professionals, hospital hygiene policy, microorganism's longevity on the surface or in air, size of the agents, etc. e.g. air particulate matters and multidrug-resistant (MDR) bacteria.[4]

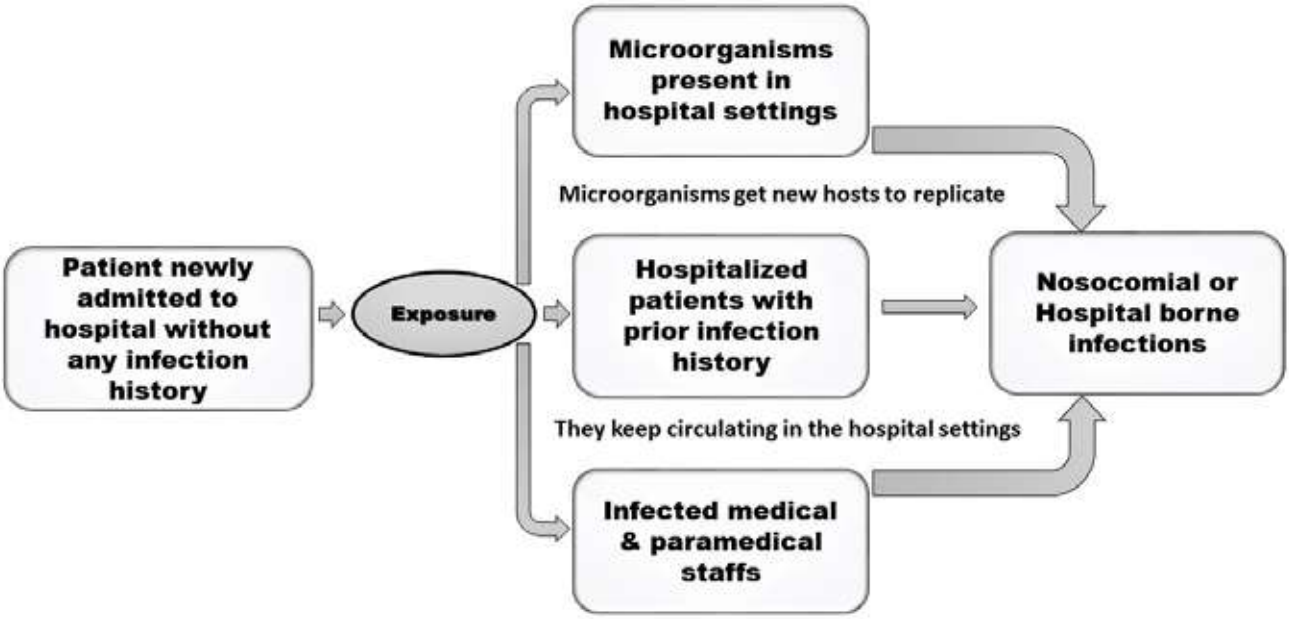

Figure 1. Source, spread and sequence of events in leading to nosocomial infections

Epidemiology of nosocomial infections: Nosocomial infections are considered either epidemic or endemic. It was reported in the National Nosocomial Infection Study (NNIS) from 1992 to 1998, that 90% of the nosocomial infections have been endemic, where 54% infections were in surgical patients, 28% in elderly patients (above 55 years), and the rest in device associated patients. Bloodstream, respiratory, surgical-site and UTI were the most common hospital-borne infections. There is also an association between the increase in MDR bacteria and nosocomial infections. Apart from this accessibility to handwashing stations and usage of alcohol gets improves compliance with washing hands. Numerous studies have also shown that doctors wash their hands less frequently than other health professionals. Proper infection control measures are needed for the control and prevention of such infections.[5]

The common sites of infections: Respiratory or Nosocomial pneumonia: Respiratory tract infections are the commonest of nosocomial infection. In an "NNIS" study pneumonia had accounted for about 31%. These types of infections occur in different groups of patients and health professionals not taking proper precautions. This type of infection is found among patients in the ICU who are on ventilators, where the rate of incidence of pneumonia is about 3% perday. A high rate of fatality is also associated with ventilator-associated pneumonia.[6-8]

Urinary tract infections: UTI is another common hospital-borne infection and around 80% of this is found to have been associated with the use of a bladder catheter. UTI can occasionally lead to bacteremia and death. The major bacteria responsible for UTI can be either commensal turned opportunistic pathogens like *Escherichia coli* or acquired infectious bacterial like MDR *Klebsiella* species.[6-8]

Surgical site infections (SSI): The incidence of such infections varies from 0.5-15% which usually depends upon the type and size of operation along with underlying patient status. The length of stay in the hospital is considered as one of the underlying factors. These type nosocomial infections are acquired usually during surgery, from surgical equipment, doctors, para-medical staff, from the commensal-flora present of the patient's skin near the operative site and rarely from blood used in surgery. These kinds of infections arise if proper aseptic measures are not followed before, during and post-surgery and it delays the healing of surgical sites that lead to septicemia and bloodstream infections.[6-8]

Nosocomial bacteremia: These infections are responsible for about 5% of nosocomial infections but fatalities rates are high due to bacteremia are considerably high about more than 50%. There is an increase in particularly for specific organisms such as methicillin-resistant *Staphyloccocus aureus* and *Candida* spp.[6-8]

Other nosocomial infections: Bedsores, burns and ulcersare the other kinds of hospital-borne infections that affect the skin and soft tissues, leading to unnecessary bacterial colonization. Secondly, gastroenteritis is the most common type of nosocomial infection among children generally caused by members of Enterobacteriaceae, rotavirus and *Clostridium* species. Other infections like sinusitis, endometritis, conjunctivitis and infections of the reproductive organs post-childbirth are also common in hospitals of developed and underdeveloped countries.[5-7]

Factors responsible for nosocomial infections: Infection source: During hospitalization, the patient usually gets exposed to a variety of microorganisms; bacteria, viruses, fungi and parasites can cause infections. These infections are acquired from another person in the hospital (cross-infection) or the patient's normal microbial flora (endogenous infection). Infections may also be acquired the infectious microorganisms present on inanimate objects or substances, a surface that had come in contact with the hospitalized patient. Such infections are known as fomite infection. If infection occurs from devices for the patients such as ventilators and catheters, they are known as device-associated infections.[9-11]

Bacteria: Bacteria are the common form of pathogens responsible for nosocomial infections. These infections causing bacteria are further divided into:

Commensal bacteria are found in the normal flora of healthy humans. The bacteria include cutaneous coagulase-negative *Staphylococci* and *E. coli* which behave as opportunistic pathogens and cause bloodstream, respiratory, urinary and gastrointestinal tract infections. They can be fatal under some circumstances.[9-11]

Pathogenic bacteria: *Clostridium* species causes gangrene, *Staphylococcus aureus* causes a wide variety of lung, bone, heart and bloodstream infections and is frequently resistant to antibiotics; beta-hemolytic *Streptococci, Pseudomonas* and members of family Enterobacteriaceae may colonize the immune-compromised sites of a patient and cause serious infections in the surgical site, lung, bacteremia, peritoneum infection.[9-11]

Viruses: Viruses are widely responsible for causing many nosocomial infections which include the hepatitis B and C viruses transmitted during transfusions, dialysis, injections, endoscopy, etc., respiratory syncytial virus (RSV), rotavirus, and enteroviruses which are transmitted by hand-to-mouth contact and via the fecal-oral route. Other viruses such as cytomegalovirus, HIV, Ebola, influenza viruses, herpes simplex virus, and varicella-zoster virus, may also be transmitted.[9-11]

Parasites and fungi: Organisms like *Giardia lamblia* are transmitted easily among both adults and children. Some other fungi and parasites cause infections during extended antibiotic treatment and severe immune suppression (e.g. *Candida albicans, Aspergillus sp., Cryptococcus neoformans, Cryptosporidium*). [9-11]

Environmental factors: Environment has always acted as a game-changing role by acting as a host for carrying airborne infections. Environmental factors play a major role in causing nosocomial infections. The environment sometimes acts as a reservoir of the agents or even sometimes acts as a source. These infections can be caused among patients, staff and non-medical staff and patient's attendants and when admitted to the hospital acts as a potential source of causing infection. Infections transmit most frequently in crowded conditions within the hospital settings. Airborne transmission occurs through fungal pathogens, like *Aspergillus* which are soilborne. *Sarcoptes scabies* (scabies) is another such organism causing major outbreaks in the health care system. [9-11]

Bacterial Resistance: Apart from their association with an increase in morbidity and mortality, hospital-borne infections have a strong association with MDR microorganisms, including "methicillin-resistant *Staphylococcus aureus* (MRSA)" and "extended-spectrum-lactamase-producing (ESBL) gram-negative bacteria", those causing huge clinical consternations. MDR bacteria increase in number exponentially through natural selection and exchange of plasmids carrying resistant genes with normal human flora which were originally sensitive to antibiotics.[12] The extensive and unprescribed use of antimicrobial drugs is one of the major factors of the emergence of MDR bacteria. Bacterial strains of *Staphylococcus, Pseudomonas, Enterobacteriaceae and Mycobacterium tuberculosis* are currently considered are superbugs and are probably resistant to almost all antibiotics. These organisms are highly prevalent in hospitals and community settings. The problem of antibiotic resistance is a major issue in developing and under-developed countries as the affordability of hospital stay and higher antibiotics become serious concern.[13]

Modes of transmission of nosocomial infections: Nosocomial infection can be both endogenously and exogenously, endemic or epidemic transmission which means the transmission of infection from the surface and when transmission occurs internally in a manner unusual to normal cases.[3, 14, 15]

Endogenous Infection: The human microfloraismajorly responsible for causing opportunistic infections in various other parts of the body such as urinary and GIT, wound's site and nearby tissues, depending on the host's immunity and ongoing antibiotic therapy

Exogenous cross-infection: Transmission of pathogenic infection happens because of : (a) direct contact with patients (infected body part, body fluids, saliva) (b) aerosols and saliva droplets (c) hospital staffs, patient caretakers (may act as carriers), visitors (d) from contaminated devices, instruments, clothes, beds and toilets used for and by the patients.[3, 14]

Endemicor epidemic exogenous environmental infections: Most pathogenic organisms like strains of *Pseudomonas, Acinetobacter, Mycobacterium* dwell well in a hospital environment as the damp and moist *conditions suit* them well and there no shortage of hosts and nutrition. They can survive for months together as spores and are generally resistant to disinfectants which are used to maintain hospital cleanliness.[16]

Infection	Measures
UTI	Limit duration of Catheter use Aseptic technique during insertion Closed drainage system
SSI	Clean operating environment & staff cleanliness Limiting hospital stay Optimal antibiotic prophylaxis Aseptic practices during surgery Surgical wound surveillance
RTI	Ventilator-associated Limit duration in ICU Non-invasive ventilation Prevention of *Legionella* and *Aspergillus* during renovations
Device-associated infections	All Catheters limit duration Local skin preparation Limitation of frequency of dressing change Antibiotic-coated catheter for short term

Table 1. Effective measures for prevention of nosocomial infections

Modes of prevention: The major illness or morbidity occurring due to nosocomial infections can be prevented through various measures if taken proper care. Table 1 shows the effective measures for the prevention of major nosocomial infections.[17]

In general prevention at various levels is going to be helpful for control and precaution from infection. This prevention at the individual level includesi. Reducing person-to-person transmission ii. Preventing transmission from the environment iii. Cleaning of the hospital environment, disinfection of patient equipment, sterilization.[18] There has to be the utilization of preventive measures and equipment in day to day activity for the prevention of hospital-borne infections,a standard guideline for health professionals introduced by WHO gives a detailed preventive measure (Figure 2).

Figure 2. Standard WHO preventive measure guidelines for health professionals

Major public health challenges: At individual level, spread of contamination through frequent contact and close contact between patients and unaffected individuals.

At environmental level, spread of infection through material and objects, improper sanitations, not using proper sterilizations, uncleaned environment and healthcare can be responsible for causing infection and when there are gatherings in hospital setting infection which are airborne are transmitted faster than it could be expected. Therefore, during epidemics, people are asked to avoid social gatherings even at healthcare.

At healthcare, level, spread through an affected healthcare professional, use of infected linen, equipment, and injection because of which infection travel from an infected individual to a healthy individual.[19]

Public health interventions: These interventions at large scale help in safeguarding and treating masses all at a given time and even over some time. The "Centre of Disease Control and Prevention's"in 1985 reported on the efficiency of Nosocomial Infection Control had reported of four components of key infection control which includes: (i) an effective epidemiologist, (ii) one infection control practitioner for every 250 beds, (iii) active surveillance, (iv) control efforts. CDC's National Nosocomial Infection Surveillance (NNIS) system has been working for more than 25 years. WHO on the other hand is working towards improving global health care and preventing healthcare-related infections.[20]

Applying intervention in hospital settings is not enough, as improvement in a continuous manner would be required to avoid contamination and support good health. Therefore, WHO has suggested multimodal improvement strategy in 5 useful steps as shown below in Figure 4, which shows the 5 key elements identified by WHO for prevention and control of multimodal strategies in a healthcare setting, the 'system change' can be implemented in Infection prevention and control which includes the availability of infrastructure, supplies (E.g. frequent hand washing intervention needs availability of wash basin and infrastructure for health professionals and patients to avoid contamination and transmission of infections), 'training and education' of health professional which will not only improve their knowledge will also help in implementing knowledge into sensible actions (E.g. knowledge about evidence based surgical site infection prevention), 'monitoring and feedback', will help in assessing the problem and continuous flow of information will improve action

(E.g. information regarding localization of the particular pathogen/microbe), 'reminders and communication' regarding right action in the right situation (E.g. awareness regarding the importance of regular hand-wash), a 'culture of safety' to facilitate an organization to value an intervention and institutional safety atmosphere for sustainable improvement.[21-24]

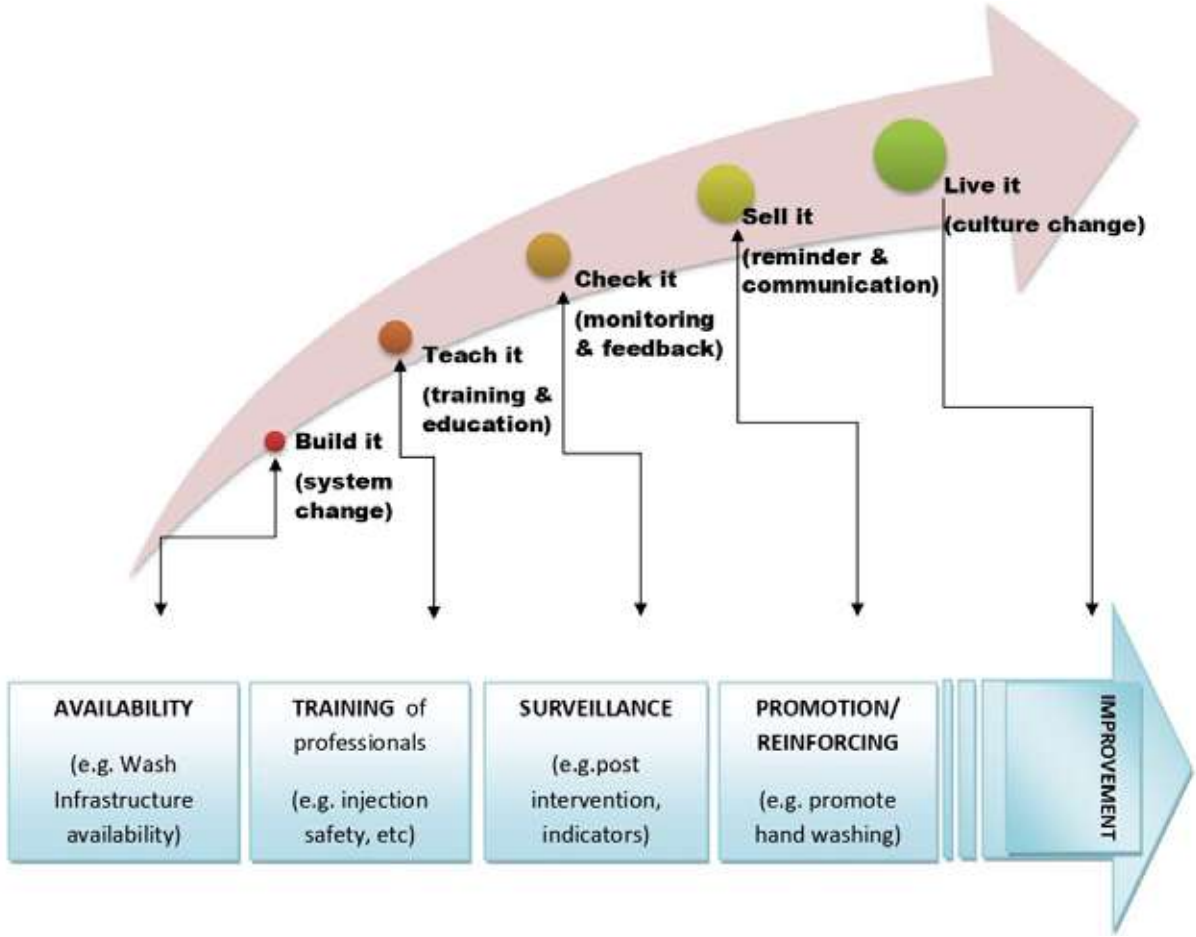

Figure 3. Infection prevention and control (IPC) multimodal strategies for health-care.

This model (Figure 3) enables the understanding of the occurrence and spread of nosocomial infections and prevent it by carefully implementing a strategic control and monitoring system in healthcare settings. Not only health professionals but a complete effort by all sections of the health care system will help in taking prevention against nosocomial infections and prevent infections.[21-24]

Conclusion

Public health challenges are difficult to overcome in-spite of various interventions. The rapid transmission of infection in the hospital setting has been one of the most difficult challenges to overcome, irrespective of development in the field of medical sciences. Surveillance mechanisms like NNIS will enable in taking proper and timely interventions at different levels for smooth functioning and prevention of nosocomial infection. The multimodal strategies would enable health professions to take strategic intervention at different stages and sectors. Further research on specific infections will increase the chances of better awareness and prevention of nosocomial infections.

Analysis of Tumour Size When Presented to Dental College: A Retrospective Institutional Study

Harsh Mohan Pathak[1], Satyabrata Pattnaik[2], Soumya Kanti Roy[2], Sanchari Sinha Roy[2], Kalyan Sundar Pal[2], Roshni Senapati[2]

[1]Associate Professor, [2]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Objective: Evaluation of presentable tumor size in oral squamous cell carcinoma was the objective of the study.

Patients and Method: The study sample comprised of ninety-eight biopsies diagnosed as oral squamous cell carcinoma presented to dental college from 2015 to 2020. Result and analysis of presentable tumor size when reported.

Results: Male to female ratio was 2.5:1. Among the 295 diagnosed OSCC cases presentable tumor sizes when reported, most of the cases were T2 (42.37%) followed by T1 (18.3%), T3 (11.86%), and T4 (6.1%).

Conclusions: Oral squamous cell carcinoma is one of the major health problems in India. Strategies must be made to improve the present scenario of health care service, where Government-run health care centres are burdened with ever-increasing patient pool, and to avail treatment in such centres is always a compromise with time and health. Oral health and cancer awareness programs should be undertaken for prevention, early diagnosis, and management of the affected population. Regular long-term follow-up is also necessary for these cases to avoid the recurrence of the disease and a better quality of life.

Keywords: *Tumor Size, Squamous Cell Carcinoma (SCC), Oral cavity, TNM Staging.*

Introduction

Oral cancer is considered to be one of the ten most common cancers in the world and is grouped with pharyngeal cancer.[1] An estimated 378,500 new intraoral cancer cases are diagnosed worldwide per year. Oral cancer is less common in developed countries, but is the eighth most common form of cancer in general; however, the ranking varies widely between countries. In some areas of northern France, oral cancer is most common among the male population. For many countries, especially younger people, the prevalence of intraoral cancer appears to be growing.[2] The global incidence of lip, oral, and pharyngeal cancers comprises around 3.8% of all carcinomas, is expected to increase by 62% within the year 2035 due to changes in demography.[3]

In Asian countries, oral and hypopharyngeal carcinomas are quite common.[3] One-third of global cases and one-half of oral cancer-related deaths are reported from Southeast Asia.[4] In countries of the Indian subcontinent (India, Bangladesh, Pakistan, and Sri Lanka) oral carcinomas are most prevalent.[2] Different studies revealed that in various part of India more than 50% of all carcinoma is oral squamous cell carcinoma

(OSCC) and it is the mostcommon cancer among males and the third most common among the female population, which is related to the deleteriousoral habits such as tobacco chewing, betel-quid chewing,tobacco smoking, reverse smoking as well as other causes such as alcohol intake, low socio-economic status, poor grooming, poor diet, and viral infections, persistent dental pain, rough or broken teeth[2,5] Squamous cell carcinoma of the oral cavity most commonly involve tongue and buccal mucosa.[6]

Oral cancer affects males more often than females, although the proportion is equal, and in recent times,an increased number of cases is being reported in elderlyfemales as well as young females.[2,7,8] It predominantly affects middle-aged and older persons.[2] However, the incidence of OSCC in persons under the age of 45 is increasing.[9,10] Etiology of oral carcinomais multifactorial and cigarette smoking, excess alcohol intake, and betel-quid use are the common risk factor for oral carcinomas.[11] However, several recent studies have identified a startling rise in oral cancer in patients who had no history of tobacco or alcohol consumption[8,12]. This retrospective institutional research includes patients who were reported in our department for over 66 months. The goal of the study was to assess the presentable tumor size of oral SCC in these patients to determine the enormity and pattern of oral SCC in the population of the eastern Indian state of Odisha.

Material and Method

In this retrospective study (January 2015 to June 2020), data of 295 OSCC biopsies were retrieved from laboratory records. It included age, gender, presentable tumor size,and histopathological diagnosis. No identifying patient information was disclosed in the study. Approval obtained from the Ethical Committee of our institution for this study.

Results

A total of 295 cases of histopathologically confirmed OSCC, which were reported during the study period was included in the study. Among them 210 (71.2%) patients were male and 85 (28.8%) patients were female [Table 1]. The age range of these patients was 24 to 85 years and most of them were in their sixth decade of life. Presentable tumor sizes, when reported, were T1-54, T2-125, T3-35, and T4-18.

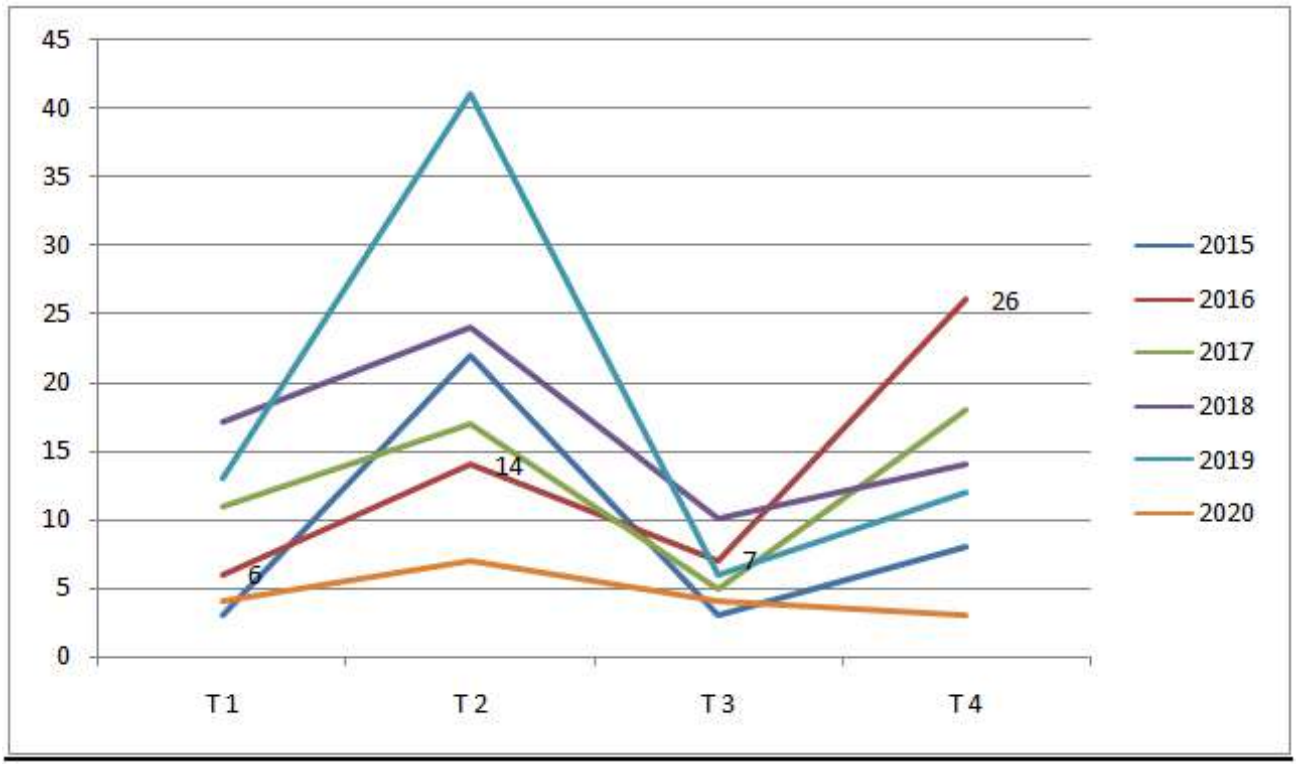

Figure 1. Year wise representation.

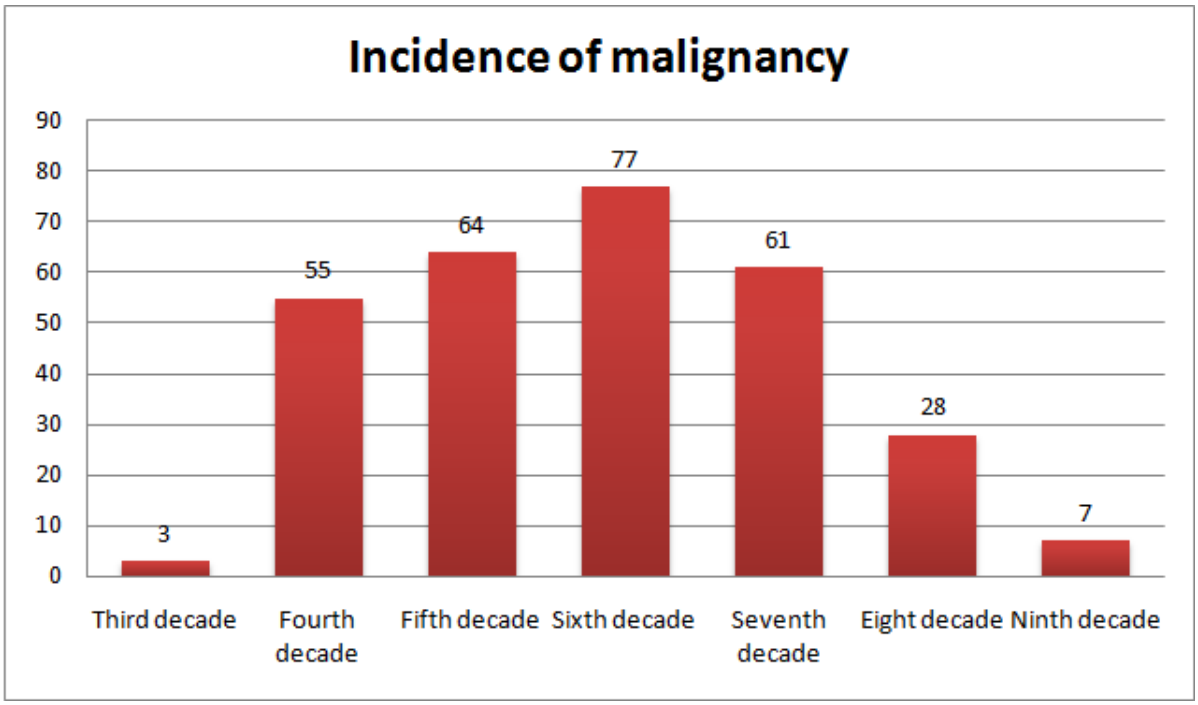

Figure 2. Incidence of malignancy

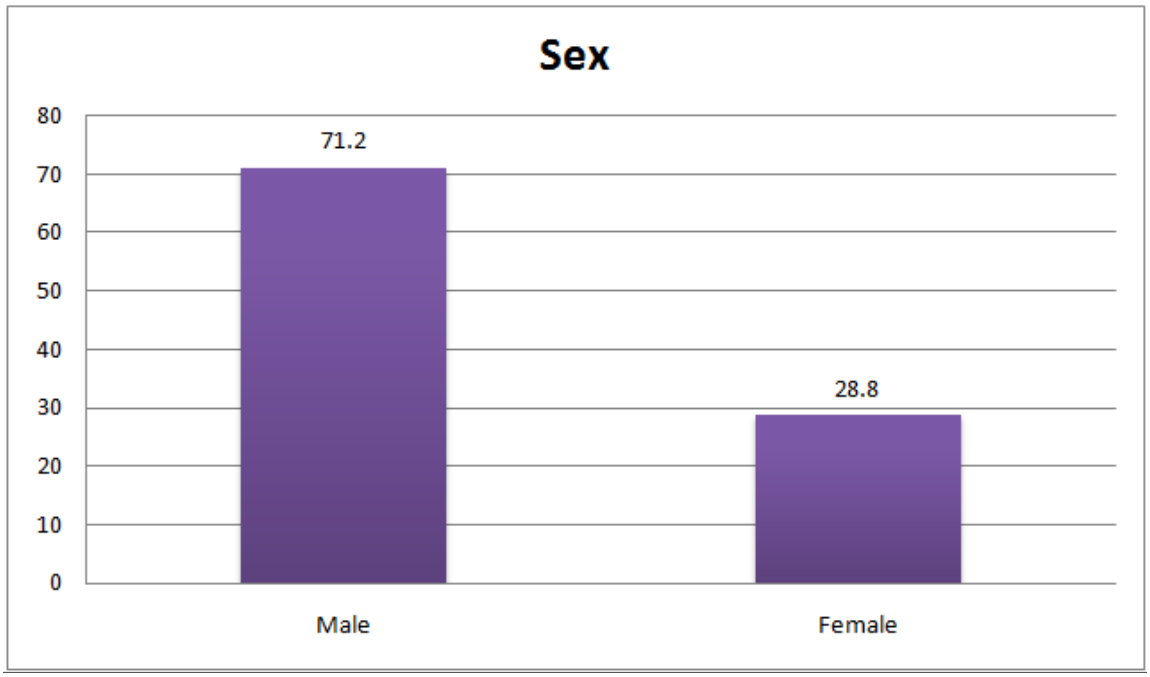

Figure 3. Gender wise representation

Discussion

Among all oral malignant lesions of oral squamous cell carcinoma accounts for nearly 90%. SCC is the prevalent carcinoma of the oral cavity with a high mortality rate and has a 5 years of survivalrate for 50% of the affected patient.[13][14]

In this study, there was an increased incidence of OSCC in males than females with a male to female ratio (M: F) of 2.5:1 which is equivalent to data of different studies which were conducted in the northern part of India. The male predilection of OSCC found in both developed (M : F=2.5:1) and developing (M: F = 3:1) countries which are attributed to increased incidence of

different oral habit in males than females[15] Recently, however, this gender distribution difference has been decreasing in developed countries because more women adopt tobacco-related habits including smoking.[15]

Most of the patients were in the age range of 40–60 years, which is consistent with other studies conducted in north India.[14,16] Most often OSCC appears after the 5th decade of life but a consistently increased incidence of involvement of patients younger than 40 years had been observed.[18] For Asian populations, the average age of presentation is 50 to 70 years of age. [17].In the present study, OSCC was diagnosed in 19.66% of patients younger than 40 years.

Tobacco consumption is a major risk factor for oral and oropharyngeal SCC.[19]Smokeless tobacco has a strong relationship with the development of oral carcinomas.[20] In Asian countries use various form of tobacco, areca nut chewing and alcohol consumption is prevalent and they play an important role in the development of oral squamous cell carcinoma.[21] Socio-cultural standards and beliefs are also in support of simple tobacco product availability. The introduction of tobacco products ready to use and aggressive ads target not just young people but also children.[14] In India, the efforts of the Government for deterrence of tobacco products' use prove to be inadequate when looked at the easy availability of the products and their rampant use.

The prevalent sites of oral SCC were buccal mucosa including gingivobuccal sulcus followed by alveolus and tongue. The findings were consistent with other studies.[14,22,23] The language is considered to be the most common site of primary OSCCs in developed countries, but in developing countries, betel quid and/or tobacco chewing results more commonly in buccal mucosal cancer.[19,24] This is mainly due to the prolonged positioning of the betel quid in the buccal pouch to achieve maximum benefit as betel quid constituents create a sense of well-being and increased ability to work by stimulating the parasympathetic nervous system.[24] Similarly, smokeless tobacco tends to incite malignant degeneration at the site of tobacco placement.[18] Tobacco contains carcinogens (chemicals that cause cancer) such as different nitrosamines (like N'-nitrosoanatabine, N-nitrosonornicotine, N-nitrosoanabasine, nicotine-derived nitrosamine ketone, etc.) and various free radicals likeglutathione reductase, S-transferase glutathione, catalase, glutathione peroxidase, superoxide dismutase, etc. They are capable of impeding antioxidant enzymes.[11] Reactive oxygen species are generated in substantial amounts in the oral cavity during chewing.[25]

According to the AJCC Cancer Staging Manual, Eighth Edition TNM staging can be classified as "clinical TNM" and "pathological TNM". They are designated as "cTNM" and "pTNM". The clinical classification should be determined before the commencement of the primary treatment based on data that are gathered through clinical examinations and different diagnostic procedures. The "cTNM" is crucial for proper treatment planning. The UICC classification suggested that for each site the specific method of investigations available for TNM classification should be listed. They are:

1. Gathering of history of the case.
2. Sign and symptoms of the condition.
3. Examination of the lesion along with the examination of the other systems.
4. Histopathological study of the primary lesion, sentinel lymph node of the regional lymph node.
5. Different imaging like CT scan, contrast-enhanced CT scan, MRI, endoscopy, plain radiographs to determine the surrounding tissue, and nodal involvement as well for the assessment of distant metastases.
6. Surgical exploration without resection and biopsy of the site of distant metastases if possible and other investigation which is necessary to establish the TNM staging.

In this study among the 295 diagnosed OSCC cases presentable tumor sizes when reported,most of the cases were T2 (42.37%) followed by T1 (18.3%), T3 (11.86%), and T4 (6.1%). In the year 2016 and 2017 presentable tumor sizes were mostly T4 (26 cases out of 53 and 18 out of 51 respectively). However, in recent years there is a reduction of presentable tumor size reported in recent years.

Most of the time there is a delay in diagnosis of OSCC can be attributed to various factors such as, but not limited to, patients' negligence due to lack of knowledge and awareness, illiteracy, poverty, and possible resort to home remedies.[22] Professional delay in making a confirmatory diagnosis can also be another factor. Multiple factors like the nature of the patient, symptoms as well as the course of the disease,

proficiency of the health service play an important role in the commencement of the treatment after the diagnosis of oral squamous cell carcinoma.[28]

Conclusion

Demographic data like age, sex, presentable tumor size in the patient of the eastern part of India which was identified previously was confirmed by this research. It is found that oral SCC is more common in the middle-aged male patient. For most Asian countries, especially India, the burden of oral cancer has increased; hence, increasing national level public awareness programs all over the country is a demand of the time for prevention, early detection, and diagnosis, and to support a tobacco-free environment. When measures are taken by Government so far could not deter people from using the tobacco products, whether a blanket ban on their production and sale is possible must be a subject of debate and discussion and utmost importance to reconsider.

Vaping: Realities in its Effect on Oral Health

Sudipta Sahu[1], Ramesh Nagarajappa[2], Kajal Kiran Sahoo[3], Debashruti Naik[4], Nikita Sahu[1]

[1]Tutor, [2]Professor & Head, Department of Public Health Dentistry, [3]Tutor, Department of Prosthodontics, [4]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Twentieth-century shows a great increase in the popularity of E-cig or electronic cigar or Electronic Nicotine Delivering System (ENDS).When smoking is considered as a leading cause of preventable death and strict measures had been taken to limit smoking in public places, this ENDS is gaining popularity worldwide among the youngsters. A new term Vaping is given to the process of consuming nicotine or other substance through a vaporising tool or popularly called E-cigar. People are using it as a smoking cessation tool also, though this fact is being debatable after many types of research on it. The increasing use of it, along with a lack of knowledge of its health effect both short and long term is worrying.

Keywords: *Vaping, Nicotine, Xerostomia, Halitosis, Glycol Vapour.*

Introduction

Since nicotine is a gateway drug that lowers the threshold for addiction to other agents, the use of e-cigarettes could lead to even more opioid addictions. It is becoming a controversial issue nowadays both nationally and worldwide.[1] Vaping is gaining popularity among youngsters without being aware of its consequences. Besides its major oral effects, general health is also becoming a field of concern due to its respiratory and ocular problems caused by glycol vapour. There are also cardiac complications related to inhalation of nicotine vapour.[2]

The emergence of E-cigar: Many countries have implemented a smoking ban in most of the public places eg- restaurant, clubs etc. So smoking cigarette is decreasing day by day due to strong imposition of law. Thus the consumer market is left with a wide-open market of an alternate form of taking nicotine. Electric devices or vaping pen is the one being promoted as a less harmful alternative with fun flavours (eg .coffee, maple syrup, mint menthol etc.) for recreational social use.[3,4]

In the developed countries, vapour lounges or vapour houses are popping up everywhere at the shopping mall, strip mall etc. Youngsters buy their favourite flavoured vaping pens and enjoying relaxing and vaping on plush lounge chairs indoors. Users drink energy drinks while vaping. Some vapour liquid contains substances like caffeine and ginseng for an energy boost or as an alternative of non-nicotinic vaping.[2-4]

Effect on oral cavity: The E-cigarette users experiences(I) xerostomia (II) Increased risk of tooth caries (III) Halitosis (IV) Dental pigmentation. The E-cigarette uses a vaping liquid that has:

(a) Diacetyl: It is a flavouring agent which is associated with serious lung disease, when heated to a high temperature and inhaled.

(b) Benzene: It is a volatile inorganic compound found in car exhaust and it is linked to leukaemia and bone marrow disease.

(c) Heavy metals like Lead, Nickel, Chromium and magnesium exceed the safe level of inhalation.

Corresponding Author:
Dr. Kajal Kiran Sahoo
Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: drkajal2@gmail.com

(d) Nicotine: It is an addictive stimulant and a potent parasympathomimetic alkaloid.

(e) Propyleneglycol: It is a food additive sweetener that increases the risk of tooth decay. When used orally it breaks down into acetic acid, lactic acid and propionaldehyde, which are all toxic to enamel and soft tissue, moreover as it is a hygroscopic material, so causes tissue desiccation.

(f) Glycerin and different flavouring which creates a palatable pleasure and increase the risk of tooth decay.

Research shows that 1 liquid nicotine cartridge contains about 200 puffs, equivalent to the amount of nicotine in one packet of 20 cigarettes.[2-5]

Vaping affects the oral cavity in 5 major ways:

1. **Receeding gingiva:** Nicotine in E-cigarette causes blood vessels to shrink and so less blood is transfer to the tissue. This causes gum recession. It can also cause periodontal pockets leading to infection & other health complications.[5]
2. **Masks gum disease:** Dentist usually spots the gum disease by probing the pocket in the inflamed gingiva. But as vaping shrinks the blood vessels in that area, the symptom of bleeding on probing go without being diagnosed by a dental professional. This helps to progress the underlying disease without being caught.[5]
3. **Amplifies bad breath:** Nicotine in vaping compromises body's ability to secret saliva, which leaves the patient vulnerable to oral bacteria. This build-up Bactria can cause infection in compromised tissue and even lead to other long term illness eg. heart disease, oral cancer, xerostomia.[5]
4. **Increases bruxism:** Nicotine of vaping stimulates masticatory muscles leading to bruxism which causes wearing down of teeth enamel, which leaves the patient more sensitive to the hot and cold temperature of food.5
5. **Increases occurrence of tooth caries:** Research shows that streptococcus mutans, when exposed to aerosols from E-cigars on tooth enamel, shows to have 4 times more microbial adhesion and decreased enamel hardness up to 27%. The viscous property of the vaping liquid allows S.mutans to adhere to the pits & fissures and increases biofilm formation by two-fold when compared to unflavoured controls.[5]

The sweetener in vaping liquid has viscous properties compared to regular soft drinks and a high sucrose diet. Other than oral effects E-cigarette also affects general health. The patient who wants to quit smoking using E-cigarettes tends to revert into the habit of smoking. This is because the nicotinic content of many vaporiser oils can be higher than that of cigarettes, making it easy to fall back into the habit. More over vaping daily doubles up the risk of heart attack and have a significant impact on lung function, especially on long term use, continuing to evolve and bought quickly in the market. First-generation e-cigarettes are disposable ones more or less looked like traditional cigarettes. Then comes second-generation E-cigarettes which contains a clearomizer instead of the atomiser.[6]

Vaping: Vaping is the process of consuming vapours of a special liquid called vaping liquid, through a battery-operated device called electronic cigarette or E-cigars or E-hookahs or vaping pen or vaporising cigarettes etc. Nowadays the E-cigars come in various shapes and sizes. Some look like pens while others like USB devices, cigarettes etc. Some popular market names of vaping liquid brands are 21st-century smoke, 777e cigs, Blue e-cigs, Bull smoke, candy king on salt, Dura smoke, Diamond mist E-liquids, Dragonite international limited, E Z smoke, E-lites, Eco pure, Fill my pod, Five pawns, Fantasia, Green Smoke, Hot vapes, Juul, J vapes E-liquid, Kandy pens, LOGIC, Lost vape, Lite-Up Anywhere, Magic Mist, Made Vapes, Mi-Pod, Mountain Moon, Njoy, Pink Sticks, P.O.E.T Electronic Nectar etc. With such appealing marketing names, they are gripping the youngsters in today's world. Their selling is also encouraged through celebrity endorsements.[7]

Parts of E -Cigars/Vaping pens:

In most of the marketed E-cigars, they have the following parts:

The mouth Piece: Users inhales through engaging this which has a small cup inside containing absorbent material soaked in vaping liquid solution.

The Cartridge: Vaping liquid cartridge holds the liquid which comes in a variety of flavours and Nicotine levels.

The Automizer/Heater: It heats & vaporises a small amount of the solution which is regulated by a computer chip. Here the vapour resembles smoke.

The Battery: This can be rechargeable lithium-ion batteries that last for 1-3 days.

The Endcap: It contains a LED light that illuminates when inhaled or the user sucks on the device.

The sensor: When the user presses the activation button or merely inhale the device, it causes the inbuilt sensor to activate the vaporising chamber. Additional components include USB, portable wall and personal chargers.[8]

Types of E-Cigars/Vaping Pens:

They are available in the market in different types. They are

Disposable E-cigarettes – It is non-rechargeable or refillable and is intended to be discarded after the product stops producing aerosol. Sometimes it is called E-hookah Examples – NJOY, OneJoy etc.

Rechargeable E-cigarettes – It has a rechargeable battery. Very often it contains an element that regulates puff duration and/or how many puffs may be taken consecutively. Examples- Blu, Green smoke etc.[9]

Pen-style, medium-sized rechargeable E-cigarettes – It is usually larger than a cigarette. It contains prefilled cartridge or refillable cartridge. It often comes with a manual switch to regulate the length and frequency of puffs. Examples – Vapor king, Totally Wicked Tornado.

Tank-style, large size rechargeable E-cigarettes – It is a much larger size with higher capacity battery and essentially contains a large, refillable cartridge. It often contains manual switches and a battery casing for customising battery capacity. Examples- Volcano, Lavatube. [9]

Evolution of E-Cigarettes: Since the year 2003 when the first generations E-cigars were first introduced by Hon Lik, it is Clearomizer is the technology which has a vaping liquid, reservoir and atomiser coil all within one single unit. Then comes third-generation E-cigarettes which are much larger than the earlier ones. Here the user can customaries tank, how much E-liquid it contained and voltage or power the device can output. The fourth and most recent generation is the most advanced one in the market. This device has regulator to regulate temperature and lower resistance coil to produce bigger and most powerful vapours.[10]

Reason to Abstain E-Cigars:

1. They usually contain nicotine- This leads it too becomes habit-forming, harming foetus if used in pregnancy and affects brain development.
2. They contain other toxins – It has carcinogens like acetaldehyde, formaldehyde etc.
3. Quitting smoking may be harder
4. They cause second-hand smoke.
5. They may not deter smokers.
6. They can harm brain
7. Experimental use may be more dangerous.

This current evidence indicates that using E-cigarettes is dangerous especially for young people and people who never smoked. Though E-cigars may help some people to stop smoking it has no FDA approval as a tool for quality smoking.[11]

Conclusion

Though it seems that electronic cigarettes are less harmful then the conventional ones, research shows that E-cigarettes confers greater susceptibility to the development of alteration in oral biological tissues when compared to ex-smokers or non-smokers. There are diverse adverse effects of E-cigarette of which common in oxidative stress. This is caused by reactive oxygen species(ROS), present in its aerosols, which depends on a set of parameters like the different volume of vapour, voltage settings, the type and state of heating systems etc. Aldehydes & free radicals found in E-cigarette aerosols trigger various type of DNA damage. The safety of electronic devices is also questionable with the potential risk of explosion & fires. Burns, lacerations etc are also common with vaping. Lastly, prospective surveys should be done addressing the potential long term effects on oral as well as a general health condition. The findings will emphasize the need for constructing persuasive vaping prevention messages, promoting public health welfare.

Van der Woude Syndrome: A Case Report

Sobhan Mishra[1], Shibasis Biswas[2], Shelly Mishra[3], Pankaj Kumar Panda[4]

[1]Professor & Head, [2]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Private Practioner, Bhubaneswar, Odisha, India, [4]Senior research officer, Apollo Proton Center, Chennai, Tamil Nadu, India

Abstract

Congenital lip pits are developmental defects that occur on the paramedian portion of the vermilion border of the lower lip. They may be unilateral or bilateral and may occur as an isolated conditionor in association with cleft lip and or cleft palate. When the labial pits occur in association with cleftlip and/or palate the condition is referred to as Van der Woude Syndrome. In 1845, Demarquay(1945) first described the lower lip pit and postulated that the condition occurs due to the indentation of the central incisor. Later in 1954, Anne Van der Woude first reported the association of congenital pitsof the lower lip with cleft lip and palate. Congenital lower lip pits are present in 88% of all VWS patients, and in 65%–75% of the cases these are associated with cleft lip and palate. The Van der Woude syndrome is a rare condition the phenomenon of a cleft lip and cleft palate combined in the same pedigree makes it unique. The VDWS should be considered in the differential diagnosis of cleft lip and palate. The dentist may be the first person to diagnose this syndrome, and therefore,should be aware of its variable expressions. A proper treatment plan at the correct time will help to satisfy the psychological and esthetic needs of the patients. Further, genetic counseling is highly recommended.

Keywords: *Van der Woude Syndrome, Cleft lip, Cleft Palate, Labial Pits, Congenital anomalies of head and neck.*

Introduction

Congenital lip pits are developmental defects that occur on the paramedical portion of the vermilion border of the lower lip. They may be unilateral or bilateral and may occur as an isolated condition or in association with cleft lip and or cleft palate. When the labial pits occur in association with cleft lip and/or palate the condition is referred to as Van der Woude Syndrome. In 1845, Demarquay (1945) first described the lower lip pit and postulated that the condition occurs due to the indentation of the central incisor. Many parents still subscribe to this hypothesis even though the condition is present since birth months before the eruption of maxillary central incisors. Later in 1954, Anne Van der Woude first reported the association of congenital pits of the lower lip with cleft lip and palate. Congenital lower lip pits are present in 88% of all VWS patients, and in 65%–75% of the cases these are associated with cleft lip and palate.[1]

The distinctive feature of VWS is the presence of lower lip pits and/or sinuses, which are present in approximately 85% of cases, but it may be absent in 15% of the cases. In some rare cases, a single barely visible pit might be the only distinguishable feature of VWS, and in others, it may be absent. Other anomalies that are frequently associated with VWS include hypodontia, submucous cleft palate, and bifid uvula, and enamel hypoplasia. Manifestations of the syndrome in other than the oral or facial areas are unusual. More extreme phenotypes in parents tend to produce more extreme expression in their children.[6]

Case Report: A seven-year-old boy reported with a complaint of difficulty in oral intake of food and liquids due to a cleft in the upper jaw. There was a history of multiple episodes of respiratory tract infections, breathlessness, nasal regurgitation of food, and a nasal twang in the voice. His history revealed that he was delivered through a Cesarean section. The maternal history revealed no history of medication or illness during pregnancy. There was no relevant family history.

An extraoral examination of the child revealed surgical scars of a corrected cleft lip, with two small pits in the center of the lower lip. They just manifested as two simple depressions (Figure 1). When the lower lip was compressed, thick mucus secretion was expressed from both the lip pits. Intraoral examination revealed bilateral clefts of the premaxilla and a median cleft of the hard palate. The uvula was completely absent with a submucous cleft of the soft palate (Figure 2). Radiographic examination revealed a diffuse radiolucent defect in the anterior maxilla, suggestive of a cleft, crowding of the maxillary anterior teeth, and a missing maxillary left incisor. All other teeth were in normal developmental stages and there was no abnormality in the skeletal growth of the jaws.

All the teeth with caries were treated appropriately in the child. The child had already undergone surgical correction of the cleft lip and was referred to higher centers for surgical correction of the cleft palate (Figure 3). Meanwhile, the child was instructed to maintain good oral hygiene. The lip pits were also excised and Z-plasty was done to maintain esthetics (Figure 4).

Figure 4. Postoperative picture

Discussion

Lip pits are rare congenital malformations seen on the lower lip, upper lip, or the oral commissure. The condition generally presents as a unilateral or bilateral depression and has a predilection for the lower lip. Lower lip pits are also known as fistula labii inferioris, labial humps, labial cysts, labial fistulae, and paramedian sinuses of the lower lip. These pits are usually circular or oval and generally show bilateral distribution, located on either side of the midline. The unilateral pits are observed mostly on the left side and rarely on the right side. The exact etiology of lip pits is not known. It may result from notching the lip at an early stage of development with fixation of tissues at the base of the notch or it may be due to a failure of complete union of embryonic lateral sulci of the lip. During prenatal development, a fusion of the mandibular arch and sulcus lateralis occurs at 5.5 weeks while the fusion of the maxillary and frontonasal processes takes place at 6 weeks. Probably, a common event may simultaneously disturb fusion in both locations resulting in the strong association between lip pits and cleft lip and/or palate. Although lip pits are generally asymptomatic, in some cases they contain salivary glands. Watery discharge from these pits, especially during mealtime has been reported. Mild cases of lip pits require no treatment. In this report, none of the patients presented salivary discharge during mealtime. However, surgical correction of these anomalies is recommended in more severe cases not only to improve esthetics but

also to remove chronic inflammation and prevention of salivary discharge from lip pits.[1]

The first report on lower lip pits by Demarquay attributed the formation of lower lip pits to the impressions made on the lower lip by the upper central incisors. Most patients tend to adopt this hypothesis even now. According to Kitamura, in a 32-day embryo, the lower lip consists of four growth centers, divided by one median and two lateral grooves. In the 38-day embryo, the lateral grooves disappear, except in the case of impeded mandibular process growth that results in the formation of a lip pit. If a cyst deriving from the epithelial wall communicated with the duct of labial glands, a congenital fistula of the lip is formed. The development of lip pits starts at day 36 of development, CL at day 40, and CP on day 50. The periods of liability of these three tissues probably vary in length and even in sequence, and perhaps they also overlap accounting for the strong association between the lip pits and cleft lip or palate.[2]

The majority of the labial and commissural pits occur without mucus exudation. However, a small percentage may be associated with cleft lip and palate, and therefore not a thorough clinical examination is recommended in individuals with pits to rule out a submucosal cleft palate which may not be obvious to the clinician. Surgical excision of the labial and commissural pits is indicated if the aesthetics of the individual is appreciably affected and exudation of mucous secretions can not be controlled. Surgical excision should include the total removal of the minor salivary glands that exude secretions at the base of the pits to prevent the formation of mucoceles or cysts.[3]

Management of VDWS is mainly focused on the surgical correction of clefts and lip pits. Surgical excision of the labial and commissural pits is indicated if the esthetics of the individual is appreciably affected and exudation of the mucous secretions cannot be controlled. Surgical excision should include total removal of the minor salivary glands that exude secretions at the base of the pits, to prevent the formation of a mucocele or cyst.[4]

Proper evaluation and treatment of VWS along with genetic counseling is important. Care should be taken during the surgical procedure for lip pits, of complete excision of the fistulous or sinus tract, which otherwise may lead to the formation of a mucoid cyst. Patients who do not undergo surgical correction should be instructed about meticulous hygiene care.[5]

More extreme phenotypes in parents tend to produce more extreme expression in their children. However, the lesser expressions of VWS are common and should be actively looked for when counseling families about cleft lip or cleft lip and palate. All the affected parents should be cautioned that they carry a risk of 50% for each child with a cleft lip or palate or both. The potential of embryocopy to detect minor malformations such as cleft lip in early-term pregnancy allows for detection of VWS.[6]

Syndromes exhibiting lip pits other than VWS are PPS characterized by multiple defects of the extremities, face, mouth, and genitourinary system. Other malformations in PPS include webbing of the skin extending from the ischial tuberosities to the heels, cleft palate and/or lip, lower lip pit with salivary drainage, genital anomalies, and synechia or syngnathia. Orofacialdigital syndrome type 1 is an X-linked dominant trait, predominantly in males with striking orodental, facial, digital, renal, and central nervous system abnormalities. Orodental signs include cleft palate, bifid tongue, hypodontia, hypoplasia of nasal cartilages, hypertelorism, median cleft of the upper lip, and lip pits. Kabuki makeup syndrome manifestations include the dysmorphic face, postnatal growth retardation, skeletal abnormalities, mental retardation, and unusual dermatoglyphic patterns. As the hallmark features of other syndromes were not manifested, it was confirmed as a classic case of familial VWS.[7]

Many mutations have been described in VWS patients, and also due to the implication of stochastic factors or modifier genes on the IRF6 function, molecular genetic testing does not seem justified at the moment. Because VWS has a high penetrance and a variable expression, genetic counseling is advised for future pregnancy.[8]

Conclusion

The Van der Woude syndrome is a rare condition the phenomenon of a cleft lip and cleft palate combined in the same pedigree makes it unique. The VDWS should be considered in the differential diagnosis of cleft lip and palate. The dentist may be the first person to diagnose this syndrome, and therefore, should be aware of its variable expressions. A proper treatment plan at the correct time will help to satisfy the psychological and esthetic needs of the patients. Further, genetic counseling is highly recommended.

Abstract

Tooth decayis an irreversible microbial infectious disease among most of the children. It is due to close interaction of bacteria S mutans and sticky high sucrose content food and enamel the outer surface of the tooth. Streptococcus. mutans transferred from mother to her baby during birth. S mutanss also inoculate and survive pre-dentate babies. Early childhood caries starts in the early phase of life, it spread rapidly in high-risk population those who remain untreated progresses rapidly in those who are at high risk, and often goes untreated. ECC outcomes hurt OHRQoL and their family economical status. The tooth decay pattern in toddlers is different from others. It can be recognized easily. There are various types of synonyms used for tooth decay in infants and children. Tooth decay cannot start without any sugary substances like sucrose lactose. Therefore, every dentist and each researcher person gave a prime focus on infant feeding or dietary patterns and feeding practice of children by giving them proper education. Not only the professional but every parent and caregiver has the key role to maintain the oral hygiene to control the disease. There are various types of treatment options for early childhood caries with different types of interventions. It depends on the degree of disease progression tooth decay, child age factor, and mainly with social factors.

Keywords: *Dental caries; Childhood infections; Dental problems; Management.*

Introduction

Tooth decay is an irreversible microbial infectious disease among most of the children. It is due to close interaction of bacteria S. mutans and sticky high sucrose content food and enamel the outer surface of the tooth. Streptococcus. mutans transferred from mother to her baby during birth. S mutans also inoculate and survive pre-dentate babies. S. mutans always break down the sucrose for energy production, make the oral environment more acidic. In the acidic environment, the ph of saliva falls below its critical ph. The low pH of saliva remains for a long period, which directly starts the demineralization of the tooth. Demineralization causes huge loss of mineral of tooth surface and dental caries progression starts.[1]In all countries developed and developing Early childhood caries became the main oral health problem trough the glove.[2]Early childhood caries starts in the early phase of life, it spread rapidly in high-risk population those who remain untreated. progresses rapidly in those who are at high risk, and often goes untreated.[3,4] ECC outcomes hurt OHRQoL and their family economical status.

The tooth decay pattern in toddlers is different from others. It can be recognized easily. There are various types of synonyms used for tooth decay in infants and children,[6]which definitions used to describe dental caries based on the condition etiology, with prime focus on rapidly uses of the nursing bottle. Most frequently used term for dental caries are rampant caries,baby bottle caries, early childhood tooth caries, nursing bottle caries, maxillary anterior tooth caries,[7,8] most of the terminology indicate the etiology of tooth decay among

e-mail: generation.saurav@gmail.com

kindergarten children.[8] Nursing bottle tooth decay in children's teeth mainly linked with the frequency of bottle feeding of children.[9] some dentist called it baby bottle-fed dental caries because of its inappropriate bottle feeding habit.[7,10] In recent years the terminology "early childhood caries" is becoming very popular among every dentist and became a good research topic for every researcher.[8,10]

Early childhood caries terminology was proposed in the year nineteen ninety-four in a workshop conducted by the Centers for Disease Control and Prevention. Its main aim to focus on multiple causative factors that's has a great hand on developing tooth decay.[12] Early childhood caries defines itself as the presence of one or multiple tooth carious lesion, missing tooth, or restored tooth surfaces in deciduous dentition in children less than seventy-two months. Decreased in the percentage of tooth decay in infants and kids in western nations, tooth decay in kindergarten children is a serious problem in every developing and developed nation. Early Childhood caries is considered as a pandemic in developing nation. Tooth decay prevalence among children in a developing nation is around twelve percentage. data from various studies from different countries state that higher tooth decay prevalence is in Africa and Asian countries.[13] The etiology of ECC is multifactorial and has been well established. ECC is frequently associated with a poor diet and bad oral health habits.[14,15]

Microbiological risk factors: The main cariogenic Bacteria is Streptococcus. mutans and S. sobrinus in the presence of sucrose (main fermentable carbohydrate) the pathogenic bacteria s mutans helps in demineralization of an organic particle of tooth structure lead to a cavity. from different studies, it is found that in early childhood caries in children s mutans is the main pathogenic organism percentage of S. mutans in ECC is around thirty percent found from plaque flora. S mutans bacterial colonies always linked with the large carious lesion, white sport carious lesion mainly. Transfer of any pathogenic organism from mother to infant or from caretaker to kids is called Vertical transmission, the mother is the main storehouse from where a kid gets MS. it conforms from old studies where the same bacterial species found from mother and child. The latest technology chromosomal deoxyribonucleic acid pattern givesmore ideas about vertical transmission of bacteria.[16,17] Recent data shows that high sucrose contain liquid diet in a bottle at night is the main risk factor,for developing dental caries but it is not the only causative factor for tooth decay.

Feeding Practices: Unnecessary use or frequent use of baby bottles with a high sugary diet is the main causative risk factor for Early childhood caries. Long term use of bottle with high lactose at night cause tooth decay. Various studies proved that there is a very close link with early childhood caries and nursing bottle feeding and night sleeping with a nursing bottle. Mother breastfeeding provides high immunity to the child and there are very few chances of gastrointestinal infection and respiratory infection to children. Ling term contact and frequent contact of the tooth with sugary milk makes the tooth outer surface porous and suitable for developing dental caries. If the frequency of intake of sugary diet (with fermentable carbohydrate) increases the demineralization process became more than remineralization which causes dental caries. Long term and nocturnal mother breastfeed has a great link with early childhood caries after one year. Due to high and long term sugar intake at night, the saliva amount decreases at night due to the high content of sugar. So for that demineralization exceed from re-mineralizationand the protective nature of saliva reduces.[18]

Dietary Risk Factors. Combination of heavy infection and MS, kids with Early childhood caries have great experience of taking a highly sugary content diet. A sugary diet breaks down very first by S.mutans and converted to organic acids on the other hand in acidic medium demineralization of enamel and dentin occurs. They frequently use baby bottles to increase exposure to fermentable carbohydrates.[19] Good oral hygiene habits have a great impact on children's lifestyle and their economic status. Environmental factors of parents that affect the oral hygiene of children are poverty, social well being, ethnicity, etc.

Prevalence: Early childhood caries is the main oral health problem in every country and it badly affects the small children, little infants, throughout the globe. It has cleared from the epidemiology of dental caries that the prevalence of Early Childhood Caries differs in every population regardless of race, culture, and ethnicity. CDC reported that the caries prevalence of children aged between 2-5 years is around twenty-four point two percent in the USA in NHANES III between 1988 and 1994. It has also found that children living annually highly income families havea low percentage of dental caries as compared to a low-income family. [20,21]

Diagnosis: Early childhood caries identified by a very dull, chalky white sports that follow the path of

gingival margin it progresses very first. ECC in early-stage mostly found in deciduous maxillary incisors. dental caries mainly found in palatal or facial surfaces of the deciduous tooth in all cases. it can be identified clinically with the presence of yellowish or brownish cavity on the tooth surface. In the older age kids whose deciduous tooth has fully erupted to occlusal level, there is no considerable tooth damage found.[22]

ECC or nursing bottle caries has some important features:

1. Tooth decay on the proximal surface of a child less than three years.
2- Dental caries of the primary tooth, missing primary tooth (due to only for toothdecay), or restoration of a tooth in kids between three to five years children.
3. Dental caries index dmft is the same or higher than four years at the age.

ECC prevention:

- There are three types of approaches to the prevention of ECC.
- Community-level- education, water fluoridation
- Professional level- early detection, diet counseling, fluoride
- Home care level- proper tooth brushing technique, proper diet
- Proper training to mothers and caretakers can give excellent oral health education to take care of children's dentition.

Tooth decay cannot start without any sugary substances like sucrose lactose. Therefore, every dentist and each researcher person gave a prime focus on infant feeding or dietary patterns and feeding practice of children by giving them proper education. Not only the professional but every parent and caregiver has the key role to maintain the oral hygiene to control the disease. Proper oral health education has the power to improve oral hygiene and prevent oral health from various kinds of oral diseases. We have to make a habit of maintaining good oral hygiene to protect our oral health from different diseases.

Treatment Plans: There are various types of treatment options for early childhood caries with different types of interventions, it depends on the degree of disease progression tooth decay, child's age factor, and mainly with social factors. It is ideal to give intervention for early childhood caries and take clinical examination it is very essential to ask the date of birth of a child for better results those kids who are in a low level of risk to develop dental caries don't need any restorative treatment. Kids with a moderate chance to develop caries need restoration for cavitated dental caries and preventive acres like flourish varnish for white sport lesion and that need observation for any future progression. High-risk kids need early gic restoration for the prevention of the progression of dental caries.

Pre-fabricated crown places on the restored primary tooth for the protection of the tooth structure. The best treatment for dental caries in the deciduous tooth of small kids is Atraumatic Restorative Treatment. In the process of ART, the carious portion is removed by spoon excavators hand instruments only filled the cavity with Glass ionomer cement. GIC is the best item for the deciduous tooth in the ART process. Atraumatic restorative treatment is a very easy process and it has lots of advantages and reduces the fear of any kind of dental treatment. No need for anesthesia or electronic device needed.[25- 28]

Fixation of Condyle with Delta Plate: A Case Report

Santosh Kumar Subudhi[1], Sthitaprajna Lenka[1], Sanchari Sinha Roy[2], Waseem M. Alam[2]

[1]Professor, [2]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Condyle fractures account for 25-35% of mandibular fractures and deserve special care from the rest of the mandible due to their anatomical distinctions and capacity for healing. Past clinical and biomechanical trials have suggested the use of two miniplates for condyle fracture fixation. Two miniplates allow the proximal condyle fragment to a certain scale, and thus are useful in low fractures. This present case report shows the use of delta-shaped mini plates (titanium) in ORIF of subcondylar fracture.

Keywords: *Condyle fractures; Titanium delta shape miniplates; fracture fixation.*

Introduction

Case Report: Patient came to the department of oral and maxillofacial surgery, Institute of Dental Sciences, SUM Hospital, S'O'A University with a history of restricted mouth opening for one month.

History of present illness: The patient had a road traffic accident one month ago due to a collision with another vehicle. There was no history of loss of consciousness,vomiting or nasal bleed. Bleeding present from left ear.

On examination:

Extra-oral examination: No gross facial asymmetry present. Laceration present in the lower chin region. The left side temporomandibular joint is tender and palpable on the left side of the face.

Intraoral examination: Mouth Opening restricted (21mm). Derangement of occlusion present.

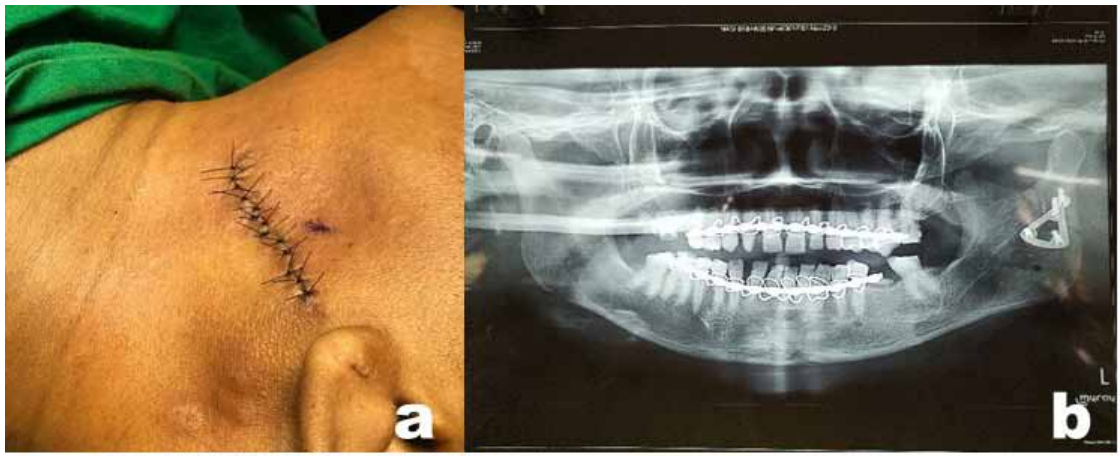

Figure 5a. Closure done with vicryl 3-0 and ethilione 4-0. b. Post op OPG

Radiological examination: To scan accurately for the possibility of fracture of mandible, the utmost2 views are given perpendicular to each other.[1] "Typical radiographic findings in the presence of a condylar fracture are: a)decreased condylar-length, b) presence of radiolucent fracture line, or in cases of overlapping segments, presence of radio-lucent density and evidence of premature contact on the side of the fracture if the radiograph was taken in occlusion with the patient.[1] In 2D axial section we see dislocation with left sub-condylar region. For this patient we had taken an orthopantomogram, an AP view and a 3D CT skull showing dislocation of left sub-condylar region.

Treatment Done: Under all aseptic condition general anesthesia administered via naso-endotracheal intubation. Fracture site exposed via retromandibular incision which was given 2 cm from the angle of mandible. Periosteum is reflected and the fracture site was seen. An IMF screw was placed in the lower ramus and the segment was pulled downward and the distal segment was reduced in its anatomic position and fixed with one 2mm delta plate and four 8 mm screws. Through irrigation was done with normal saline and betadine. Layer by layer closure was done with vicryl 3-0 and ethlione 4-0.

The way to repair condylar fracture is either by open or closed reduction, that often has provoked debate.[2,3] Though various rigid fixations has been identified, this is the most acceptable modality today with miniplates. Miniplate osteosynthesis produces a fixation (rigid) which can easily be adjusted to bone curvature, which involves a basic procedure only. "Choi and Yoo compared the biomechanical reliability of four different positioning strategies (4-screw monocortical miniplate, 4-screw bicortical mini dynamic compression plate, 4-screw 2.4 mm plate, and a double monocortical miniplate) in formalin-fixed corpse mandibles, and considered the double miniplate to be the best.[4-6] A 2-plate modality is easier if there is sufficient bone on both side of the fracture, but fixation with two miniplates might be a more painful treatment than fixation with a single miniplate". 2 miniplates (double-plate technique) is the most effective as they better neutralize the forces of tension/compression and pressure and provide greater stability.[7] The 2 plates are positioned with an some amount of gap between the fracture line and screws to achieve more stability. This drawback was resolved by Meyer et al.'s decision, taking into account the anatomical conditions, to choose a different type of trapezoidal shaped plate. Use of one single resorbable plate is not accepted in condyle mechanically loaded sites where the osteosynthesis has shown to be fragile and low.[8] In the early 1990s the 3D osteosynthesis plate was incorporated in maxillofacial surgery. The benefits are: reduced size paired along with the more rigidity of the plates. Special designed plates like the delta plate or the trapezoid plate are available as an alternative to the modified 2-miniplate technique, and bio-mechanical & clinical trials has shown that such plates require adequate strain neutralization. Thus, such plates offer adequate stabilisation with the benefit of a smaller plate for ORIF of fractures of condyle and sub-condyle. [4]The surface is bent towards the inclination of the mandible in the delta-shaped plate; therefore, the tensile lines and the compressive force distribution extend parallel to

either sides of the plate. "The plate is 1 mm thick, 20 mm long, and 5 mm broad at the top and 12 mm wide at the surface. There is an arm with 2 longitudinally spaced holes at the top of the plate; two more holes in the 2 corners of the base of the plate.[9] Using the new delta-shaped plate for condylar neck fractures has 3 major advantages: I neutralization of the different strains at the anterior, lateral and posterior borders; ii) extra stability offered by a compression miniplate; and iii) a small osteosynthesis plate".[9] The Delta plating device is capable of distributing the necessary loads in every directions. This plate allows for stable osteosynthesis in the mandible's condylar neck area and this form of osteosynthesis can withstand physiological strains inside the injured temporomandibular joint as defined by Lauer et al.[9] He showed, in 9 cases, 2 incisions of risdons & 7 incisions of retro-mandibular were administered to reveal the condyle, found fracture area & repaired using delta plate. All the observed clinical subjects showed excellent stabilization and decrease in the condylar region. Recovery to function was rapid with a brief duration of postoperative intermaxillary fixation. The condyle was medially displaced in one subject, and was displaced out from glenoid fossa. Extracorporeal approach was performed & the head of the condyle was attached to remainder of the ramus. After 2 weeks this individual presented with signs of plate contamination and then the contaminated plate was removed. Fracture of the plate or bending and loosening of the screw are known indicators of either insufficient stabilisation of the fracture or inappropriate reduction of the fracture. We have not found any of these concerns in all the topics tested.[10]Because of the involvement of internal maxillary artery and superficial temporal artery, postoperative edema and hemorrhage was typically seen in the condylar area, in this case the postoperative edema and swelling was considerably less. Just one patient had an prolonged edema cycle in which extracorporeal plating approach was performed. He was prescribed post-operative steroids. Antibiotics and hormones play an significant part. Higher antibiotics were given to all patients. In every cases steroids were avoided except one that involved extracorporeal approach. Postoperative wound infection hasn't happened in any of the cases.[10] Five patients from 9 cases were put in intermaxillary post-operative fixation for a period of 1 to 2 weeks. Within one week of surgery, restoration of function and immediate functional loading are possible. [11]Facial nerve branches, retromandibular vein and parotid fluid can be detected intra-operatively, & also at the same time they should be removed safely to prevent injury to essential structures. For neither of our cases we have experienced any temporary facial nerve palsy. For all nine cases, post-operative follow-up was conducted over a span of six months to one year. Radiographical testing has shown that the osteosynthesis is fairly stable. Functionally stable and well rehabilitated, all patients diagnosed with delta plating device were. Just one patient had plate contamination, and eventually removed the contaminated layer. In our view, condyle fracture reduction is best treated with the current 3D delta plate method, that provides excellent stabilization & neutralizes the condylar region's changing strains.[11]

Conclusions

While separate study agree that closed reduction and immobilization is the treatment of choice for condylar fractures, modification of ORIF usually yields better outcomes. The retromandibular approach has been used as the traditional and favoured approach to the condyle's face. ORIF with 3D plate stabilizes for any sub-condylar fractures is completely important for early functional regeneration.[12] 3D plates are known as having greater stability than traditional mini plates. The geometrical structure of the 3-dimensional disk, that adapts easily to the fracture, provides greater stability and work. The delta plate which was used in our analysis is a titanium-formed non-compression layer. The scale and shape of the plate helps the surgical surgeon to adjust and repair sub-condylar fractures quickly. Revised delta plate with compression holes, trilock system provides more advantages to the new system. This delta plate can also be used in an intra-oral technique, which was aided endoscopically. The risks associated with this plating device are very small, as is the case with all other condyle surgical procedures. After a week of immobilization, early recovery and practical activation became feasible. The condylar fracture handled by delta plate had a good feature and aesthetics on a long-term follow-up. These platelets achieved surgical speed, relaxed adaptation and adequate stability. With this technique, the practical and cosmetic result has proved that this plating device is one of the latest developments in the management of sub-condylar fractures. No special armamentarium was needed as only the plate shape varies, and the holes in the screw and screw are the same as the standard mini plate method. A basic mouth opening procedure and variety of motions without intensive physiotherapy rehabilitated all of our patients at the earliest possible time. Most of the analysis was performed on a small sample size

during this review. For prospective research studies with greater sample sizes will be helpful.

A Portrayal of Changing Oral Condition in Today's World: A Review

Kajal Kiran Sahoo[1], Sudipta Sahu[2], Debashruti Naik[3]

[1]Tutor, Department of Prosthodontics, [2]Tutor, Department of Public Health Dentistry, [3]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

We cannot solve our problems with the same thinking We used when we created them-as stated by Sir Albert Einstien. Today's diverse change in the oral condition of the patient needs meticulous understanding by the dentist of the underlying problem and how to solve it in stipulated time, money, environmental and social condition of the patient. Health care systems worldwide deliver services for diseased and drug addicts but most lack oral health care services. Lack of appropriate settings, valid assessment protocol for conducting oral health studies, and poor collaboration between dental and general health care sectors for the diseased and drug addicts is interfering terribly with the accurate picture of today's situation. Moreover, lack of appropriate policies to improve access to dental services, lack of interest among dental professionals in treating the diseased and addicted persons, and low demand for dental care from these sections is leading to today's ineffective all-around dental treatment.

Keywords: *Oral Health, Oral Hygiene, Oral Diseases, Health Policy.*

Introduction

The later part of the twentieth century saw a massive transformation in oral health. The dramatic advancement in the medical field during the last five decades resulted in more number of medicated elderly persons and drug-addicted youngsters. Though there are remarkable achievements in recent decades in the health sector, millions of people worldwide have been excluded from the benefits of socio-economic development and the scientific advances that have improved healthcare and quality of life. Systems are becoming more complex and people's expectation of oral care is changing dramatically. In developing countries growing number of development organizations, private foundations, and non-governmental organizations are becoming active in the oral health sector.[1]

Diseases Affecting Oral Condition: Prevalent diseases previously are majorly modulated by the present day's food habits, stress, environmental conditions, bad oral habits of chewing tobacco, smoking, etc. The common diseases which affect oral cavity and treatment are Diabetes, Arthritis, Anaemia, Tuberculosis, Leukoplakia, Syphyllis, Bells Palsy, Parkinson's disease, Plummer Vinson's disease, Pemphigus, Nicotinic stomatitis, cleidocranial dysostosis, ectodermal dysplasia, lupus erythematosus, radiation, hypertension, heart disease, kidney dysfunction, thyroid diseases, menopause, epilepsy, etc.[2]

Medications affecting the population: Nowadays because of the invention of newer drugs and newer treatment modalities most dental patients are taking multiple drugs and have a complicated medical history. As older people are leading a longer more productive life even though having cardiovascular, endocrine,

Corresponding Author:
Dr. Kajal Kiran Sahoo
Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: drkajal2@gmail.com

or degenerative disorders they are more likely to seek dental treatment. These patients are challenges to the dentists nowadays. Alarmingly studies show that in a normal dental patient population, 43.1% were taking medications. Out of these 17.4% were taking more than 1 medication. • 14.2% takes analgesics eg. Aspirin, Acetaminophen • 12.1% of women at childbearing age take contraceptives. • 9.4% takes antihypertensives, diuretics, etc. eg. Dyazide • 9.4% takes miscellaneous drugs eg. Vitamin, Antacid, Crocin, etc. which can be bought without a prescription. • 7.6% takes psychotherapeutic drugs eg. diazepam, clonazepam • 6.6% takes hormones including insulin, oral contraceptives, Thyroid hormones, and estrogen. • 4.9% takes antibiotics like penicillin, tetracycline, etc. • 3.8% takes antihistaminics which does not need prescription • 3.1% takes heart medicines eg. Digitalis, Nitroglycerin, etc. • 2% of patients were on hypoglycaemic drugs. [3,4]

Drug affecting the population: There is a definite increase in the number of people misusing illicit drugs including opiates, cannabis, and heroin. This addiction is leading to a distinctive dental and oral profile which would impose a burden of a more customized treatment approach by the dentist nowadays. Drug addiction is leading to damage to many parts of the body as an oral cavity, nasal floor, lungs, liver, brain, and heart. Addicts also suffer from physical, psychological, emotional, and behavioral problems. Injection of a drug can have two problems-Firstly repeated use of unsterilized needles leads to HIV/Hepatitis risk. Secondly, the agents used to dilute drugs leading to bacterial endocarditis.[5]

Oral Health Problems Associated with Opiates

The opiates which are generally used are morphine, Heroine, Synthetic Methadone, etc.

With its use in oral cavity presents with

1. Generalized tooth decay, especially on smooth and cervical surfaces, are common.
2. Salivary hypofunction leading to xerostomia.
3. Burning mouth and eating difficulties.
4. Teste impairment.
5. Mucosal infections.
6. Periodontal diseases eg- Adult periodontitis, Necrotises Gingivitis, etc.
7. Bruxism.
8. Candidiosis
9. Mucosal Dysplasia.

Oral health problems associated with cannabis

The cannabis which is generally used is Hashish, Marijuana, etc. With it uses oral cavity presents with

(g) Increased risk of oral cancer

(h) Dry mouth

(i) Periodontitis

(j) Tartar on tooth

Oral health problems associated with stimulants: The stimulants which are generally used are Cocaine, Amphetamines, Cracked cocaine, etc. Cocaine is different types of damages on the face and oral cavity depending on how the drug is taken. Cocaine itself is very acidic and thus it damages enamel when comes in contact with teeth. With its use oral cavity presents with

1 Local application of cocaine leads to gingival recession.

2 Bruxism is a very common complication, which simultaneously leads to progressive dental attrition.

3 Crack cocaine is the most dangerous as it is smoked. Snorting cocaine leads to damage in tissue in the upper palate leading eventually to the nasal septum perforation, palate perforation, changes in senses of smell, and chronic sinusitis.

4 Cocaine also leads to a movement disorder called transient chorea. This is manifested also spasms of muscles of mastication leading to buccolingual dyskinesia, which looks like a strange smile of the patient.

5 Methamphetamine abusers show bruxism, xerostomia, and rampant caries leading to a condition called MEETH MOUTH. It is a condition of blackened, stained, rotting, crumbling, and falling apart teeth. It has a distinct pattern and of caries on the buccal and cervical smooth surface of anterior teeth. Since these drugs are stimulants, it causes people to clench & grind their teeth due to stress. The patients who struggle with meth addiction crave sugary foods and drinks which leads to more damage or teeth decay.

6. Amphetamines or so-called CLUB Drugs like ecstasy, ketamine, Molly, MDMA also leads to

similar oral condition. All these stimulant drugs cause dry mouth, dehydration, etc. Furthermore, mucosal involvements such as ulcers, vestibular swelling, edema, and necrosis are reported in ecstasy drug users.[6, 7]

Oral Health Problems Associated With Deaddiction:

(I) Methadone is a synthetic opioid widely used in the management of opiate addiction has side effects on oral health.

8. Other drugs used during drug addiction treatment are antidepressants(like tricyclics etc), anti-psychotics(like phenothiazines, etc), and anti-anxiety drugs like diazepam. All these drugs have side effects of salivary hypofunction leading to dry mouth and all negative effects of xerostomia like difficulty in chewing, swallowing, tooth decay, and periodontitis. Halitosis is also a very common finding in these patients.[8]

The role of oral health care (OHC) in addiction rehabilitation/Oral health and relapse: During treatment, drug withdrawal may result in dental pain which interferes with treatment procedure and abstinence and may lead to relapse. In a French case-control study of the impact of illicit drugs on oral health and the use of drugs for toothache, 52% of intravenous heroin users and 21% of other illicit drug abusers admitted using drugs as pain-killers. A similar finding on the use of illicit drugs for toothache emerged from another study. Those quitting opiate use, therefore, require special care for pain control, and this should be integrated into their rehabilitation program. These addiction treatment centers which provide OHC seem to be more successful in promoting both the oral and general health of their patients.[9]

Challenges for dental professionals in coping with the changing oral condition: The variable changes that are occurring in the oral condition nowadays require both objective & subjective evaluation. Objective evaluation is done by clinical examination by the dentist and subjective evaluation is done through series of questionnaire or interview, which provides self-perception of patient-related to self know and oral health and its association with occurrence and relapse of addiction, self-conceived barrios to utilize dental service and oral health-related quality of life. Except for cigarettes and alcohol drug abuse was limited to a small population who tended to be socially disadvantaged. But today drug abuse is evenly distributed across all social strata. There are some barriers to coping with this changing oral condition. They are drug addict's cooperation and compliance in oral health maintenance is not there in most cases. Problems with their long-term follow-up common. The multifactorial and complex nature of drug abuse and addiction behaviors and tendency towards poly-drug abuse among addicts cause difficulties in determining the dependent effects of each group of drugs. Dental professionals also have a negative attitude towards these drug-addicted patients and have an unwillingness to treat them. The addicted patients also have problems with compliances with treatment procedures and fail to accept the suggested treatment plan. Lack of appropriate policies to improve access to oral health services and poor collaboration between dental and general health care sectors serving drug addicts are also an obstacle to effective treatment.[10]

Conclusion

Thus today's diverse change in the oral condition of the patients needs meticulous understanding by the dentists of different drug side effects, drug interactions, the underlying progression of the disease, and how to solve all these through patient dental service delivery.

Advances in Cephalometry in Relation to the Shift in Soft Tissue Paradigm for Orthodontic Treatment Planning

Rashmita Sahoo[1], Nihar Ranjan Sahoo[2]

[1]Tutor, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India, [2]Assistant Professor, Department of Dentistry, MKCG Medical College, Berhampur 760004 Ganjam, Odisha

Abstract

The discovery of imaging and its use in orthodontics is a subject of technology describing biology. Developments in arch-wires,brackets and composites changed the mechanics of orthodontic treatment. The developments in imaging technology have changed the perception of the clinician as well as the patient towards esthetics. The newer imaging technology helps to study the craniofacial growth pattern of younger patients and to know the effect of orthodontic treatment on this dynamicprocess of growth. Earlier, in 20th century, 2-dimensional (2D) radiography was used,but in 21st century, the new 3-dimensional (3D) scanners use less ionizing radiation and give more information than conventional radiographs. This article is a review of the imaging technology used in orthodontic diagnosis and treatment planning from the use of the cephalostat to the introduction of cheap,reduced radiation Cone Beam imaging of 3D cephalograms.

Keywords: *Imaging, video cephalometry, 3D cephalogram.*

Introduction

"Adsanitatemgradusestnovissemorbum"- a Latin proverb means that, "The first step towards cure is to know what the disease is". Diagnosis is a Greek word meaning to discern among, to know differences between: Diagnosis is the determination of the presence or absence of the abnormal or undesired.

In orthodontic diagnosis, during the beginning of 20th century, only plaster cast was used. With the cast, we can get three dimensional view of dentoalveolar region of the jaws, but we are unable to get a picture of the relationship between the jaws and the cranium. To overcome these limitations and to know precisely the interrelationship between the functional components of craniofacial complex, roentgenographic cephalograms were introduced in 1930. Cephalometry had its beginnings in craniometry. Craniometry is defined as "the art of measuring skulls of animals so as to discover their specific differences". Cephalometry is measurement of the head including the soft tissues. Due to varying thickness of soft tissues there result many inaccuracies.

Even though these cephalograms overcome the limitations of the previous diagnostic method, they have got their inherent drawbacks. Despite the drawbacks, cephalometric radiography remains a vital clinical tool. And so, advanced technologies are now being used to overcome the limitations and make the cephalometry as a more acceptable tool in orthodontic diagnosis and treatment procedures.

History: The earliest method used was to assess the facial proportions from an artistic point of view, with beauty and harmony as the guiding principles. An intricate quantitative system which defined the proportions of the human body (canon) was developed by the Egyptians. The top three squares were subdivided by horizontal lines into five parts to draw the face in accurate detail. Indian iconometry studied by Ruelius showed that face height was used as the module of Buddhist proportional systems.[2]

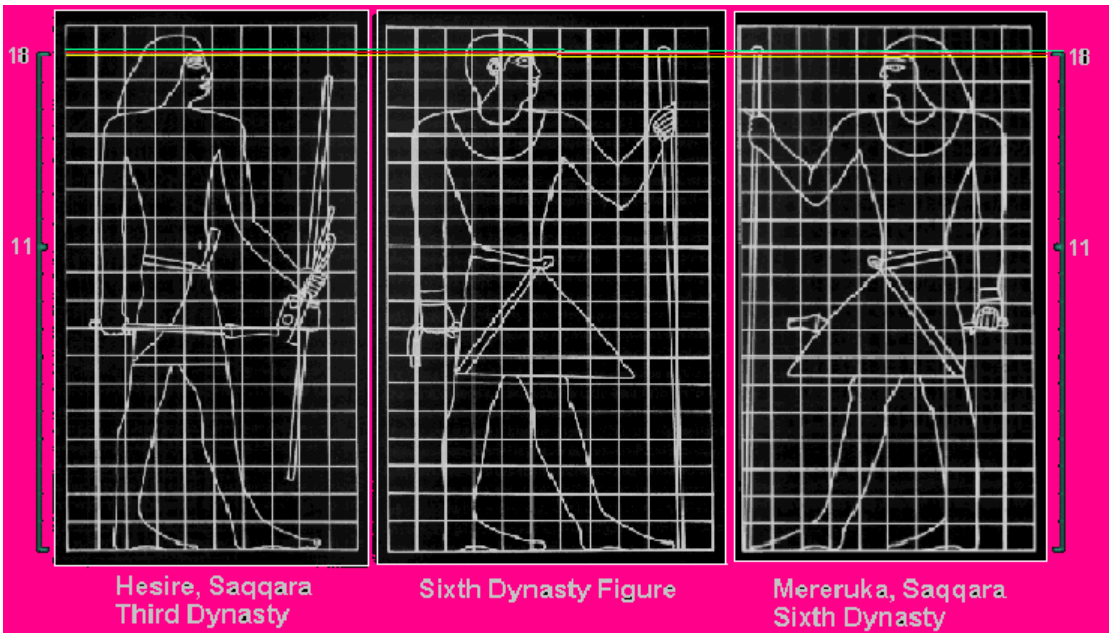

Figure 1. History of Cephalometry

Leonardo da Vinci (1459-1519) studied facial proportions, projected a coordinate system on the face, indicated a preference for 'proportional analysis' and each face was posed in 'natural head position'.[2] Petrus Camper (1722-89) oriented cranium in space horizontally parallel to a line drawn from the center of the acustic meatus to a point below the nose. It is used as the reference line for different measurements used to characterize evolutionary change in facial form and aging. Spix (1815) modified the Camper horizontal as a line from the prosthion tangent to the occipital condyle, but the face was rotated upwards yielding slightly greater prognathism.[3] Retsiusintroduced the terms prognathic and orthognathic where the angle between the horizontal line and nasion- prosthion line was used to determine the facial type. Roentgen (1895) discovered the X-rays which revolutionized the dental profession. Pacini and Carrera (1922)first described a method for standardization of head radiography by using a large fixed distance from the x-ray source to the cassette. Hofrath and Broadbent (1931)both developed a method for standardization of radiographs by fixing a constant focal-spot to object distance & a constant object to film distance. They used special holders the 'cephalostat' to hold the head in position.[4] Krogman and Sassouni (1957) introduced the term roentgenographic cephalometry for measurement of the head from bony and soft tissue landmarks on the radiograph.[4]

Uses Of Cephalometry:

1. Growth and Development: The first and major use of cephalometry is to appraise the growth and development. With the cephalometrics, the orthodontists can time his mechanical procedures to coincide pubertal growthspurt sand predict with some degree of accuracy what the end result will be.
2. Craniofacial Abnormalities: Cephalometrics aid in diagnosing various craniofacial abnormalities like impactions, congenital absence of teeth, cysts, supernumerary teeth, tonsillar and adenoid tissue, cleft lip and cleft palate and mandibular prognathism etc.
3. Facial Type: Sometimes the patients with clinically excellent occlusions will be having difference in facial and dental components Cephalometrics is useful in gaining knowledge about the compensations.

Two important relationships decide the facial type:

I. Position of maxilla anteroposteriorly in the face with reference to the cranium.

II. Relation of mandible to maxilla

4. Case analysis and Diagnosis There are three basic components a Cephalometrics analysis

I. **Skeletal Analysis:** It includes facial type anteroposterior apical base relationship.

II. **Profile analysis:** It is primarily an appraisal of the soft tissue adaptation to the profile of lip size, shape and posture; of soft tissue thickness over the chin; of nasal structure contour and relationship to lower face.

III. **Denture analysis:** It is an appraisal of tooth relationship with each other and with their respective bony bases.

5. Progress Report: Serialtracings offer much more information on developmental changes and on stability of orthodontic accomplishment. Usually, it is recommended to take the cephalograms for every three to four months.

6. Functional Analysis: For the functional analysis, the following cephalometric records are recommended.

I. Cephalogram in postural resting position, initial tooth contact and occlusion used to view the amount of interocculsal clearance and path of closure.

II. Wide open mouth cephalogram used to view the outline of the condyle

III. Cephalogram in end to end bite or Incision used to analysis the curve of free and amount of space between the posterior segments when the incisors in the contact.

IV. Phonetioncephalogram used to show the tongue and soft palate position and may assist the speech therapist.

V. Special view with barium, Iodochloral or other radio opaque media to determine the soft tissue function. They are particularly useful in cleft lip, cleft palate patients helping to analyze velopharyngeal function. Radio opaquing paste over the profile will assist in visualizing the soft tissue outline which is useful in cephalometric profile analysis.

Advantages of Conventional Cephalograms

I. Anteropostero and Vertical jaw discrepancy can be diagnosed with cephalometry.

II. The jaws are related to cranium only with the aid of cephalometry.

III. Predictions of growth and treatment outcome are made possible with cephalometry.

IV. Cephalometry is an important tool in assessing the growth and development and it is useful in research field.

V. Diagnosis and treatment planning in the field of orthodontics is improved to a significant level with the aid of cephalometry.

Disadvantages of Conventional Cephalograms:

I. Cephalometry is two dimensional; we are viewing the three dimensional objects in a two dimensional image where there will be uneven magnification of structure.

II. Identification of landmarks is difficult; there is always intra and inter examiner discrepancy in identifying the landmarks.

III. Conventional cephalometry is time consuming because of the dark room processing, time taken for identification of landmarks and construction of planes and then performing the cephalometric analysis.

IV. Difficulty in merging these cephalograms with the presents developing 3D imaging techniques.

V. Double registration of points is not possible

VI. Storage of cephalograms demand sufficient space and staff.

VII. The orthodontist finds difficulty in communicating the patient regarding the diagnosis & treatment plan.

VIII. There is no room for the patient to take part in the treatment plan processing.

Need for Development: Necessity is the mother of inventions. Three basic necessities in the field of orthodontics, that evolved in the 21st century required developments in conventional cephalometry. They are:

1. The soft tissue paradigm
2. Shift from paternalistic approach to autonomy
3. A significant development in understanding of inherent errors and drawbacks in conventional cephalometry.

1. The Soft Tissue Paradigm: The twentieth century was mainly dominated by the Angle's view, i.e. the 1st aim of orthodontic treatment was to achieve the dental occlusion and the 2nd aim was to correct skeletal jaw relationships. In that view the soft tissues were thought to be taken care by themselves. When the hard tissues were correct, the soft tissues

also were presumed to be correct and no treatment was needed for them. Unfortunately, this is not happening in all cases, especially when the teeth are displaced to a good occlusion without correcting the skeletal problem.[4] In the soft tissue paradigm, the 1st aim of treatment is to obtain the best possible adaptation and proportions of the soft tissues and the 2nd aim is functional dental occlusion. So, to incorporate soft tissue goals in diagnosis and treatment planning conventional cephalometry needed modifications and innovations.

2. **The Concept of Autonomy:** Diagnosis now has changed according to the functional and psychosocial ramifications of dentofacial deformity. Similarly, the treatment planning which has become a more interactive process to set up the priorities, between the patient and/or parents and the orthodontist. The ethical understanding of the doctor-patient relationship has changed. Previously the orthodontist chose the preferred treatment plan for the patient (paternalistic or father-like approach), and the patient (or parent) accepted or rejected the plan, with little room for consideration for alternatives. Today the orthodontist is expected to outline the patient's problems, use inputs from the patient to establish priorities in dealing with the problems, present reasonable treatment alternatives, and explain the risk-benefit considerations of each alternative, including the option of no treatment.

In the past decade, technology that facilitates communication with patients has been developed, particularly computerized graphic imaging to permit visualization of the facial effect of treatment before final treatment decisions are made. This technology and the personal interaction it promotes allow the orthodontist to "design the face first and measure what is needed to get there". In designing the face the patient is now given the chief priority. This approach is called Autonomy. Patients do not understand cephalometry and when cephalometry changes are shown along with the soft tissue changes the patients understand the scenario better.

Advances in Cephalometry: The advances in radiography which in turn revolutionized the conventional cephalometry in great extent. These are to be dealt under the following headings;

1. Digital radiography
2. Digitization of conventional cephalograms
3. Digital cephalometry
4. Computerized cephalometry
5. Video cephalometry
6. 3-dimensional cephalometry

1. **Digital Radiography:** Digitization of radiographs has been widely used in medicine since long time. But in dentistry, its use started in 1980s after the development of intra oral sensors. Unfortunately, it could not take extra oral radiograph like the panoramic and cephalometric image. So, its use became limited. Again, the development of low-cost, time saving, intra- and extra-oral digital radiographic technicand increased use of computer, has made digital imaging a major alternative to standard film imaging.

It became more advantageous both for the orthodontist and the patient in many aspects like the ability to gain cephalometric analysis and superimposition immediately on the chair side computer, can manipulate the images to aid diagnosis and patient motivation, decreased radiation exposure, and the ease of storage.

Principles:

Conventional Imaging: Standard intraoral film usually contains silver halide grains which are sensitized on exposure to x-ray photons and turned to black in the processing. Here the radiographic film acts both as the radiation-detector and the image display.

Digital imaging: In digital radiography, pixels or small light sensitive elements are used. These pixels are arranged in grids and rows on the sensor and are of different shades of grey according to the amount of exposure. Here the radiation detector (sensor) and image display (monitor) are different.[2]

Image Acquisition:

Indirect acquisition: In this method a conventional radiograph is scanned using a flatbed scanner with a transparency adaptor, or by using a charge-coupled device video camera to produce a digital image. This image can then be manipulated with the help of different software packages.

Semi-direct digital imaging: A photostimulable phosphor storage plate (PSP) is used for the image production. It emits light when put in the laser scanner after exposure to produce the desired image. The scanner stimulates the phosphor plate and stores a record of the

number of light photons detected. Helium-Neon lasers with wave length of 600nm are commonly used. The plate should be scanned as early as possible to prevent any loss of data, though it can store energy for a longer period. Then the plate is exposed to view box light to clear the latent image.

Image plates are of similar size in comparison to conventional films and come with disposable plastic barriers. Image plates are reusable and can be reused for thousands of exposures provided there are no surface damage.

Direct Digital Imaging: In this method the image is acquired using a Charged Coupled Device, Complementary Metal-Oxide Semiconductor, or other Electronic Device. The sensor used is a charged coupled device (CCD) but it can't store information and should be connected to monitor. The CCD contains silicon crystals and are arranged in a lattice which converts light energy into an electronic signal and the image is visible in the monitor.

The main advantage of this system is the gain in time as the image is directly visible on the computer monitor immediately after the radiation exposure. Earlier the sensors size was very small and were unable to produce the required image but recently the size of the sensors are of similar to conventional film sizes.

Extra-oral digital imaging: Both direct and semi-direct digital imaging system is available for extra oral imaging but the direct system is very expensive and required extra armamentarium. So semi-direct digital system (PSP method) is widely used. Naslund et al. studied the effect of dose reduction obtained with PSP on the identification of cephalometric landmarks. They found that even if the dose reduced up to 75% it did not affect the localization/identification of cephalometric landmarks.

Merits of Digital Imaging:

1. **Dose reduction:** Up to 90% dose reduction reported by some authors as compared to conventional E-speed films in the diagnosis of caries.
2. **Image manipulation:** By using the software provided by the manufacturer the image can be manipulated according to the need. The following can be manipulated:
   - **(a) Contrast enhancement:** to compensate for over or under exposure.
   - **(b) Measurements:** by using digital callipers, rulers and protractors for image analysis.
   - **(c) 3-D reconstruction:** to reconstruct intra- and extra- oral images.
   - **(d) Filtration:** by the addition of filters to the airspace around the face
3. **Time:** Much time is saved as the image can be seen immediately after exposure.
4. **Storage:** The images can be stored in CD/DVD/ HARD DISK memory for a quite longer period of times.
5. **Teleradiology:** The digital image file can be compressed to reduce the size of the memory and can be shared by internet or other electronic medium.
6. **Environment friendly:** No chemicals are used for developing the images. Both CCD and PSP plates can be used for thousands of images.

Demerits of digital imaging

1. **Cost:** Costlier in comparison to conventional system of imaging.
2. **Sensor dimensions:** Earlier CCD size was bulky to position it correctly but now conventional film size sensors are available.
3. **Cross-infection control:** As the same sensor is used for many patients, there is every chance of cross infection if proper asepsis is not maintained.
4. **Medicolegal:** Image can be manipulated for fraudulent purpose. So,different manufacturers have developed software like 'audit trails', to track and recover the original image.

Digitization of Cephalograms: There are three method of cephalometric radiographic analysis.

1. Manual tracing and direct measurement
2. Direct computer digitization
3. Indirect computer digitization

1. **Manual tracing and direct measurement:** The cephalometric radiograph is traced on an acetate tracing sheet with the help of pencil. Then measurement of required angles and distances is done for different analysis with the help of ruler and protractor.

2. Direct computer digitization

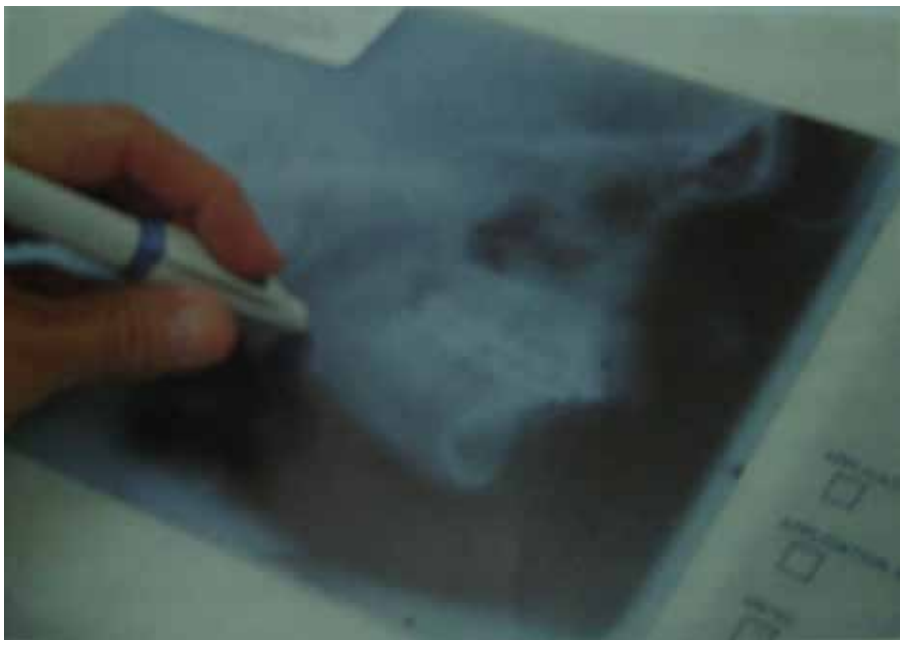

Figure 2. The radiograph is placed on a digitizing tablet and the landmarks are marked with a potentiometer which is electronic pen or "Cross hair" cursor.

Advantages of direct computer digitization: It allows the clinician to identify points directly on the film in the conventional manner, but relieves him of the tedious task of measuring lines and angles. The direction of development and improvement of technology is to programme the computer to identify the anatomy and point which relieves orthodontist of the task of identifying this structures themselves. This might be accomplished through the use of a scanner frame grabber to acquire the cephalometric image for computer storage and analysis. Moustafa et al gathered cephalometric radiographs with a video camera & frame grabber and described software for the detection of soft tissue contour and automated hard and soft tissue landmark location, which they reported to be as reliable.[5]

3. **Indirect computer digitization:** The image is stored in the computer through a video camera (or) scanner or through digital radiography. Then it is displayed on the monitor to digitize by a 'mouse' or electronic pen.

The future of digital radiography: In the current digital world, everything is moving towards digitization and to work almost paper free. Now patient records, photographs, radiographs, and study models can be stored digitally and can be shared online for consultation or discussion. It is always important to accept the new technology and used wisely to improve the patient care and save time and energy in clinical practice.

Computerized Cephalometric Systems:

Computerized cephalometric have two components.

1. Data Acquisition
   - Through
   - ionizing radiation & digitizer
   - sonic technology with microphones
2. Data Management-Various analyses, predictions can be done in those data with the use of different computerized cephalometric systems.

Available Computerized Cephalometric Systems: There are a lot of computerized cephalometric systems are available. These include different software programs which use one or more of the cephalometric analyses, comprehensive hardware and software packages.

1. **Jiffy Orthodontic Evaluation:** Rocky Mountain Orthodontics was the first to provide computer-aided cephalometric diagnosis to the dental profession in late 1960s. Then they developed a new software package known as JOE (Jiffy Orthodontic Evaluation). JOE is a static analysis programme. JOE generates tracing of lateral and frontal

Cephalogram, do the measurements for Ricketts, Jarabak, Sassouni-plus, Steiner and Grummons analysis.Thus, generates the amount of deviation from norms and the number of orthodontic problems.

In 1975, Greenberg and Johnston tested the accuracy of the RMDS (The Rocky Mountain Data System) and found it to be equal in accuracy to estimates using constants from an independent growth sample.[2]

2. **PorDios:** PorDios (Purpose on Request Digitizer Input Output System) is a cephalometric system which is very easy to manipulate according to the need of the individuals.

   PorDios can correct the measuring problems if any in the two dimensional cartesian co-ordinate system. It has a library of mathematical procedures (both angular and linear) for arranging and estimating projections and points.

   PorDios works with a digitizer in normal way, and capable of working with Scanner and Video camera also. It can perform different cephalometric analyses, including Downs, Steiner, McNamara, Ricketts, Tweed, Bjork, Burstone, and Coben and can produce occlusograms from photocopies of dental casts.

   PorDios has built in calculations for showing any discrepancies from the norms. The user can change the standard deviation and mean values for different ethnic groups. The main system can alter the orientation of a picture in order to have the profile looking to the left or right side of the screen. It is available in different languages like English, German, French, Italian, Spanish, Danish and Greek.[1]

3. **Dentofacial Planner:** Dentofacial Planner is a software used in diagnosis & treatment planning for orthodontics and orthognathic surgery, introduced by Dentofacial Software Inc, Canada.

   The Software is divided into orthodontic subsystem and Surgery subsystem. The skeletal and soft tissue regions can be manipulated by both the subsystems.

   Orthodontic subsystem is cando superimpositions,facial growth prediction, simulate the tissue effects of usingorthopaedic and orthodontic appliances. The programmehas the pre-programmed analyses like Steiner, MacNamara, COGS, Downs, Ricketts, Grummons, Harvold, Legan and Jarabak.

   The surgery subsystem estimates the skeletal and soft tissue effects of orthognathic surgery and create a so-called Surgical Treatment Objective. Dentofacial Planner has facilities of displaying a treatment planning tracing superimposed over the load-state tracing, an option for reverting the tracing to its state at load time, CO-CR registration of the mandible, whichhelps in customization of sections for tempomandibular joint tomograms for each patients by means of analyzing a sub-mental vertex x-ray.

4. **Quick Ceph Image:** Quick Ceph Image is a software package designed to do cephalometric analysis and mapping. There are thirteen different types of analyses can be doneby this programme namely Ricketts, Steiner, Jarabak, MacNamara, Downs, Iowa, Roth, Burston, Sassouni, Frontal and SMV and Model analyses like arch length & Bolton discrepancies.

   Other functions this programmeare CO-CR conversion, prediction of facial growth, Steiner box for arch length discrepancy, treatment simulation for both orthodontic and orthognathic cases and superimpositions.

Quick Ceph Image can take both intra- and extra-oral pictures using a video camera and can store them.

Advantages:

1. Curvature in cephalometric lines can be accurately edited.
2. Performs orthodontic and surgical movements in single window.
3. Integrates Model Analysis Measuring ALD: Bolton discrepancy.

Drawbacks:

1. Requires high-resolution digital cameras
2. Optical disc storage preferred.
3. Expensive.

Schwartz (1993) evaluated Quick Ceph Image diagnostic system and found that computer generated surgical prediction tracing was 22% greater than the outcome. Lew, using Quick Ceph found that computer generated soft tissue prediction were accurate except in the lower lip area.[2]

5. **The DigiGraph:** The DigiGraph is a product of

Dolphin Imaging Systems, USA. It is a combination of video imaging and three-dimensional sonic digitizing. Spiro J. Chaconas, G. A. Engel, Marc S. Lemchen and Anthony A. Gianellyintroduced it to the Orthodontics in 1990. [6-8]

The DigiGraph Work Station is a unique device that allows the clinician to perform non-radiographic cephalometric tracings and analyses, video imaging, and treatment planning, including manipulation of the patient's tracing overlaid on the video image. It also takes facial, intraoral, and model photographs. It is capable of generating a 2-D or 3-D facial analysis. The system contains monitor, keyboard, RGB video camera with light source, a sonic digitization probe with receptor microphones and a head holder. With the DigiGraph, any point can be located in three planes of space.

Figure 3. DigiGraph.

The machine has the following capabilities:

1. A landmark can be identified as point in three dimensions;
2. A cephalometric analysis can be made independently of the head position;
3. Neither parallelism of the x-ray in the midsagital plane nor the symmetry of anatomic morphology between left and right sides is necessary (Lim, 1992).

Advantages of using DigiGraph:

The DigiGraph Work Station is a powerful clinical tool that offers advantages in a wide range of orthodontic activities:

1. **Non-Radiographic Cephalometrics:** Lateral and frontal cephalometric tracings and virtually any set of measurements can be produced in moments without radiation. Progress records can therefore be taken as often as desired. Tracings from different treatment stages can be superimposed and manipulated on the screen.
2. **Video Imaging:** Live patient images can be displayed on the computer screen. A non-radiographic tracing can be superimposed over the corresponding facial image, giving the practitioner and patient the opportunity to see the tracing and facial soft tissues together. Live intraoral and dental cast video images can also be displayed and recorded for future reference. Paper or photographic copies can be generated in second, and images can also be stored to be recalled at any time.
3. **Treatment Planning:** The orthodontist can alter any screen image, using computer "cut and paste" procedures, to derive a Visual Treatment Objective. As the clinician modifies the facial

image, the superimposed cephalometric tracing and measurements change correspondingly.

4. **Patient and Parent Consultations:** During a patient's initial appointment, the staff can obtain all records within a few minutes. The orthodontist can then evaluate the data and be fully prepared for an immediate consultation.

6. **The indigenous system- Digi -Ceph:** Digi-ceph is an advanced system for computerized cephalometric digitization, automatic analysis, plot superimposition, storage and retrieval. This system has been developed by Department of Dental Surgery at the All India Institute of Medical Sciences, New Delhi with the help of Center for Biomedical Engineering, IIT, New Delhi.

This advanced system is capable of producing 13 cephalometric analyses following digitization of the cephalometric landmarks either directly in cephalogram or indirectly on the cephalometric tracing. User can create his own analysis. The output data shows values and their comparison with the selected Indian ethnic group.

The software has 10 data banks (one temporary and 9 permanent). The temporary data bank can be used for casual information, while other data banks 0-9 can be used for different users or can be used for different modalities of treatment. The data can be retrieved even by partial information about the subject. The system has been in use at AIIMS since 1990 and is being used for routine case analysis and research work that involves cephalometrics.

Video Cephalometry: By using video imaging technology orthodontist can take both frontal and profile images and manipulate them to provide anesthetic treatment goal. In orthognathic surgery case, patients can visualize what they will look after the treatment which helps them motivated for the surgery. The video image looks more realistic than the conventional photograph simulation in which gaps in between photo cuts will be there and also dental movements can't be simulated.

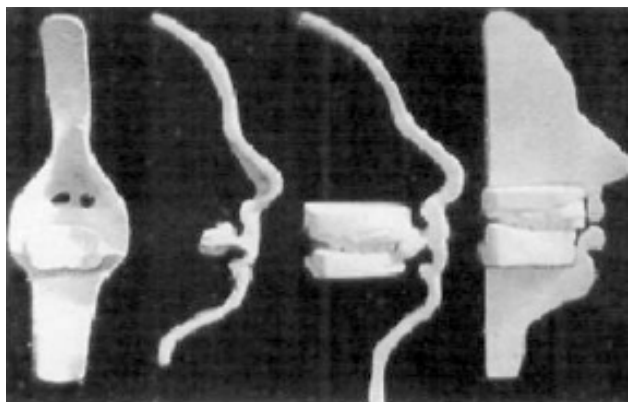
Esthetic awareness and videoimaging: Video imaging is the newer technology which gives more realistic simulation of images for the esthetic point of view. Its use in the treatment planning will be of great help in modern clinical practice. Studies shows thatmore and more patients are listing esthetics as a major reason to go for surgical treatment. So, the esthetic parameters would be the major factor in satisfying the patient in surgical treatment cases.

Holdaway thought "we should determine beforehand that the proposed orthodontic treatment will not result in adverse facial change", so soft tissue analysis is more important. The orthodontic treatment planning using video cephalometry will have better visualization of the facial response to the dental/soft tissue manipulation. So, the clinician can test different treatment plan before deciding the final one. Video cephalometry can quantify the osseous or dental movements of the treatment plan more accurately to reduce the guess. But it needs a lot of research and understanding for the application of this technology. In adolescent patient the complexity of growth prediction of both hard and soft tissues greatly complicates the predictability of VCD outcome. Hence judicious use of this technology in this type of cases will be helpful. But in adult cases, video cephalometric planning will be more predictable because of the completion of the growth of the tissues.

Three-Dimensional Imaging:

History:

- Van Loon in 1915 proposed the necessity of a 3 D system to define the relationship of dentition to the face and for treatment planning. So, he made a plaster cast of the face and the labial surface of maxillary incisors to orient the plaster cast of the dentition thereby creating the "face dentition".



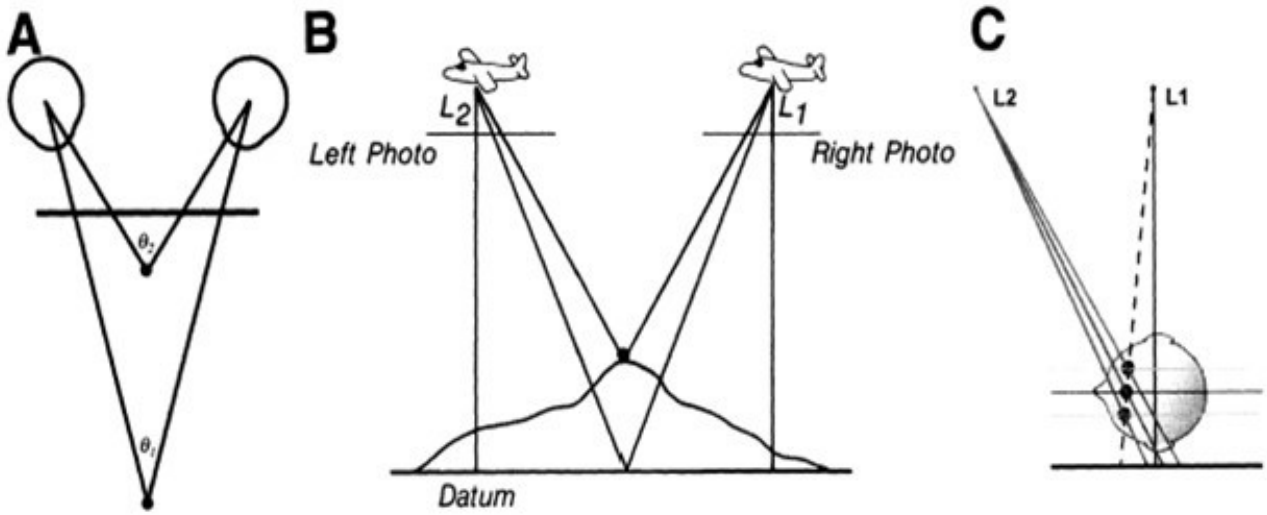


Figure 4. Face dentition

- Simons [1922] introduced gnathostatic models
- Baumrind and Moffitt proposed "coplanar cephalometry". Two images taken with the x-ray source in the same plane but in different location, but patient in same position.9,10
- Cutting et al proposed "biplanarcephalometry".

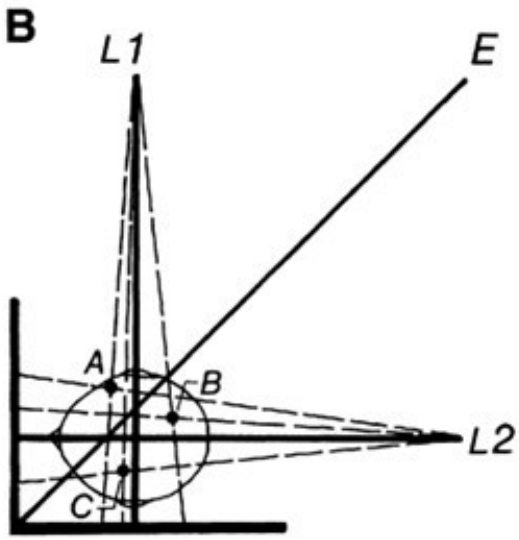

Figure 5. Biplanarcephalometry; Biplanarcephalometry

Two images taken with the x-ray source right angled to each other. Film cassettes right angled to each other but the patient in the same position.

Cephalometrics is a three-dimensional entity. Broadbent and Bolton,since their introduction of the cephalostat, had described about the role of coordinating the lateral and frontal (PA) cephalogramsto get a distortion free craniofacial image. By placing the films in position with respect to the head, if we draw lines from the x-ray source to individual landmark of either film as threads in space, thenit will look like a pair of pyramid of thread, intersecting at right angle throughout the inner space of the patient's head (Fig. A). If both the films are joined with the corner, they meet each other and flattened into one plane, then each thread will flatten to the side of other film with certain distance (Fig. B). The Orientator is the diagram of the flattened threads. On superimposition over the abutted pair of films, the points in each film that correspond to any particular locus in the other can be visualized.

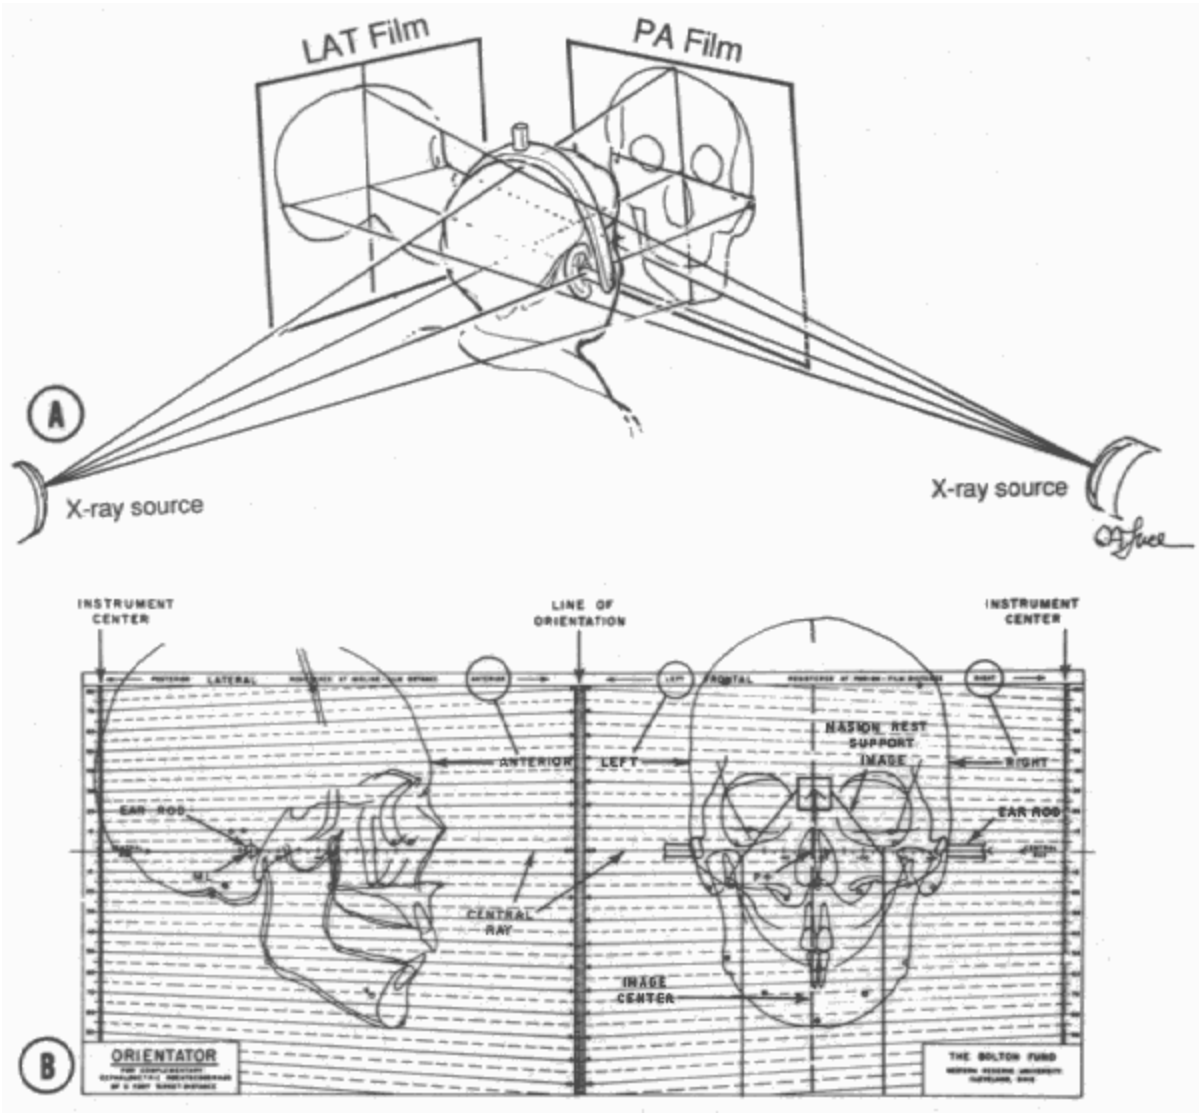

Figure 6. Orientator

Broadbent and Bolton used this to correct the distortion arises due to the spread x-ray beam. The principle of the Orientator then becomes identical with that of one standard photogrammetric tool for this purpose, the ray intersection method.

Cone Beam Computed Tomography (CBCT): CBCT was firstused indentistry in the United States between 2001 and 2004. The initial machines were providingonly a one-to-one, 3D view of the patient's head but the cost and radiation was more. But due to the evolution of a new technology,several CBCT manufacturers come with a combination of partial rotation around the patient's head and pulse technology. A CBCT scanner wasdeveloped which takes a 3D image with lesser radiation than a panoramic radiograph.[11]

Currently, the treatment planning has changed and giving more stress to soft tissues and the facial profile as we are moving from 2D to 3D imaging. This change is possible due to introduction of conebeam computed tomography (CBCT), which captures 3D images in short time and with a very less amount of radiation.[12,13] Images from conventional (fan-beam) CT and CBCT can be combined to create 3D models of the cranio-facial skeleton, the teeth and the soft-tissues.[14-16] By placing these models into the neutral head posture (NHP)[17-19], we can now convert them into "3D cephalograms" if taken at a fixed distance from the subject with the subject's head in a cephalostat.

CT-based 3D cephalograms have resulted the development of 3D cephalometric analyses.[19-25]

However, the problem of the unreliability of internal reference systems and the lack of tools to assess and measure symmetryin some 3D measurements needs to be addressed.

Conclusion

As we begin the millennium, it is time to look at the technologies that may help clinicians provide better patient care. As computer technology has become more sophisticated, it became possible to combine the benefits of the Cephalometry, patient's photographs, study models into one diagnostic practice as well as an effective way to improve patient-parent relationship, and practice management.

There is also potential to remove much of the human errors by using computerized treatment simulation in clinical practices having some imaging skills. For this reason, there have been developments to use computer vision and robots to assist in complex surgeries. Treatment effects could be monitored much more accurately in these vein clinical problems may be revisited to determine if our knowledge based on to dimensional records is accurate.

While there is room for growth in cephalometry, particularly in videoimaging, frontal imaging, 3-D imaging, database generation, quantified studies on accuracy of prediction and the integration of videoimaging & 3-D imaging into clinical practice, these diagnostic and treatment planning aid has clear utility. There is substantial evidence that these technologies offer the practicing orthodontist advantages in following areas:

- Provides the graphic method of communication with patients that can overcome the deficiencies inherent in verbal description of treatment goals and/or outcomes.
- All parties including doctors and patients can be involved in making treatment decisions.
- Improvement in quantification of treatment plans, particularly in the area of orthognathic surgery. With coordinated videocephalometric technology, the surgeon can visualize a plan and have the computer integrated records provide a quantified plan to take to the operating room.
- The use of images in communication with other professional enhances the communication of the problems present and development of potential solutions.

All these advantages due to the advancement in the cephalometry make this diagnostic tool still vital in the field of orthodontics.

Essentials of Oral Carcinoma: A Review

Sashikant Sethy[1], Radha Prasanna Dalai[2], Sourav Chandra Bidyasagar Bal[1], Asima Biswal[3]

Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), [3]Private Practitioner, Bhubaneswar, Odisha, India

Abstract

In recent periods Oral carcinoma has become a highly significant threat to whole public health in the world and, specifically for dentists. Oral carcinoma comes within the top ten rankings among all carcinoma in the world. lots of research work is going on about the carcinoma, after that prognosis rate is not so impressive to date which is going to be a great challenge to medical science. Oral squamous cell carcinoma can be represented as "natural course", which originated from non-aberrant keratinocytes cells, with history of long term exposure to a various stimulus that breaks down homeostasis process of it, Leads to hyperplasia, dysplasia in terms of various degrees, carcinoma in situ with lots of clinical oral manifestations. This nature course offers a roadway for various research approaches in medical science. The very early recognizable clinical alteration that can any epithelium on his path to creating an Oral squamous cell carcinoma is predominantly the generation of malignant fatal disease, like leukoplakia, lichen planus, erythroplasia are most common.

Keyword: *Oral carcinoma; Public health challenge; Management, Medical research.*

Introduction

In recent periods Oral carcinoma has become a highly significant threat to whole public health in the world and, specifically for dentists. Oral carcinoma comes within the top ten rankings among all carcinoma in the world. lots of research work is going on about the carcinoma, after that prognosis rate is not so impressive to date which is going to be a great challenge to medical science. By this paper, we are going to high light the causes, histologic concept which will helpful for future researchers. Cancer of the oral cavity is malignant and develops from the upper and lower lip. Maximum oral cancers are squamous cell carcinoma because more than ninety percent of oral carcinoma are histologically originating from squamous cells.[1] Various types of differentiation found in oral cancer and the metastasis lymph nodeare present most of the time.[2]

Epidemiology: Carcinoma of the oral cavity is 2 to 3 times more in males than females in the maximum population throughout the globe. Data from all around the world says, all types of carcinoma in the oral cavity and pharyngeal region come and together represent the 6th most common carcinoma all around the globe.[3] As per the report of IARC incidence oral carcinoma of vermian lip border, tongue, the floor of the mouth, buccal mucosa, salivary glandare high three lakhs diagnosed cases mortality rate is about 1.5 lakh annually. The incidence of oral carcinoma in south Asian countries is high in countries like Pakistan, India, Sri Lanka. A high incidence of oral cancer is found in some parts of Europian countries like Hungary, Slovakia.[3] Oral carcinoma prevalence varies as per the Human Development Index of the UNDP. As per the HDI index, prevalence is high in a developed nation.[3]

Definition: Carcinoma of the oral region most of the time is highly malignant which develops commonly from the lower lip, upper lip buccal mucosa, and tongue. Most often it arises from the squamous cell so-called as Oral Squamous cell carcinoma because in the oral cavity, ninety percent of carcinoma this carcinoma has

various levels of differentiation and metastasis of the lymph node involvement is there most of the cases.[2]

Risk factors: Carcinoma of the oral cavity can be preventable. The use of smoking and smokeless tobacco and consumption of alcohol is the main risk factors for developing oral carcinoma, consuming them all simultaneously has the power of electric effect to develop oral cancer[4,5] according to the report of IARC in the year 2007, snuff uses in smoking tobacco has a carcinogenic effect,it can cause pancreatic as well as oral carcinoma.[6] The chances of developing oral carcinoma are three to four times more in smoke tobacco users as compared with non-users.[7] The chance to develop oral carcinoma is thirty-five percentage less in population those people who stop smoking for more than 4 years ago than the people who are current smokers, and not higher in population with no smoking tobacco use evidence for since twenty years when compared with nonsmokers or non-smokeless tobacco users.[8] An environment in which smoke tobacco uses is more is also a high risk; the risk for carcinoma in the oral cavity is more than eighty-seven percentagehas higher chances of developing carcinoma. The use of smoking tobacco and smokeless tobacco made the immunity power of our oral cavity very weak and made the road to develop mild to severe form of gingivitis, periodontitis, and carcinoma of the oral cavity.[9,10]The smoke generated from smoking tobacco has various elements that develop cancer and these contain has various groups like nitrosamines, carcinogenic aromatic amines. nitrosamines, aromatic amines are called as pre-carcinogens, which must suffer coordinated alterations by oxidative enzymes, so that the final product becomes poor in electrons]. Like oxidation, enzymatic metabolism can also produce carcinogenic products, like free radicals, which has unpaired electrons that make them extremely reactive being capable of promoting mutations by complex mechanisms.[11] Tobacco use makes direct interaction oral epithelium to free radicals of oxygen and nitrogen that can affect antioxidant defense mechanisms. Free radicals like ozone, hydrogen peroxide,hydroxyl radical, ROO,NO are most commonly found in the oral precancer lesion and cancerous lesion.[12]

Alcohol: For developing oral carcinoma alcohol has a great hand. it has a local effect as well as a systemic effect. Alcohol (ethanol) increases the permeability of oral mucosa, which absorbs the lipid particles of oral epithelium. Which latter causes epithelial atrophy and alcohol also interfere with DNA synthesis. Alcohol has a direct effect on decreased salivary flow. It also affects the liver's general function to deal with toxic or potentially carcinogenic compounds.[13]

Other factors for developing oral carcinoma: Among other factors for developing oral cancer, there is the human papillomavirus (mainly linked with fatal carcinoma of the oropharyngeal region and UV radiation.[14] According to the IARC HPV16 is the main causative for the development of oral carcinoma in the oral cavity. HPV18 has also the capability of causing oral carcinoma. The most preferable site for HPV to develop oral carcinoma are pharyngeal tonsils and the portion of the tongue which is inside oropharynges, prevalence of HPV18 to develop oral carcinoma is about 75% in the pharyngeal region. The presence of Human papillomavirus 16, and 18 are the best prognostic biomarker for detecting oral pharyngeal carcinoma.[15] Most of the studies state that Human papillomavirus gives a contribution to carcinoma by 2 viral coted proteins, one is E6 protein helps in degradation of p53 cellanother one is E7 helps in degradation of the tumor suppressor genome product called retinoblastoma protein, UV radiationalso has a great contribution inupper and lower lip carcinoma. [16]

Microscopic and macroscopic aspects Carcinogenesis: Oral Squamous Cell Carcinoma takes many years to develops and in between this period,various neoplastic sites are transforming and changes occur in the oral cavity.[17] The process of a normal cell to transfer into carcinoma is a very complex multistage phenomenon. It develops when epithelial cells of the oral cavity go through by various genetic changes most often oral carcinoma starts with the changes of a less number of normal keratinocytes. These types of changes can be expressed via cytogenetic changes and epigenetic processes that purely change the progression of the normal cell cycle, DNA mechanisms, cell apoptosis that leads to various mutations, by direct contact to various biological factors, carcinogens.[18-20]

For a Better approach to oral carcinoma, oral carcinoma always considered as a fatal disease that involves multiple interactions between various cells, generated by the original carcinoma tissue, the recently generated cells, and tissue. The Oral Squamous cell carcinoma contains CAFs, immune cells and some other tissue during genetic expression oncogenic changes occurs which on the other hand contributes to the huge production of cytokines, EMT, and changes in the

microenvironment. CAFs have some important role in developing metastasis and proliferation.. most of the immune response gets suppressed in squamous cell carcinoma due to the huge production of cytokines. Most Oncogenic mutation in gene expression has a great hand in contribution to micro-environmental modification like ROS deposition, huge production of cytokines, and EMT. The most vital things in the tumor microenvironment are CFAs. Which has a great contribution tothe process of metastasis and invasion most important feature in most is that the adaptive immune response is suppressed by cytokines' huge production.[20]

Oral carcinoma keynotes: Oral carcinoma is always a preventable disease. Highly risk factors are smoking tobacco, chewing tobacco, and alcohol (long term exposure), these things have dynamic and synergistic adverse effects. More prevalent in humans for more than fifty years. a genetic mutation in keratinocytes gave way to develop carcinoma. The pre-cancerous lesion is always a precancer of oral cancer. Most common site ore tongue, lip, buccal mucosa, the floor of the mouth. The biopsy is the most usual method to detect. Screening program reduces the mortality rate

Potentially malignant disorders and dysplastic changes: Oral squamous cell carcinoma can be represented as "natural course", which originated from nonaberrant keratinocytes cells, with history of long term exposure to a various stimulus that breaks down homeostasis process of it, Leads to hyperplasia, dysplasia in terms of various degrees, carcinoma in situ with lots of clinical oral manifestations. This nature course offers a roadway for various research approaches in medical science. The very early recognizable clinical alteration that can any epithelium on his path to creating an Oral squamous cell carcinoma is predominantly the generation of malignant fatal disorders, like leukoplakia and erythroplasia which are the most common ones. Leukoplakia and lichen planus is a white precancerous risk factor, by freezing out other diseases which are already known to not favorable for neoplasm. The microscopic picture exhibits various epithelial modifications like acanthosis, hyperplasia.[19, 20.]

The OSCC originates from epithelial dysplasia phenomena of epithelial cells and represents itself by a neoplastic proliferation mechanism which directly damages ontogenically local epithelial membrane. The power of metastasis is directly linked with the various degree of new growth differentiation of the carcinomatous cells. According to World health organization International Classification of tumors are of three types,well differentiated, moderately differentiated, and poorly or undifferentiated tumor. From Histological pattern of some recent studies says that pattern of invasion (various bonding patterns between invading tumor cells), which has the best prognostic factor in oral squamous cell carcinoma. World health organization classification is very needful and helpful histologically. Till a recent date, there are no particular biomarkers for oral carcinoma. Some new studies show that high levels of interleukin-8 and Spearmidline N1 acetyltransferase 1 can differentiate between patients with Oral squamous cell carcinoma and healthy patients, with high sensitivity.[20-22]

Conclusion

The prognosis of most patients is still poor, despite therapeutic advances in this and many other malignancies. Early screening and early treatment process remain the key point to improving the survival rate of patients In recent days there are lots of technique with well equipped medical facilities to prevent the metastasis of all kinds of carcinomas throughout the glove and in medical science, there is various reasonable information which is capable for early diagnosis and better treatment of another third of cases, where the Oral Squamous cell carcinoma countenances this type of chances. Everything is possible and it is in the own hand od each human being to modify their way of lifestyle and create barriers to all risk factors which are the main cause for carcinoma. Various oral health Education to the people in a different community and especially those people with high risk to develop oral cancer, a good fundamental knowledge to reach the main point of oral carcinoma. Carcinoma of the oral cavity causes various degrees of damage in speech, deglutination and food chewing where mild to severe pain is the main sign. Among the various triggering factor which develops the oral pain, there are various types of mediators in the new growth microenvironment, lack of palliative therapy, a dense fifth cranial nerve innervation, and continuous different oral function, and mild to severe pain due to treatment and opioid resistance.

Evolution of Modified Glass Ionomer Cements: A Review

Susant Mohanty[1], Priyanka L. Kalimireddy[2]

[1]Professor & Head, [2]Senior Lecturer, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneshwar, Odisha, India 751003

Abstract

Glass ionomer cement has been the subject of extensive research over the last few decades. Refinements were made to the composition of GICs in an attempt to formulate an ideal restorative material (RM) having strength, adherence, natural appearance, and anticariogenicity. Contrary to early glass ionomers, the new restorative systems are easy and practical to use. The emergence of GIC as a 'material of choice' for various applications in dentistry is mainly due to its fluoride-releasing and chemical bonding properties. This article throws light on the evolution and the course of recent advancements of Glass ionomer cement.

Keywords: *Restorative material, glass ionomer, cement.*

Introduction

"Necessity is the mother of invention". There has been a never-ending need to upgrade and advance materials and techniques in dentistry due to changing professional perceptions and to meet the patient's demands. Currently, the patients demand higher aesthetic and biocompatible restorations at lower costs. In this day and age restorative dentistry is switching from metallic to non-metallic materials.[1]

Back in the 1960s, there was an availability of a variety of restorative materials including amalgam, composite, cast alloys etc, but none of them could be categorized under ideal restorative materials. An ideal restorative material is the one that is aesthetic, biocompatible, adhesive, anticarcinogenic and relatively economical.[2] Researchers then began their experiments to create a material that would not only act as a restorative but also replace enamel and dentin.[3] This led to the advent of Glass ionomer cementin 1969 as reported by Wilson and Kent in 1970s.[4]

Materials made of calcium or strontium aluminofluorosilicate glass powder (base) combined with a water-soluble polymer (acid) are the glass polyalkenoates.[4] With Kent calling such materials "glass ionomer" cements the name has become part of the dental jargon. The advantages of glass ionomer cement include adhesion, good marginal seal, fluoride release and biocompatibility but it had a disappointing clinical performance in primary molars as they are sensitive to dehydration early in the setting process and are brittle materials making them unsuitable for use in stress-bearing areas which is why attempts have been made to enhance properties of the glass ionomer cement by modifying the chemical composition of the original powder.[5,6]

History of GIC'S: What began with a small group of dentists and researchers in Londonin 1950s researching to produce a new RM that has similar properties of enamel and dentin and went through a long list of attempts at modifying silicate cement and other modifications are still undergoing attempts for a better one.[7,8]

The first zinc polyalkenoate cement by Smith in 1968 resulted in the introduction of the first adhesive

RM for dental purposes. The contemporaries Wilson and his group decided to use the polyalkenes acid as a liquid for silicate cement powder.[3]

The first GIC had strength and fluoride release property from silicate glass and biocompatibility and adhesion from polyacrylic acid liquid turned out to be a hybrid cement consisting of calcium fluoroaluminosilicate glass powder and polyacrylic and itaconic acid liquid.[9]

This class of material has achieved widespread use as translucent materials for restoration, fast setting liners and bases, for binding composite to the tooth structure, fine grain luting cement, fissure sealants and metal reinforced core build-up materials.[10,11]

Over the last few decades,compositional changes to both powder and liquid components, as well as clinical experience, has highlighted the practical advantages and disadvantages of GIC.[12]

Modifications of GIC:

Resin Modified Glass Ionomer: Small quantities of light-polymerizable resin groups (usually 2-hydroxyethyl methacrylate or HEMA) into the acidic liquid component was added to modify conventional GIC's physical properties and translucency.[13]

Metal Reinforced Glass Ionomers: Addition of amalgam alloy powder and sintered silver particles to the glass component to form a "Cermet" (ceramic-metal). Evidence of significant improvement in the physical properties of GICement was seen. Further research on this material witnessed diminished caries resistance compared to conventional glass ionomers.[13]

High-Viscosity Autocare Glass Ionomers: High viscosity GIC was introduced to have a strong and adhesive restoration with fluoride releasing propertiesto treat in remote undeveloped regions lacking access to dental care.[13, 14]

Polyacid Modified Composite Resins (Compomers): The term "Compomer" strikesas an intent to combine components and favorable properties of both GIC and composite. They possess the aesthetics of composites and fluoride-releasing trait of GIC though the fluoride release compared to the conventional GIC was negligibleas there was no fluoride uptake by the cavity walls due to the resin bonding agent acting as a barrier.[13]

Zirconia Reinforced GIC: Zirconia infused glass ionomer cement (ZIRCONOMER) is a recent addition to the GIC family which has been introduced to address all the issues that have plagued the conventional ionomer till now. The combination of Hydroxyapatite and zirconia (HAp/ZrO_2) at 4% volume concentration to the GIC powder refined the mechanicalattributes.[15]

Fibre-Reinforced GIC: Improved curing depth, wear-resistance, and flexural strength and reduced polymerization were observed when alumina fibres were mixed with glass powder. This polymeric rigid inorganic matrix technology involves the incorporation of a continuous network/scaffold of alumina and silicon dioxide ceramic fibres.[16]

Proline-Containing GIC: An amino acid–containing GI cement with better surface hardness, quick setting,and increased water sorption properties without adversely affecting the amount of fluoride release. Due to low cytotoxicity and good biocompatibility, it was also considered to use as a bone cement.[16]

Calcium Aluminate GIC: Properties of this GIC show a mix of calcium aluminate and luting GIC. Advantages include pH greater than 7 during curing, reduction in marginal leakage, improved biocompatibility, and greater stability and strength.[16]

Powder-Modified Nano Glass Ionomers: Described by De Caluwé et al, the mix of conventional glass ionomerwith nano-sized glass particleslike nano-apatite and nano-fluorapatite decreased setting time and enhanced compressive strength and elastic modulus after being stored in distilled water for 7 days.[18]

Nano-Filled Resin-Modified GIC: Incorporation ofnano-sized fillers and bioceramic particles to RMGICswas done to improve mechanical properties.[19,20] Increased ionic bonding with a tooth was observed instead of micromechanical bonding.[18]

Chlorhexidine Impregnated GIC: Approximately 10 ppm of fluoride release by GIC was observed during the 1st 48 hrs following its placement in the prepared cavity.To improve the antibacterial characteristics Chlorhexidinedigluconate can be added to it.[21]

Conclusion

Glass ionomers have been a mainstay of restorative dentistry due to its unique advantages. With time various modifications of this cement have been introduced

with added advantages and manageable disadvantages. Though the quest for newer materials gave us some great restorative systems, one still cannot replace GIC completely in restorative dentistry due to its advantages such as biocompatibility, fluoride release, and its workability in the moist environment.

A Smart Way of Making Dental Practice Painfree

Kajal Kiran Sahoo[1], Sudipta Sahu[2], Debashruti Naik[3], Nikita Sahu[3], Sarmistha Mohanty[4]

[1]Tutor, Department of Prosthodontics, [2]Tutor, [3]Senior Lecturer, [4]Post Graduate Trainee, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Local anaesthesia in dentistry has been used in dentistry for more than a century ago. The emergence of giving local anaesthesia through nerve blockade marked a new era of patient comfort while permitting more extensive and invasive procedure in dental practice. Though ages effective LA is the most important pillar upon which systems have been developed that utilizes computer technology in the LA administration. The core mechanics behind the Computerised controlled local anaesthesia Device (CCLAD) is a microprocessor that controls delivery of LA solution at constant pressure and controlled volume while monitoring the variation in the tissue resistance. This fine high suffusion flow rate of LA provides a rapid onset of anaesthesia in most dental patients. Although local anaesthesia in injection form remains the backbone of pain control in dentistry, researches are being made in constant search of new & better management of pain. These researches are focused on the advancement of local anaesthetic agent delivery devices and techniques involved in both pharmacological and non-pharmacological form. Paradoxically the injection of LA seems to be the greatest source of patients fear and inability to control pain remains a significant concern to the dental practitioner. This review article will aim towards the products, device and techniques available till now which will make dentistry more patient-friendly and non-invasive.

Keywords: *Painfree Dental Practice; Local anaesthesia; Computerised controlled local anaesthesia Device.*

Introduction

At the beginning of dentistry extractions were practised without anaesthesia and toothache was cured with few glasses of wine, brandy or herbal potions. Then with the discovery of syringes and opiates, anaesthesia became effective in dentistry. Then came the anaesthetic virtue of ether,by which the famous surgeon John Collins Warren removed a neck tumour from the volunteer, Mr Albert Abbot, who felt no pain. Then an American dentist HovaceWells was first to show the anaesthetic property of nitrous oxide. Nowadays local anaesthetic in dentistry mostly involves blocking of small and large nerve terminals through contact with active molecules of esters and starches. The local anaesthesias that are in use in present-day dentistry are lidocaine, prilocaine, bupivacaine, mepivacaine and articaine.[1] Different types of local anaesthesia routes that are preferred in dentistry are infiltration,intraligamentary,intrapul pal, intraosseous etc. But all of these routes of local anaesthesia needs needle to deliver the LA agent at the respective sites. In most of the time, the needle prick induces anxiety in children and adult dental patients even before the proper administration of LA. This poses the drawback in the dentist-patients relationship. So many alternative method to alleviate pain are tried like topical anaesthesia, CCLAD, Jet injector, Iontophor electronic dental anaesthesia etc. Desensitization of the injection site & CCLAD is most of the recommended strategies nowadays.[2]

Method of desensitisation of the injection site: The method which are involved to reduce pain at the injection site before the injection of proper L.A are – (a) Application of topical anaesthesia; (b) Pre-cooling of the injection site.

(a) Application of topical anaesthesia: Topical anaesthetics acts on peripheral nerves and reduce the sensation of pain at the site of the needle prick, before proper LA administration. Thus it generates a positive response towards dental treatment in the patients. Traditionally topical anaesthetics contain Lidocaine or Benzocaine as active ingredients and are used in the form of solutions, gels, creams and sprays. The topical anaesthesia used in dentistry are listed in table 1. [3]

Table 1. Topical anaesthesia used in dentistry

Benzocaine	• It is an ester-based LA that is commonly associated with hypersensitive reactions • Its poor water solubility hinders cardiovascular absorption and so effects the surface for a prolonged period • Aerosol agents may be used on soft palates to reduce gaging and gel agents used before infiltration anaesthesia • 20% of concentration produces an effect within 30 seconds.
Lidocaine and Lidocaine hydrochloride	• It is an amide-based local oral topical anaesthetic agent • It is used as 2% or5% gel, 5% ointment or 10% spray • The onset of action of the anaesthetic agent is 1-2 minute.
Prilocaine	• It is used in combination with other topical anaesthetics • It is used as 4% prilocaine or 4% prilocaine with 1:200000 Epinephrine
EMLA or Eutectic mixture of local anaesthesia	• It is 1:1 mixture of 2.5% prilocaine and 2.5% of lidocaine.
Cetacaine topical anaesthetic	• It contains 14% benzocaine, 2% butamben and 2% tetracaine-hydrochloric acid. • It is used in local pain in all mucous membrane. • It is used by using a cotton swab or micro brush.
Oraqix subgingival anaesthetics	• It contains 2.5% lidocaine and 2.5% prilocaine • It is gel anaesthetic that is administrated by insertion into gingival sulcus where it provides anaesthetic effect to enable deep scaling and root planing.

(b) Pre-cooling the injection site – In dental surgeries, palatal injection poses the most painful of all the injections. So palatal cooling is effective for relieving pain perception. It is done by (a) application of dichlorodifluoromethane sprayed cotton pellet for 5 seconds, (b) application of refrigerant eg. 1,1,1,3,3-pentafluoropropane/1,1,1,2 - tetrafluoroethane (c)application of ice popsicle etc.[4-6]

Computer-controlled local anaesthesia delivery system: Research shows that CCLAD produces lesser pain ratings and disruptive behaviour than cartridge syringe in children.CCLAD refers to the appliances that utilise computer technology in the administration of LA in patients. It precisely controls the flow rate of LA and modulates the fluid pressure by the use of computer microprocessor & electronically controlled motor to deliver the LA at a constant slow rate respecting the tissue resistance.[7] The well-known device under different commercial brands are:

1. The Wand (Milestone Scientific Livingstone, NJ)
2. Comfort Control Syringe (CCS, Dentsply, USA)
3. Quicksleeper (Dental Hi-Tec France) and
4. iCT (Dentium, Seoul,Korea)
5. Anaeject (Nippon Shika Yakuhin, Japan)
6. Ora star (Showa Uyakuhin Kako, Japan)

Basic theory of CCLAD: CCLAD reduces pain by controlling injection speed through the resistant tissue and also from the anaesthesia taking effect at the same time with injection,which then sequentially allow the

anaesthetic to be injected into already anaesthetised tissues. Because of these series of processes, the patient feels less pain.[8]

The design of CCLAD varies depending on:

I. Whether the anaesthetic cartridge is included in the main unit or not

II. Speed and mode of injection

III. A device having the possibility of aspiration or not

IV. Weight of the device

V. Ease of injection management.

The Wand system has 3 parts a base unit, a foot pedal and disposable handpiece assembled.

Base: It contains a microprocessor and connects to both the foot paddle and handpiece attachments that accepts the local anaesthetise cartridge. This microprocessor controls a piston that expels the local anesthetic solution by pushing the LA plunger up into the cartridge.[9]

Disposable handpiece: The LA solution expels through the microbore tubing, WAND handpiece and attached needle to the tissue

Foot pedal: Pressing lightly on foot pedal expresses slow injection rate (0.005 ml/second) appropriate for needle insertion, palatal injection and PDL injection. Heavier pressure increases the rate of LA solution administration (0.03 ml/second) for buccal infiltration and nerve blocks and release of foot pedal stops injection.[7-10]

Along with these, WAND is added with STA mechanism, that is Single Tooth Anaesthesia feature. This STA unit adds Dynamic Pressure Sensing(DPS) technology, which enables the dentist to feel the needle tip placement in PDL etc. The handpiece of CCLAD system seems to be a pointed ball pen rather than a syringe,which the patients particularly pediatric dental patients finds less scary than a conventional cartridge and syringe. The first computer-controlled L.A delivery system was introduced in 1997 as the Wand, (Milestone Scientific) to improve functional design and accuracy of the dental syringe. It was in the market quite for a long time due to its ease in operation, lightweight and a circumference that was half of the traditional syringe. But the Quick sleeper and Comfort Controlsyringe(CCS) have three times the size and weight handpiece that of the traditional syringe as they have both syringe and motor in this handpieces.[9,10]

CCLAD handpiece must be held stable for a longer period than a conventional cartridge to ensure safe administration of anaesthesia. So new products are introduced which offer lightweight designs. Further technical advances are awaiting to develop much lighter CCLAD. In the aspect of injection speed of local anaesthetic solution Wand,Quick sleeper & CCS have injection speed of three, four and five stages respectively. The iCT device allows three stages which allow the full cartridge to be injected 250,120 & 50 seconds. In the aspect of whether aspiration can be done or not,it is an important fact that all Wand,CCS and Smartjet have the option of aspiration before injecting the local anaesthesia to the particular tissue.[7-10]

Advantage of CCLAD: CCLAD has more accurate needle insertion for deep nerve block.In the second or recurrent visits, the children who receive CCLAD shows less disruptive behaviour than the children receiving an injection with a cartridge system. Thusthe use of CCLAD can be carried as a possible step towards a pain-free pediatric dental practice in coming days.[7-10]

Disadvantages of CCLAD: The added cost of CCLAD and single-use hand piece for different patient injection might not be affordable to every practitioner. If the cost is reduced it may be possible for every practitioner to use it his/her clinic. In many cases, a total of 4 minutes is required to completely express a cartridge, which may cause impatience and stress in the patients. CCLAD doesn't reduce the discomfort of needle insertion in case of palatal injection.[9,10]

Conclusion

Thus the most accepted mode of pain control is by administering local anaesthesia with the use of needle though it may be an anxiety-provoking procedure for both children and adult dental patients. Of all the alternative method of delivering anaesthesia, CCLAD is the most accepted mode of delivering anaesthesia without pain. Though it is of high cost and time taking procedure to deliver anaesthesia it can be considered by the dentist.

Sialadenitis: A Review of the Literature

Sthitaprajna Lenka, Santosh Kumar Subudhi[2], Subrat Padihary[2]

[1]Professor, [2]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Salivary glands are tubulo-acinar exocrine organs responsible for the formation and secretion of the saliva. Salivary gland inflammation is known as sialadenitis which can originate from various non-infectious and infectious causes. Although several other viruses also can involve the salivary glands which include Choriomeningitis, Coxsackie A. ECHO. Cytomegalovirus (in neonatal) and parainfluenza, mumps is the most common viralinfection. Most bacterial-infections arise due to ductal obstruction or decreased salivary flow which allows the retrograde spread of bacteria through the salivary ductal system. Viral infections, bacterial infections, allergic reactions, and systemic diseases are the major causes ofsialadenitis and it may be acute or chronic. The etiology, diagnosis, and treatment of these conditions are discussed.

Keywords: *Salivary glands; Sialadenitis; Etiology, Diagnosis, Treatment.*

Introduction

The oral cavity depicts many pathological processes from the ubiquitous collection of tissues. The salivary glands may be classified as major and minor glands. Major glands are paired glands; these are Parotid, Sublingual and Submandibular glands. Inflammation of the salivary glands is known as sialadenitis. Pathogenesis - (1) Retrograde contamination of the duct and parenchymal-tissues by bacteria inhabiting in the oral cavity. (2) Stasis of salivary flow promotes acute suppurative infection. Viral infections, bacterial infections, allergic reactions, and systemic diseases are the major causes of sialadenitis. It may be acute or chronic.

Acute Suppurative Sialadenitis: Acute suppurative sialadenitis most frequently involves the parotid gland followed by the submandibular gland. This may be explained because of the serous saliva produced by the parotid gland which has less bacteriostatic activity than that of mucinous saliva of the submandibular gland. Although acute suppurative parotitis can occur in individuals of any age, patients most frequently affected are aged from 50 to 70 years. The reduction of the secretory flow and stasis of saliva, typically as a result of dehydration, is an integral pathogenetic factor of acute suppurative sialadenitis. In acute suppurative sialadenitis, bacterial organisms usually enter from the oral cavity in a retrograde fashion. Staphylococcus aureus is the most common causative agent and accounts for 50% to 90% of cases.[1,2]

Usual clinical presentation is the sudden onset of diffuse swelling of the affected gland associated with induration, erythema, pain, and tenderness. Some patients complain of reduced mandibular movement and difficulty in swallowing. Patients frequently have systemic signs of toxemia, including delirium, high fever, and leukocytosis. Association with systemic sepsis is more common in infections of the parotid gland than the submandibular gland. The respective intraoral duct orifice may become red and swollen with purulent discharge recognized on the massage of the gland. The diagnosis of acute suppurative sialadenitis is based on the clinical features with the culture of the purulent material from the duct. Any abscess formation

can be determined using computerized tomography or ultrasound scanning. Sialograms are contra indicated in cases of acute suppurative infection of the salivary glands. Initial treatment of acute suppurative sialadenitis should be conservative, with eliminating the causes, improved oral hygiene, adequate hydration to increase the salivary flow, repeated massage of the affected gland, and administration of appropriate oral or intravenous systemic antibiotics, usually for a penicillinase-resistant Staphylococcus. Irradiation of the glands is no longer recommended. Incision and drainage by surgical intervention are indicated in cases involving abscess formation.

Obstructive Sialadenitis and Sialolithiasis: This is the most frequent type ofchronic sialadenitis, accounting for about 30% of all chronic sialadenitis cases and approximately 1% of all salivary gland diseases[3,4]. Although sialolithiasis is the most common cause of obstructive sialadenitis by far, two major factors are playing a role in the pathogenesis of the disease[4]. One is a mechanical obstruction by sialoliths, salivary gland cysts and tumors, and lesions of the oral mucosa. The other factor is a disturbance of the electrolyte concentration of saliva, resulting in the development of viscous secretory products. Sialoliths develop as a result of deposition of calcium salts around a nidus such as bacterial colonies, cellular debris, mucous plugs, or foreign bodies.

The peak age of incidence of sialolithiasis is between 30 and 60 years, with a mean of about 45 years[3] and slight male predominance. About 80% of cases of sialolithiasis develop in the submandibular gland, followed by the parotid gland[3]. Then the other salivary glands submandibular gland is more susceptible to sialolithiasis because its saliva has higher mucin content, increased viscosity, a more alkaline pH, higher concentrations of calcium and phosphate, and antigravity flow within the duct. In the submandibular gland, 57% of stones are localized near the hilum, 34% in the distal area of the submandibular duct (Wharton's duct), and 9% in the intraglandular ducts[5]. The formation of sialoliths in the main ducts produces swelling of the distal salivary gland tissue with or without pain. The episodes of the symptoms are frequently recurrent and exacerbated by eating. When sialoliths occur in the submandibular gland duct, induration can be observed on the floor of the mouth, and the duct orifice becomes erythematous and swollen. Sialoliths in the minor salivary glands are mostly asymptomatic presenting as a small, firm nodule. Ductal obstruction blocks secretion and leads to stasis of the saliva within the duct, which becomes predisposed to retrograde bacterial infection; Streptococcus viridans is a commonly involved pathogen.

The diagnosis of sialolithiasis is principally based upon clinical and imaging examinations[5]. Sialoliths of the distal area of Wharton's duct and the hilum can be detected by bimanual palpation of the affected area. Plain radiography is a helpful method to diagnose sialolithiasis, but 90% of submandibular stones are radiopaque while most parotid stones are radiolucent. Sialography is very accurate in the diagnosis of sialolithiasis but is usually unnecessary and is contraindicated in the acute setting of sialadenitis. Instead, high-resolution ultrasound and CT are the most useful diagnostic tools. The first steps of management of sialolithiasis in the submandibular and parotid glands include conservative method, such as adequate hydration, sialagogues, and gland massage as well as minimally invasive approaches, such as basket retrieval and interventional sialendoscopy to remove the stones, depending on their location and size[5]. When these measures fail, extracorporeal shock-wave lithotripsy may be the treatment of choice. Extirpation of the affected gland is recommended only in the minority of recalcitrant cases.

Chronic Sclerosing Sialadenitis (Kuttner Tumor): Chronic sclerosing sialadenitis is the salivary gland inflammatory disease, which was first described by Kuttner in 1896[6]. Chronic sclerosing sialadenitis produces a hard swelling of the salivary gland that cannot be easily distinguished clinically from neoplasia. This inflammatory process almost exclusively affects the submandibular gland.

Recently it has become increasingly recognized that chronic sclerosing sialadenitis exists to the group of immunoglobulin G4 (IgG4) related sclerosing (systemic/autoimmune) diseases[7,8]. This notion is further supported by the fact that chronic sclerosing sialadenitis has been associated with one or more extrasalivary IgG4-related sclerosing diseases, which are characterized by infiltrating of the chronic inflammatory cell containing abundant IgG4-positive plasma cells, accompanied by atrophy of the normal parenchyma and sclerosis. The close association suggests that at least some cases of chronic sclerosing sialadenitis share common pathogenesis with other sclerosing diseases involving disturbance of IgG4 as a systemic disorder. Chronic sclerosing sialadenitis can appear at any age between 12 and 83 years. Clinically, the patients appear

with a firm swelling of the submandibular gland with or without recurrence of pain associated with eating. This appearance of a firm, enlarging growth can lead to the erroneous clinical diagnosis of a neoplastic salivary gland, particularly carcinoma. The glandular involvement is usually unilateral, but it can be bilateral. Cases with swelling of bilateral submandibular glands and lacrimal glands, similar to Mikulicz's disease, have been reported[9]. As mentioned above, chronic sclerosing sialadenitis is sometimes associated with the extrasalivary IgG4- related sclerosing diseases; therefore, a systemic examination is recommended for patients with chronic sclerosing sialadenitis.

Radiation Sialadenitis: Radiotherapy is the most commonly used modality for treatment of the head and neck cancers[10]. When the major salivary glands are included within the fields of radiotherapy, many patients develop swelling and tenderness of the irradiated glands as well as elevation of the serum amylase level within hours of receiving even the first treatment in a course of fractionated radiotherapy. These symptoms may be transient, but a significant proportion of the patients will suffer persistent salivary gland dysfunction, resulting in xerostomia accompanied by a variety of complications, such as dysphagia, abnormal taste sensations, oral mucositis, dental caries, and periodontal disease. The saliva secreted from irradiated salivary glands has a lower pH, lower protein and secretory antibody contents, higher salinity, and increased numbers of cariogenic microorganisms. The severity of salivary gland damage and dysfunction depends on the dose and the duration of irradiation. The important pathogenetic factor of radiation sialadenitis is the direct irradiation effect on the salivary gland tissue rather than the result of radiation-induced changes in the vasculature[11]. Considerably serous acinar tissue of the parotid gland is more radiosensitive than mucous glandular tissue of the submandibular gland[12]. The radiosensitivity of the acinar cells depends on the content of secretory granules, containing a large number of heavy-metals limited by the membrane[13]. Released heavy metals as a result of the irradiation may cause membrane lipid peroxidation utilizing a redox system, thus enhancing the process of apoptotic cellular death[13].

Recurrent Parotitis: Recurrent parotitis is a well-recognized entity in children, represented by recurring episodes of swelling of the parotid gland. Although it is relatively rare, it is still the second most common salivary gland inflammatory disease in children, next to mumps[14,15]. Recurrent parotitis is generally associated with nonobstructive sialectasis of the parotid gland. However, the sialectasis may be both the cause and the result of the recurrent exacerbations of the parotitis[16]. The age of onset of recurrent parotitis has been reported to be between 3 months and 16 years, but it mostly starts between three and six years with a peak during the first year of school[14] and with a male predilection. Recurrent parotitis presents as an intermittent, painful swelling of either unilateral or bilateral parotid glands during mastication and/or swallowing, generally accompanied by fever and malaise. The disease is often clinically misdiagnosed initially as mumps. The number of attacks varies individually, but most commonly occurs every three to four months[14, 15]. The swelling lasts from several days to 2 weeks, and typically resolves spontaneously, regardless of the treatment. Between the episodes, the patient is free from symptoms. Recurrent parotitis is generally self-limiting, and after puberty, by age between 10 and 15 years. Although it usually is not accompanied by purulent secretion, the majority of affected glands grow bacteria on the culture of saliva. Sialography has been considered the most important and accurate diagnostic tool, though its rolehas become secondary to ultrasonography now. The main treatments of an acute phase of recurrent parotitis are either conservative observation or antibiotic treatment. Penicillin V is a good choice for acute infections. Other treatments are much more invasive when applied to adults with persistent severe disease, including duct ligation, parotidectomy, and tympanic neurectomy.

Viral Sialadenitis Including Mumps and Cytomegalovirus: Viral infections involving the salivary glands are more common than those of bacterial origin. Viral sialadenitis is a manifestation of a systemic infection, and the salivary glands are affected by a hematogenous spread of virus rather than a direct infection to the organ as in bacterial sialadenitis. A variety of viruses are known as causative agents of sialadenitis, including the paramyxovirus (mumps), cytomegalovirus, HIV, coxsackie A virus, Epstein–Barr virus (EBV), echovirus, herpes virus, lymphocytic choriomeningitis virus, adenovirus, and influenza A and parainfluenza viruses[17]. Mumps is by far the most common cause of parotid swelling and is the most common viral agent involving the salivary glands[18]. Mumps is caused by a highly contagious paramyxovirus. The frequency has reduced with a vaccine made from attenuated live mumps virus. The peak incidence is between the ages of four and six years, but infection can

be seen in other age-groups. The incubation period is two to three weeks, with a clinical onset characterized by swelling and pain of single or both parotid glands. Systemic symptoms include fever, malaise, myalgia, and headache, and usually, resolve before the parotid swelling. Adults infected with mumps are more possibly to develop severe symptoms and complications, while in children symptoms are usually not severe. Generally based on clinical presentation the diagnosis is made. Demonstrating antibodies to the mumps V and S antigen by enzyme-linked immunoadsorbent assay can confirm the diagnosis. Some laboratories use molecular method that are based on a nested polymerase chainreaction. Many cases are subclinical, and studies have shown that greater than ninety-five percent of adults have neutralizing antibodies. Orchitis occurs in 10% to 20% of infected males, but it is usually unilateral, and sterility only infrequently arises; in about 5% of those infected aseptic meningitis occurs. The disease is generally self-limiting with a good outcome. Swelling and other acute symptoms usually subside within two weeks. There is no specific treatment apart from controlling the symptoms with analgesics.

Cytomegalovirus is a member of Betaherpesvirinae in the subfamily of Herpesviridae. Most infections are acquired during childhood in developing countries,whereas, up to 50% of young adults are seronegative in developed countries. Cytomegalovirus is not highly contagious,thus the infection requires close contact with an infected person excreting the virus in their urine, saliva,or other bodily fluids. Cytomegaloviruscan be transmitted via breast milk and can also be sexually transmitted, transplanted organs, and rarely from blood transfusions. Cytomegalovirus infection without symptoms iscommon in infants and young children. The symptomatic disease can affect almost every organ of the body in immune-compromised individuals,resulting in fever of unknown origin, encephalitis, pneumonia, colitis,hepatitis, retinitis, neuropathy, uveitis,and myelitis. Cytomegalovirus infections are frequently associated with salivary glands, but significant clinical manifestations of cytomegalovirus-infected patients are usually seen in other organs. Diagnostic procedures include the enzyme-linked immunosorbent assay. Since the majority of infections resolve instinctively no treatment is usually required for cytomegalovirus infection in the healthy individual. Now in infants, antiviral drug therapy is being evaluated.

Conclusion

This article thus deals with various infectious and noninfectious causes of sialadenitis like Acute Suppurative Sialadenitis, Obstructive Sialadenitis, and Sialolithiasis, Chronic Sclerosing Sialadenitis (Kuttner Tumor), Radiation Sialadenitis, Recurrent Parotitis, Viral Sialadenitis Including Mumps and Cytomegalovirustheir diagnosis and treatment.

Endoperio Lesion: An Overview

Sumit Dash[1], Debkant Jena[1], Siba Jena[2], Swapna Kumari[3], Narottam Praharaj[3], Manali Nath[4]

[1]Professor, [2]Senior Lectrurer, [3]Tutor, [4]Post Graduate Trainee, Department of Conservative Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The most common problems associated with tooth pain were endoperio lesions. It was very difficult to diagnose endoperio lesions by clinical or simply intra oral peri-apical radiograph. 50 % of tooth mortality rates are responsible for the endoperio lesion, the correct diagnosis was needed for appropriate treatment planning. This paper review the current diagnostic tools and treatment planning of endoperio lesion to achieve the best outcome.

Keywords: *Endoperio lesion; current Diagnostic Tools; Treatment Planning.*

Introduction

In daily dental practices, there are many patients we encounter with severe pain due to the endoperio lesion. As per definition these lesions, are localized in the particular area originate either from pulp or tissue of periodontium surrounding the involving tooth. Both of these issues have a common mesodermal origin. The first case was described by *Simmering and Goldberg*[1] in 1964. *Turner and Drew*[2] described the effect of periodontal and pulp tissue like fibrosis, calcification, and cystic degeneration. In the study done by *Seltzer et al*[3], he found that 94% of extracted teeth which were periodontally involved had pulpal changes such as atrophy & inflammation with necrosis.

Endodontic & periodontium illness represents the greater part of the tooth mortalities[1]. The different pathway through which microorganism communicate with periodontal tissue is

- Anatomic/Developmental origin:[10]
- One of the most common routes of infection is apical foramen which makes the communication in between pulp and Periodontal ligment.[11]
- The second factor was anatomical deformities like developmental grooves. The gap between cementoenamel junction can cause exposure of dentinal tubules.[12,13]
- The other potent factor was accessory canals present in the apical area of tooth.[14,15]
- Type of Furcation area may affect the degree of infection in the root 2% to 59 %.[17-19]

Pathological Origin: The factor pathologically derived and irritate the pulp due to various conditions like dental trauma, resorption, and loss of cementum due to irritants. The iatrogenic factors are those due to unintentional errors during the procedure by the dentist like root fracture, canal perforation during biomechanical preparation due to over instrumentation in root canal treatment. Root perforation opens the gateway between pulp and periodontal tissues which can lead to the poor prognosis of the tooth. The second most important factor was vertical root fracture during the obturation compaction leads to fracture line in root leads to a fracture in the root which further leads communication between the pulp and periodontal lesion.

Etiology: There are two main categories of endoperio lesions are living and non-living pathogens are tabulated below.[11, 23]

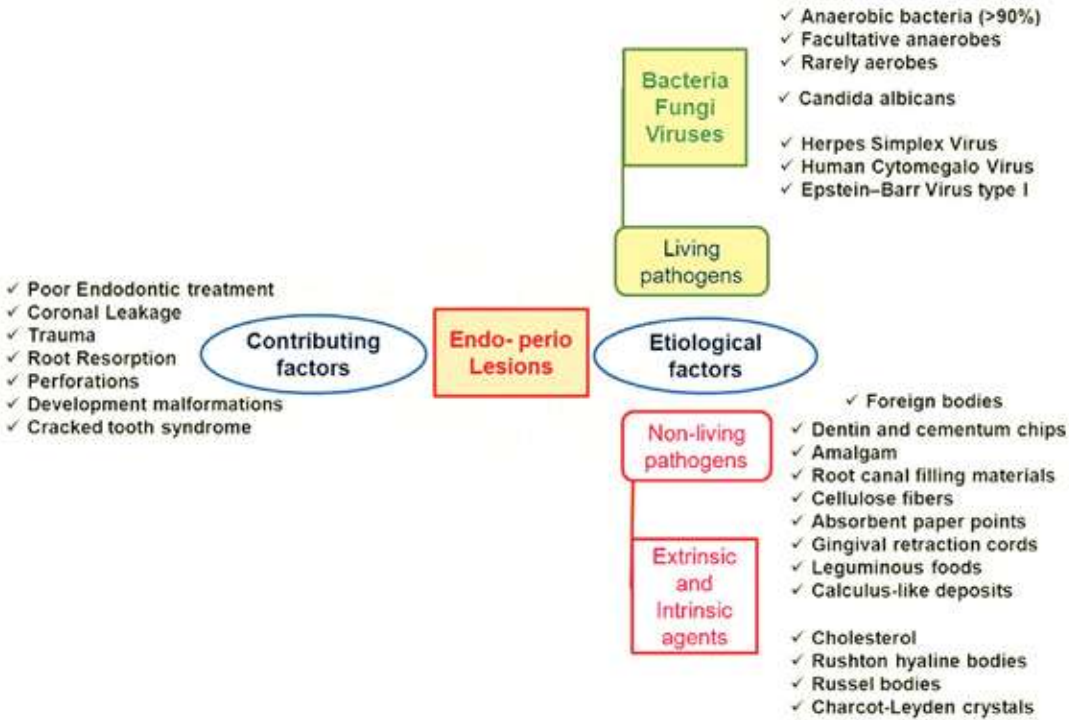

Figure 2. Main categories of endoperio lesions

The most common bacteria found in the endoperio lesions are Porphyrominas gingivalis, Actinobacillus actinomycetemcomitans, Porphyrominas gingivalis, Bacteroide forsythus, Ekinella corrodens, Fusobacterium nucleatum, Prevotella intermedia.[24] In many studies, we found fungal species Candida albicans are predominant in endodontic and periodontal lesions and virus found that EBV and herpes virus can also causative agents.[27,28] It has been found that the causative agents like cytomegalovirus, Ebstein Barr, the herpes virus can be responsible.[27,28]

I. Classification:

- In 1972 Simon et al were the first to give classification on endodontic periodontic lesion[29] based on diagnosis, prognosis and treatment.

– Primary endodontic lesion

– Primary periodontal lesion with secondary endodontic involvement

– Primary periodontal lesion

– Primary endodontic lesions with secondary periodontal involvement

– True combined lesion

- **Guldener & Langeland classified according to pathologic relationship[30]**

– Periodontal–endodontic lesion
– Endodontic–periodontal lesion
– Combined lesions

- **In 1996, Torabinejad & Trope gave the classification based on a treatment plan**

– Periodontal origin
– Endodontic origin
– Combined endodontic and periodontic lesion
– Lesions with communication
– Separate endodontic and periodontal lesions
– Lesions with no communication

- **Grossman's classification was based on therapy:**

– The condition of the tooth which requires just endodontic therapy
– The condition of the tooth which requires just periodontal therapy
– The condition of the tooth which requires both endodontic as well as periodontal therapy

Table 1. Classification on endodontic periodontic

Endodontic Origin	Periodontic Origin
1. Pulp non-vital.	1. Pulp vital except in advanced lesion.
2. Sharp throbbing pain	2. Dull, chronic pain.
3. Swelling in and extending beyond the	3. Swelling generally confined to attached mucosa
4. Tracing the fistulous tract leads to apical region or in the region or in the region of a lateral canal.	4. Tracing leads to mid root.
5. The fistulous tract is narrow and tortuous	5. Due to extensive loss of periodontal structures he fistula is wide in cervical area and can easily be probed.
6. Mobility in an acute stage involving multiple teeth limited to an isolated tooth.	6. Generalized mobility
7. Bone loss involving crestal and furcal bone limited to an	7. Generalised crestal bone loss either horizontal or verticle.

- Rateitschak et al gave a classification based on endodontic therapy

– Type I- In a condition where the pulp was dead and the disease by primarily endodontic origin
– Type II- In this condition the main cause of the disease by periodontal tissue which affects the pulp and sometimes caused pulpitis.
– Type III- In this condition pulp was dead and both origins were affected

II. Diagnosis:

The diagnosis can be made by clinical and radiography finding,

On clinical examination, swelling of the gingiva, Pus discharge, pocket formation, sinus tract can be seen as associated teeth. On radiographic examination bone resorption can be seen there is wide radiolucency present in the apex of the tooth. It was very difficult to distinguish between the origin of the disease.

The clinical features of endoperio lesions are:

- **Primary endodontic lesion:** The large carious lesion, the presence of sinus in the periapical area, Presence of pain with mobility with a tender to percussion, periapical radiolucency can be seen with periodontal pocket and pain on biting pressure.
- **Primary periodontal origin:** Pain on palpation, grade I mobility, the vitality of pulp will positive, plaque and subgingival calculus, periodontal

abscess, vertical bone loss and periodontal pocket with sinus tract at the lateral aspect of the root which can be appreciated on a radiograph.

- **Primary endodontic with secondary periodontal lesion:** Exudates and marginal gingivitis, root perforations, fractures, ill-placed post, a dull ache, or shooting sharp pain in chronic conditions with localized mobility with deep periodontal pockets.
- **Primary periodontal/secondary endodontic lesions:** Gingival inflammation and plaque around multiple teeth, Generalized mobility, localized/ generalized recession exudates, and pus. Pulp test may be positive in cases of the multi-rooted tooth and wide deep multiple periodontal pockets.
- **True combined lesion:** Chronic dull ache and swelling are present when calculus and periodontitis are around single/multiple teeth but in acute conditions, the pain will be more with generalized mobility with mobility of the involved tooth. Vitality tests will give negative responses except in the case of a multi-rooted tooth. At the edge of swelling the probe suddenly drops till apex of the tooth. This swelling is characterized as ‘ blown out’’.

Discussion

It is a challenge to treat endoperio lesions. In the study, Dahlen et al suggested that the vitality of tooth was an important factor for final diagnosis.[31] Kerekes and Olsen found that the microorganisms are the same in both periodontal pocket and root canal treatment.[32] Kurihara et al found that the is dissimilarity in microflora microbiologically and immunologically in pocket and root canal area.[33] Drucker et al [34] reported that Prevotella species associated with severe pain and commonly found in the root canal and periodontal pocket. Lin et al[35] demonstrated in the study there was no association of bacteria with the symptom. When we started with the treatment in combined endoperio lesion the endodontic treatment was done before periodontal therapy, the canal was completely clean with endodontic instruments with proper irrigation protocol which improve the reattachment procedure. The most common postoperative dentinal hypersensitivity. The time between to procedure is still not mentioning in any study it was still controversial. In various studies, the result found that endodontic treatment performed 2.5 months before periodontal surgery.[32,35] Miranda et al. showed that there was no change in the clinical parameter endodontic performed before the periodontal surgery.[36]

Reconstruction of Maxillary Defect by Means of Bipedicled Forehead Flap: A Novel Surgical Technical Report

Harshmohan Pathak[1], Sobhan Mishra[2], Jayant Kumar Dash[3], Sudipta Sahu[4], Kalyan Sundar Pal[4]

[1]Associate Professor, [2]Professor & Head, Department of Oral & Maxillofacial Surgery Institute of Dental Sciences, [3]Professor and Head, Department of Plastic & Reconstructive Surgery, Institute of Medical Sciences & Sum Hospital, [4]Post Graduate Trainee, Department of Plastic & Reconstructive Surgery, Institute of Medical Sciences & Sum Hospital, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Forehead and temple region of act as tissue reservoir for harvesting flap for reconstruction of the orbital, periorbital and mid-face defect. Depending on requirement different kind of flap can be harvested from this region and for this sound knowledge of vascular anatomy of this region is required. Usually large free flaps are adapted to cover a large maxillectomy deformity. Here, in this case, a bi-pedicled forehead flap harvested based on frontal and parietal branch of the superficial temporal artery and was used for rehabilitation maxillectomy with external skin deformity.

Keywords: *Forehead flap, Bipedicled, Maxillectomy.*

Introduction

The Indian physician Sushruta was the first to described skin flaps reconstruct amputated noses as a result of punishment in his book 'Sushruta Samitha' which written in 500 BC[1]. "Szymanowski, Burow, Esser, Lexer, Joseph, and Davis" were the surgeons who introduced the concept of the flap in the Western world in the 19th century.[2] In 1830s forehead flap was first performed by Warren in America. Kazanjian, refined the midline forehead flap and also describe major blood supply of flap via the "supratrochlear" and "supraorbital" arteries. He also described the method of closure of the donor site[3,4].

Forehead and temple region of act as tissue reservoir for harvesting flap for reconstruction of the orbital, periorbital and mid-face defect. Depending on requirement different kind of flap can be harvested from this region and for this sound knowledge of vascular anatomy of this region is required. Usually large free flaps are adapted to cover a large maxillectomy deformity. Here, in this case, a bi-pedicled forehead flap harvested based on frontal and parietal branch of the superficial temporal artery and was used for rehabilitation maxillectomy with external skin deformity.

Surgical Technical Note: Bi-pedicled forehead flap used for reconstruction of the defect of the maxilla was done in a male patient with squamous cell carcinoma of maxilla operated in Institute of Dental Sciences, Bhubaneswar. The malar defect of size 10 cm periphery was apparent after the three-dimensional clearance done for extensive squamous cell carcinoma of the maxilla (Figure 1). The forehead flap was designed taking the superficial temporal artery (frontal branch) as the feeder vessels of the flap (Fig 2). Total length of used flap was 125% of the defect and was planned to rotate under the skin over the lateral brow region to cover surgical deformity. De-epithelialization on the region which was supposed to come under the skin of the lateral brow.

The prepared pedicled flap was comfortably reaching the defect without any compression and tension at the pedicled end.Now to give the cover to the maxillary defect we decided to turn the flap over itself to serve the purpose, de-epithelializing it again at the turning point or pivot (Fig 3). The secondary deformity over the forehead was covered by the STSG ("split-thickness skin graft") harvested from left thigh. The patient was provided with an obturator postoperatively and was recalled regularly there was no complications with the donor as well as the recipientsite (Fig 4).We recommend the use of bi pedicled forehead flap for the use of reconstruction of the cheek and malar process as a simple but innovative technique.

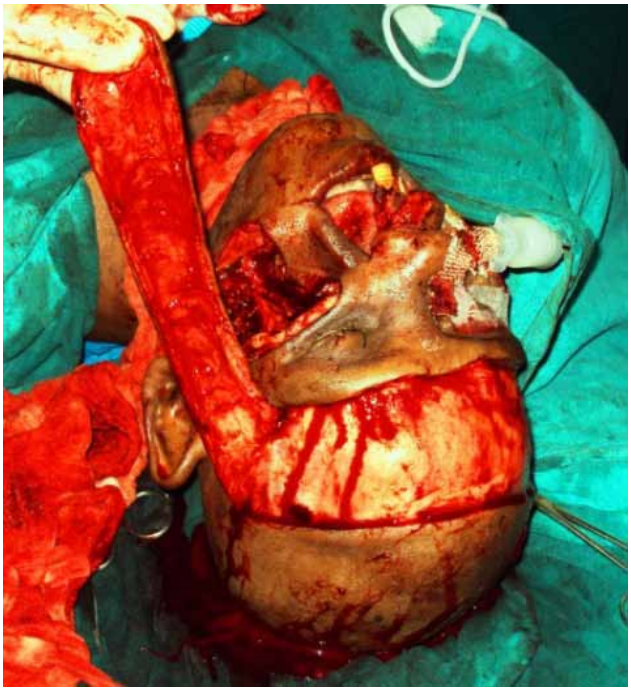

Figure 1. Raising of Flap Post Maxillectomy

Figure 2: Rotation of Flap

Figure 3. Securing flap on defect according to the technique described

Figure 4. Three Month Postoperative View (without obturator)

Discussion

Flaps can be classified depending on the blood supply of it, depending on location and depending on the type of tissue involved.

Depending on blood supply type of the flaps are as below: (by Nihai and Mathes)

Type I: one vascular pedicle flap

Type II: flap with dominant and minor pedicle.

Type III: flap with two dominant pedicle.

Type IV: flap with segmental pedicle.

Type V: flap with one dominant pedicle and minor segmental pedicle.

Depending on location it can be local, regional or free flap. Again depending on tissue content it can be cutaneous, fasciocutaneous, musculocutaneous or composite type which contain bony component along with cutaneous, fascia and muscle.

The forehead flap is a regional axial flap containing skin and muscle. Forehead is supplied by superficial temporal artery, supra-trochlear and supra-orbital vessel. Forehead flaps used are often long concerning their breath because the distance to be travelled by the flap en-route to its destination is considerable and involves a jump over intact skin. If the flap incorporates the entire vertical width of the forehead, it is quite safe to carry it beyond the midline, even as far as the hairline of the opposite temple.

Forehead flap can be used to reconstruct various kinds nasal of defects of, defect of the upper eyelid, intraoral and extraoral mucosal and skin defect, defects created by maxillectomy. It can also be used for reconstruction of the floor of the mouth, a portion of the tongue and for covering the chin in reconstruction of mandibular defect.

Depending on the site this flaps can be classified as below:

1. "Median forehead flap based on primarily on Supratrochlear artery, supplemented by the dorsal nasal artery."
2. "Paramedian forehead flap based on primarily on Supratrochlear artery, supplemented by supraorbital artery."
3. "Laterally based forehead flap based on primarily on Superficial temporal artery, supplemented by the posterior auricular artery."

To harvest the lateral forehead flaps the boundaries of the flap outlined. The contour should follow the eyebrows (must not extend beyond the level of the lateral canthus to avoid injury to the facial nerve) to the anterior border of pinna at the level of the zygomatic arch and along forehead hairline more pleasing cosmetically. Bevelled incision is given along margin. This bevelled margin helps to minimize the deformity along the remaining edges of the forehead and scalp. In case of larger flap outline can be extended up to opposite side temporal hairline.

To transfer the flap from its origin a tunnel is created. Through this tunnel, the distal end of the flap id transferred to the site of the defect and used for reconstruction. Depending on the location of defect flap passed through the following route –

1. "Directly through the cheek (cheek portal)"
2. "Deep to the zygomatic arch"
3. "Posterior part of submandibular incision of neck dissection"

The secondary defect created due flap harvesting is covered by a skin graft.

Local flaps are not sufficient to close the skull base and mid-face defect because they have inadequate well-vascularized bulky tissue.

The pedicled temporoparietal fascia was used by Andrew et al for the closer of the maxillary defect but it appears to be inadequate for the closure of the defect and forehead appears to be a good option for the same.

H. Nakajima et al described the arterial anatomy of the forehead and the vascular supply of different forehead flaps. Arterial supply of the temporal region distributed in four tissue layers[5].

1. "Skin and superficial temporal fascia network"
2. "Loose areolar fascia/subgaleal network"
3. "Deep temporal fascia network"
4. "Temporal muscle network"

There is a good communication between this arterial network and depending on this vascular anatomy different type of individual or combined flaps have been outlined in this region,

Superficial temporal artery was the first used Dunham in 1893 for the pedicle flap for reconstruction of facial defects.[6]

The skin flap islands based on the frontal and parietal branches of the superficial temporal artery was demonstrated by Ozdemir et al for closer of different mid-face deformities.[7] Bi-lobed forehead flap was designed by Harun et al. It was based on the frontal branch of the superficial temporal artery. This was used to reconstruct the defects of upper and lower eyelids 2 and lateral canthus.[8] This flap involves the reconstruction of nose passed on through the centuries commonly known as the Indian method was popularized by two Indian surgeons

when they perform a reconstruction of the nose by using a median forehead flap. It was published in the Gentleman's Magazine of London.[9]

For closer of huge, full-thickness deformities of the midface and forehead acts as a great tissue reservoir.[10] The temporal branch of the superficial temporal artery and supratrochlear artery are the arteries depending on which the forehead flaps are harvested. The superomedial orbit crossed by them approximately 1.7 to 2.2 cm lateral to the midline, and in a paramedian position approximately 2 cm lateral to the midline.[11] For complex deformities of the nose, orbit, zygomatic region, and cheek region bi-pedicled forehead flap considered as a valuable resource.

Endodontic Treatment in Cases of Allergic Reaction to Rubber Dam

Debkant Jena[1], Sumit Dash[1], Lora Mishra[1], Shasrirekha G[2], Siba Prasad Jena[3]

[1]Professor, [2]Professor & Head, [3]Tutor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

The oral cavity is a complex area to handle with about thirty-two teeth, highly vascular tongue, oral mucosa, and gingival. It becomes challenging for the clinician to handle a single tooth in focus with patients movement of vascular tongue and especially in very apprehensive subjects. Hence rubber dam has proved to be a boon not only protecting the tongue, mucosa, and gingiva but also increasing the point of focus for the clinician. Secondly, it reduces infected aerosol procedures thus protecting the clinician and the attendee. Sometimes rarely patients do have allergies to latex or rubber dam and they are not aware. Hence the clinician must ask for leading questions to rule out latex allergy. If the subject does have a latex allergy modifications are required before the treatment.

Keywords: *Endodontic Treatment; Allergic Reaction; Rubber Dam.*

Introduction

To induce a desirable working area in the oral cavity there should be proper moisture control, visibility, and good accessibility. If a file or reamer is mistakenly swallowed during root canal treatment without rubber dam placement then it is likely to confront a lawsuit as Grossman stated that "in the eyes of the court, when an endodontic instrument escapes from dentist's fingers and is ingested or aspirated, expert opinion is unnecessary to justify claims of negligence". Rubber dam sheets are available as heavy, medium, light, and in different colors and standard sizes. Readymade sheets are available in 5×5'' and 6×6'' and rolls according to need which may be conveniently cut into necessary size. It is usually made up of latex material. For patients with latex allergy, non-latex rubber dam material is used in clinics.[1-3]

Case Report A: A 67-yr-old, female patient was referred to the undergraduate clinic for root canal treatment of a mandibular first molar with symptoms of pulpitis.

The past medical history was non-contributory. The patient only reported food and fruit allergies, although she was unaware of the cause of the allergies and the exact model of their manifestation.

During the first appointment, an access cavity was prepared, a dental rubber dam isolation was done, and instrumentation was started with the operating student wearing gloves throughout the procedure. After 20 min, the patient complained of a slight itchy feeling on the lips. The treating student attributed the event to a possible irritation caused by the irrigation solution, and the treatment was carried on.

During the second and third appointments, the same feeling on the lips caused even greater discomfort. Still, the treating student did not give the incident the appropriate consideration. On the afternoon of the third appointment, the patient called the student to report

Corresponding Author:
Prof. Debkant Jena
Professor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India
e-mail: debkantjena@soa.ac.in

pruritus, redness, and inflammation on her lips, perioral, and intraoral region, together with inflammation and burning of her tongue, followed by inconvenience in breathing.

The patient was seen the next morning by the faculty. It was then that contact dermatitis stomatitis due to an allergic reaction to rubber dam was diagnosed. The student was advised to avoid latex products when treating the patient. The patient was advised to proceed with dermatological tests to identify the source of the allergies.

In the remaining appointment, the patient was seen in a separate treating room, the student and the supervising dental staff wore non-latex dental gloves, and a polyvinyl chloride dam was used. The symptoms did not reappear.

Case Report B: A 75-yr-old, retired, female nurse was referred by a general practitioner for root canal treatment of an acute apical abscess of the left maxillary canine. The past medical history of the patient revealed an allergy to penicillin as well as to latex. Five years before treatment in our facility, she had a life-threatening experience of an immediate type I hypersensitivity reaction. The incident occurred when after wearing a brand new brassiere for only 30 min, she developed pruritus with erythema and edema. She did not understand what exactly was happening, and because she was outdoors, she could not get self-examined. After 1 hr of discomfort, she started feeling dyspnea and dizziness. She was carried unconscious to the hospital, where an immediate type I hypersensitivity reaction with laryngeal edema and urticaria was diagnosed. Among other clinical and laboratory examinations, a skin prick test was performed, which indicated an allergy to natural latex. She did not report having undergone multiple surgeries in childhood or a tendency to develop atopy, and she did not report any food allergy. After her life-threatening experience, she was advised by her physician to minimize contact with latex products.

Because a diagnosed latex allergy was reported in her medical history the treatment was intelligently modified. She was always scheduled to be the first appointment of the day. No antihistamines or corticosteroids were administered. Care was taken to exclude any latex products from the room. The dentist and the assistant wore vinyl gloves (Romed, Wilnes, The Netherlands), and for tooth isolation, polyvinyl chloride dams (Hygienic, Akron, OH) were used. Rubber stoppers were not used on endodontic instruments. No symptoms resulted.

Discussion

The case-report A, who was not aware of her sensitivity to rubber dam, was fortunate to experience a non-life-threatening, nonfatal allergic reaction to rubber dam. The patient was terrified, and the student was in an unpleasant position, having caused discomfort to the patient by neglect. The patient did report an allergic sensitivity to fruit, but the student did not insist on getting more details, because she did not evaluate the information that was given as relevant to her practice. Patients sensitive to papaya, banana, avocado, chestnut, apricot, kiwi, pineapple, peach, nectarine, plum, cherry, melon, fig, grape and passion fruit these fruits seem to be predisposed to develop latex allergy. Even food such as potato, tomato, and celery are on the list. From the moment the itching started, the student should have been alarmed.[4-5]

As far as the patient in case report B is concerned, everything seemed to be under control once the sensitivity was reported. Efforts were made to create a latex-free environment during all stages of the therapy. Her occupation as a nurse alone could not indicate her to be a person at high risk because in the period she was practicing, the use of latex gloves wasn't recognized as an occupational hazard in the medical community. Therefore, she couldn't have been exposed to latex allergens because of her occupation.[6-9]

Non-latex gloves and a dam were used. At the stage of obturation, the practitioner was careful not to extrude the gutta-percha cone into the periapical tissues. There have been reports that GP and rubber seem to be chemical isomers and gutta-percha could trigger an allergic reaction as well in patients with sensitivity to latex.Some fruits such as bananas and avocado pears contain cross-reacting proteins with latex. An interesting finding from this study is that patients who were allergic to latex but not to fruits lacked the 30-kD protein band. Signs of allergic reactions to these fruits include pruritus, tightness in the throat, breathing difficulty in patients allergic to fruits have an 11% risk of a latex reaction, patients allergic to latex have a 35% risk of a reaction to fruits.[10-12]

There are noted precautions for latex-sensitive patients such as taking thorough history which are tailor-made to evaluate latex allergy. Refer the patient to the general physician asking the physician for latex-sensitive testing. Precautions should be taken as an emergency medical kit with non-latex airway bags, masks, bandages & tape should be available at a wink of an eye. It is advisable to schedule latex-sensitive patients as the first patient of the day. Better to use glass syringes over plastic or pre-filled or single-use syringes since the plunger may contain rubber. Use of non-latex devices (gloves, dams,etc) & rubber dam napkins. After taking all precautions if a reaction occurs then discontinue the treatment & observe the patient for at least 20 min, medical intervention may be needed.[13]

Root canal treatment in patients with rubber latex allergy could be uneventful if certain precautions are taken.

- Thorough history with particular questions on allergies to latex and previous allergy to rubber material experience should be noted. The dentist should be aware of the latex-fruit syndrome and be cautious when treating a patient who reports an allergy to fruits.
- In case of a positive latex allergy history or cases of high-risk patients, confirmative diagnosis is necessary with either in vitro tests such as serological tests or with more reliable in vivo tests such as a skin prick test, use test or patch test.
- The dentist should be in touch with the patient's general physician informing him/her about the procedure to follow and consult on the need for any premedication with corticosteroids.
- The first aid kit must be routinely checked to ensure that it is equipped with corticosteroids and epinephrine for intravenous or subcutaneous injection. Oxygen masks should be ready in case they are needed.
- An environment without latex has to be created to treat such a patient. The patient must be the first patient of the day to prevent the previous entrance of anyone carrying latex allergens into the treating room.
- Nonlatex gloves should be used. Gloves from synthetic materials such as nitrile and styrene-ethylene butadiene styrene (SEBS), are available in the market. It has been found that the cornstarch powder used in surgical latex gloves forms a complex with latex proteins, which is gradually aerosolized. The complex is kept as a reservoir on surfaces, unwashed hands, and clothes, and even worse, is transported when handling non-latex products, sensitizing the patient.[14]
- For tooth isolation, alternative materials like Polyethylene or polyvinylchloride dams have been proposed. Under the rubber dam,a cellulose separator could be used to prevent its contact with the mucous membrane.
- The practitioner should avoid any product with questionable latex content during the treatment of such a patient. The misleading "hypoallergenic" labeling that can be found on many natural rubber products refers to the sensitivity to residual levels of processed chemicals that those products can provoke. It is therefore essential to avoid them and make sure that non-latex products are used.
- Endo files, reamers must be used without a rubber stopper. As an alternative inerasable ink or wax could be used to point out WL in files and reamers
- As far as the selection of the obturating material is concerned because gutta-percha is the only widely acceptable material, special care should be taken to avoid its extrusion into the periapical tissues to prevent any possible allergic reaction.
- The patient must be advised to avoid products containing natural rubber in his everyday life to avoid sensitization. The list of such products seems to be endless, because there are over 40,000.15,16

Conclusions

The daily practice of endodontics needs to be readapted, and alternatives to the routinely used products must be incorporated in the dental office to treat patients with latex allergy with safety. It is the clinicians' responsibility to be careful of the prevalence of rubber allergy and to be able to perform endodontic therapy without endangering the patient's life.

A Case Report of a Submental and Submandibular Space Infection

Santosh Kumar Subudhi[1], Subrat Kumar Padhiary[1], Harsh Mohan Pathak[2], Kalyan Sundar Pal[3]

[1]Professor, [2]Associate Professor, [3]Postgraduate Trainee, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In most of the cases of space infections are secondary to an odontogenic infection. In space infection, spread occurs through the fascial plane because of the degradation of connective tissue by action of different enzymes produced by microorganisms. Different factors like age, nutritional status of the host, host defense, virulence of the microorganism play an important role in the spread of the infection. Sometimes it may take the fetal course if not treated on time because of its local and systemic complications. It should be treated as an emergency condition to prevent its rapid progression leading to fatal outcome. Here the case report describes an old lady suffering from fascial space infection and treated by incision and drainage. Incomplete removal of any odontogenic infection may cause the recurrence of the infection or infection that may spread to fascial spaces.

Keywords: *Odontogenic infection; Fascial space infection; Host defense; Management.*

Introduction

Odontogenic infections originate from the tooth and its supporting structures. Odontogenic infection arises when oral flora from spread alveolar process to deeper tissue plane of the head and neck region. Different Streptococcus (particularly alpha-hemolytic Streptococcus) are major pathogens of space infection. Spaces in the head and neck region are the potential spaces between the layer of fascia which contains loose connective tissue, areolar tissue, and contain different vital structures. Primary spaces are involved first. Direct secondary space involvement is unlikely.[1] Untreated cases produce systemic complications and also obstruct respiratory tract obstruction. Pathogens of the space infection produce hyaluronidase, streptokinase, and other enzymes which are the cause of the spread of the infection and cellulitis. Decreased host defense, increased bacterial resistance, nutritional status of the patient, the virulence of bacteria also with socioeconomic status and local factors like hygiene of the patient also plays an important role in the spread of the infection. In this article, we reported the case of fascial space infection which first involved buccal space which migrated to superficial temporal space even after drainage from primary space.[2]

Case Report: A lady who is in the 6th decade of life presented with swelling and pain of the bilateral submandibular and submental region for the last 3 days. The swelling appeared after extraction of right mandibular 1st premolar which was carious and had a periapical abscess. There was a 7-day window period between the extraction of the tooth and the development of the swelling. The patient has a history of diabetes and was not under medication for the same.

On general examination, the patient appears toxic, dehydrated, with mild pyrexia a complaint of severe pain

in the right submandibular region anterior neck region, and difficulty in swallowing. Overlying skin appears erythematous. On palpation there was pain and there was a mild rise of temperature than the adjacent area. There was pain on palpation. Swelling was fluctuant. Intraorally there was vestibular obliteration in the right canine and premolar region. Mouth opening and tongue movement was restricted. The patient complains of difficulty in swallowing too. Partially healed socket irt right mandibular 1st premolar region.

Orthopantomogram done for diagnostic purposes. The patient diagnosed with right submandibular and submental infection. Both the spaces drained through a single incision placed over the most fluctuant part of the swelling. Hilton's method is used to drain the abscess. Rubber drain placed and intravenous piperacillin withtazobactam 4.5 gm and metronidazole 500mg with intravenous fluid given. Pus sample send for culture and sensitivity. There was no bacterial growth found in the culture media in 48 hours a patient was under antibiotic therapy.A blood investigation report reveals patient was diabetic and insulin started as per endocrinologist and balanced diabetic diet advised.

Figure 1. Pre-operative picture

Figure 2. Pre-operative picture 2

Figure 3: Picture after drainage.

Discussion

Sublingual space is a paired, v-shaped space lies lateral to the muscles of the tongue including the hyoglossus, genioglossus and geniohyoid. Situated at the midline and communicate with the opposite side space anteriorly.[3] Again sublingual space also connected with the submandibular space around the posterior border of the mylohyoid muscle. So infection of the unilateral submandibular gland can spread easily to the sublingual and to contralateral submandibular space and submental space and my cause Ludwig's angina which is a serious life-threatening complication itself. Again the from the sublingual space the infection spreads backward

direction in the substance of the tongue within the cleft created by the genioglossus and hyoglossus muscle. It follows the course of the sublingual artery. Through this route, the infection can spread to the epiglottic region and cause swelling of the inlet of larynx. Because of anatomical continuity of the submandibular space with the submasseteric, pterymandibular space and the spread of infection may occur in these spaces. More posteriorly the parapharyngeal and peritonsillar space may also involve by infection which causes serious airway obstruction. Infection from the submandibular region, can spread downwards along and beneath the investing layer of deep cervical fascia, towards clavicle and subsequently to mediastinum causing mediastinitis. A prevertebral layer of deep cervical fascia, lincoln's highway or carotid sheath, space between the alar and prevertebral fascia (danger space) play an important role in the spread of infection to the mediastinum.[4-7]

It is difficult to recognize mediastinitis in the early stage and it is one of the major causes of high mortality in case of deep space infections. Primary mediastinitis appears as pyrexia, dysphagia, odynophagia, retrosternal chest pain, swelling over the neck and the chest region along with the chest pain. Physical examination reveals the patient having tachycardia, tachypnea, crepitus over the neck and chest, positive Hamman sign (crunching sound on auscultation of heart) along with other signs and symptoms.[8] Even though the symptoms are not always marked in the primary stage of the disease. The diagnostic criteria for descending mediastinitis described by Estrera et al. are as follows:

(a) Symptoms of clinically severe oropharyngeal infection

(b) Radiographic findings of mediastinitisutilizing CT

(c) The presence of a mediastinal infection, which is detected during an operation or autopsy

(d) A relationship between an oropharyngeal infection and mediastinitis.

Aggressive treatment is necessary for these complications. The airway should be maintained along with early administration of antibiotics in proper dose and frequency, removal of the offending tooth and surgical drainage and decompression of the fascial plane. Intravenous fluids are also given. To main the airway fiberoptic intubation was done in the patient and it is preferred over blind intubation. Surgical airway may be required in cases of severe respiratory obstruction. Laryngotomy, cricothyroidotomy (tracheotomy) are always preferred over tracheostomy, or rather emergency tracheostomy is avoided because of 1. Identification of landmarks that may be required before it, is most of the time quite difficult due to associated massive edema and tissue distortion.[9] 2. The surgery itself may lead to the spread of infection to deeper tissues due to additional incision required. 3.There are high chances of getting pneumonia as sequelae of tracheostomy which itself is a life-threatening condition. 4. Tracheal stenosis is observed in 25–50% of cases following tracheostomy.[10-12]

Again in the presence of pre-existing diseases like malignancy, HIV infection, diabetes mellitus, a patient undergoing chemotherapy within 1 year, chronic renal diseases require dialysis cause compromised host defense and this patient can easily have affected odontogenic infection and they can spread to the deep spaces easily because of reduce host defense. Particularly in diabetic patient host defense is compromised in any way like poor blood perfusion through the capillaries, impaired diapedesis of the neutrophils, abnormal phagocytosis late maturation, and degranulation of the neutrophil, etc. again acidosis produces in the presence of diabetes mellitus impair the immune system of the host.[13-16]

Conclusion

So these patient needs to recognize the situation of immune compromise and modify the treatment accordingly. Some of the modification includes the use of a higher dose of antibiotic, use of broad-spectrum antibiotic, use of proper oral hypoglycemic agent or insulin in required dose to control blood glucose level, etc. in immune-compromised patient macrolides and tetracycline should be avoided.Again complete removal of the infected foci is also necessary for complete resolution otherwise it may cause serious complications in later stages.

Acute Management of Maxillofacial Trauma: A Review of Literature

Bijayalaxmi Panigrahi[1], Santosh Kumar Subudhi[2], Sthitaprajna Lenka[2]Shibasis Biswas[1]

[1]Post Graduate Trainee, [2]Professor, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Management of trauma has progressed dramatically over the past few decades thereby reducing mortality in the golden hour. Challenges exist, however, one such region is maxillofacial injury in a patient with polytrauma. Because of the regions close to the brain, cervical spine and airway, serious injuries to the maxillofacial area may complicate the early treatment of a trauma patient. In case of maxillofacial injuries, the normal procedures of airway respiration and circulation (ABC) management are also changed or augmented by other approaches. In an often-challenging situation these modifications have their own difficulties and pitfalls.

Keywords: *Advanced Trauma Life Support.*

Introduction

Advanced Trauma Life Support (ATLS), established by American College of Surgeons, is the most commonly recognized quality of care for initial assessment and treatment of critical casualties.

Initial Assessment: The methodology of inspecting, listening, and sensing helps to find out airway obstruction and potential airway complications.[1,2] The approach to airway management, particularly in patients with unconscious trauma, should be complimented with C-spine safety. In high-velocity trauma involving the mandible, the swallowing function is altered due to pain and inadequate reflex control, resulting in difficulty in keeping the airway clear.[3] It is therefore necessary to preserve the airway from blood and vomiting in order to avoid aspiration and further pulmonary complications. Trachea palpation shows any potential failure or deviation. Larynx to stridor should be ausculted. Any tracheal tug or laryngeal stridor is explaining an impending threat to the airway. The "difficult intubation" tray should be accessible at all times with complete equipment to handle, including tracheal tube introducer, supraglottic airway machines, combitubes, endotracheal tubes, tracheostomy collection, and craniotomy kit.[4] Where management by traditional definitive airways is less possible, it is advisable to have an experienced team at hand to create surgical airways for rescue.

Strictly speaking, with constant monitoring of saturation, maxillofacial trauma patients should be given sufficient oxygenation, regardless of the injury. The spinal collars should be applied with great care in order to avoid any inadvertent future movement of the mandible complicating the airway. Unlike other polytrauma, maxillofacial patient's airway is at constant risk. The strategy is therefore a systematic analysis of the airway as delayed airway compromise may occur as a result of tissue displacement, bleeding, and swelling.[2] High-volume suction should be available to clear the mouth and oropharynx from blood and secretions.[5] However, care should be taken not to irritate the oropharynx with suctioning as it predisposes the patient to vomit. Furthermore, at this moment close observation of the patient should provide an idea about the reaction of defensive reflexes such as gagging and swallowing. When airway is clear, the oropharyngeal guedel can be used effectively. The positioning of guedel itself, however, causes retching, laryngospasm and sometimes eventually displaces the tongue thereby further aggravating the airway. The rule is emergency endotracheal intubation, without any protective reflex. Bag-mask ventilation is

the method of choice in patients with a patent airway and an absent spontaneous respiration. A tightly fitted mask with concurrent jaw thrust is always necessary to keep the ventilation running. Nonetheless, obese patients and beard patients have problems thus reducing ventilation effectiveness. In trauma patients, mask ventilation would ideally be a "two-person procedure," one that keeps the mask closely fitted to the mouth, and the other that operates the tube. Similarly, caution should be taken to execute adjunctive airway movements such as chin lift and jaw thrust. In the case of alleged C-spine damage, the head tilt and "sniffing the morning air" positions are absolute contraindications. The treatment strategy for patients with suspected C-spine injury is to keep the patient supine in order to help minimize morbidity of the C-spine as well as to immobilize the cervical spine using strong cervical collars.These collars may reduce exposure to the oropharynx which may be important. Unfortunately, the question that needs to be addressed in this scheme is how efficiently a trauma team can intubate the patient? A research shows, on this basis, that trauma patients with noisy or obstructed airways present. The unsuccessful rate of intubation is an unprecedented 12 percent.[6]In a study conducted by Martin et al., 10.3 percent of 3423 emerging intubations needed several attempts and were rated as "difficult."[7]

Primary Survey

Primary survey is performed to evaluate the system and vital function in question. The treatment plan is based on injuries, vital signs and mechanisms for injury. The primary survey is progressing sequentially on the following: 15

A – Airway with cervical spine immobilization

B – Breathing

C – Circulation with hemorrhage control

D – Disability (neurological status, as expressed by the patient)

E – Exposure of the entire body (looking for occult injury)

Definitive Airway: The definitive airway principle is that maxillofacial trauma is generally much more significant than other parts of the body as opposed to trauma. The key signs are set out in Table 1. The traditional conclusive, clear airway solutions are orotracheal intubation, nasotracheal intubation, and airway surgery. Laryngoscope-aided orotracheal intubation is the most feasible and effective method of treatment. However, if the C-spine is not clear, manual in-line axial stabilization during orotracheal intubation is prudent. While evidence in the literature indicates that some cervical movement is inevitable,[8,9] orotracheal intubation in an unknown cervical spine is comparatively healthy. It is easier to do, faster and induces minimal mobilization of the cervical spine in professional hands.[10] In extreme avulsive facial injury or in laryngeal or tracheal collapse, orotracheal tube positioning is difficult and surgical airway is the alternative. Another successful option is nasotracheal intubation, which can be done in patients without communicated midface or skull base damage. This is especially important in controlling airway obstruction due to lower face injury, and is ideal for patients with insufficient mouth opening. The method are supported by two forms, either blind or fibreoptic. A qualified professional's conventional blind technique is fast, efficient and requires no premedication. At the other hand, the enthusiasm for fibreoptic technique is restricted by the presence of copious secretions or blood in the airway, the sensitivity of the technique and the required increased time. Similarly, laryngeal mask airway (LMA) and combi tube are solutions to a failed or complicated intubation, but not one that is definite. These tools build support by bridging the airways before they enter a definite airway. It doesn't protect the airway from regurgitation and aspiration, however. The combi tube can be used instinctively in emergencies or in prehospital settings with little experience needed and simple placement.[11] Though suggested, retrograde intubation is very time-consuming and required expertise through cricothyroid puncture. Therefore, it is of limited use in emergency situations.[12] The manipulation of the cervical spine should be kept minimal during the airway maintenance technique and whatever approach you adopt, always note the dictum "to do no more harm."

Table 1. Indications of definitive airway in maxillofacial injury

Indications of definitive airway in maxillofacial injury
Absent spontaneous breathing
Comatose patient (glasgow coma scale <9)
Airway injury or obstruction
Persistent oxygen saturation <90%
High-risk for aspiration
Systemic shock (systolic blood pressure <80)
"Cannot ventilate cannot intubate" situations

If non-invasive strategies for securing airways fail, the only alternative left is surgical airways. They are of two types: cricothyroidotomy and tracheostomy.[13] In emergency, cricothyrotomy is the most effective approach and can be done by needle (needle cricothyrotomy) or surgical scalpel (surgical cricothyrotomy).[14] While some schools advocate needle cricothyrotomy, the standard use of it is debatable. The failure rates and insufficient oxygenation prevent its use, and in emergency, surgical cricothyroidotomy is the appropriate method of choice. In most cases, tracheostomy is done as an elective treatment, until cricothyrotomy stabilizes the patient. While percutaneous tracheostomy claims to minimize operating time and surgical complications in good hands, there is no evidence of its daily use in emergency.

Airway management in maxillofacial trauma protocols[2]

- Assess and identify obstructions to the airway.
- Clear the airway, position the patient. Perform chin lift and jaw thrust manoeuvre
- Confirm the nasal and oral passage are clear then use artificial airways and
- Perform bag-valve-mask ventilation. Preferably "two-person technique"
- Oro-endotracheal intubation
- In unsuccessful orotracheal intubation or "cannot ventilate cannot intubate situation" perform surgical airway [Figure 1].

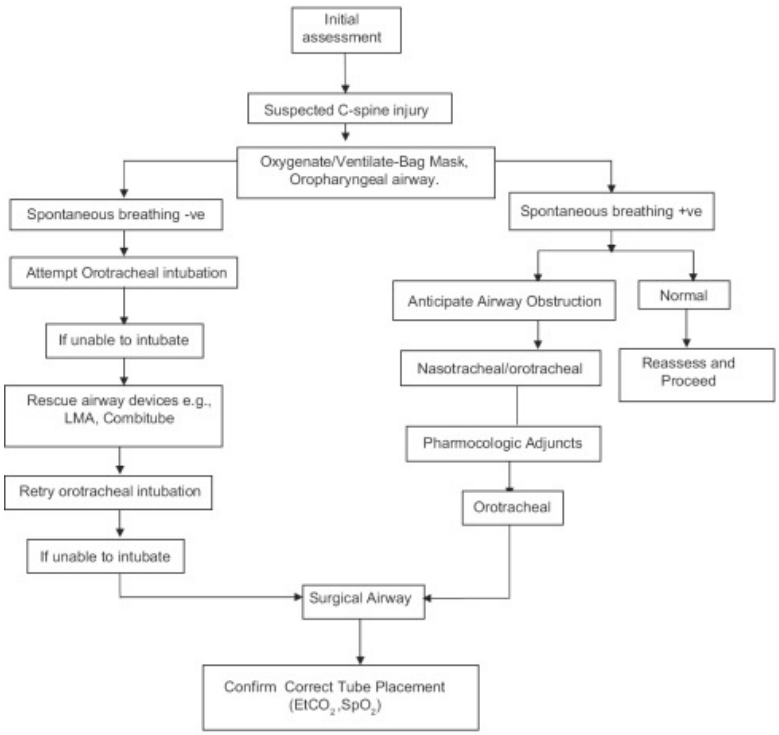

Figure 1. Surgical airway

Breathing: Breathing is evaluated by measuring the patient's respiratory rate, and subjectively quantifying the depth and intensity of inspiration. Breath sounds should be consciously filtered out bilaterally. Pulse oximetry is an obligatory adjunct and end-tidal carbon dioxide monitoring is a beneficial adjunct. Rapid breathing action, and use of respiratory accessory muscles, hypoxia, hypercapnia, and asymmetrical chest wall excursions and diminished or absent breathing sounds all require treatment while proceeding.At this point, pneumothorax tension needle decompression can be completed quickly with conclusive thoracostomy of the tube performed after completion of the primary survey.[15-18]

Circulation and Haemorrhage control: Following the development of airways and the treatment of respiratory issues, priority must be paid to circulation. Maxillofacial injuries are particularly vulnerable to serious haemorrhages and life-threatening haemorrhages can range from 1.4% to 11%. One in ten of the complex facial fractures substantially bleeds. The principal vessels involved are an ethmoid artery, ophthalmic, internal carotid vidian branch, and maxillary artery. Bleeding can be easily controlled in most cases, but rarely extreme epistasis ranging from 2% to 4% of all facial bleeding occurs from the maxillary artery, causing haemorrhage management difficulties.Through careful examination of the pharynx for lacerations and tears, it is important to distinguish bleeding from the skull base fracture and oral bleeds.[19-23]

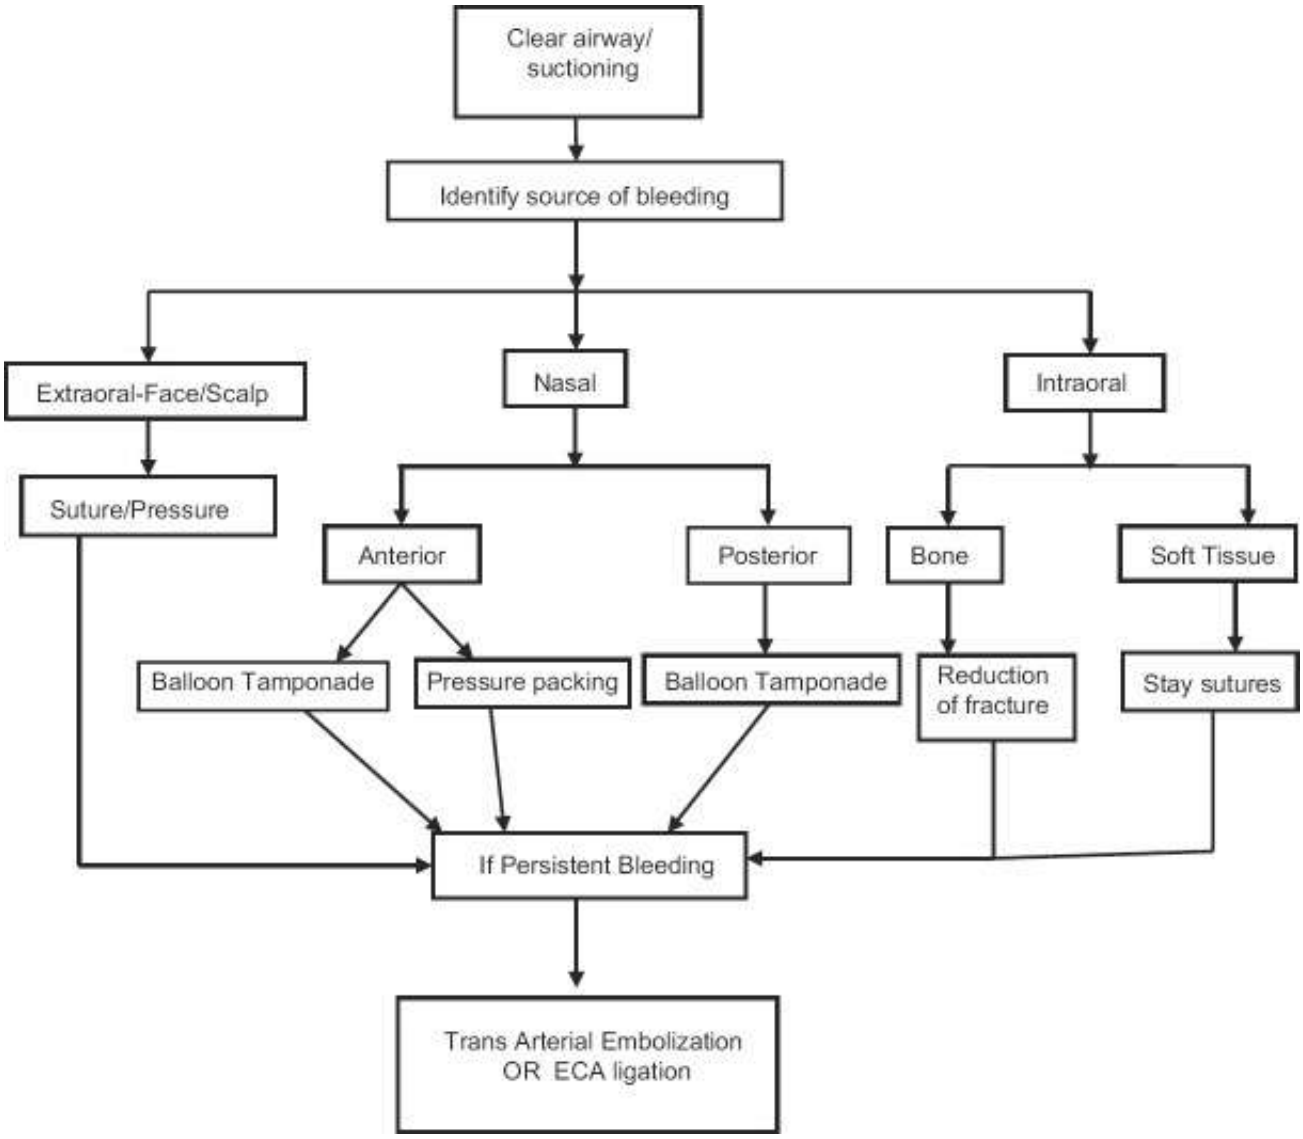

Figure 2. Clear airway/suctioning

Secondary Survey: Upon completion of the primary test, serious life-threatening injuries were treated, and vital signs were stabilized, the provider starts the secondary check that requires a history and full head-to - toe inspection. A history of the injury process is important to obtain, since certain causes of trauma (falls, motor vehicle collisions, car vs. pedestrian accidents, gunshot wounds, etc.) are typically associated with patterns in injury, which may alert the provider to new potential injury. Current medicines are important, particularly for elderly people, because anticoagulants can be a significant cause of excessive bleeding, and b-blockers can decrease cardiac output and suppress tachycardia.[24-27]

The family members, paramedics, or other traumatized patients can be a best source of knowledge in a patient who is unable to respond. A helpful mnemonic for having a brief history is "Complete," which looks at the following important areas: allergies, medications, past diseases/pregnancy, last meal, and injury-related events/environment. The physical exam carefully examines each region of the body to accurately classify all the wounds and reduce the possibility of missed injuries. The systematic analysis starts with the head and skull, and progresses to maxillofacial structures, neck and c-spine, chest, abdominal, perineal region, pelvic and neurological system. Since several of those structures overlap, a detailed and systematic approach should always be taken to ensure completeness.

Cervical Spine and Maxillofacial Trauma: In a complex maxillofacial trauma situation, fracturing of the cervical spine should always be considered, unless otherwise confirmed. The occurrence in all maxillofacial trauma is very small and ranges from 1 percent to 10 percent.[27-34] Due to the proximity of the cervical spine, any force of such magnitude that causes facial fractures can potentially traumatize the c-spine and its ligamentous attachments. In general, without the addition of a radiographic test, the patient can be exempt from spinal injury if the following are shown. Patient with neurological conditions (norm GCS); Not under the consequence o drugs/alcohols/others; Absences of pain in posterior midline cervical spine; devoid debilitating.[35]

Conclusions

The seriousness of all maxillofacial injuries is due to the fact that they pose an immediate threat to life as a result of their proximity to both the airway and the brain. Even so, each situation is unique; therefore, even for the most seasoned of professionals, the management is exacting. No treatment strategy can be defined as sure and flawless in any given scenario. The need of the hour is a multi-pronged strategy involving multi-departmental cooperation. Although new technologies and equipment advances have helped to ease the crisis, the prompt action, sheer skill, and mind presence of emergency personnel and surgeons are what counts.

Coronavirus Disease 2019 (COVID-19): Impending Encounters for Dental Health Professionals in India

Ramesh Nagarajappa[1], Debasruti Naik[2], Gayathri Ramesh[3]

[1]Professor and Head, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Associate Professor, Department of Dentistry, Chamarajanagar Institute of Medical Sciences, Chamarajanagar, Karnataka, India

Abstract

Originating in Wuhan, China, the epidemic of coronavirus disease 2019 (COVID-19) has become a major public health challenge for not only China but also countries around the world. The outbreaks of the novel coronavirus have constituted a public health emergency of international concern as announced by the World Health Organization (WHO). For dental care provision to active or suspected COVID-19 cases, no universal protocol or guideline is available till date. Major challenges to worldwide health systems will have far-reaching consequences on the global economy if the spread of the virus is not effectively controlled as a consequence of the COVID-19 outbreak. So, in a nutshell, there is no point in being cynical about the future of the dental profession.

Keywords: *Challenges; coronavirus; COVID-19; infection; dentist.*

Introduction

India's tally of Coronavirus disease 2019 (abbreviated "COVID-19") rises to 24,506, death toll at 775 as on 26th April 2020.[1] Caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infection, COVID-19 has become an emerging respiratory disease. The first COVID-19 case was reported to the WHO country office in China on 31 December 2019 which originated in Wuhan, China.[2] The Director-General of the World Health Organization (WHO) declared coronavirus disease 2019 (COVID-19) outbreak a pandemic at a media briefing on 11th March 2020.[3] COVID-19 has been recognized in over 200 countries, areas and territories, with a total of over 23,14,621 confirmed cases and over 1,57,847 deaths, as of 20 April 2020.[4] The monitoring of this infectious disease outbreak is done by International centers for disease control and prevention. Fever, cough, and acute respiratory disease, with severe cases leading to pneumonia, kidney failure, and even death is the symptoms of COVID-19 infecton.[5]

Demand for urgent dental treatment decreased by only 38% despite the large-scale community transmission of COVID-19 in China during the epidemic.[6] This reflects public need during this pandemic will always be essential for urgent dental care. Several dental institutes, regulatory and advisory bodies still do not have a clear vision about the worldwide impact this pandemic can have on dental services although it has been six weeks since COVID-19 outbreak was declared as a pandemic. From advising practitioners to close their practices in California, USA;[7] to reducing the number of routine check-ups in the UK;[8] to no advice at all from several dental associations around the world, there were varied responses and actions from dental associations around the world. The varying degree of COVID-19 outbreak in different countries owes to such unclarity.[9]

However, this COVID- 19 pandemic could last over 18 months according to the US Government COVID-19 response plan published by the US Department of Health and Human Services (HHS) on 13 March 2020.[10] There will be increase in the suffering of the individuals in need of urgent dental care and it will also incense the burden on hospitals emergency departments, although closing dental practices during the pandemic can reduce the number of affected individuals. This article is an attempt to understand the current imminent of the pandemic and how it will impact the future outlook for the profession of dentistry. Taking into consideration the severity of the pandemic COVID-19, and in the light of the massive commitment of several dental associations we have used existing research, personal life experience, assumptions, and industry data to try to make some sense of all of this psychosis.

To curb the spread of the new virus, India has been under a nation-wide lockdown since Mar 24, 2020, which has now extended till 3rd May by the Government. Special challenges are posed by India for the country's disease containment strategy due to its grossly under-funded and patchy public health system, with huge variations between different states, despite India not being among the worst-hit countries. There have been several reported instances of patients trying to flee isolation wards in government hospitals and hide travel history over the past few weeks. Many tried to dodge the mandatory home quarantine even with exposure to suspected cases of COVID-19 and infected persons.

India's latest containment plan, a 20-page document which specifically talks about "non-pharmaceutical interventions" "Quarantine and isolation are important mainstay of 'cluster containment," states that the above mentioned are worrying developments in the backdrop of the plan. Quarantine refers "to separation of individuals who are not yet ill but have been exposed to COVID-19 and therefore have a potential to become ill". Isolation refers to "separation of individuals who are ill, suspected, or confirmed COVID-19 cases".

People escaping hospitals or quarantine in the past week have been certain repeated reports. "How can this impact the ongoing control measures for COVID 19? One key issue is the trust deficit in the public health system in many parts of the country. Other important factors include fear of isolation and stigma attached to those who are being quarantined and isolated. It is difficult for people in India to understand the importance of isolation and quarantine, even though it is a response to a pandemic. The faith in the public health system cannot emerge immediately as a response to the pandemic".

"An overstretched public health care system forces millions of Indians to turn to the unregulated private health care sector. The Indian Government's consumption on health as a percentage of GDP still hovers around 1·5%, one of the lowest in the world. For around 52% of family units in urban areas, and 44% of families in rural areas, the private segment is the primary source of human services when they are debilitated, as per government data.[11] Trust in Government is a significant part in a crisis health response".

Current and upcoming dentistry: Dental specialists currently face a test they have not been set up for. None of the dental specialists would have imagined a circumstance like this one, where there is a drawn-out time of interference. It is hard to foresee what's on the horizon for dentistry. How about we consider the month government evacuates all limitations as month zero. Expect customer spending to return inside seven days of month zero. It is normal that consumers will spend on basics followed by a time of liquidity crunch where spending will diminish once more. For dentistry, this may imply that patients at first spotlight just on crisis strategies or the treatment that truly matters to them.

Patient administration: Practices are utilizing each conceivable strategy (mailers, voice messages, web-based life, and practice sites) to educate patients about the workplace terminations for ordinary dentistry. Patient screening conventions, should proceed significantly after the limitations are lifted (figure 1).

Patients are understanding and are not ready to face challenges themselves. Practices need to rehash the exacting Centers for Disease Control and Prevention (CDC) and Occupational Safety and Health Administration (OSHA) rules that are being executed.

Staff supervision: The most awful effect of works on being shut is on staff compensations. A considerable lot of the staff have less squirm room undoubtedly.

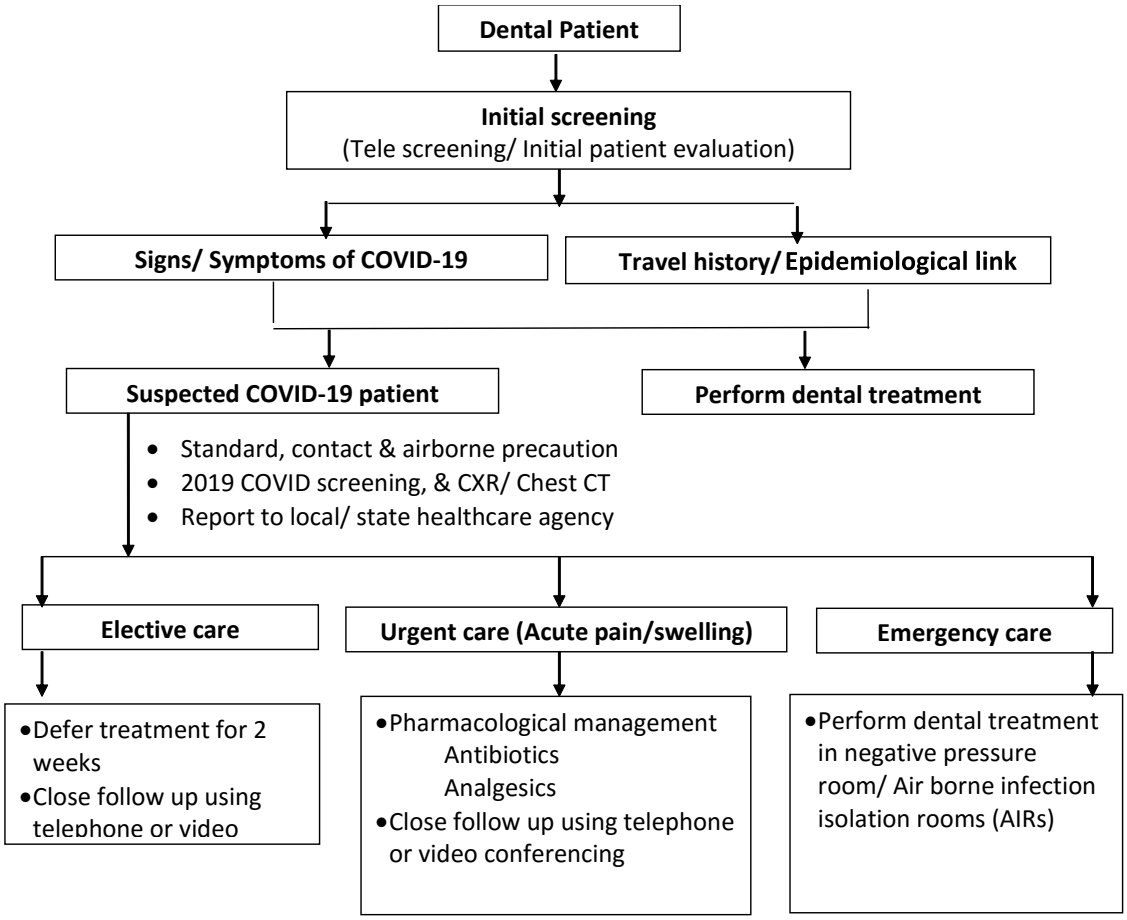

Figure 1. Patient Screening Protocols.

Employing partners and hygienists: There is a great deal of disarray among dental alumni in regards to recruiting associates because of this emergency. All things considered; dental specialists will hold on to perceive how patients are reacting. In the event that they rapidly recoup, at that point there will be an earnestness to recruit to make up for lost time. Professionals will probably react dependent on how their financers, for example, banks, acclimate to the new reality. Some may at present grow their practices while others may concede the move for what's to come. The circumstance may at first be somewhat harder for dental hygienists, however it will level soon.

Dental inventory organizations: Personal protective equipment (PPE, for example, gloves, outfits, goggles, and face masks, just as cleaning, diagnostic, surgical, and wound care items have been delivered fundamentally by huge providers in China. This reliance on China will most likely diminish and local creation will soar. This will mean the cost of expendable things may go up later on. The stock calendar will be upset during the months to come and dental specialists will see a ton of delay purchases on numerous items.

Insurance: The insurance agencies are being immersed with calls about pandemic inclusion and they face an exceptional circumstance where they may need to remunerate the entirety of their policyholders. This will put them under huge tension. The insurance agencies will in general oppose the cases by pulling in all the lawful supports. There is likewise the probability that dental specialists will react with a joined supplication to the administration sooner rather than later.

Banks: It is sensible to anticipate that banks should give a go for a couple of months, in any event in regards to paying practice advance premiums.

"The most suggested rules show that dental specialists ought to maintain a strategic distance from the booking of any patient: just such pressing dental sicknesses can be considered during the COVID-19

episode. This activity will definitely restrain the relational contact, the holding up time of patients in dental cupboards and, when all is said in done, the conditions inclining patients to be contaminated. At the point when the dental specialists treat patients, they should intercept the possibly contaminated individual before they arrive at the working zones; for instance, those with a fever estimating >37.5°C and the offering of a couple of conversation starters about the patient's general wellbeing status over the most recent 7 days, and about the danger of having been in contact with other tainted people".

"Dental patients who cough, sneeze, or obtain dental treatment including the usage of a high-speed handpiece or ultrasonic instruments make their secretions, saliva, or blood aerosolize to the environment. Dental mechanical assembly could be defiled with different pathogenic microorganisms after use or get presented to a contaminated clinic condition. From that point, diseases can happen through the cut of sharp instruments or direct contact between mucous layers and tainted hands".[12]

"Because of the extraordinary qualities of dental methodology where an enormous number of droplets and aerosols concentrates could be created, the standard defensive measures in every day clinical work are not compelling enough to forestall the spread of COVID-19, particularly when patients are in the incubation time frame, are uninformed they are tainted, or decide to cover their contamination".

Efficacious Infection Control Protocols: "Hand cleanliness has been viewed as the most basic measure for diminishing the danger of transmitting microorganism to patients.[13] SARS-CoV-2 can endure on surfaces for a couple of hours or as long as a few days, contingent upon the sort of surface, the temperature, or the stickiness of the environment.[14] This fortifies the requirement for good hand cleanliness and the significance of intensive sanitization of all surfaces inside the dental center. The utilization of individual defensive gear, including masks, gloves, outfits, and goggles or face shields, is prescribed to shield skin and mucosa from (conceivably) tainted blood or emission. As respiratory droplets are the principle course of SARS-CoV-2 transmission, particulate respirators (e.g., N-95 masks validated by the National Institute for Occupational Safety and Health or FFP2-standard veils set by the European Union) are suggested for routine dental practice. The 4-handed method is advantageous for controlling contamination. The utilization of salivation ejectors with low or high volume can diminish the creation of droplets and aerosols".[12,15,16] Fumigation of the work environment should likewise be possible to free all the debasements from nature we work in. All biomedical waste relating to persistent consideration ought to be painstakingly arranged according to the Bio-Medical Waste (Management and Handling) Rules,1998 revised periodically through an approved biomedical disposal organization by the State Pollution Control Board.

Appraisal of Patients: "During the flare-up of COVID-19, dental facilities are prescribed to set up precheck triages to quantify and record the temperature of each staff and patient as a standard technique. Precheck staff ought to ask patients inquiries about the wellbeing status and history of contact or travel.[17] Patients and their accompanying people are given clinical masks and temperature estimation once they enter our emergency clinic. Patients with fever ought to be enlisted and alluded to assigned medical hospitals. On the off chance that a patient has been to pandemic areas inside the previous 14 days, quarantine for at least 14 days is proposed. In zones where COVID-19 spreads, nonemergency dental practices ought to be postponed.[12,15,16] It was accounted for that dental practice ought to be deferred in any event multi month for convalescing patients with SARS.[16] It is obscure yet whether a similar proposal ought to be suggested for patients with COVID-19".

Oral Examination: "Preoperative antimicrobial mouth wash could diminish the quantity of organisms in the oral cavity.[12,18] Procedures that are probably going to initiate coughing ought to be maintained a strategic distance from (if conceivable) or performed cautiously.[17] Aerosol-creating method, for example, the utilization of a 3-way syringe, ought to be limited however much as could be expected. Intraoral x-ray assessment is the most well-known radiographic method in dental imaging; be that as it may, it can invigorate saliva secretion and coughing.[19] Therefore, extraoral dental radiographies, for example, panoramic radiography and cone beam CT, are proper options during the episode of COVID-19".

Handling of Emergency Cases: "Dental crises can happen and fuel in a brief period and consequently need prompt treatment. Rubber dams and high-volume salivation ejectors can help limit airborne or scatter in dental method. Besides, face shields and goggles are basic with utilization of high or low-speed drilling with water spray.[20] According to our clinical experience

during the flare-up, if a carious tooth is determined to have symptomatic irreversible pulpitis, pulp exposure could be made with chemo mechanical caries expulsion under rubber dam seclusion and a high-volume salivation ejector after local anesthesia; then, pulp devitalization can be performed to diminish the agony. The filling material can be supplanted delicately without a devitalizing operator later as per the maker's suggestion". After treatment, environmental cleaning and disinfection procedures were followed. "On the other hand, patients could be treated in a segregated and very much ventilated room or adversely compelled rooms if accessible for suspected cases with COVID-19. Perilous cases with oral and maxillofacial compound wounds ought to be admitted to the clinic quickly, and chest CT ought to be endorsed if accessible to avoid suspected contamination on the grounds that the RT-PCR test, other than tedious, needs a research facility with pan-coronavirus or explicit SARS-CoV-2 identification capacity".[21]

Dental Contemplations: "Bioaerosols are natural particles suspended in vaporous media.[22] Subgingival scaling for treating periodontally undermined teeth with the guide of a ultrasonic scalers will create vaporizers containing blood.[23] An ongoing report demonstrated that the ultrasonic scalers and tips delivered altogether more airborne contrasted with a handheld curette, paying little attention to the scaler type employed.[24] The continuous and interminable presentation to bioaerosols produced during such dental systems notwithstanding the generally little molecule size of the bioaerosols add to an expanded danger of contamination among dental professionals.[25] It is as yet sketchy whether the security provided by surgical masks worn by dental experts go about as a defensive boundaries for such little particles notwithstanding the way that these covers may not fit consummately in clinical practice. Simultaneously, it is critical that the probability of distinguishing, detailing and reporting dental calling related diseases is generally less".[26]

Conclusion

In all probabilities, the virus will stay with us. There will be changes in behavior such as less travel, reduced smoking, increased use of pneumococcal vaccines, higher online sales and food ordering, higher interest in online courses, social distancing, more movies about viral outbreaks - the list is endless. Albeit the vast majority of the public consideration is concentrating on the immediate causes and control proportions of COVID-19, potential health moments coming about because of individuals' feelings of trepidation of it ought not be ignored. Understanding the current circumstance is useful as far as anticipating future dental needs. Numerous reasons do conjecture that individuals' prerequisites for dental administrations may develop explosively in the post-COVID-19 period.

Awareness in Oral Hygiene Status in Diabetic Cases: An Institutional Study

Sreepreeti Champatyray[1], Saurjya Ranjan Das[2], Ipsita Mohanty[3], Neeta Mohanty[4], Jagannath Patro[5]

[1]Assistant Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [2]Associate Professor. Department of Anatomy, Institute of Medical Sciences, [3]Assistant Professor, [4]Professor & Head, [5]Postgraduate Student, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Objectives: The objectives of the study were to: (1) assess the knowledge and awareness of diabetic patients of their risk for systemic and oral diseases as complications associated with diabetes, (2) to assess their attitudes toward sustaining good oral health through proper oral hygiene and regular dental check-ups, and (3) to the extent that they are aware, to determine how they became aware.

Method: One hundred self-administered questionnaires were distributed to assess the main objectives of the study. Only completed questionnaires were used in the current study data analysis.

Results: A majority of the participants suffering from Type 2 diabetes (58%). The awareness of diabetic patients of their increased risk for oral diseases was not upto the benchmark point . Their attitude towards good oral hygiene status was not desired. Likewise, 43% brushed their teeth once daily and 49% never used dental floss. Regarding participants' sources of awareness towards to dentist about diabetics is 50%.

Conclusions: Diabetic patients are found to have little knowledge of their increased risk for oral diseases. Inorder to promote proper oral health and to reduce the risk of oral diseases, health professionals in both thedental and medical fields need to take the responsibility to develop programs to educate the public about theoral manifestations of diabetes and its complications on oral health.

Introduction

Diabetes mellitus has been increasing at such an alarming rate worldwide that recently the World Health Organization (WHO) declared the disease an epidemic. The number of estimated cases of diabetes has increased from 30 million in 1985 to 135 million in 1995, and is projected to increase to 366 millionby the year 2030.[1] The prevalence of diabetes mellitus currently affects more than 62 million Indians, which is more than 7.1% of the adult population. The average age on onset is 42.5 years. Nearly 1 million Indians die due to diabetes every year. In addition to the more common complications that arise as a result of this disease, diabetic patients who do not carefully control their blood glucose levels will be at high risk of systemic and oral complications. The mostcommon complications include macrovascular diseases,coronary artery,and cerebrovascular diseases. Additionally, microvascular complications manifest as diabetic retinopathy, neuropathy, andnephropathy among others.[2]

In terms of its oral consequences, diabetes manifests itself in several ways. When diabetes mellitus is left uncontrolled for an extended period, it affects salivary glands and which results in xerostomia or sialosis (dryness of mouth).[3-7] When not enough saliva is produced to wash and cleanse the oral cavity. This could be a factor in the increased risk for dental caries often observed in dental patients.[8,9] Furthermore, peridontitis is perhaps the most widely noted oral manifestation of diabetes mellitus. Several researches have advanced the notion that there is a bidirectional relationship between periodontitis and diabetesmellitus.[10,11] In this paper, we had a survey of one hundred individuals for oral hygiene awareness in diabetic patients.

Thus, the purpose of the current study was to: (1) assess the knowledge and awareness of diabetic patients of their risk for systemic and oral diseases as complications associated with diabetes, (2) to assess their attitudes toward sustaining good oral health through proper oral hygiene and regular dental check-ups, and (3) to the extent that they are aware, to determine how they became aware.

Method

In the current study, a self-administered questionnaire was used and utilized to assess the main aims of the study. The questionnaire questions were related to participants age and sex, type and duration of diabetes, and their awareness for systemic and oral diseases and other characteristics related to oral hygiene in diabetics patients. Various response formats were used in the questionnaire such as 'yes,' 'no,' 'I do not know,'encircling disease name, they were aware of as a complication of diabetes, or filling blank spaces.

Clinical findings in diabetic pts		
Age		
Gender		
Dryness in the mouth		
Delayed healing in extraction socket		
Bleeding gums		
Gingival recession		
Tooth mobility		
Generalized stain & calculus		
Periodontal pocket Depth of pocket >2mm, > 3mm		
Tooth Decay		
Bad breath		
Mouth ulcers		
Infections		
Brushing frequency Once a day Twice a day		

Figure 1. Questionnaire form for diabetics individuals

One hundred questionnaires were distributed to the diabetic patients attending the outpatient diabetic clinic in the department of Oral Pathology And Microbiology, IDS Eligible participants were confirmed diabetes mellitus patients. Data were collected over one year. However, questionnaires with uncompleted answers were excluded and a total of 100 completed questionnaires were entered on an Excel spreadsheet and imported into Statistical Package for Social Sciences (SPSS) version 13 (SPSS Inc.,Chicago, IL, USA) for data statistical analysis.

Results

The diabetic patients participating in the current survey were 90% nationals, of whom 59% were male and 39% were female. The mean of the age was 35 years. In our study we found both the type 1 and 2 diabetics, type 1 is 40%,type 2 is 58%. We also recorded delay extraction socket or delayed healing is 25%.

Mouth dryness/xerostomia is 67% of cases, bad breathe is 31% in cases related to periodontitis like periodontal pocket is 22%, bleeding gums is 52%,gingival recession is 52%,stain and calculus not having 53%. 46% don't have grade ll mobility whereas 30% have tooth mobility. 26% of individuals suffering from infection whereas in mouthulcer patients is 27%. Individuals suffering from dental caries are 32%. Patients are advised for brushing and flossing habits once or twice they are 43% and 49%.

Table 1: Represents Results of Diabetic Individual

Male	59%	
Female	39%	
Age	35 years and above	
Type 1	40%	
Type 2	58%	
No. of Visit	46%	
Delayed Healing	Y----26%	N----25%
Mouth Dryness/Xerostomia	Y-67%	N- 26%
Bleeding Gums	Y-52%	N----43%
Gingival Recession	Y---52%	N—50%
Stain And Calculus	Y---30%	N- 53%
Tooth Mobility	Y-30%	N-46%
Infection	Y-26%	N-33%
Mouth Ulcer	Y-27%	N-19%
Tooth Decay	Y-32%	N-31%
Bad Breathe	Y-31%	N-38%
Periodontal Pocket	Y-22%	N-25%
Brushing Frequency	Y-43%	N-59%
Flossing Frequency	Y-49%	N-13%
Do the PT Talk About Diabetic to Dentist?	Y-50%	N-47%

Discussion

The prevalence of diabetes worldwide has been increasing epidemically. It was declared by WHO that 366 million people are expected to suffer from diabetes mellitus by 2030. In the current study, more than half of the participants (58%) had Type 2 diabetes, 26% suffered from Type 1 and, unexpectedly, 16% of participants did not know what type of diabetes they had. The data presented in this study reveals an important finding: it demonstrates that diabetics have more knowledge

about their increased risk for systemic complications associated with diabetes than they do for oral and dental complications. The percentage of participants who were aware of their increased risk for eye disease was 85%, heart disease 75%, kidney diseases 90%, periodontal disease 60%, dental caries 54%, and oral fungal infections 42%.[12] Similar findings were reported by several researchers,who assessed the knowledge diabetic patients had of their risk for periodontal disease, their attitude toward oral health, and their oral health-related quality of life. The researchers found that only 33% of the participants were aware of their increased risk for periodontal disease.[13] Similarly, Eldarrat (14) found that diabetic patients' awareness of their increased risk for oral diseases was low compared to their awareness of systemic diseases and a significant association was found between glycemic control and oral infections. Furthermore, Moore et al.[15] assessed oral health attitudes, behaviors, and knowledge of participants with Type 1 diabetes and found that most of the participants were unaware of the oral health complications of diabetes mellitus and the need for preventive care.

It is well known that a significant reduction of salivary flow leading to xerostomia is the most common oral manifestation of diabetes. It is of paramount importance to inform and make diabetics aware of the beneficial properties of saliva. Saliva's function of washing and cleansing the oral cavity is known to prevent the accumulation of plaque and debris, which could be a contributing factor in diabetics' increased risk for periodontal disease and dental caries.[8,9] This study also revealed the additional important finding that diabetic patients have limited knowledge of the associations between oral health and overall health. Similar results were reported by several investigators who found that of 299 participants, only 29% brushed their teeth on a twice-daily basis.

The data of the present study showed that about 40%of the participants had not visited a dental clinic within the last year. The main reason to visit a dental clinic within the last year was to receive treatment for pain and/or discomfort. Only 14% visited for regular check-ups. Early detection and treatment of tooth caries, periodontal disease, and other oral diseases would be of enormous benefit to protect diabetic patients from the harmful oral complications associated with diabetes. Furthermore, it is necessary for dental professionals and related government agencies to promote awareness of the relationship between diabetes and oral health to prevent harmful dental complications and expensive treatment.

Conclusion

Within the limitations of the current study, the data presented in this study demonstrated that diabetics have more knowledge about their increased risk for systemic complications associated with diabetes than they do for oral and dental complications. For promoting proper oral health and to reduce the risk of oral diseases,health professionals in both the dental and medical fields need to take the responsibility to develop programs to educate the public about the oral manifestations of diabetes and its complications on oral health.

Tumor Associated Macrophages: A Review with Institutional Study

Sreepreeti Champatyray[1], Priyanka Debta[2], Neeta Mohanty[3], Saurjya Ranjan Das[4]

[1]Assistant Professor, [2]Professor, [3]Professor & Head, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [4]Associate Professor Department of Anatomy, Institute of Medical Sciences & Sum Hospital, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aims: To study the expression of tumor-associated macrophages in different grades of squamous cell carcinoma and find the association between their expression and local recurrence, metastasis.

Methodology: Thirty tumor biopsy samples of oral squamous cell carcinoma in T1N0M0 and T2N0M0 stages. Ten biopsy specimen of normal oral mucosa that are taken during minor oral surgical procedure with patient consent.

Result: Macrophages were found to have better specificity for local recurrence, metastasis, and survival. Further, higher expression of biomarkers was associated with shorter survival. We have analyzed the differential expression of MMP 9 in different grades of OSCC & compare their expression with different TNM staging of tumors.

Conclusions: Concluding this review of tumor-associated macrophages in comparison with OSCC cases. Since metastases are the principal cause of death in cancer patients, a greater understanding of the process of tumor invasion and metastasis is essential in leading to the identification of new therapeutic targets.

Keywords: *Immunohistochemistry, OSCC, Tumor-Associated Macrophages.*

Introduction

Oral carcinoma is amongst the leading malignancies worldwide, with squamous cell carcinoma (SCC) as the most common type accounting for over 90% of cases[1]. The high rate of relapse in tumor indicates the inadequacy of current prognostic predictors,that is, histological and clinical assessments, in predicting metastatic potential,as well as the need to investigate additional determinants among oral cancers[2]. In recent years, it has been accepted that to effectively treat cancer, the tumor must be considered as an entity containing both the cancer cells and the surrounding tissue which together forms the tumor microenvironment (TME). In squamous cell carcinoma, the TME may even be dominant over cancer cells[3]. TME contains a mixture of heterotypic cells such as cancer-associated fibroblasts (CAFs), smooth muscle cells, endothelial cells, neutrophils, lymphocytes, and macrophages[4].

Normally macrophages are important cells in wound healing providing aids for tissue cell growth, tissue matrix remodeling, and angiogenesis. There are 2 types of macrophages M1 & M2. M1 macrophages phagocytose & destroy microbes,eliminate cells, present to the antigen to T-cells for an adaptive immune response & produce high levels proinflammatory cytokines &

e-mail: saurjyadas@gmail.com

helps in tumor suppression. M2 macrophages promote IL-4,IL-10,TGF,PGE2 exposure to TH2 responses, suppresses TH1 mediated inflammation & helps to increase tumor development. Hence Macrophages are described as "double-edged sword" means capable of both promoting & opposing tumor growth[5,6]. Tumor-associated macrophages (TAM) have differentiated into the M2 phenotype which involves angiogenesis, immunosuppression & activation of tumor cells. TAMs release reactive oxygen species, tumor necrosis factor (TNF)-α, Interleukin (IL)-6 and IL-1β, promoting DNA damage, transformation and cancer cell survival.[6]

This tumor-associated macrophages conglomerate with oral squamous cell carcinoma in a metastatic role as a review paper.

Aim: To aim & evaluate the expression of TAM in different grades of OSCC cases.

Objectives:

- Evaluation of expression of TAM infiltration in OSCC.
- Comparison of TAM expression with clinical parameters of OSCC.
- Comparison of TAM with different grades of OSCC.
- Comparison of TAM expression with local metastasis in OSCC cases.
- Correlation of expression of TAM in OSCC cases.

Tumor Associated Macrophages: Macrophages are derived from CD34+ bone marrow progenitors that continually proliferate and shed their progeny into the bloodstream as promonocytes[7]. They then develop into monocytes and extravasate into tissues where they differentiate into a specific type of ''resident'' tissue macrophage[8]. Macrophages also form a major component of the inflammatory infiltrate seen in both primary and secondary tumors.

Broadly macrophages divides into

(a) Classically activated type 1 Macrophages- M1

(b) Alternatively activated type 2 Macrophages- M2

M1 macrophages phagocytize & destroy microbes, eliminate cells, present to the antigen to T cells for an adaptive immune response & produce high levels of pro-inflammatory cytokines. M2 macrophages promote IL-4, IL-10, IL-13, TGF, PGE2 exposure to TH2 responses, suppress TH1 mediated inflammation IL -10. M2 regarded as an increase in tumor development. Thus macrophages described as "double-edged sword" means capable of both promoting & opposing tumor growth[6]. M2 macrophages are called as TAM

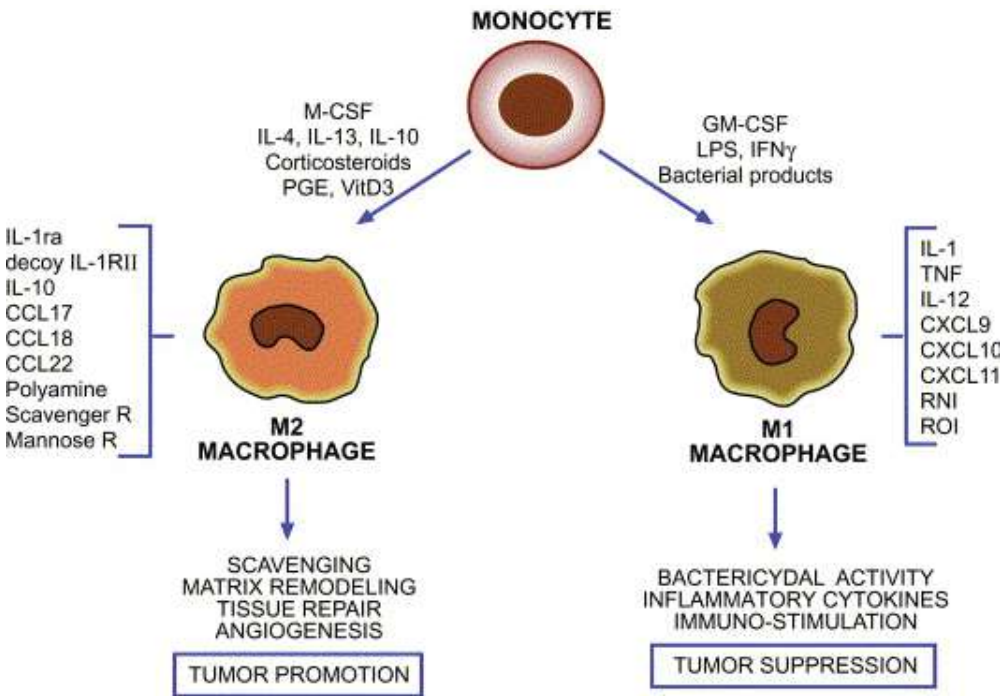

Figure 1: Shows Dual Role of Tumour Associated Macrophages

Roles of TAM: Tumor Invasion: In polyomavirus middle T oncoprotein (PyMT-)induced mammary tumors, macrophages are present in areas of basement membrane breakdown and invasion during the development of early-stage lesions [7]. TAMs secrete a variety of proteases to breakdown the basement membrane around areas of proliferating tumor cells[8]. This finding, together with other results showing the up-regulation of proteolytic enzymes like cathepsin B in macrophages present at the same locations, indicates that TAMs could be involved in the invasion of tumor cells into surrounding normal tissue[8].

Tumor Growth: TAM infiltration positively correlates with tumor cell proliferation as measured by MIB-1 levels in breast carcinomas[14], Ki67 levels in endometrial carcinomas[10], or mitotic index in renal cell carcinoma[9]. This phenomenon is known to involve factors like TGF-h1 being expressed by inflammatory cells in wounded tissues.

Tumor angiogenesis. TAMs release several potent proangiogenic cytokines and growth factors, such as VEGF, TNF-a, IL-8, and bFGF. Additionally, they express a broad array of angiogenesis-modulating enzymes, including MMP-2, MMP-7, MMP-9, MMP-12, and cyclooxygenase- 2 (COX-2).[9] In areas of transient (avascular) and chronic (perinecrotic) tumor hypoxia, macrophages cooperate with tumor cells to induce a vascular supply for the area by up-regulating several angiogenic growth factors and enzymes. These diffuse away from the hypoxic area and together with other pro-angiogenic stimuli in the tumor microenvironment, stimulate endothelial cells in neighboring, vascularized areas to migrate, proliferate, and differentiate into new vessels[2].

Immunosuppression: Macrophages in hypoxic areas secrete factors that suppress the antitumor functions of immune effectors within the tumor. Unlike macrophages from healthy tissues, which are capable of presenting tumor-associated antigens, lysing tumor cells, and stimulating the antitumor functions of T cells and NK cells, TAMs in the tumor microenvironment lack these activities, leaving the host without the ability to mount an effective antitumor immune response[2,6].

Metastasis: A subpopulation of TAMs associated with tumor vessels secretes factors like EGF to guide tumor cells in the stroma toward blood vessels where they then escape into the circulation[7]. In the stromal compartment (both the acellular regions and others where they are in close contact with tumor cells), TAMs secrete growth factors to stimulate tumor cell division and/or undefined factors that promote tumor cell motility[9,10]. TAMs seem to play roles in both the release of metastatic cells from the primary tumor as well as the establishment of secondary tumors at distant sites.

To summarize, analysis of the expression of protumor molecules by TAMs in human tumors and functional studies in macrophage depleted murine tumor models have shown TAMs to play an important part in various key steps in tumor progression. It seems that in early preinvasive lesions, tumor cells release chemokines to attract macrophages and other inflammatory cells into stromal areas surrounding the tumor. Macrophages are also found in dense clusters as part of leukocytic infiltrates in areas of focal breakdown of the basement membrane. Tumor cells are thus able to escape the confines of the basement membranes and migrate across into the stroma of surrounding healthy tissues, where they, together with macrophages, stimulate angiogenesis. These newly formed vessels sprout into the early tumor, providing nutrients and oxygen for tumor growth and supplying multiple exit routes for metastasizing cells[13,14].

Methodology

The present study was done in the Department of Oral & Maxillofacial Pathology & Microbiology, IDS between 2013 to 2016. Approval from the institutional ethics committee of " Siksha O Anusandhan University was obtained to carry out this work.

Clinicopathologic information on each case including age, gender, site of location, habit was collected from the department.

Inclusion Criteria: Patients of all age groups with histopathological diagnosed primary carcinoma cases.

Exclusion Criteria:

- Metastatic tumor in the oral cavity
- Patients having carcinoma with any secondary infections.
- Patients having carcinoma with immuno compromised disease (HIV)
- Tumors which are under treatment of chemotherapy or radiotherapy.

Sample size of the study:

- 30 blocks specimens i.e. 10 well-differentiated, 10 moderately differentiated, 10 poorly differentiated & 10 normal block

Table 1. Scoring criteria for evaluating expression of TAM in our study.

Macrophage Count	Total Score
< 10 %	Score – 0
10-30 %	Score – 1- 2
30- 50 %	Score – 3- 4
>50 %	Score - 5 -6

The results were categorized as negative & positive respectively, based on total score: if total score: 0-2- Negative; 3-6 – Positive. For evaluation of inter/ intra examiner consistency slides are observed by two more examiner for scoring of TAM. The results were categorized as negative & positive respectively based on scoring are:TAM Negative- 13; TAM Positive – 17

Results

The data was collected from individuals cases & organized systemically. Compiling all data was formulated in various tables & graphs were derived from statistical analysis,for easy interpretation of results was done using SPSS software.

Table 2. Comparing the macrophage count with habit

		N	Mean	Std. Deviation	P-value
Macrophage Count	Smoking	8	1.50	.756	0.119
	Chewing	15	1.73	1.033	
	Both	7	2.43	.535	
	Total	**30**	**1.83**	**.913**	

Table 3. Comparison of Stage of TNM with TAM

	N	Mean	Std. Deviation	p-value
Stage I	9	1.11	.782	0.0001
Stage II	15	1.87	.743	
Stage III	6	2.83	.408	
Total	**30**	**1.83**	**.913**	

Table 4. Comparison of expression of TAM between normal group & OSCC group (positive & negative cases)

			mac_rec1		Total	X^2	P-value
			1.00	2.00			
Type of tumor	Normal	Count	10	0	10	9.855	0.002
		% within Type of tumor	100.0%	0.0%	100.0%		
	OSCC	Count	13	17	30		
		% within Type of tumor	43.3%	56.7%	100.0%		
Total		Count	23	17	40		
% within Type of tumor		57.5%	42.5%	100.0%			

Graph 1. Shows Comparision of Stage of TNM with Tumor-Associated Macrophages

Table 5.comparison of expression of TAM between positive & negative cases of OSCC group

	mac_rec1	N	Mean	Std. Deviation	Std. Error Mean	P-value
Macrophage Count	1.00	13	.92	.277	.077	
	2.00	17	2.53	.514	.125	0.0001

Table 6. Tumor-Associated Macrophages with Metastasis using t-test

	Metastasis	N	Mean	Std. Deviation	t	P-value
Macrophage Count	No Metastasis	24	1.58	.830	5.261	0.0001
	Metastasis	6	2.83	.408		

Table 7. Significant relation between TAM in different grades of OSCC group

		N	Mean	Std. Deviation	P-value
Macrophage Count	Normal	10	.50	.527	0.0001
	Well	10	1.40	.843	
	Moderate	10	1.80	.919	
	Poor	10	2.30	.823	
	Total	40	1.50	1.013	
	Total	40	1.63	1.125	

Observation: Table 2 represents the comparison between TAM count with a habit of OSCCcases which is not significant. Table 3 represents the Comparision of the Stage of TNM with TAM is statistically significant. ($p < 0.05$). Table 4 represents a comparison of expression of TAM between normal group & OSCC group positive & negative cases which is statistically not significant ($p > 0.002$). Table 5 represents the comparison of expression of TAM between positive & negative cases of OSCC group shows statistically significant. Table 6TAM with Metastasis using t-test shows statistically significant. Table 7 Significant relation between TAM in different grades of OSCC group shows statistically significant. Graphrepresents Comparision of Stage of TNM with TAM is statistically significant with mean values (stage I- 1.111, stage II- 1.867, stage III-2.833) ($p < 0.05$).

Discussion

Squamous cell carcinoma (SCC) is considered a major problem worldwide due to its extremely high prevalence (90%) among oral cancers[2,6]. The high rate of relapse in this tumor indicates the inadequacy of current prognostic predictors, that is, histological and clinical assessments, in predicting metastatic potential[2]. So there is a need to investigate additional determinants. So in this study, we have investigated macrophages infiltration in different grades of OSCC cases. So in our study, we evaluated the expression of macrophages in different grades of OSCC cases. There are many method to evaluate MMP 9 like Gelatin Zymography, Immunofluorescence (IFC), Gel Electrophoresis, PCR, IHC, Western Blot Assay, ELISA.

There are various method used to evaluate macrophages are immunofluorescence (IFC), Immunohistochemistry, flow cytometry, qRT-PCR. & routine H & E stain[11,12] In our study we have used H & E (Hematoxylin & Eosin) stain to evaluate TAM as cancer-associated inflammation includes the so-called tumor-associated macrophages (TAMs) which are generally thought to resemble M2-type macrophages and we can see the presence of macrophage with our routine H & E stain.[12,13]

For Macrophages: scoring criteria < 10% is scored as 0, 10-30 % is scored as 1-2, 30-50 % scored as 3-4, > 50 % is scored as 5-6.

OSCC is the most common malignant neoplasm. It may occur at any intraoral site & generally involve tobacco users in the middle age group. Higher incidence of OSCC seen frequently in males[15]. In our study we found 80 % of OSCC cases below 60 yrs of age, 60 %were males & 40 % were females; majority cases (53.33%) had a lesion in the buccal mucosa. According to Taiming Dai et al[15,17], there was a significant difference in comparison of MMP-9 expression between men and women, suggesting there might be a higher potential for OSCC invasion in male patients.

In our study, we have compared smoking & non-smoking form of tobacco with the infiltration of TAM. We found that TAM infiltration is not significantly associated with different forms of tobacco habit pattern [13]. In our study mean score of both TAM expression increases from stage 1- stage III, and it was statistically significant ($p<0.05$) which suggest that MMP 9 expression is directly proportional to clinical stages of tumor & this finding is in concordance with a study done by Taiming Dai et al [15], where as in other studies like Aparnat et al [9], Elahi et al[68] they have not found any correlation between TAM & MMP 9 expression with different stages of TNM. There was a statistically significant infiltration of TAM in OSCC cases as compared to the normal groups. Total no. of OSCC cases were divided into positive & negative groups according to the expression of TAM. We have found MMP 9 expression 23 positive cases & 7 negative cases & TAM expression 17 positive cases & 13 negative cases. The difference between TAM expression in positive & negative cases was found statistically significant.[8] We also found that there was a statistically significant correlation between the infiltration of TAM in OSCC cases[15,17]. We also found that there was an increase expression of TAM with different histological grades of oral squamous cell carcinoma: TAM in Well-differentiated 1.40+_.843, mod differentiated 1.80+-.919,to poorly differentiated 2.30+-.823 (lower to higher mean & s.d value) . Thus their expression is increasing from well to poorly differentiated squamous cell carcinoma. But the difference between the expression of TAM in different grades of OSCC was not statistically significant[15] found that positive correlation between the macrophage count. They also suggested that macrophage in OSCC, which jointly promote the invasion and metastasis of the tumor.

The positive expression rate was much higher in OSCC in comparison to normal mucosa and it had a close correlation with TNM staging of the tumor and condition of local metastasis TAM over-expressed in many other malignant tumors like breast, prostate, liver,

lung & bladder cancers their expression was correlated to poor prognosis[9,10,11,12]. We have compared TAM expression in OSCC cases with local metastasis which is found statistically significant ($p < 0.05$) which in concordance with the other studies done by Daiming Tai et al [16]. Thus it is proved that invasion & metastasis of tumors are regulated by quantities of factors in a cellular mixture of OSCC[4]. It may also be helpful to evaluate local metastasis in OSCC cases. Since metastases are the principal cause of death in cancer patients, a greater understanding of the process of tumor invasion and metastasis is essential in leading to the identification of new therapeutic targets.

In this study, we have used H & E stain instead of IHC for macrophages identification due to lack of funds, but the expression of macrophages can be better evaluated by using specific IHC markers like CD 68, CD 13. In this study, although special care has been taken to avoid false-positive results,but IHC is very technique sensitive. Thus further studies should be done with a larger sample size along with the use of other specific method to confirm the expression of both TAM in OSCC cases & their expression should be correlated with the IHC technique.[17]

Conclusion

Concluding this review of tumor-associated macrophages in comparison with OSCC cases. Since metastases are the principal cause of death in cancer patients, a greater understanding of the process of tumor invasion and metastasis is essential in leading to the identification of new therapeutic targets. In this study, we have used the H & E stain instead of IHC for macrophages identification due to a lack of funds. In this study, although special care has been taken to avoid false-positive results,but IHC is very technique sensitive. Thus further studies should be done with a larger sample size along with the use of other specific method to confirm the expression of both TAM in OSCC cases & their expression should be correlated with the IHC technique.

Newer Behaviour Management Techniques in Children

Sonu Acharya[1], Susant Mohanty[2], Sheetal Acharya[3]

[1]Professor, [2]Professor & Head Department of Pediatric and Preventive Dentistry, [3]Lecturer, Department of Periodontics and Implant Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Children are not miniature adults. They should be treated as a different entity and not just as adults who are shortened. Children have their apprehensions and fear. The most commonly encountered is the fear of the unknown. This is something that is innate, inborn. Fear of dentistry is there in every individual, whether young or old. This is mostly subjective. Children show exaggerated fear for dentistry as this is something new to them. The pediatric dentists are trained in behavior management for reducing fear. There have been many method, both pharmacological and non-pharmacological for behavior management in children. But with changing times, we know that Child's behavior has also undergone a sea change. Here we discuss some newer behavior management techniques, recently introduced and included in our guidelines.

Keywords: *Behaviour management, Children, Newer, Pediatric dentistry.*

Introduction

Pediatric dentists are expected to identify and effectively treat dental diseases of children that are within the knowledge and scope acquired during their professional studies. Effective and efficient treatment has to be provided to the child and for that, the parents also have to understand their roles.[1] Behaviour guidance should be done and this means that inappropriate behavior has to be converted to appropriate behavior within the societal norms with the help of empathy and learning. The main idea behind behavior management by pediatric dentist is to gain the confidence of the parents and the child. Its always better to know the scientific basis of implementation of any behavior management technique and also to look into cultural sensitivities, tolerance level, flexibility in a child and parent before applying any of these method.[2] Children are not miniature adults. They should be treated as a different entity and not just as adults who are shortened. Children have their apprehensions and fear. Behaviour management should never be used as a punishment or assertiveness for a child.[3] All the method which are to be used to tame the child should be age and gender appropriate. The pediatric dentists have to realize the potential of the child and then try to implement any behavior management technique for that particular child. In short, it has to be customized, following the child in the present scenario.[4] We know that the parenting method have changed a lot in recent times. The old pattern of parenting is not to be seen nowadays, with nuclear families or single parents. Behavior management also has seen some changes.

The Newer Method: Before applying any type of behavior management technique on the child for making them cooperate, we have to assess the child as well as assess the parental influence on the child.

Basic behavior guidance method:

(a) Communication and communicative guidance: The appropriate use of communication and commands have been used since a long time for both cooperative and uncooperative children. Always try to make the patient comfortable with verbal and non-verbal communication skills. Encourage the child to talk with you what he wants to, to reassure them that they are in good hands. We try to develop a student-teacher relation with the patient. The pediatric dentist role is as a facilitator. Once a rapport has been established, the talks can become minimal and related to procedure only.[5]

(b) Positive pre-visit imagery[6]: The child patients are shown positive pictures or images of dentistry and

dental treatment before the procedure starts. It can also be shown at their homes before even visiting the clinics. The objective of this is to provide the children and parents with visual information of what to expect from the pediatric dentists. It also provides the children with a chance to ask questions to the dentist about the procedure if they come to know about it before visiting the dental clinic.

(c) Ask-tell-ask[7]: This technique involves enquiring about the child's visit and feelings toward or any planned procedures (ask); explaining the procedures through appropriate demos and non-threatening language, appropriate to the understanding level of the patient (tell); and again enquiring if the child understood and how he feels about the impending treatment (ask). If the child still has apprehensions about the procedure, the dentist can again explain the procedure.

(d) Memory restructuring[8]: Memory restructuring is a behavioral management approach in which memories associated with an unpleasant or difficult event (e.g., first visit, local anesthesia, restorative procedure, extraction) are restructured into positive memories using information suggested after the event has taken place. Restructuring involves four parts: (1) visual reminders; (2) positive reinforcement through verbalization; (3) concrete examples to encode sensory details; and (4) sense of accomplishment. A visual reminder can be a photograph taken in the dental office. Positive reinforcement through verbalization can be to ask the child to tell his/her parents about what good behavior she showed at the dental clinic. Concrete examples could be to show how she followed the commands given by the dentist at the operatory and in doing so she can open her/his mouth wide open as he/she did in the dental chair, which will lead them to be set an example of self-accomplishment. The objectives here are to fade out the negative memories of difficult dental visits and only remember the good times.

(e) Descriptive praise[9]: This is a type of positive reinforcement. Here the pediatric dentist praises the child for a particular behavior. (eg-thanks for sitting still, you are doing a great job by opening your mouth so big.) Rather than general praise as 'good job or well done.'

The objective is to reinforce good behavior:

(e) Teach back[10]: In this method, the pediatric dentists or their attendants ask the patient to teach them what they have learned when he/she was given a behavior management technique demonstration. This is done in less literate people or those who can't remember much. The dentist asks them to demonstrate what they have seen, if the patient cant they repeat it for the. Eg-can you demonstrate to me how to floss your teeth.

(f) Motivational interviewing[11]: Motivational interviewing tries to change the behavior of the patient by helping them to change. This method does not reinforce change but utilizes the autonomy of the patient so that their self-confidence is increased. The motivational interviewing puts the onus on the patient to change. The method included are OARS(Open-ended questions, affirmations, reflective listening, summarizing). This is useful in patients who are showing more anger, resistant to changing behavior.

(g) Treatment Deferral: Dental problems are rarely life-threatening and sometimes in unprecedented conditions like the present COVID-19 situations, these also can be deferred. The emergency treatment can be rendered to alleviate the pain but maximum restraint is required to defer the treatment to a more suitable time frame. Sometimes treatment has to be deferred when suddenly a cooperative child becomes uncooperative and hysterical when getting treatment done. Caries risk assessment has to be done in each patient before the treatment can be deferred. The oral hygiene measures have to be told to the patient and the parents. An individualized preventive program, including appropriate parent education and a dental recall schedule, should be recommended after evaluation of the patient's caries risk, oral health needs, and abilities.[12]

Advanced Behavior Guidance: Sedation: As a pediatric dentist we must decide what is acceptable behavior from our young patients. The decision will depend on our personality, experience, and philosophy. Having defined the acceptable behavior, for ourselves, we can then plan to modify the unacceptable behavior to an acceptable one. The judicious plan of conscious sedation has a place in pediatric dentistry but it is most often abused without trying the nonpharmacological means. Concious sedation is often to be used for longer

procedures for apprehensive and nervous patients. This can also be used for uncooperative and abusive children but it does not teach the children to behave properly when next they are to be taken for dental treatment. The pediatric dentist must establish the frequency of use of these sedation drugs so that he does not have to use the same drugs over and over again. Sedation is a very safe and efficient modality to decrease anxiety and increase effective communication. The onset of action is fast, the effects easily can be titrated and reversible, and recovery is rapid and complete. Also, the nitrous oxide/oxygen inhalation mediates a variable degree of analgesia, amnesia, and gag reflex reduction. The need to diagnose and treat, as well as the safety of the patient and practitioner, should be considered before the use of any kind of sedation.[13]

2. **Protective stabilization:** There are times when the child has to be restrained and this is a matter of deep concern for parents, staff, and the treating dentist as it becomes inhumane. The broad definition of restraining means to limit the movement of the patient without his consent. The restraining can be done with the help of devices, another person, or a combination of both. This method can harm the patient physically and psychologically. The dentist should use the safest and least invasive method available for stabilization. The decision to use protective stabilization depends on on-patients emotional development, alternative behavior management guidelines, dental needs of the child, whether the quality of treatment is being hampered, medical condition of the patient. This method needs an informed consent to be taken from parents. If still the child cannot be managed, the child has to treated under sedation or general anesthesia. The proper documentation of the stabilization has to be done always-why was the method used, the condition of the child, the type of restraining device used, consent taken or not.[14]

Conclusion

The children have to be dealt with in a proper way when it comes to behavior management. All the method have to individualized according to the patient demands. The basic method have to be applied first and gradually going for advanced method.

Dental Health Care Needs for Elderly Population

Narottam Praharaj[1], Debasruti Naik[2]

[1]Tutor, Department of Conservative Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The mouth is considered as the mirror of general health of every individual and concerning this in mind, poor dental health can be a menace aspect for general health trouble in the elderly population. Due to increase in their chronic diseases in elderly patients, they are more vulnerable to oral diseases. Thus, the geriatric population forms a distinctive group in provisions of implementation of health care. This review article discuss about the significance of dental health care needs in geriatric population.

Keywords: *Dental health, Geriatric population, Preventive measures.*

Introduction

Dentistry focusing on geriatric population deals with the service of dental care to old age people which involves diagnosis, prevention as well as management as well as dealing of all dental related problems related with age related diseases. In certain decades, there is an unexpected increase of the 65 plus residents globally where India is also not left behind from this blast growth. Due to advance technology and progressing development in the medical ground, it has raised the lifespan of the senior citizens. This rapid altering in the longevity of life has challenged the dental health professionals to provide and make advanced treatment for the geriatric population.[1] The mouth is considered as the mirror of general health of every individual and concerning this in mind, poor dental health can be a menace aspect for general health trouble in the elderly population. Due to increase in their chronic diseases in elderly patients, they are more vulnerable to oral diseases. Thus, the geriatric population forms a distinctive group in provisions of implementation of health care. This review article discuss about the significance of dental health care needs in geriatric population.

Demographic profile of geriatric population: According to reports and based on the advanced therapeutic modalities in treatment part of medical research, the life expectation has improved to 67.9 years and is setting a distressing increase in the health conditions of geriatric population globally.[2] In developing countries, reports suggested that by the end of the year 2020, the proposed inhabitants of all individual people aging 65 years as well as above will be approximately 470 million globally. And by the year 2050 where one third of the world inhabitants will be over 60 years. If we look into the data of our country India, then the geriatric population was 20 million in the year 1951 and 57 million in 1991 which was followed by very rapid increase in the year 2001. According to the observed growth rate of population by age during this period, the growth of 65 years and above people groups was much added extra than that of the existing total population. Therefore, it is likely to rise with a proposed population of 324 million by the year 2050.[3]

There is a total number of 2 lakhs and above centenarians in India and among them 5.2% of the elderly population which consists of 28 lakhs or more male and 31 lakhs female. The two most important prominent characteristics concerning the old age of India are as

follows: a) the growth of geriatric people is very much quicker than the development of the overall population and b) the female dominancy in the gender wise increase in the total population.[4]

Health conditions of Geriatric Population: During the old age, the intake of multiple medications can be seen by the elderly people. Because of this multiple medications consumptions due to diseases results in decreased salivary flow and this will lead to compromised conditions of the oral mucosa. Normal flow of saliva in any human being has an important role to play as it helps in neutralizing the manufacture of several acids done by micro organisms which in addition helps in teeth mineralisation. Saliva gives several defending reimbursement for the oral cavity because of its content of immunoglobulin A as well as lactoferrin. If there is a lack of salivary reduction then there will be increase in number of oral microorganisms as well as their metabolic by products in the oral cavity.[5]All these things will ultimately leads to an augment in dental diseases like caries and periodontal diseases leading to tooth loss. Maintenance of oral hygiene can be hampered due to alteration in physical as well as mental status that will result in worsening of co-ordination and motor skills. Improper maintenance of oral hygiene will contribute to prolific growth of oral microflora. Total amount of food intake sometimes reduces in nearly everyone of the elderly because of the alteration in diet as well as altered taste. Therefore it is very difficult to meet the nutritious need of the elderly people. With rise in requirement for certain vital nutrients and higher catabolic rates, it is difficult to store pace on with the overall age alterations in the elderly body.[6] Therefore, there is a need of keeping a record of the whole dietary status as well as the manifestation of signs along with symptoms of the elderly people in regular intervals.

Residual Ridge Resorption: Residual ridge resorption (RRR) is usually meant for the alteration that will stress the alveolar ridge followed by any kind of tooth extractions that will carry on long subsequent to healing of the extraction socket. The majority important characteristic is the remaining bony architecture of the maxilla-mandible jaws which undergoes a long catabolic remodelling mechanism during this healing process.[7] The elderly people goes through decrease in residual ridge resorption frequently. The missing teeth are need to be reimplanted or replaced by prosthesis. Sometimes long chronic health issues and economic measures also makes a considerable difference in the selection of action as the substance costs are in general prohibitively high. In the elderly patients bone resorption activity keep on continuing throughout life which ultimately results in failure of altering amount of jaw structure, that make the patient to condition called dental cripple.[8]

Prosthetic rehabilitation in the elderly: In the elderly people many of them undergoes through the condition called tooth loss due to extraction of teeth or may be due to some other reasons. Eventually this all will lead to edentulous or partial edentulous jaw. There will be poor retention as well as steadiness of complete dentures which is the most common dental health linked complaints in edentulous patients. Poor retention generally leads to loss of bony alveolar in the jaw structure.[9] There may be multiple reasons for resorption and the reasons may differ among everyperson. This happens after loss of teeth and the process of resorption process at analtering speed for the rest of the life. Sometimes systemic conditions as well as local conditions of the patient affects the resorption rate of the alveolar bone.[10]

Many times the missing teeth in the elderly people doesn't always mean that it needs to be replaced with dental prosthesis in edentulous person till they are satisfy socially as well as functionally.[11] That is why they hold-up in covering dental treatments and this decision promote complicates for their chances for absolute rehabilitations.

Due to ever growing number of elderly patient cases who are in need of oral physiotherapy necessitates new treatment strategies. Sometimes financial measures also play a major role in the preference of treatment because the materials to be used for prosthesis and other dental treatments are usually prohibitively very high.[12,13]

Dental sanitationin addition todental mucosal lesions: Due to missing teeth in the elderly person and also difficulty in chewing and other physiologic functional conditions, they prefer dentures for their jaws. Prolonged use of dentures leads to various oral mucosal lesions like denture stomatitis, flabby ridge as well as irritation hyperplasia, angular chelitis and traumatic ulcers as well as even cancer can also be linked with long duration utilization of unhealthy or grossly damaged out not fixed dentures. Many oral mucosal lesions are found out to be provocative as characteristics feature in may studies.[14]

Candida albicans is one of the widespread microorganisms that is related to denture tiring. Patients wearing dentures at night as well as smoking as a habit has been correlated in various studies.[15] There has been a significant effect of denture cleanliness, age of the patient and drugs utilization as linked with wearing of denture that had been reported in studies. Moreover sometimes due to less salivary flow rate in elderly patients, there may be predisposition of oral mucosa to the alteration of pathology for the reason that of its related linkage with the presence of yeasts within the oral cavity.[16]

Ill fitting dentures induce trauma to the oral cavity which ultimately believed as the major cause for denture sore mouth as well as hyperplasia of tissue. Sometimes new dentures also develop ulcers within a small number of days after fitting of denture. Therefore, patients should be advised to follow up regularly every four to six weeks for new dentures in addition to every six months after that. Immediate and proper intervention should be made to avoid trauma due to age changes of the mucosal changes inside oral cavity.[17]

Protocols for Oral health care for old age people: Everybody has to deal with ageing which is to be anticipated, irreversible and also a reality. As people starts getting to their old age, the objectives of their oral health planning need to be refocused with regard to the common health as well as financial conditions of the aged people. That is why it is imperative that people could necessitate to do with to have right of entry to oral health care that is generally based on concepts of preventive methodalong with which can be actively involved in making actions about oral health from their early 50's or 60's. This timely oral health planning will help them maintain into their old age dental needs.[18]

There has to be sustainable oral health care need in any dental treatment scenario specially in case of elderly people. Oral health intervention should always be based on evidence based practice containing existing information on the occurrence, divisionas well as determinants of oral diseases based on its cost effectiveness of any type of intervention. Therefore, there should be oral health surveys which can supply latest as well as genuine information about all the aspects of dental health status, disease as well as their determinants. Also, there will be gradual decrease in immunity which will stimulate in increasing the menace of transmittable disease. Infections like pneumococcalor influenza or tetanus as well as zoster are very common among the elderly population.[19]

Mechanism of Dental health services: Expansion in the medicinal field have encouraged the disableolder generation to exist longer. According to the reports, there has been a rapid increase in the rate of longevity in the old age population, therefore, there has been a speedy demand in the requirement of residential dental care services. Old age people find difficulties in approaching the dentist and also it is cumbersome to bring them to the dentist.[20] Therefore, the best decision could be if any dentist could reach the elderly people. There should be some provisions and services to be made out to reach them who are in need of dental care. While planning out the comprehensive dental treatment plan for the elderly patient, care has to be taken out for their medical condition.

According to the researchers, Macentee and Waytt, developed an index known as Clinical Oral disorders in elders (CODE) for disabled geriatric people. CODE guide is based ahead of clinical measures of 27 disorders that covers 5 major areas: Jaw movement, dentures, mucosal health, teeth and periodontium. But all these things are united with a psychosocial index which forms a very brief indicator of oral dysfunction in the elderly.[21]

Kenneth Shay, a researcher has provided a five point Geriatric Dental Assessment tool called OSCAR:[22]

O- Oral – Teeth, restoration, prostheses, periodontium, pulpal status, oral mucosa, saliva

S- Systemic – Normative age changes, medical diagnosis, pharmacologic agents

C-Capability – Functional ability, self care, oral hygiene, transportation to appointments

A-Autonomy – decision-making ability, dependence on alternative

R-Reality – Prioritization of oral health, financial ability or limitations.

Dental health researchers should try to deliberate on OSCAR assessment tool as it influence the treatment plan that requests the meticulous integration of dental as well as non dental measures.

Challenges regarding dental health care services to geriatric population: With improved and rising

long life span in elderly patient, the dental disease pattern as well as treatment requirements are varying according to the advanced dental technologies, the old age persons are retaining more natural teeth into old age than before. Therefore, there is an increase in the need of numerous dental treatments including restorations, prosthesis as well as esthetics as well as even implants all of which require special care. The challenges arise in elderly people when their unwillingness towards treatment as well as suboptimal perception of treatment requirement, and the limitations on operational time could be harassing to health care professionals. Many have restricted mouth opening or they will be unable to keep it open for long time. Therefore, there is a need of modifying the approach towards these patients.[23]

Conclusion

Oral health is important in every phases of life assume superior value at extreme old age also. The negative impact on the oral well being of the elderly persons affects the general health also. Therefore, there is a need to take special care for the dental treatment needs of the geriatric people.

Management of Oral Health During Pregnancy

Narottam Praharaj[1], Debasruti Naik[2]

[1]Tutor, Department of Conservative Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Good oral health is an important aspect towards overall health for all the women throughout their lifespan. For every expecting women and also women those who are of reproductive age, for them health status of their oral cavity is very much an important module of the general health. During pregnancy there is a rapid physiologic change that leads to occurrence of remarkable strain on a woman's body together with the oral cavity. Both intended for mother and children, maintaining and achieving good oral health is very important. There are evidences that poor wellbeing of the mother such as dental decay, periodontal diseases previous to and during pregnancy have been linked to poor birth for example preterm birth and low birth weight. Oral health is a significant part of overall health. During pregnancy, an expectant women goes through lot of hormonal changes and these hormones sometimes increase the risk of gingival diseases that will hamper the health of any would me mother and might increase the menace of premature delivery or low birth weight infant. It is very much necessary that oral health care need should be recognized for every pregnant women and it is also the sole responsibility of every pregnant women that they should feel responsible care of their oral health as an important aspect of their pregnancy course. This review article highlights the importance of health of oral cavity for all expectant pregnant women.

Keywords: *Pregnancy, Oral Health, Precautions.*

Introduction

For every expecting women and also women those who are of reproductive age, for them health status of their oral cavity is very much an important module of the general health. During pregnancy there is a rapid physiologic change that leads to occurrence of remarkable strain on a woman's body that includes whole of the oral cavity. Both for mother and children, maintaining and achieving good oral health is very important. There are evidences that poor wellbeing of the mother such as dental decay, periodontal diseases previous to and during pregnancy have been linked to poor birth for example preterm birth and low birth weight. With respect to all these, according to National Maternal and Child Oral Health Resource Centre (NMCOHRC, 2008), enforcement of healthy oral habits for women during pregnancy time plays a very important role in promoting the oral health for their children following birth. Therefore in general, healthy oral cavity is an important aspect towards overall health for all the women throughout their lifetime.[1] This review article highlights the importance of oral health for pregnant women.

Periodontal diseases and preterm/low birth weight babies: According to evidences it has been reported that periodontal disease is a type of infection caused by bacteria which can be noticeable in up to 40% of women who are pregnant which can lead to devastation of the gums, bones as well as ligaments opinionated by teeth. Many researchers have correlated periodontal

disease with premature delivery where there are chances of delivery earlier than 37 weeks of gestation as well as low birth weight where the new born baby may have weight less than 5.5 pounds.[2] Poor health outcomes will definitely result in infant mortality as well as long term health complications amongst infants.[3]

Protocols for health sector workers regarding health care of oral cavity during pregnancy: The health care professionals should take part in a key role in making the women for healthy pregnancies by providing oral health education. They should also link the pregnant women to dental check up during their pregnancy period. Surrounded by the health care system, multiple health professionals from all the required fields should reach pregnant women to provide proper health care.[4]

Protocols to be followed by the pregnant women.[5,6]

1. Brushing your teeth two times a day by using tooth brush and fluoride toothpaste and dental floss daily.
2. Foods that contain sugars should be limited to mealtimes only.
3. Carbonated beverages should be avoided during pregnancy and water or low fat milk should be chosen.
4. Natural fruits should be preferred instead of fruit juice to fulfil the suggested dose of fruit intake regularly.
5. Required dental management should be obtained previous to delivery during the second trimester of the pregnancy and the dentist should always be in contact during this period for any kind of emergency consultant.
6. Small amounts of nutritious foods should be taken throughout the day.
7. Maintain oral hygiene during pregnancy especially by brushing two times a day with fluoridated toothpaste.

Oral disease management for pregnant women[7,8]

Dental health professionals should develop a comprehensive treatment plan such as:

(a) A proper plan should be developed for all the dental needs and maintenance of optimal oral health as well as disease prevention strategies to be based on benefits, risks and all alternatives.

(b) Before delivery timetable should be plan out to carry all the procedures.

(c) Emergency care and treatment to be provided strictly during the second trimester of the pregnancy if required.

(d) Dentist should give proper instructions regarding intake of medication for dental pain during pregnancy.

(e) Oral health education should be provided by the dentists to reduce the bacterial load during pregnancy.

Drug administration during pregnancy[9]: All dental professionals should mandatorily do their duty to fully inform about the safety of drugs administration during pregnancy to all the expected women. According to FDA, it has issued specific guidelines to endow with therapeutic guidance for using drugs during pregnancy. Major medications are usually contraindicated during pregnancy because of its adverse effects both for the mother and the child. Paracetamol is generally considered as the safest drug during pregnancy. Others drugs especially analgesics and antibiotics that are most commonly prescribed for dental pain need to be avoided during pregnancy.[10,11] That is why, it is very important for the pregnant women to take good care of their teeth and gums during pregnancy.[1] Because there will be lot of hormonal changes during pregnancy which will increase the risk of developing gingival diseases that will ultimately affect the health of developing baby.

Tips to maintain good oral health care during pregnancy

Before Pregnancy: Dental appointment should be made prior to before getting pregnant so that the existing dental treatment can be done in advance of getting pregnant. Along with all the dental treatment, regular maintenance of oral cavity like brushing two times daily with toothpaste plus rinsing mouth after every meal should be done.[12]

After Pregnancy:

(a) Dentist should be aware of pregnancy so that routine dental care should be carried out. Any urgent procedure can be done in the second trimester as well as all elective dental procedures should be postponed after the delivery.

(b) All the history of medications should be mentioned

to the dentist as well as if any specific medical advice has been instructed by the gynaecologists then the dentists should be aware of this.[13]

(c) Dental x rays should be done if required during pregnancy but safety precautions measure has to be taken properly by the dentist. Now a day advance technology in x-ray has been considered as much safer than in past decades.[14]

(d) Dental check up should not be skipped simply because of pregnancy. During pregnancy lot of hormonal changes takes place which can increase the risk of dental diseases that is why regular dental check up should be done.[15]

(e) Good oral hygiene practice should be followed in order to prevent or reduce oral health problem.

(f) If any pregnant women is coping with morning sickness and if it is keeping away from brushing teeth then the toothpaste should be change to a bland tasting. Dentist should be recommending the required toothpaste brands for pregnant women.[16]

(g) Mouthwash should be used for rinsing if any pregnant women suffers from morning sickness and have frequent history of vomiting.

Effect of oral health on babies: During pregnancy, women is already on the verge of being a mother. So she has to take care of her and should focus on assembling everything perfect for the baby. A mother will always care for her and her unborn child and not only general health but also oral health. Routine visit to the dentist will enable to measure the current oral health status as well as rule out a preparation for the dental treatment needs after the delivery. When pregnant women care her own mouth, it will definitely make a disparity for her baby, equally before plus after birth.[17]

Facts:

1. If routine night time brushing and dental flossing gets skipped then it might direct to plaque as well as bacteria build up and ultimately tooth decay.[18]
2. Lots of hormonal changes can cause danger to the health of would be mother's gingival health plusit might cause pregnancy gingivitis. Bleeding gums due to inflamed gingiva as well as untreated gingivitis will lead to periodontitis. Several research reported that there is a definite link between preterm delivery, low birth weight babies and gingivitis.
3. Pregnant women who are having history of frequent morning sickness should be aware of stomach acid that create its way hooked on to the mouth and can deterioratethe strength of tooth enamel. This will put the pregnant women at a greater risk for dental diseases.
4. All pregnant women needs vitamin which contains folic acid during pregnancy.
5. Eating the right food with proper nutrition will keeps the mouth healthy as well as strong.
6. A nutritious meal containing calcium as well as limited amount of sugars in the food are best for both mother's and baby's oral health.

Mother's oral health is associated to the health of her unborn baby –as bacteria can be traced in her mouth.[19,20] If the amount of bacteria will be more in any pregnant women, then it has chances that it will cross the threshold the bloodstream through her gingival tissues and travel into the uterus by triggering the production of chemicals called prostaglandins – that are supposed to induce premature labour. After the delivery of the baby, there are also few chances of potential vertical transmission of bacteria from the mother to her newborn. A pregnant women should always keep it in mind that she has to take care for her own oral health as well as her unborn baby's health.[21,22]

Anaesthesia: Local anaesthesia with epinephrine can be used during pregnancy but only during second trimester if indicated for extraction or any surgical procedures in dentistry. The drug is absorbed slowly in case of lidocaine with epinephrine which will prolongs the length of anaesthesia. [23-26]

According to National Consensus Statement, few guidelines have been issued for pregnant women[27,28]

(a) Guidelines given should be customized based on risk assessment.

(b) Get routine dental care.

(c) Good home care should be practiced.

(d) Healthy and nutritious food should be eaten.

(e) Fluoride composed water should be consumed.

(f) 600 micrograms of folic acid should be consumed.

(g) Prenatal classes should be participated.

(h) Tobacco related habits should be stopped.

(i) Second hand smoke should be avoided.

(j) Consumption of alcoholic beverages should be stopped.

Conclusion

Oral health is an important part of general health. During pregnancy, women goes through lot of hormonal changes and these hormones sometimes increase the risk of gingival diseases that will hamper the health of expectant women and might increase the threat of premature delivery or low birth weight infant. It is very much important that the doctor recognizes oral health care need for every pregnant women and it is also the sole responsibility of every pregnant women that they should take proper care of their oral cavity as an important aspect of their pregnancy course.

E-Cigarettes in India: An Overview

Karishma Rathore[1], Debasruti Naik[2], Stithaprajna Lenka[3], Dharmashree Satyarup[4], Nikita Sahu[5]

[1]Tutor, [2]Senior Lecturer, Department of Public Health Dentistry, [3]Professor, Department of Oral Surgery, [4]Professor, [5]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Knowing its harmful effects, e-cigarettes are still famous among all the tobacco consumers. E-Cigarettes however wanted to capture the market in India also since 2016 but has failed to make its mark because of the prompt action by the government as compared to the scenario in the western countries. This article will provide the knowledge and information regarding E-Cigarettes legalization and utilization in India.

Keywords: *E-Cigarettes, Harmful effects, Government actions in India.*

Introduction

The undesirable special effects of cigarette smoking on the physical condition was first acknowledged by the Advisory Committee to the U.S. Surgeon General in 1964. The electronic cigarette (e-cigarette) is a type of new-fangled class of electronic nicotine delivery systems (ENDS) that was introduced in 2004 globally.[1] Gradually E-Cigarettes became the most trending and used product among tobacco users all over the world covering many countries worldwide. It is more common in youth and tobacco product users. Knowing its harmful effects, e-cigarettes are still famous among all the tobacco consumers. E-Cigarettes however wanted to capture the market in India also since 2016 but has failed to make its mark because of the prompt action by the government as compared to the scenario in the western countries. This article will provide the knowledge and information regarding E-Cigarettes legalization and utilization in India.[2]

Electronic Nicotine Delivery Systems (ENDS)have a special form of cigarettes called E-Cigarettes which is the most common form.[3] These cigarettes are chiefly a kind of device that is used by not burning any tobacco leaves rather thanit is vaporized with a mixture by utilizing a battery. And then this mist is being breathed by the cigarette.[4]

"The main constituents of the solution, in addition to nicotine when nicotine is present, are propylene glycol, with or without glycerol and flavoring agents," as reported by the World Health Organisation (WHO) with the aim of these constituents inside the E- cigar contains many toxic substances.[5] Most of the E-cigarettes come in various shapes and sizes but it will resemble as ordinary cigarettes, cigars as well as smoking pipes but now within late brands, designer E-cigarette is in the market that resembles like whistles or pens.[6]

Working mechanism of an E-Cigarette: E-Cigarettes depends on many factors such as the characteristics of the unit circuit, liquid mixtures used, and the user's behavior as well as the battery's strength for better efficiency. The effectiveness of e-cigarettes is directly proportional to the manufactured goods capability to heat the solution to a state so that it can transform into vapors. And the end product is the crucial components like circuit strength and the battery's voltage. The solution will be faster in heating up vaporize if the voltage and circuit are stronger.[7]

"Battery voltage and unit circuitry differences can result in considerable variability in the products' ability to heat the solution to an aerosol and, consequently, may affect the delivery of nicotine and other constituents, and may contribute to the formation of toxicants in the emissions," as reported by WHO in the year 2014 which describes that factors such as "length of puffs, depth of inhalation and frequency of use" might have an effect on nicotinebeing utilized by consuming e-cigarettes.[8]

E-Cigarette aerosol composition: The aerosol produced by the e-cigarette aerosol and the users keep breathing those aerosols from the piece of equipment and then breathe out which contains many injurious as well as potentially detrimental substances, plus substance like Nicotine, very ultrafine particles which can be breath in deep into lungs,it also contains volatile organic compounds as well as cancer-causing chemicals along with few heavy metals such as tin, nickel, and lead. Sometimes it is difficult for the consumers to know the correct composition of E-Cigarettes as they are often commercially marketed as zero percent nicotine but are bring into being to have nicotine in it.[9]

Harmful Effects of E-Cigarettes: WHO reported that it can have unsympathetic effects during pregnancy and may contribute to cardiovascular disease.[10] Nicotine itself is not a carcinogen but it may function as a tumor promoter. Nicotine seems concerned with fundamental aspects of the biology of malignant diseases, as well as of neurodegeneration.[11]

Facts: Mostly E-Cigarettes are frequently used by the youths among the tobacco products. More than the adults, youths are being affected in the countries. According to reports,58.8 % of adults are the users of the e-cigarette were mostly of aged 45 years and older. Many of them were current or former cigarette smokers.[12]

Indian Market Scenario: The estimated value of E-cigarette was very high in the industrial market. According to global market reports, there are as many as more than 466 brands for e-cigarettes production but the Indian market has fewer numbers out of that.[13] According to the market research organization, they have estimated that by the year 2030 the global e-cigarette would rise high more than four times the current production as well as consumption. Therefore, based on that report, the Indian market scenario was also expected to take a rise in its consumption but because of the government abrupt decision towards the banning of e-cigarettes it is still in a very controversial estimated topic. The most popular variety of e-cigarette ENDS is the most commonly used product across the globe as reported by WHO IN 2014.[14]

The central government informed the parliament of India that between the years 2016 and 2019, most of the e-cigarettes were imported more than 19 crores.[15] The chief supplier of these e-cigarettes were mostly from countries like China, Hong Kong, the US, and Germany. According to the market reports, the school going students are more affected and excited about using this new variant of e-cigarette and that is why the consumption rate of e-cigarette has grown among these teenagers including high school students.[16]

Fines under the new law: The provisions are being made by the Indian Government after the prohibition of this e-cigarette was made considering its production, manufacturing, importing, exporting and transport, sale, distribution, storage, and advertisement.[17]

1. If anybody in India will be recognized for production, manufacturing, importing, exporting, transporting, and sale including online sale too,it will become a cognizable offense that will be meant for punishment under the law of Indian government.[18]
2. One year of imprisonment or a fine of Rs 1 lakh or might be both for the first offense will be applicable as a punishment as decided by the law of the Indian government.
3. If someone is caught in commencing the offense again then the punishment will be extended upto 3 years with a fine of Rs 5 lakhs.[19]
4. If anybody is found in storing the e-cigarettes will get a punishment of imprisonment up to 6 months or a fine of Rs50,000 or maybe both.[20]
5. Persons who have already the storage of e-cigarettes have to declare as well as the deposit of the stocks of e-cigarettes to their nearest police station on their own as soon as possible after this ordinance comes into effect.[21]

At the present scenario, the Indian Government has declared to stop the sale, storage spaceas well as production of e-cigarettes in India. This decision was being moved by the Union Finance Minister of India, Nirmala Sitharaman who said that said the decision of banning e-cigarettes was taken as per the union recommendations of a Group of Ministers (GoM), which was headed by her.[22]

As soon as the commencement of the ban on e-cigarettes comes into force, immediately all the activities related to e-cigarettes like production, manufacturing, consumption, sale, exporting and importing, distribution, storage, and its advertisement would become illegal in India.[23,24]

Giving justification on the ban of e-cigarettes the union minister of India said that E-cigarettes were being promoted as a way to search out people out of their smoking habits but reports have shown that many people are not using it as weaning mechanism but are rather addicted to it. The government justified its decision of banning e-cigarettes from the country as e-cigarettes are more vulnerable to health hazards and this decision will also protect the youth of its country.[25]

As soon as the parliament of India passes the bill on banning e-cigarettes, 15 states and one Union territory immediately had taken action on this and had banned e-cigarettes. These include Karnataka, Punjab, Mizoram, Kerala, Bihar, Jammu & Kashmir, Maharashtra, Uttar Pradesh, Tamil Nadu, Puducherry, Jharkhand, Rajasthan, Himachal Pradesh, Meghalaya, Nagaland and Odisha [26]. So, the purpose of the government has been to zip the problem in the bud itself," as reported by the union minister of India.[27]

"You see, in a country as vast as India, once a particular product has a very big consumer base and social acceptance, it is very, very difficult to ban it," the health minister of India Dr. Harsh Vardhanonce said in a television interview in the late 2019. Because many opposition political parties were also opposing on banning e-cigarettes as they were only focusing on the economic growth and the profits the industries could make from these e-cigarettes business and forgot about the harmful health hazards of the tobacco product.[28]

Outcome on Ban of e-cigarettes in India: With the ban on e-cigarettes in India, it has unexpectedly benefitted the traditional tobacco or cigarette companies in India like ITC and Godfrey Philips. These companies were facing competition from e-cigarettes in the tobacco market in India. "Why ban when you can tax (heavily)? Banning e-cigarettes while keeping tobacco products is bizarre. Neither health nor fiscal grounds for this decision, so what's the logic," as reported by a member of the Prime Minister's Economic Advisory Council.[29]

Conclusion

The Indian Government has taken a significant decision on e-cigarettes. It has taken care of the health hazards of its people as mostly the adults as well as the high school going students in India have started getting addicted to this new variant of e-cigarettes. Therefore, new research is needed to be conducted in the future in this field as no doubt e0cigarettes are an option for a replacement for traditional cigarettes but its harmful hazards towards health cannot be overlooked.

Abstract

Vestibular migraine (VM) is a distinct clinical entity which accounts for major vestibular symptoms among the adult and children. It is presently thought of as a major etiology for episodic dizziness. The pathophysiology for VM is not completely understood and is always a puzzling dilemma. Patients often present with vertigo, headache, photophobia, and phonophobia. The clinical examinations and laboratory investigations are usually within normal limits. The diagnosis of VM is often challenging as there are no confirmatory tests available. The treatment is often similar to the migraine headache. The present-day management is to take the similar prophylactic medications needed for migraines such as beta-blockers, antidepressants, and anticonvulsants drugs. It is always a challenging disease for clinicians and often creates a puzzle for diagnosis and treatment. Accurate management of VM needs a proper understanding of the present literature which are discussed details in this review article.

Keywords: *Migraine,Vertigo,Vestibular migraine, Migraine related vertigo.*

Introduction

Dizziness is a common clinical symptom in daily medical practice. The patient presenting migraine along with vertigo or dizziness is called Vestibular migraine (VM). It is also called as migraine-related vertigo (MRV), migraine-associated vertigo (MAV), and basilar artery migraine or migrainous vertigo. This clinical entity is a type of migraine leads to vertiginous presentations along with the classical symptoms of migraine. VM was first described by Dieterich and Brandt in 1999[1] and it corresponds to a type of migraine where important symptom is vestibular. It is more commonly found in persons with the absence of aura and predominantly involves female, as a ratio of 5:1(F/M).[2] It is documented that 1% of the population suffers from VM which accounts for the commonest central etiology of vertigo and the second commonest cause of vertigo in total.[3] VM is often confused with vestibular disorders which are an important cause for dizziness. In clinical practice, common disorders that manifest in vertigo are benign paroxysmal positional vertigo (BPPV), Meniere's disease, vestibular migraine,and vestibular neuronitis in falling order of frequency.[4] VM represents the 2nd commonest cause for vertigo after benign paroxysmal positional vertigo.[5]

Method

A search was done on medical literature with the help of Pub Med (MEDLINE), SCOPUS, and Google Scholar. The literature search was done between 1980 to 2018 years with the help of the keywords of migrainous vertigo,vestibular migraine, migraine-related vertigo, and migraine-associated vertigo. Articles were selected based on pathophysiology, epidemiology,clinical presentations,diagnosis, and treatment. A sum of 38 manuscripts was found and the detailed search was summarized in our review article.

Epidemiology: VM is more commonly seen than other vestibular disorders.[6] Vertigo and migraine are common clinical entity which affects 7% and 14% of the general population respectively. The simultaneous occurrence of vertigo and migraine may be one percent if found at random. Moreover, a present study documents that 3.2% of the populations have vertigo and migraine. [7] It affects females about three times more common than males. It has been reported that lifetime migraine prevalence is 16%, lifetime vertigo prevalence is of 7%, and a co-morbidity of 3.2% rather thana 1.1% expected chance of individual.[8]One study documented that VM has a prevalence of 0.89% in a year and constitutes for approximately ten percent of patients found for vertigo and approximately ten percent of patients seen for migraines.In one study, the 1-year prevalence of VM in females aged 40-54 years is 5%.[9]

Etiopathology: The basic pathophysiology is trigeminovascular reflexfor vestibular migraine is aparasympathetic reflex such as trigeminovascular reflex which causes vasodilatation of the large intracranial vessels. The trigeminal nucleus caudalis is activated and C1-C2 dorsal horn neurons cause vasodilatation of intracranial blood vessels.[10] In trigeminovascular reflex, the vasodilatation effect of parasympathetic stimuli may be activated by neurokinin A(NKA), calcitonin gene-related peptide (CGRP) and substance P(SP) released from trigeminal nerve endings.[11] The neural pathway for the vestibular system often give to both peripheral and central migrainous mechanism. [12] There are two possible mechanisms for explaining the vertigo in migraine. Transient vertigo has been thought to be a brainstem aura that may be related tothe alteration inflow of the blood.[13]Also there is direct communication from the posterior part of the parietal cortex into the vestibular nuclei which gives straight access to cortical mechanisms towards migrainous aura to connect vestibular information processing and reflex action. Few studies documented that repeated circulation/vascular problems like ischemia due to vasospasm of the inner ear and extravasations of plasma during migraine attack may lead to injury to vestibule and cochlea permanently.[14,15] The symptomatic presentations of patients often the same to peripheral vestibulopathy. Also,abnormality in ion-channel defect and calcium channel alters labyrinthine function and its central pathways often give a consistent hypothesis for the management of VM.[16]

Genetics: Different studies have documented the genetics of the VM. Series of cases documented a hereditary risk towards prevalent among patients suffering from VM, but these risk factors cannot be associated with any particular genetic alteration. One study was done among twenty-four patients suffering from recurrent benign vertigo and two hundred twenty family members who underwent a clinical assessment, revealed forty percent of the first degree relatives suffering from the same type of recurrent vertigo episodes whereas in contrast to 2% of unrelated spouses.[17] One study reported that VM might be heterogeneous or monogenic.[18]There is no relation between sodium and gene linking to calcium channel for familial migraine.[19] There is a location at chromosome 11q which commonly seen in females among familial migraine-related vertigo. [20]There is 12.0MB interval on chromosome 5q35 which contain gene of familial migraine-related vertigo. [21]Etiopathology for VM is still unclear.

Clinical Presentations: VM includes the clinical symptoms such as vertigo along with clinical manifestations of migraine. The vestibular manifestations by migraine usually mimicsome other labyrinthine lesions like benign paroxysmal positional vertigo and episodic vertigo in Meniere's disease.[22] Patient often complaints episodic sensation of spinning,imbalance or sensation of rotation or giddiness or feeling of light headedness last for seconds to hours or days. The patient often presents with severe episodic pulsating headache. The patient has usually no hearing loss when associated with a classical type of migraine. In the majority of cases of basilar migraine, patients present with the sensorineural type of hearing loss and ringing sound in the ear which may mimic the Meniere's syndrome. The physical examinations of patients suffering from MRV are usually normal between two episodes. During episodic attack, the patients generally manifest a nystagmus either peripheral or central vestibular

abnormality. The non-paroxysmal type of positional nystagmus is often seen during the episodic attack of VM.

The peripheral vestibular lesions whichmimic to VM areendolymphatic hydrops,benign paroxysmal positional vertigo,vestibular neuritis,and perilymph fistula. The central lesions which mimic to VM are transient ischemic accident,multiple sclerosis,vestibular-basilar artery insufficiency, neurodegenerative disorders, and familial ataxia syndrome.[23] The International Headache Society(HIS) has declared established diagnostic criteria of migraine (Table 1).[24] However, the vertigo is found in this classification only in respect of benign paroxysmal positional vertigo and basilar migraine. So, it is thought the higher prevalence of VM is more than the chance of association.

The classification of migraine is into: 1. Common migraine(without aura)-There include unilateral and pulsating headache. The headache is more by photophobia (sensitivity to light), phonophobia(sensitivity to sound), and physical activity.All neurological tests are usually normal; 2. Classical migraine(with aura)-There are 2 to 3 episodes of headache which proceeded by reversible CNS problems like ataxia, dysarthria, diplopia, one side numbness/weakness,vertigo, and tinnitus. This phase is known as aura and neurological investigation is within normal limits; 3. Basilar migraine(Type of classical migraine)-There are presentations of spasm of the basilar and vertebral artery. There are brain stem hypoxia featureslike dysarthria, diplopia,ringing sound in the ear,vertigo,hearing loss, low level of consciousness, and weakness/numbness of limb. The symptoms stay for few minutes to hours. The headache often originates at the cervical and occipital areas; 4. Vestibular migraine-Vestibular presentations are additional features due to spasm of vestibule-cochlear artery along with classical migraine; 5. Complicated migraine/Migrainous infraction-It is a classical type of migraine but the neurological presentations do not become normal in one week and MRI reveals an area of ischemic infarction of the brain. VM was jointly described by Barany Society and the subcommittee of IHS.[25] It is seen in the appendix of the 3rd edition of HIS as a first stage for new clinical types.[26] The criteria for the diagnosis of VM which accepted internationally are based onvestibular clinical presentations and migraine symptomatology of moderate to severe, a past migraine history, a temporal association between migraine symptoms, and vestibular symptoms. The duration of acute episodes is often limited between 5minutes to 72 hours. The clinicians should find any aural symptoms to differentiate between Meniere's disease and VM (Table.2). VM is a multi-factorial chronic disease and common among genetically susceptible people. It is characterized by headaches with phonophobia, photophobia, vertigo, nausea, and vomiting. VM affects around 18% female and 6% male presenting neuro-otological manifestations like vertigo,decreased hearing, ringing sound in the ear, and fullness of the ear during crisis. Patients may present this symptomatology without the presence of aheadache.[27] The physical assessment is often normal between the attacks. At the time of the attack of migraine-related vertigo, patients often present a nystagmus that suggests neither peripheral nor central vestibular abnormality. During the attack of vestibular migraine, non-paroxysmal positional nystagmus is common.[28] Loss of hearing is never a clinical presentation of classical and common type of migraine but sensorineural hearingloss or ringing sound in ear is associated with 80% cases of basilar migraine resembling to the Meniere's syndrome. During aura,positional or spontaneous nystagmus can be seen whereas there are no neurological deficits inpatient. There is often familial history of headache is found. The aggravating factors are mental and physical stress,menstrual period,taking contraceptive pills, smoking habits,exposure to light and sound,deprivation of sleeping,staying in an empty stomach,and a certain diet. Vertigo in the migraine patient may go to the presentations of headache and be a part of the migrainous aura. It is often difficult to think whether migraine and vertigo are two separate presentations with similar etiopathology.

Diagnosis: The diagnosis of VM is often difficult as there are no gold standard tests available for getting the diagnosis. The clinical diagnosis of VM may be difficult as it shares features with many clinical conditions. There is no worldwide decision for a group of clinical presentations covered under this disease or what medical term should be utilized. The vestibular symptoms and headache in VM may not be temporarily associated, which often hide the association. The newer guidelines for diagnosis of VM need a minimum of 5 episodic vestibular symptomatic attacks ranging from moderate to severe grade of intensity. The vestibular episodic attacks varying in length,span from few seconds to days and most of fall between 5minutes to 72 hours.[29] Diagnostic tests often show non-specific abnormal results which are also found in migraine patients who do not have

vestibular symptoms.Laboratory tests like complete blood count(CBC),C-reactive protein(CRP),erythrocyte sedimentation rate (ESR) are usually done in all cases of VM. The confirmatory diagnosis of VM needsto rule out of the vestibular symptoms. For excluding the vestibular causes, the different vestibular function testing,hearing assessment,and neuro-imaging are required. Vestibular-evoked myogenic potential(VEMP) is an investigation for vestibulocollic reflexes and peripheral vestibular excessive sensitivity to loud noise which helpful for diagnosis of VM.VEMPs have abnormal reporting in VM patients but the findings are usually heterogeneous. These findings show lower electromyography (EMG) amplitudes,bilateral or unilateral loss of cervical VEMP responses,shifting of maximum VEMP response from 500 to 1000Hz, and increased latencies.[30] VEMP findings are not very specific for VM .Approximately 38% of VM patients present with cochlear features like decreased hearing,ringing sound in-ear,and fullness of ear.[31] The loss of hearing loss in VM varies from mild to moderate degree without much progression. There is documentation of mild both sides downward sloping type of hearing loss over many years among patients of VM.[32]Caloric electronystagmography (ENG) may be needed to differentiate peripheral vestibular diseases from VM.There is a reduced caloric response in peripheral vestibular hypo-function,labyrinthitis and vestibular neuritis.[33] A video head impulse test is useful to differentiate the vestibular disorders from VM.[33] MR angiographyor MRI brain can rule out intracranial lesions for vertigo-like cerebrovascular diseases.[33] Swaying sensation rather than vertigo is described by the patients of cerebrovascular diseases along with neurologic findings like diplopia,visual field loss,limb weakness, or sensory loss.[32]As per a new study, there isan alteration of gray matter in VM in comparison to the control group with raised gray matter mass of frontal lobe, temporal lobe of left side,left thalamus and occipital lobe and reduced gray matter in the left cerebellum.[34]It also needsan examination of MRI for the VM patients. Caloric hypoactivity, oculomotor abnormalities, and hearing loss are rarely seen in VM.

Physiological Tests: Physiological tests are not sufficient alone for diagnosis of the VM as these are inconsistent and patients have a high incidence of VM without vestibular presentations.[35] However, the physiological tests may be employed to differentiate from other vestibular lesions and to confirm the vestibular lesions if present. Approximately ten to twenty percentages of the patients of VM have one side decrease in labyrinthine activity.[36] Patients with MRV have increased postural sway than patients with no VM. There is reduced amplitude in vestibular evoked myogenic potentials in patients of VM.[37]

Treatment: The management of VM needs treatment of vertigo attack and prophylactic treatment. The drugs used for prophylaxis are the same as for migrainous headache which includes beta-antagonist, anti-depressants, and anticonvulsants.[38] There are two treatment options and these are prophylactic and abortive medications for migraines which can be used for the treatment of VM. One study documented 38% of VM patients responded to Zolmitriptan versus placebo with 22%.[39] The drugs that are prescribed for prophylaxis in migraine patients can also be used for the VM. Different drugs are flunarizine, propranolol, bisoprolol, and metoprolol.[40,41] Serotonin has an important role in the pathophysiology of migraine and also causes vestibular symptoms. Deprivation of the amino acid such as tryptophan which is used in serotonin synthesis resulting in more vertigo.[42] Tricyclic antidepressant which enhance central serotonin level may be useful in prophylactic medication of VM particularly in anxiety associated patients.[43] GABA like drugs such e.g. gabapentin are also helpful for patients with VM.[44]

Table 1: Diagnostic criteria of Vestibular migraine(International Headache Society and Barany Society)

Vestibular migraine
A. At least five episodes of vestibular symptoms of moderate to severe intensity lasting 5min-72hours.
B. Current or previous history of migraine +/- aura according to the International Classification of Headache Disorders (ICHD).
C. One or more migraine features ++ with at least 50% of the vestibular episodes.
D. Not better accounted for by another vestibular or ICHD diagnosis.
Probable vestibular migraine
A. At least five episodes with vestibular symptoms+ of moderate to severe intensity lasting 5min-2 hours.
B. Only one of the criteria B and C for vestibular migraine is fulfilled.
C. Not better accounted for by another vestibular or ICHD diagnosis.

Table 2: Difference (Clinical presentations) between Vestibular migraine and Ménière's disease.

Clinical Presentations	Vestibular migraine	Ménière's disease
Headache	Present	Absent
Vertigo	Present and less duration	Present and more than 24hours duration
Family history of headache	Present	Absent
Phonophobia and photophobia	Present	Absent
Hearing loss	Absent	Present
Sensation of ear blockage	Absent	Present
Tinnitus	Absent	Present
Antimigraine medications	Good response	No response

Conclusion

Exact diagnosis of VM is often a taxingsituation for clinicians. The pathophysiology for VM is always a puzzling dilemma for clinicians. The increased prevalence of VM and its impact on quality of life need more understanding of the pathophysiology for better care of VM. The presence of two symptoms of vertigo and headache simultaneously does not represent a definite causal relationship. There is always a challenge for the VM from both basic science and clinical aspect to enable appropriate and ethical treatment of this disease. In VM, the patient's profile is commonly young adult female or male and clinical presentations like vertigo of variable duration and headache. Each episode of vertigo is usually rotatory sensation and or feeling of unsteadiness which lasts for minutes to hours. Other clinical presentations are bilateral aural fullness, photophobia, phonophobia, and tinnitus. During taking history, most of the VM patients have motion sickness. VNG often reveals positional nystagmus not focusing on central or peripheral lesions. Migraine prophylaxis is often helpful for the treatment of VM.

Cervical Lymphadenopathy-A Clue to Systemic Diseases: A Recent Update

Shazina Saeed[1], Shamimul Hasan[2], Rajat Panigrahi[3]

[1]Assistant Professor (Grade III), Amity Institute of Public Health, Amity University, Noida, Uttar Pradesh, [2]Professor, Department of Oral Medicine and Radiology. Faculty of Dentistry, Jamia Millia Islamia, New Delhi, [3]Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Lymph nodes are distributed along with the lymphatic system all over the body. Enlargement of lymph nodes (lymphadenopathy) may result from an infection, hyperplasia during the immunologic response, and sometimes also by infiltration by cancer cells or lipid cells. Lymphadenopathy may be regional or generalized and or caused by local or systemic factors. Therefore, the differential diagnosis of lymphadenopathy is critical. Oral physician during routine physical examination also includes the examination of any enlarged lymph node in the head and neck region. Lymphadenopathy may be the only clinical presentation or one of the few findings, and enlarged lymph nodes may often raise the suspicion of an underlying pathology like lymphoma, leukemia, and Acquired Immunodeficiency Syndrome (AIDS). This review focuses on the various causes of cervical lymphadenopathy, and the systemic approach to the differential diagnosis and the management along with the health care team.

Keywords: *Cervical lymphadenopathy, Diagnostic aids, Differential diagnosis, Malignancy.*

Introduction

The principal constituents in the lymph system are lymph nodes, the lymphatic vessels as well as the moving cells of immunity which compositely have the basic responsibility to protect the host against infections.[1] Lymphadenopathy frequently occurs as a clinical symptom of an array of disorders. It is described as an alteration in the size, number and consistency of lymph nodes, due to the infiltration or dissemination of either inflammatory cells or malignant cells into the nodal architecture.[2] Cervical lymphadenopathy is described as an enlargement of cervical lymph nodes, with a diameter greater than 1 cm.[3] Cervical lymphadenopathy generally describesa transitory reaction to a non-malignantlocal or generalized infection. However, infrequently, it might be a precursor to an underlying pathological state (autoimmune disorder/malignancy). Lymphadenitis distinctively refers to lymphadenopathies having inflammatory origin.[4] Lymphadenopathy is widely divided into 3 types- localized, generalized, and dermatopathic.[5,6] Generalized lymphadenopathy refers to the enlargement of lymph nodes in more than two noncontinuous areas, whereas, a single site is involved in localized lymphadenopathy. In primary care patients with undiagnosed lymphadenopathy, approximately three-fourths of patients manifest with localized lymphadenopathy and a quarter with generalized lymphadenopathy (Figure 1).[7,8] Dermatopathic lymphadenopathy (DLN) is often seen in patients with skin diseases exfoliative or eczematoid inflammatory erythrodermas, especially mycosis fungoides and Sézary

e-mail: drrajat@gmail.com

syndrome, but has rarely been described in the absence of clinical skin disease.[9] According to its duration, it can be acute, sub-acute, and chronic lymphadenopathy. Acute lymphadenitis is usually seen with bacterial/ viral infections and persists for upto 2 weeks. Subacute lymphadenitis includes a wide array of potential etiologies and lasts between 2-to-6-weeks. Chronic lymphadenopathy persists for more than 6 weeks and occurs due to the infiltration and dissemination of inflammatory/neoplastic cells into the nodal tissues.[4,5,6] Categorizing localized and generalized lymphadenopathy is necessary for making a diagnosis. Thus, a patient presenting with a palpable cervicofacial lymph node poses a significant diagnostic and therapeutic challenge. In most of the cases, without physical examination and investigation result in a delayed incorrect diagnosis and may come as an iatrogenic complication due to misdiagnosis.[10]

Etiology: The Head and neck region is regarded as the commonest site for lymphadenopathy. The spectrum of lymphadenopathy may be represented by the pneumonic "MIAMI" and encompasses malignancies; infections, and autoimmune disorders, miscellaneous and iatrogenic causes.[2] In India, the leading cause for lymphadenopathy is attributed to infection, of which locoregional infections, tuberculosis, and filariasis predominate. According to a study by Iqbal et al., tuberculosis accounts for 70.45% of cervical lymphadenopathy, then comes reactive lymphadenitis (13.63%), metastases (11.36%), lymphomas(4.54%), and chronic nonspecific lymphadenitis (2.27%).[6,11]

Table 1-Depicting etiological factors of cervical lymphadenopathy.

1. **Infectious Etiology-** Various infectious etiologies like viral, bacterial, fungal, protozoal and pararsitic infectious may result in cervical lymphadenopathy.

(a) Viral infections- Herpes group of viruses (HSV, Varicella, EBV, CMV), HIV, Rubella, Measels, Adenovirus, Rhinovirus, enterovirus, Parvovirus B19etc may cause lymphadenopathy.

(b) Bacterial infections- Staphylococcus, Streptococcus, Tuberculous mycobacteria, Non Tuberculous mycobacteria, Treponema, M. leprae, corynobacterium diphtheria, Brucellosis, yersinia pestis, tularemia, mycoplasma pneumoniaetc may cause lymphadenopathy.

(c) Fungal infections- Candida, histoplasmosis, blastomycosis, dermatophytes (linea), coccidoimycosis.

(d) Parasitic/protozoal infections- Toxoplasmosis, trapanosoma, leishmania, rickettsia, microfilaria.

2. **Neoplastic Etiology-** A wide array of neoplastic conditions may have associatedlymphadenopathies.

(a) Squamous cell carcinoma- Odontogenic etiology (chronic irritation due to sharp tooth cusp, ill-fittingdentures), Tobacco induced conditions, SCC with Lichen planus of lip.

(b) Malignanat lymphomas- Hodgkin's & Non-Hodgkin's lymphoma (burkitt lymphoma).

(c) Leukemias- Acute myeloid leukemias, .Acute lymphoblastic leukemia

(d) Lymph node metastasis from solid tumors- Neuroblastoma, Rhabdomysarcoma, Nasopharyngeal carcinoma, metastatic lung, breast, thyroid, renal carcinoma.

3. **Metabolic Disorders-** A wide array of metabolic conditions may have associated lymphadenopathies.

(a) Inborn metabolic storage disorders- Niemann-Pick disease, Gaucher disease, Amylodosis, Tangier disease, Glycogen storage diseases are associated with cervical lymphadenopathy.

(b) Endocrine disorders- like Thyrotoxicosis, Adrenal insufficiency.

4. **Drugs & Lifestyle Exposure-** A variety of drug and lifestyle induced entities may have associated lymphadenopathy.

(a) Drug induced- A number of drugs like Isoniazid, Phenytoin, Allopurinol, Captopril, Penicillin, Cephalosporin, Carbamezipine, Heparin,,Gold, Hydralazine, Primidone, Pyrimethamine, Quinidine, Sulphonamides causes cervical lymphadenopathy.

(b) Lifestyle exposure- Alcohol, ultraviolet (UV) radiation, and tobacco can cause cancers with secondary lymphadenopathy.

5. **Miscellaneous-**A number of miscellaneous entities may cause cervical lymphadenopathy.

(a) Granulomatous infections- like Mycobacteria (M. tuberculosis, M. leprae, M. avium, M. kansai, M. marinum, BCG vaccination) spirochaetes (T. pallidum, T. pertenue, T. carateum) actinomycosis,

brucellosis, yersinia, nocardia, histoplasmosis may cause cervical lymphadenopathy.

(b) Vasculitis- like Wegener's granumatosis, Giant cell arteritis, Systemic lupus erythematosus(SLE), Rheumatoid arthritis, Polyarteritis nodosa, Churg-Strauss

(c) Immunologic abberrations- like Sarcoidosis, Orofacial granulomatosis, Crohn's disease, Primary biliary cirrhosis

(d) Hypersensitivity pneumonia (farmer's lung) & chemicals (beryllium & silicon) may also cause lymphadenopathy.

Clinical Evaluation: Since the diagnosis changes with age, sex, location, duration of symptoms, shape, and size an organized and detailed history, thorough clinical correlation and tissue diagnosis are mandatory.[12]

History: Factors which aid in classifying the cause of lymphadenopathy should include patient's age, location (localized vs. generalized) and duration of lymphadenopathy, foreign travel history, drug history, exposures, and associated symptoms.[13]

Age And Duration: About half of the healthy children demonstrate palpable lymph nodes. Most lymphadenopathy in children is non-malignant or due to infection.[14] The incidence of childhood neoplasms change with the age. In general, lymphadenopathy secondary to neoplasia arise in the adolescents.[4] The majority of acute lymphadenitis cases have an infectious etiology and subside after 2 weeks. This is in contrast to chronic lymphadenopathy, which persists for more than 6 weeks and has an underlying pathology (malignancy, metabolic disease or opportunistic infections).[15]

Associated Symptoms: A detailed review of systems helps in knowing any red flag symptoms. Upper respiratory tract infections encompass constitutional symptoms of fever, chills, sore throat, cough, and body ache. Along with fever, sweating in the night and unknown weight loss (< 10% of body weight) is suggestive of Hodgkin/non-Hodgkin lymphoma. Persistent productive cough lasting more than 3 weeks,evening rise of temperature, hemoptysis, and weight loss are suggestive of tuberculosis. Idiopathic fever, rash, fatigue, and pain in bones increase the suspicion of any autoimmune disease.[13,16]

Concurrent Illness and Past Health: A detailed and meticulous history is mandatory taking in account history of foreign travel, animal/insect contact (esp. cats, dogs, rodents and ticks), preceding infection (tonsillitis and periodontal infections), occupational history (mining and metal industries like lead, beryllium, and silicon), chronic use of medications (Isoniazid, phenytoin, and allopurinol may cause lymphadenopathy), immunization status (lymphadenopathy may occur after diphtheria-pertussis-tetanus, Polio and typhoid fever vaccine), sexual history (genital sores may have accompanying lymphadenopathy) and family history (few diseases have a familial predisposition, like lipid storage diseases and Li-Fraumeni syndrome).[13,15,16]

Physical Examination: General Malnutrition or poor height and weight indices are suggestive of underlying chronic disorders such as tuberculosis, immunodeficiency, or malignancy.[17] Physical examination usually includes inspection, palpation, and ENT assessment. However, cases with suspected systemic disorders would necessitate palpation of lymph nodes of the region.

Characteristics of the Lymph Tissue: A meticulous and comprehensive lymphatic examination should be carried out to eliminate generalized lymphadenopathy.[6] Lymphadenopathy in the supraclavicular region poses the highest risk for malignancy. Elderly individuals > 40 years of age have 90% risk and 25% risk is associated with individuals <40 years.[18] The lymph nodes when examined for tenderness, mobility, and consistency with adjoining tissue/adjoining lymph nodes.[19,20] Any acute infection is known by localized lymphadenopathy in which the lymph nodes are distinct, soft, tender, and mobile. However, firm and mildly tender/non-tender lymph nodes represent chronic infections.[21,22] In lymphadenopathy of metastatic cancer, the lymph nodes may bepainless, stony hard, and are fixed to adjacent tissues; but in lymphoma, they are larger, distinct, not tender, rubbery, and not fixed.[21,23] Firm, discrete, and mobile nodes with free overlying skin are typically seen in the initial stages of TBlymphadenitis. The nodes may become matted with inflamed overlying skin in the later stages. Advanced stage of TB lymphadenitis is marked by softened nodes with abscess and sinus tract formation.[24]

Figure 2- show lymphatic drainage patterns, and etiologies of lymphadenopathy of the regions.[6]

If a group of lymph nodes may betender and bigger, but several – mostly bilateral – are involved,

other situations should be taken into consideration in the differential diagnosis. In infections bilateral growth suggest a viral or streptococcal infection.[15] (Figure 3)

Diagnostic Aids: Apparent benign causes (such as infection) of cervical lymphadenopathy do not require further investigations. However, ancillary aids like serological studies, imaging, and biopsy are recommended for idiopathic conditions. Imaging shows the dimension and spread of the node more accurately than palpation. Ultrasonography is done to study lymph nodes of superficial parts like the neck.[25] Computed tomography determines lymphadenopathy in the thorax or abdomen and pelvic region.[26,27] Diagnosis through Fine needle aspiration cytology (FNAC) or excisional biopsy is the only gold standard for diagnosing lymphadenopathy.[6] In India tuberculosis predominates among the granulomatous infections.

Following history taking and examination, (Figure 4) can show the wayto physicians for further evaluation with peripheral LAP.[6,26,29]

Differential Diagnosis: Differential diagnosis of cervical lymphadenopathy is essential to rule other diseases that present with overlapping features. Pain (tender/non-tender), location (unilateral/bilateral), relation with underlying structures (mobile/fixed nodes), consistency (rubbery/matted), and associated constitutional features (fever, cough, weight loss, arthralgias, rash, etc.) may help in arriving at a definitive diagnosis.

Table 2- Differential diagnosis protocol for cervical lymphadenopathy.[29]

Majority of the disorders are associated with generalized lymphadenopathies. Mononucleosis like syndrome present with Fatigue, malaise, fever, atypical lymphocytosis, and splenomegaly in around 50% of patients. Diagnostic tests are Monospot, IgMearly antibody or viral capsid antigen test. 80 to 90% of patients are asymptomatic in toxoplasmosis, often present as mild symptoms; few patients may have hepatitis, and IgM toxoplasma antibody is the diagnostic test.Tuberculosis lymphadenitis usually present with painless, matted cervical nodes and purified protein derivative(PPD), Fine needle aspiration cytology (FNAC), and biopsy are the diagnostic aids. Secondary syphilispresent with painless, shotty nodes, typical cutaneous rash, condyloma lata, mucous patches in the mouth,and Rapid plasma regain (RPR) is the test of choice. Initial stages of HIV infection manifest as “Flu-like” illness, rashand HIV antibody testing is done. Lymphoma present with fever, night sweats, weight loss in 20 to 30% of patients, along with nodal involvement, and biopsy is used for diagnosis. Leukemia present as blood dyscrasia and bruising. Blood smear and bone marrow aspiration are the investigative test. Measels and rubella present with fever, conjunctivitis and rash and Clinical criteria, serology is used for diagnosis. Hepatitis B present with Fever, nausea, vomiting, icterus, and Liver function tests, HBsAg are used as diagnostioc aids.

Management: Management of Cervical lymphadenopathy is based on the underlying pathology. Usually, the condition is self-limiting and necessitates regular surveillance.[17] Vigilantreview at a 2-to 4-week time is generally recommended for benign lymphadenopathy.[13] Antibiotic treatment targeting Staphylococcus aureus and streptococci (cephalosporins, amoxicillin/clavulanate, or clindamycin) should be given to patients who exhibitunilateral, acute anterior cervical lymphadenitis, and systemic conditions.[30] Corticosteroids therapy should not be given until a definitive diagnosis, as it may potentially mask

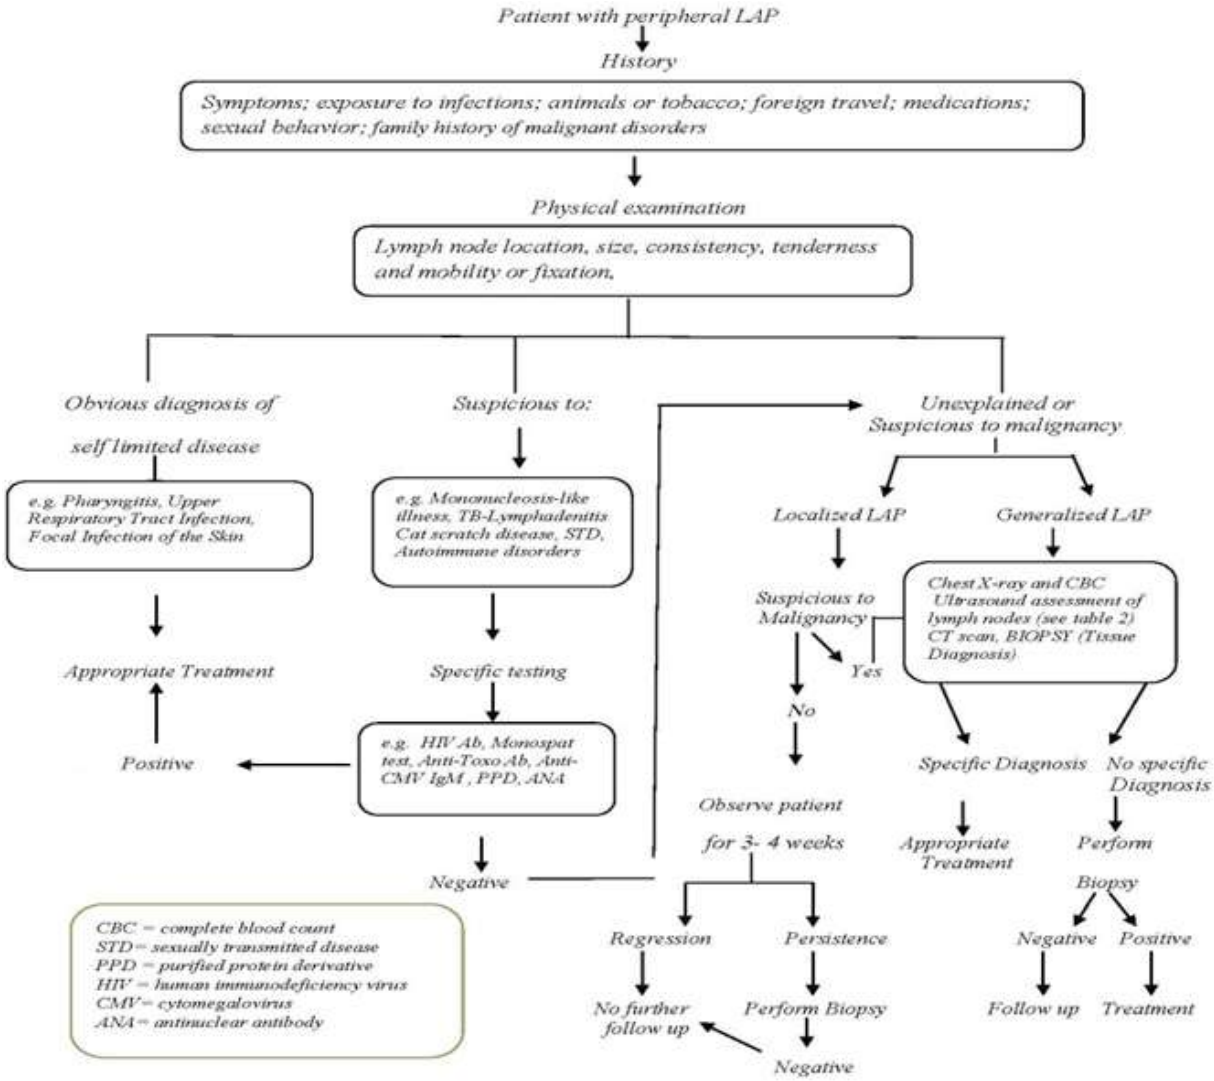

Figure 4: Diagnostic evaluation of cervical lymphadenopathy. histopathology of leukemia or lymphoma.[31]

Conclusion

Cervical lymphadenopathy may be a manifestation of benign pathology or may present as a sign of an underlying systemic disorder. Detailed history, meticulous clinical examination, and a plethora of diagnostic modalities are required for a confirmatory diagnosis. An Oral physician should be aware of the various etiologic causes of cervical lymphadenopathy and understand the significance of cervical lymphadenopathy as a clue to systemic pathologies.

Abstract

Periodontal disease represents various chronic inflammatory state of marginal, attach and free gingiva around the tooth, alveolar bone, various types of periodontal ligaments which attach the tooth to the bone or anchorage system of tooth, all are tooth-supporting system. The disease of supporting the structure of the tooth starts from a mild form of gingival inflammation. The use of smoke tobacco is a topmost modifiable risk factor for severe periodontal disease. The use of smoke tobacco has various links with periodontal disease severity. From the various survey it is found that periodontal condition is worst among Smoked tobacco users than non-users. Giving proper treatment to various periodontal diseases is a great challenge, because at the early stage same patients are not aware of these things. To date there is not some bleeding from gum, mild pain maximum patient doesn't aware of these things. When bleeding from gum during hard food chewing, hard or normal brushing patients reports complain. Gingivitis periodontitis like disease are non-violent, some time asymptomatic but they have a negative impact on mastication, esthetic of individuals. Sometimes it has effects the speech of people. Disruptions in the function of neutrophils can lead to develop gingivitis periodontitis. Down syndrome, neutropenia can lead to periodontal disease. Developing age can leads to periodontitis.

Keywords: *Periodontal Disease; Quality of Life;Adverse effect.*

Introduction

Periodontal disease represents various chronic inflammatory state of marginal, attach and free gingiva around the tooth, alveolar bone, various types of periodontal ligaments which attach the tooth to the bone or anchorage system of tooth, all are tooth supporting system. Disease of supporting structure of tooth starts from mild form of gingival inflammation. Gingivitis occurs due to retention of dental plaque due to various bacterial activities. When gingivitis remain untreated for a long time period it converted to severe periodontitis, which leads to loss of alveolar bone, periodontal ligament, recession of gingiva. Periodontal pocket is a tread mark of the periodontal disease, which latter became the main reason for tooth loss. All types of periodontal disease has linked with type I,II diabetes and various heart disease.[1-3]

Periodontitis is two types one is generalized when affected percentage tooth segment is minimum thirty percent and another is localized when affected tooth segment is less than thirty percent or less number of teeh are affected. Retention of biofimis the main cause gingivitis or periodontitis but the rate of progression of the disease depend on the host factor of oral environment and various genetic factors. In recent days the periodontal diseases has big hand in contribution of etiologic factors. The main objectives of our article are diagnosis, preventive measure and treatment plan for various periodontal disease. Thisarticle mention the difference between gingivitis and various forms of periodontitis.

Periodontitis mainly found in elder people, but rarely found in children. The loss of tooth supporting structure due to periodontitis is depends on amount of plaque deposition, risk factors present in that person and immunity capacity. Main identifying feature of various periodontitis is pocket formation and alveolar bone loss, but the bone loss pattern is not unifrom. Periodontitis case definition depends on the disease progression,

magnitude of disease (attachment loss, size of pocket, loss of alveolar bone). Most commonly use definition of severe periodontitis depends on both loss of attachment and size of pocket (mainly depth) recommended by CDC (center of disease control).

From the data of various study says that severe periodontitis is due maximum loss of tooth supporting structure, which has great role in tooth loss around fifteen percent worldwide. [4-7]

Risk factors for periodontal disease: Risk factors are mainly two types modifiable and non modifiable. Use of smoke tobacco is a top most modifiable risk factor for severe periodontal disease. Use of smoke tobacco has various links with periodontal disease severity. From the various survey it is found that periodontal condition is worst among Smoked tobacco users than non-users. Most of the smoke tobacco users found with no sing of bleeding from gingiva and no sing of gingival inflammation as compared normal individual. The main cause behind this is hyper keratinization of gingiva.[8,9,10]

Type I, II Diabetes is most common in people with long term systemic diseases, which make susceptible these kind of people to periodontal diseases. Percentage and Severity of periodontal disease grows in people with prolong DM (DIABETES) mainly patient with uncontrolled DM. periodontal disease has negative impact on metabolism of patient with DM. it also has negative effect on inflammatory response and synthesis of insulin. Adverse effect of diabetes found on tooth supporting structure of some young patient suffering with DM I, II.

A study report from USA gives data that less education, illiteracy, low financial conditions among Africans and Mexican citizen have worst periodontal health.[11,12,13,14]

Periodontal disease like gingivitis, periodontitis begins due to bacterial activities of bio-film. Around eight hundreds of bacterial species found in dental bio film till now. Multiple Gram –ve bacteria or unit of pathogen leads to periodontal disease.

Microbial biofilm: Severe form of periodontitis has close link with special colonies of Aa (*Aggregatibacteractinomycetemcomitans) in longitudinal studies. Porphyromonasgingivalis has also link with periodontitis. But till date it is not cleared about the relationship among changing structure of dental plaque and mild to severe periodontitis.*[15,16]

Many people have suffered from various viral diseases through out their life. After a Long time from cure of the disease the viral deoxyribo nucleic acid and ribose nucleic acid found from the body. The contribution of virus in development of periodontitis is in controversy till now. Antiviral drugs decrease the measurement of depth of periodontal pockets and gingival swelling.[17,18,19,20]

Supra-gingival and sub-gingival calculus contains biofilm. Supra-gingival calculus found above the gum margin and its color is yellowish white. Sub-gingival calculus found below the margin of gum and its color is greenish. The sub-gingival calculus is more calcified and not easily removed. Ca and phosphate ion present in saliva form the supra gingival calculus. Serum transudate calcified the the subgingival calculus.[21]

Pathogenesis of periodiontal disease: Dental biofilm alone can not be the causative factor for periodontitis or gingivitis. When the equilibrium is lost in between dental plaque and host body the gingivitis starts. Various changes found in biofilm, genetics of host body which leads to severe periodontitis and severe gingivitis. Epithelial tissue act as barrio to the harmful pathogenic organism. Lagerhans cell reside in the epithelium presents lymphoid cell against lymphocyte.[22]

Role of T cells: When lymphocyte arrives at damage point, the cell mainly B category converted to antibody generating cell. The capacity of antibody against severe periodontitis depends on antibodies strength and number. T cell has some hand in cell mediate immune reaction. T cell done it by the help of T helper cell by stimulatin g them. T1 and T2 cell has great contribution in development of periodontitis at starting point of periodontitis and on latter stage of periodontitis respectively.[23]

Susceptibility: All types of gingivitis Mild, moderate severe are reversible in nature. But in some case it converted to mild to severe periodontitis. Maximum studies gives data that in those individual who don't have any kind of gingivitis have excellent periodontal status for a long period of time. From data of some studies says that if some individual stop his/ her regular brushing constantly for minimum twenty one days he or she will develop mild gingivitis due to formation of plaque or biofilm. Maximum individual develop different kinds of gingivitis according to formation of dental plaque and inflammatory response. Another fact

is that inflammation of gingival also depends on quality of individual. Some case inflammations also depends on some genetic elements.

No such elements are there for act as resistance to periodontitis or gingivitis. The inflammatory mediators like interlukin1, TNF has linked with destruction of periodontal supportive structure. This inflammatory factors speed up the inflammatory processes. Many drug like nifedipine, phenytoin can cause mild to severe gingival growth. Various changes found in secretion of body hormone can leads to periodontitis.[24,25,26,27,28,29]

Genetics in periodontal disease: Participation of various genetic factors in long periodontal disease has studied in various survays. Survey among young Indonesian people gives data that young people don't develop any kind of periodontal disease with out taking any oral care facilities, only genetics factor plays a great role in this aspect. Various genes plays a key role in developing periodontal disease like periodontitis

Diagnosis of periodontal disease: Giving proper treatment to various periodontal diseases is great challenge, because at the early stage same patients are not aware about these things. Till date there is not some bleeding from gum, mild pain maximum patient doesn't aware about these things. When bleeding from gum during hard food chewing, hard or normal brushing patients reports complain. Mild to severe periodontitis is found with clinical sings like bleeding, loss of stippling on attached gingival, marginal gingival position apical to CEJ, rolled out margin, gingival enlargement, clolor of gingival changes from pale pink to red, ginhival sulcus depth increase more than 4mm, grade I to grade III mobility found. Mild to severe pain also noticed due to pus discharge. Hallmark periodontal diseases are most of the time with out any pain. [30]

Chronic generalized periodontitis is clinically detect by LOA (loss of attachment), amount of bleeding during clinical procedure, pocket depth more than 4mm. and by IOPAR, OPG.

After detection of diseases the dentist remove the dental calculus, plaque and educate the patient how to mentain the oral hygiene. Mostly patient is advice to avoid the risk factors like chewing tobacco, smoking tobacco etc. These are modifiable risk factor and in the hand of individual. Knowledge and willingness of patients has a great hand on mentainance of oral hygiene and treatment of this disease.

Many people develops periodontal disease due to deposition of biofim and some doesn't develop periodontal disease this is due to resistance capacity difference in both type of people. In some case periodontitis growth is rapid and in some individual growth is very slow. In another case it is found that various site of gingiva has great hand on progression of mild to severe periodontal disease.

Regular oral screening programme is very essentital for diagnose the periodontal disease at starting stage. Curing of mild gingivitis at early stage can halt the progression of converting mild gingivitis to periodontitis. Education regarding oral hygiene health can be beneficial In prevention of periodontal disease. Patient with absence of risk factors has very less chance of developing periodontal disease.[30-34]

Treatment of mild, moderate, severe gingivitis can be done by hand scaling or ultrasonic scaling. All biofilm and supra subgingival calcalculus are removed by scaling. By scaling the etiological factor for developing periodontal disease reduced. Self care home therapy is very use full in minimize the chance for developing disease. Various types of drug (doxycycline) can use in the treatment of periodontal disease.

Gingivitis periodontitis like disease are non violent in nature, some time asymptomatic but they have negative impact on mastication, esthetic of individual. Some times it has effects the speech of people.

Disruption in the function of neutrophils can leads to develop gingivitis periodontitis. Down syndrome, nutropenia can leads to periodontal disease. Developing age can leads to periodontitis.[30-34]

Conclusion

Use of smoking tobacco diabetes mellitus type I,II are main modifiable risk factor for developing gingivitis and periodontitis. Various risk indicators for periodontal diseases are bacteria like porphyromonas G, tannerella F, Aa. Predisposing agents for developing gingivitis ,periodontitis are the use of smoke tobacco, smokeless tobacco, the physical status of the individual, uncontrolled DMI,II, excess mental stress, less intake of Ca and Vit–D,

Modifiable risk factors are in the hand of individual they can modify easily and the disease condition can be minimize. But it is very difficult to take control over the

non modifiable risk factors like genetic agents. Excellent diagnosis of periodontal disease has a key role in the proper management of periodontal disease. Because in country like India the prevalence of periodontal disease is more among all age groups. Various types of nutrition has great effect on periodontal disease in elder age groups. The main objective of differential diagnosis of periodontal disease, advanced treatment plan, khowledge can reduce the chance of further advancement of the disease which, would latter affect the QoL of individual. The gravity of any kind of gingivitis or periodontitis depends on various internal and external environment agent. Good prognosis depends on the quality of the drug, immune power of individual.

Stabilizing Teeth with non Surgical Treatment: A Case Report of Splinting

Susant Mohanty[1], Sonu Acharya[2], Jnana Ranjan Swain[3], Bismay Singh[3]

[1]Professor and Head, [2]Professor, [3]Senior Lecturer, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be Univerisity) Bhubaneswar, Odisha, India

Abstract

The management of tooth mobility is one of the prime objectives of traumatic injury. The treatment of trauma-associated tooth mobility may include occlusal therapy, extraction, splinting and various treatments too. This article discusses a case report on the management of tooth mobility in trauma associated patients.

Keywords: *Traumatic Injury; Tooth Mobility; Non-Surgical Treatment, Tooth Stabilization.*

Introduction

In children traumatic exposure to anterior/posterior teeth is common including facial fracture due to unprotected/uncontrolled playing activities. So there is a major prevalence of traumatic injuries during 0-6 years of life i.e 10-30%. And according to Kenwood and Seow the prevalence is more than 30% among < 7-year children. These type of injuries mostly seen in male rather than female and anterior teeth are most frequently affected. Most of the trauma during childhood are sports-related and less control over extremities.[1]

So the prevention of sports injuries in children is most important. And to prevent these injuries parents and pediatric dentists are plays a significant role. For the protection of lips and oral soft tissues from bruises and laceration, the mouthguards are designed. There are different types of mouthguards used for different purpose including stock mouth guards, mouth-formed mouthguard, costume fabricated, etc. other preventive measures are helmets, face masks, jaw joint positioner.[1]

Stabilization of teeth with nonsurgical therapy may offer a good modality for trauma associated tooth mobility.[2] The treatment protocol may vary for displaced/ partial displacement of the tooth including no treatment or extraction or repositioning of the tooth. Stabilization of teeth can be achieved by splinting which can be provisional or permanent.[3] A splint has been defined as 'an apparatus used to support, protect or immobilize teeth that have been loosened, replanted, fractured or subjected to certain endodontic surgical procedures.[4] Minimum tooth mobility and increased occlusal function is the major advantage of stabilization done by splinting.[5] A splint should restore the arch stability and integrity, redirect the forces to reduce stress and tension[6] there are two types of splints i.e removable and fixed splint. And new splints are available in the market like Ribbond, Fiberglass, Synthetic fibers, etc. The ideal properties of the splint are that it should be simple, economic, stable, efficient, hygienic, non-irritating, not interfering with treatment, aesthetically acceptable, not provoke iatrogenic disease.[7] However the splints are contra indicated in moderate to severe increased tooth mobility.[8] Here we present a case report of a patient with trauma who was timely managed with the provisional splint and non-surgical therapy.

Case Report: A 3-year old female patient presented with the chief complaint of mobility of upper anterior teeth (Figure 1). And the patient fell on the table while playing with her brother. Proper case history was taken including:

- History of trauma- she had no such medical history of any diseases like bleeding disorders, allergies, epilepsy and also no history of vomiting and loss of consciousness or amnesia. And past dental history was also normal and never visited any dentist.
- Initial neurologic assessment was done by checking any unusual communication and normal respiration without any obstructions of the airway.
- Also other examination had performed like vocal function, TMJ movement, neck movement, function of the eye, and ability to protrude the tongue

Clinical Examination:

Extraoral examination- The face was symmetrical with a swollen upper lip.

Intraoral examination- The patient had Grade IIImobility of 51,61. And minimal laceration of gingiva in 51, 61 region. 51 was more displaced buccally than 61 with no evidence of crown fracture.

Investigation was done by taking an intraoral periapical radiograph. And there was no evidence of alveolar bone fracture and root fracture. And also the tooth had not distressed the permanent tooth buds.

Diagnosis and treatment done- A diagnosis of the trauma was made when she fell during playing. Initially Phase I therapy such as scaling was done followed by occlusal adjustment. The management of tooth mobility was planned with the idea of placing ligature wire and splinting about 52,51,61,62 (Figure 2). Ligature wire was braided to the desired length and adapted on the tooth. The labial surfaces were etched with 37% phosphoric acid for 20 seconds. Then the area is cleaned, dried thoroughly, a bonding agent is applied, and curing light was given for20 seconds. Wire was stabilized on the labial surface using composite. Composite resin was then placed on the wire and light-cured. Excess material was removed and finishing and polishing was done. The tooth was checked for mobility. The patient was given instructions on oral hygiene, advised to use an interproximal brush, and was recalled after 15 days for review. During the review, the patient was satisfied with a sense of well being and a great sense of mastication after splinting as the tooth mobility was minimized. The splinting was then removed and the post-operative photograph was taken (Figure 4).

Figure 1: Preoperative photograph

Figure 2: Tooth Repositioning and Ligature wire Splinting done

Figure 3: 15 days follow up

Figure 4: Post- Operative photograph

Discussion

Tooth mobility is defined as a visually perceptible movement of the tooth away from its normal position when a light force is applied.[9] (Gher 1996)Composite and wire splints are perhaps the most commonly used in clinical practice and are flexible splints when the wire has a diameter of no greater than 0.3–0.4 mm.[10] Tooth mobility has been described as an important clinical parameter in predicting prognosis.[11] For this reason and patient comfort, splinting has been the recommended therapy to stabilize teeth. In the past, direct stabilization and splinting of teeth using an adhesive technique required the use of wires, pins, or mesh grids.[12] Splinting done using ligature wire is cost-effective and economical for the patient when compared to fiber splints.[10]

Conclusion

This article has described the ligature wire technique for splinting mobile anterior teeth. The mobility of teeth is a common complaint of patients with trauma. A dental splint is an appliance designed to immobilize and stabilize mobile loose teeth. Various methods of splinting should be applied depending upon the prognosis of mobile teeth and periodontal conditions of surrounding teeth.

Abstract

Rhinoscleroma (RS) is a chronic granulomatous disease caused by *Klebsiella rhinoscleromatis*. In all the patients, the nose is affected but sometimes extends to any parts of the airways. Diagnosis of this disease is done on the basis of the histopathological examination or direct evidence of the bacteria in nasal exudates. The differential diagnoses of the RS are syphilis, malignancy and midline granuloma. Streptomycin is drug of choice, although fluoroquinolones and cephalosporin also provide good results. Surgery is opted in case of obstruction or deformity. Here, we reported a case of 11-year girl diagnosed as RS on the basis of the histopathological examination. This case was treated by endoscopic removal of the mass in the nasal cavity followed by a course of ciprofloxacin. She was found asymptomatic at the last visit of 1 year after treatment and there was no evidence of recurrence.

Keywords: *Rhinoscleroma, nasal cavity, pediatric patient,Mikulicz cells, Russel bodies.*

Introduction

Rhinoscleroma (RS) is an uncommon granulomatous disease often found in mucosal lining of the respiratory tract and occurred by the causative agent of the *Klebsiella rhinoscleromatis*, rod shaped Gram-negative bacteria.[1] There are several cases of RS reports reported from several parts of the world like South East Asia, tropical Africa,Middle East, India,South and Centralparts of America but in recent years, few cases are also detected in non-endemic zones as of high migration of population from different part of the world.[2] After the nasal cavity, other common sites affected by RS are nasopharynx(18-43%), paranasal sinuses(22%) and the larynx(15-40%).[3] RS is common in rural areas where socio-economic status is very low. This disease is more in crowding area, low quality nutrition and low quality hygiene. It is common in females than males (13:1) and found in the 2nd and 3rd decades of life.[4] It is thought that decreased iron in the body may leads to this disease. [4] Here, we are reporting this case of RS in a 11-year-old child.

Case Report: An 11-year-old girl attended outpatient department of Otorhinolaryngology with complaints of rhinorrhea,nasal bleeding and nasal block in the right nostril since 3 months. Anterior rhinoscopy showed a friable mass in the right nostril. Examinations of throat and ear were within normal limits. Diagnostic nasal endoscopy demonstrated the same appearance of the nasal mass with presence of granulomatous lesions inside the nasal cavity attaching to the floor of the nose (Fig.1). Routine blood tests and serological tests for

e-mail: santoshvoltaire@yahoo.co.in

HIV were within normal limit. Chest X-ray was normal. Computed tomography(CT) scan revealed opacity/ mass in the right nostril (Fig.2). The re was no evidence of bony erosion in the nasal wall. Biopsy was taken from right nasal cavity and sent for histopathological examination (HPE). HPE revealed extensive inflammatory infiltrates along with lymphoplasmacytic and histiocytic predominance. The plasma cells showed Russel bodies (Fig.3). Intrahistiocytic bacilli correspond to *K.rhinoscleromatis* which was also recognized. After confirmation of the diagnosis, the treatment was done with ciprofloxacin (250 mg twice daily) for 3months with satisfactory follow up. The endoscopic examination revealed no evidence of recurrence after 1 year of treatment.

Fig. 1: Diagnostic nasal endoscopy revealed granulomatous mass in the right nasal cavity.

Fig. 2: CT scan of the paranasal sinus showing radio-opaque soft tissue mass in the right side nasal cavity.

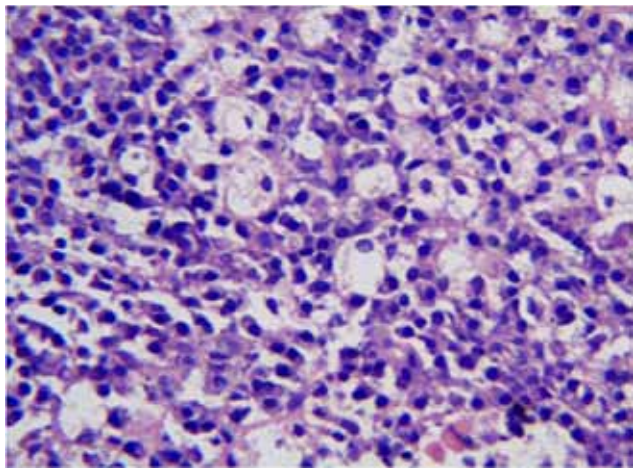

Fig. 3: Histopathological picture shows Mikulicz cells which are large vaculated foamy cells with small nuclei and Russel bodies which are bright red degenerated plasma cells with background of several plasma cells (HEX400).

Discussion

RS is a chronic granulomatous disease due to infection of *Klebsiella rhinoscleromatis*, gram-negative encapsulated bacilluswhich belongs to Enterobacteriaceae family. In anaerobic condition, it forms spores in anaerobic condition which can produce exotoxin and leads to scleroma formation without presence of bacteria.[5]It is often associated with poor socioeconomic condition,malnutrition,poor hygiene, HIV infection and overcrowding. Rhinoscleroma is common among females and often affects the middle age group people.Bilateral nasal cavities are usually affected. In our case, the lesion is confined to one side nasal cavity. Sometimes, it affects the nasopharynx and larynx. Involvement of the larynx may lead to severe stridor. Pediatric patients are rarely affected, however very few cases are reported in the medical literature. The cellular immunity may be affected in this patient;however, this diseased person was immunocompetent.

This disease has three stages: Catarrhal stage, granulomatous stage and fibrotic stage. The catarrhal stage is nasal variety where findings and histopathology may not be specific. In case of granulomatousstage of RS, granulomatous lesions are seen this can block the nostrils. The biopsy is diagnostic in granulomatous stage.[6] This stage may be associated with extra-nasal extension involvement of larynx is the commonest (60-80%) and may be complicated to stridor.[7] In the third stage or stage of fibrosis, there is extensive fibrosis which leads to nasal block rather than proliferative masses.

The fibrotic variety is usually difficult to diagnose as the causative bacteria is usually not seen.

Clinical symptoms of the patients with RS are nonspecific and often presents with mucopurulent nasal discharge,cough,breathing difficulty due to nasal block, dyspnea, nasal bleeding and headache.[8]This disease slowly progress with characteristic of remission and relapse. Patients often require medical advice only when the obstructive granulomatous stage leading to obstruction at the nasal cavity.

The investigations of RS include diagnostic nasal endoscopy, imaging and histopathological examination. Nasal endoscopic examination helps to find the lesion in nasal cavity and its extension to other parts of the upper airway. Computed tomography (CT) scan of the nasal cavity andsinuses reveal lesions in the sinonasal area. Histopathological examination confirms diagnosis. One study documented RS in children where the lesions appear as amyloid like protein in histopathological examination which may be due to an autoimmune reaction.[9] One study revealed RS in three siblings staining at the non-endemic area and thought to be due to neutropenia acting as a predisposing factor.[5] The differential diagnosis of the RS includes tuberculosis, actinomycosis, leprosy syphilis, histoplasmosis, paracoccidioidomycosis, sporotrichosis and parasitic infections such as mucocutaneous leishmaniasis.[10] The RS should also be differentiated from Wegner's granulomatosis, carcinoma and lymphomas. The specific diagnosis of the RS is based on the histopathological examination and the bacilli appear rod-shaped. This bacillusis positive to Warthin-Starry stain and periodic Acid-Schiff (PAS).Staining of immunoperoxidase with anti-capsular antiserum is also helpful for identification of the causative bacteria.Bacterial culture with MacConky agar or blood is also helpful for identification of the bacilli in approximately 50% of the cases.[11] The histological picture of the RS is characterized by the presence of Mikulicz cells, inflammatory cells consisting of multiple plasma cells along with few eosinophils and Russel bodies. These Russel bodies are originated from disintegration of plasma cells. The Mikulicz cells are vaculated cells with clear cytoplasm possessing the bacteria. The cause of transformation of the histiocytes into Mikulicz's cells is unknown.[12] Untreated patients of RS often progress to involve other areas of the respiratory tract. If laryngotracheal part is involved, this may lead to the obstruction of the airway which threatens to life.[13] The sclerotic stage of the RS shows extensive fibrosis, which may cause stenosis and disfigurement. Biopsy from fibrotic stage is often not specific. In this patient, the stage of the disease was with granulomatous type as multiple numbers of Mikulicz cells were found. Immunoperoxidase monolayer assay (IPMA) method for antigen of the capsule of *Klebsiella rhinoscleromatis* is very reliable for the confirmation of the RS. The differential diagnosis is usually other granulomatous diseases of the noses, nasal polyps and sarcoidosis.Presence of extra-nasal sites should be carefully evaluated by diagnostic nasal endoscopy or imaging tests in order to disease process which often need prolonged treatment.[3]

The choice of drug is streptomycin although cephalosporins, fluoroquinolones and ciprofloxacin have had some good outcome. Ciprofloxacin has good antibacterial spectrum and excellent tissue penetration with fewer side effects. Surgical treatment is useful inpatients with severe nasal obstruction or nasal deformity. The treatment period is around three to six months which targets intracellular bacilli. Currently criteria comprise the antibiotics fluoroquinolones therapy with demonstrable efficacy but the clinical and endoscopic examination must be necessary until negative biopsies for eradication of the disease.[13] Surgery is often reserved for the disease particularly orolaryngotracheal forms where stenosis is detected.[13] These may require endoscopic laser or debridement of the stenotic part of the airway or may need open surgery preceded by tracheostomy.[14]Mortality due to RS is extremely rare,but may happen due to upper airway obstruction in case of undiagnosed disease or due to complication of the surgical procedure.

Conclusion

Rhinoscleroma (RS) is a rare clinical entity and should be ruled out in case of nasal mass of a pediatric patient. Surgical removal cannoteliminate the lesion and may lead to recurrence in the stage of fibrosis. The clinical presentations are usually non-specific and granulomatous stage of this disease often evokes the possibility of the RS. Histopathological examination confirms the diagnosis where Mikulicz cells are pathognomonic for *Klebsiella rhinoscleromatis*. The diagnosis of the RS is often difficult and delayed because of its clinical polymorphism. However, early diagnosis and prolonged treatment are important criteria for avoiding recurrence and late squeal.

Foreign Body Bronchus and Rigid Bronchoscopy– Our Experiences at a Tertiary Care Hospital

Santosh Kumar Swain[1], Surya Kanta Pradhan[2], Sanjeev Gupta[2], Kamalakanta Jena[2], Priyanka Debta[3]

[1]Professor, Department of Otorhinolaryngology, IMS and SUM Hospital, Siksha 'O' Anusandhan (Deemed to be University), K8, Kalinga Nagar, Bhubaneswar-751003, Odisha, India, [2]Clinicians, Department of Otorhinolaryngology, Apollo Hospital, Bhubaneswar-751003, Odisha, India, [3]Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), K8, Kalinga Nagar, Bhubaneswar-751003, Odisha, India

Abstract

Background: Foreign body inhalation is often encountered in emergency department. Foreign body can be lodged in any site of the tracheobronchial air way. Rigid bronchoscopy is one of the established technique for removal of the inhaled foreign body with fewer complications.

Material and Method: We have done a retrospective study in our tertiary care center to determine the clinical presentation, nature of foreign body, age of presentation, location of foreign body, management of foreign bodies and duration of hospital stay in our population.

Result: The most common foreign body in our study was peanut(15.7%) followed by ground nut (12.2%), coconut pieces (7%), small led bulbs (7%) and corn (7%).Most common sites for foreign body lodgment was right main bronchus (40.3%) followed by left main bronchus (29.8%) and trachea (17.5%).

Conclusion: Rigid bronchoscopy is an effective technique for removal of the foreign body from tracheobronchial airway with fewer complications.

Keywords: *Foreign body bronchus, Rigid bronchoscopy, X-ray chest, CT scan Chest, Ventilating bronchoscope.*

Introduction

Foreign body in ear, nose and throat is not uncommon. We as otolaryngologists handle these situations almost every day. Fortunately, most of these situations are not life threatening and can be managed in emergency department or in OPD. But foreign bodies in airway are life threatening emergencies and should be managed promptly to avoid asphyxia and death. These are most commonly seen in children of 1-4 years and sometimes reported in adult patients. Most cases present with sudden onset difficulty in breathing but sometimes they present as cough, wheezing, dyspnoea, pneumonia and emphysema. In maximum number of cases there is a clear history of foreign body aspiration and clinical features correlate with radiological features and diagnosis can be made promptly. But in certain cases CT scan neck and chest is required before going for definitive treatment. Rigid bronchoscopy with foreign body removal is the treatment of choice but some surgeons remove foreign bodies using flexible bronchoscopes. We have done a retrospective study in our tertiary care centre to determine the clinical presentation, nature of foreign body, age of presentation, location of foreign body, management of foreign bodies and duration of hospital stay in our population.

Material and Method

We have conducted a retrospective study in the Department of ENT & Head and Neck Surgery, Apollo hospitals, Bhubaneswar from January 2010 to January 2019. 57 Patients coming to the hospital with acute onset respiratory distress with suspected history of foreign body aspiration were included in the study. All the patients were investigated as per the protocol and X- ray chest was done in all most all cases and CT scan chest with or without virtual bronchoscopy was done in doubtful cases. Rigid bronchoscopy was done in all cases under general anaesthesia and in most of the cases we have successfully retrieved the foreign body. Our inclusion criteria was any patient with acute onset respiratory distress with suspected foreign body aspiration and our exclusion criteria was critically ill patients with other comorbidities and fever.

Results

57 patients were studied in this period of 8 Years (January 2010 to January 2019). 24 (42.1%) patients were in the age group of 1-3 years followed by < 1 year 16 (28.0%). The incidence is lowest in above 10 years' children 2 (3.5%).

Table 1: Incidence Rate

Age	No	Percentage
<1	16	28.0
1-3	24	42.1
3-5	8	14.0
5-10	7	12.2
>10	2	3.5

The number of male and patients 29 (50.8 %) are slightly more than female patients 28 (49.1%) but the ratio is nearly equal.

Patients who presented to us with acute onset respiratory distress and history of foreign body ingestion/ aspiration X- ray chest was done and 17 (29.8%) patients had definitive diagnosis of foreign body in airway. In 24 (42.1%) doubtful cases CT scan chest was done and it had confirmed the diagnosis in 23 cases. All these patients under went rigid bronchoscopy and foreign body was retrieved in 53 cases and in 4 cases there was thick mucus plug and debris which was cleaned.

Table 2: Sex ratio description

Sex	No	Percentage
Male	29	50.8
Female	28	49.1

We have also studied the location of foreign body lodgment and the data showed the most common site was right main bronchus 23 (40.3%) followed by left main bronchus 17 (29.8%) and trachea 10 (17.5%). The least common site is glottis followed by bilateral bronchus. We did not find foreign bodies in 4 (7%) cases and there was thick mucus plug causing airway obstruction. And these patients were managed conservatively.

Table 3

Location	No	Percentage
Glottis	1	1.7
Trachea	10	17.5
Right Main Bronchus	23	40.3
Left Main Bronchus	17	29.8
B/L Bronchus	2	3.5
No Foreign Body	4	7.0

The most common foreign body in our study was peanut 9 (15.7%) followed by ground nut 7 (12.2%), coconut pieces 4 (7%), small led bulbs 4 (7%) and corn 4(7%). We have removed various types of vegetative, plastic and metallic foreign bodies.

Table 4

Type of Forign Body	Broom Stick	Nail	Coconut	Screw	Peanut	Led Bulb	Tamarind Seed	Plastic Piece	Corn	Ground Nut	Whistle	Tracheostomy Tube	Spring	Vegetable Piece	Bengal Gram	Safetypin	Earpin	Beatle Nut	No Fb

Percentage	1.7	5.2	7.0	3.5	15.7	7.0	3.5	5.2	7.0	12.2	5.2	1.7	1.7	3.2	3.5	7.0	1.7	1.7	3.5

We have also studied the duration of hospital stay and the requirement of ventilator. Most of the patients 44 (77.1%) were discharged next day and few patients required long term ventilation and stayed for more than 2 days in the hospital 13 (22.8%).

Table 5

Day of Discharge	No	Percentage
Next Day	44	77.1
> 2 Days	13	22.8

One of our patients had some hypoxic injury after the surgery but he had recovered well after the ICU care and we had zero mortality in our series.

Discussion

Foreign body (FB) in airway is an uncommon but life threatening emergency in Otorhinolaryngology practise. Most of the cases are accidental. It is the fourth leading cause of accidental death in children of less than 3years. [1] It's most commonly seen in children of the age group 1-3yrs.[2] It' similar as per our study as we have maximum patients in the age group of 1-3 years. [3] The etiological factors affecting children may be lack of molar tooth, talking or laughing during eating, putting things in mouth while playing and lack of coordination between deglutition and laryngeal closure. In adults FB aspirations are seen in semi-comatose and elderly people. It is a challenge to ENT specialists to diagnose and treat FB in airway. Some patients given proper history of FB aspiration but most of the time parents and relatives are unknown of FB aspiration. A high index of suspicion is needed to diagnose a case of FB aspiration and quick management to avoid dreaded complication and respiratory arrest. Any patient coming to the emergency with complaints of sudden onset cough, stridor, dyspnoea and refractory LRTI and single sided pneumonia should be evaluated in the line of FB aspiration.[4] As per our study most of the foreign bodies are vegetative and most common is peanut (15.7%) which is in similarity with the literature.[5] These are the most difficult FBs to remove. Other foreign bodies which are commonly found are pins, nails, seeds, plastic parts of toys and pens and screws. The organic foreign bodies react with the surrounding and form granulations and can cause complete blockage of the airway. Depending on size of the foreign body it may lodge in different segment of airway i.e. larynx, sub glottis, trachea and bronchus. Larger foreign bodies get impacted in larynx and smaller ones go into the bronchus. Most of these FBs predominantly found in right main bronchus (40.3%) also go as per literature.[6, 7] But few studies by Piva et al and Fraga et alstate that the FBs are mostly seen in left main bronchus.[8, 9] There are three phases in foreign body aspiration. Initially there will be chocking, coughing and gasping, after that there will be a silent phase and finally there will be a complication phase like pneumonia and atelectasis. Clinical presentation depends on the site of lodgement. It may range from complete obstruction when the size is large and site is larynx to no symptoms when the size is small and the site is terminal bronchiole.[10]Sometimes they mimic other respiratory problems like asthma with features of cough wheezing and mild dyspnoea but the unilateral signs differentiate them from asthma. Most of the times FB can be diagnosed with X-ray neck and chest but a negative X-ray can't rule out FB aspiration as most of the foreign bodies are radiolucent. In our study only 29.8 % cases were diagnosed with X-ray chest. They may also reveal pneumonia, emphysema and atelectasis which help in confirming diagnosis. HRCT neck and chest is required when there is doubt about the history of aspiration and presence of radiolucent foreign body is suspected. It also confirms the location of foreign body. Virtual bronchoscopy is the reconstructive image of CT scan which also helps in localisation and confirmation of foreign body. A study by Behera et al indicated that virtual bronchoscopy using multidetector computed tomography (MDCT) scanning is effective in diagnosing the presence of radiolucent vegetable foreign bodies in the tracheobronchial airway.[11] When the history is doubtful and all the radiological tests are negative then a conservative approach should be followed and rigid bronchoscopy can be avoided.[12] Rigid bronchoscopy is the gold standard for treatment of foreign body in trachea or bronchus. It is always done under General anaesthesia. After giving GA the air way is examined using a telescope and the position of the FB is confirmed. Then the ventilating bronchoscope is introduced and kept just above the FB. Any secretion around the FB is cleaned and after that it has to be taken out. Check bronchoscopy is done to confirm any residual FB. The procedure should be done quickly after receiving the patient in the emergency. Ventilating bronchoscope is the instrument of choice through which the anaesthesiologist maintains the saturation of the patient and the surgeon removes the FB in the mean time. Most of the patients get discharged on the next day (77.1%) but some patients require long term ventilation (22.8%) and longer hospital stay. In the expert hands the mortality is near zero if it's done in

correct time. Sometimes for larger foreign bodies we may have to do a tracheostomy and remove the FB from trachea.

Conclusion

Foreign body in airway is mostly seen in children and always accidental and life threatening. It should always be diagnosed and managed quickly to save the patient. History with clinical signs and sometimes X-ray and CT scan diagnose these conditions. Ventilating rigid bronchoscopy and FB removal under general anaesthesia is the procedure of choice. In experienced hands the mortality is near zero. All the parents and caregivers should be educated how to avoid such conditions.

Effects of Cleft and It's Clinical Implications

Sumita Mishra

Associate Professor, Department of Orthodontics & Dentofacial Orthopedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, India

Abstract

The most common malformation of the head and neck region affecting individuals and their surroundings physically, mentally, psychologically and socially is cleft lip and palate. There are of various types with their distinct clinical features and characteristics. Prenatal diagnosis, effective understanding can help formulate a good treatment approach with specialists from various fields working as a team. Parents counseling and follow up forms the mainstay approach of these children.

Keywords: *Lip, Cleft, Harelip, Unilateral, Bilateral.*

Introduction

The most common congenital malformation of the craniofacial region is cleft lip and palate1,2. Clefting in birds is physiologic as it helps them to fly at greater altitudes and equalize pressure in the middle ear.

Epidemiology: In India, the incidence of cleft is 1 IN 800. In white Americans, the incidence is 1 IN 800 too. In comparison, black Americans show an incidence of 1 IN 2000. Isolated cleft palate presents an incidence of 1IN 2500. Sex differences (Male to Female ratio) presents cleft lip as 2:1, CLEFT PALATE as 2:3, cleft lip & palate as 2:1. In Racial differences, Japanese being greater in comparison to Caucasians and Afro-Caribbean. The incidence of occurrence is more on left side as compared to right side. Monozygotic twins show a 40% concordance in comparison to di-zygotic twins (5% concordance).

Concept of Cleft:

Neutral Zone Concept: The cheek, lip and pharyngeal musclesbalance against the developing upper and lower arches. The force they exert neutralize the tongue forces maintaining dynamic equilibrium[3]. With the change in equilibrium, the form and relationship of the arch with the teeth changes (Figure 1).

Aberrant muscle forces in clefts: The first nine weeks of fetal life is of significance for the development of cleft lip and palate. The re is failure of fusion of the lip and the palatal segments: both right and left. There is break in continuity of the buccinators mechanism. This results in aberrant muscular forces that displace tissue masses (Figure.2).

In unilateral complete clefts of the lip and palate cases, the premaxillary portion of the noncleft segment is pulled antero-laterally. Premaxilla is carried forward in the facial skeleton in the larger segment[4,5]. There is excessive growth in the premaxillary-vomerine suture in bilateral complete cleft lip and palate (CBCLP) patients.

Palatal arch form: The facial versus tongue muscle forces dictate the shape of the palate. Palatal growth rates correlate with the amount of scarring during closure of the cleft space.

Classification: The various types of cleft are explained underneath (Figure. 3):

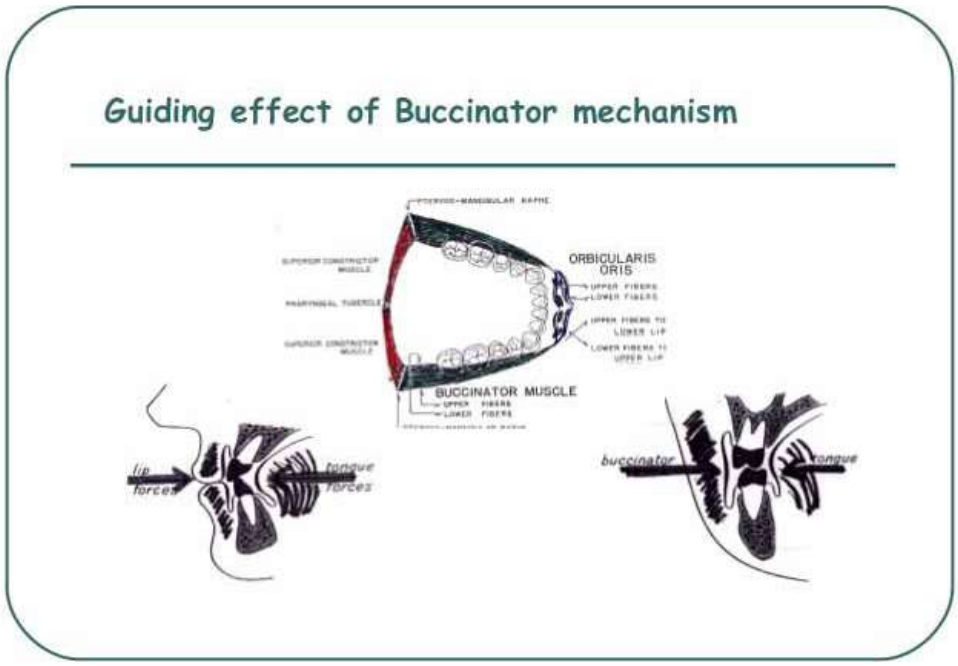

Figure 1. Neutral Zone Concept

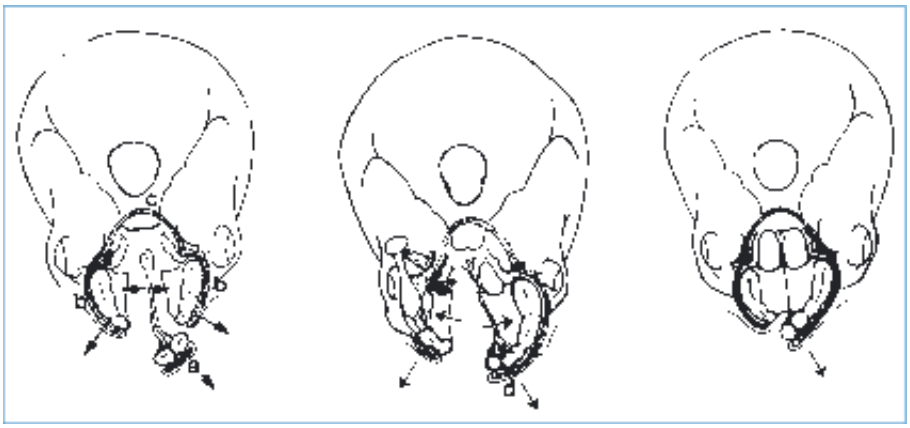

Figure 2. Aberrant Muscle Forces

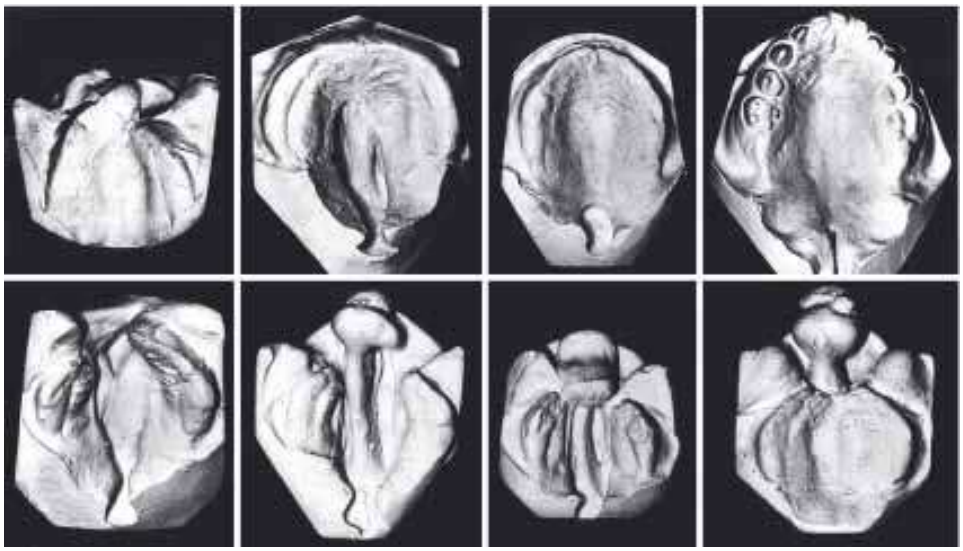

Figure 3. Categories of cleft

1. Clefts affecting lip and palate: simultaneous or separate.

   Cleft affecting the primary and/or secondary palate: complete/incomplete, unilateral/bilateral.

2. Submucous clefts affecting the secondary palate

Clefts of the Lip: Clefts may be unilateral or bilateral (symmetrical or asymmetrical).[6,7] Unilateral cleft lip presents asymmetric and less premaxillary protrusion (Figure 4). Bilateral cleft lip shows marked protrusion of premaxilla.[8]

Figure 4. Unilateral Cleft Lip

Cleft of lip and alveolus: Cleft involves the lip as well as the alveolus.[9,10]

Complete unilateral cleft of the lip and palate: Themedial portion of orbicularis muscle is attached to columella & the lateral portion to the nasal alar cartilage.[11] There is thinness in the medial vermillion border. There is distortion in the perpendicular plates of the sphenoid with flattening of the ipsilateral lower cartilage.[12] Cephalometric findings indicate Increased width of maxilla, increased nasal width withless significant changes in the pharyngeal airway and mandibular length.

Incomplete cleft lip: It presents with a defect in the bulk of orbicularis oris muscle.

Complete bilateral cleft lip: Medial aspect shows complete absence of orbicularis oris muscle.Premaxilla is protruded to varying degree. The various nasal defects include short columella, bilaterally flattened dome, and bilaterally horizontal nostrils(Figure.5). There is protruding premaxilla at birth, marked palatal hypoplasia, retruded maxillary shelves and buccal teeth in class I/class II occlusion. Cephalometric findings indicate increase in width of maxilla, increase in width of nasal cavity, increase in mandibular length and retrognathia.

Figure 5. Bilateral Cleft Lip

Isolated Cleft Palate: It involves hard palate, soft palate and structures of the secondary palate. There is variation of the geometric form. Cephalometric findings show decrease in total length of maxilla, decrease in mandibular length, bimaxillaryretruded jaws with reduction in size of pharyngeal airway.

Submucous Cleft Palate: It shows the presence of bifid uvula (Figure6),zonapellucida.

Figure 6. Bifid Uvula

Syndromes associated with cleft lip & palate: Vonderwoudesyndrome, Downs syndrome, Oral-facial digital syndrome, Treachercollin syndrome, Pierre robin syndrome, Apert syndrome, Trisomy of chromosome 18, Turner's syndrome

Treatment: The treatment is taken care of by a team comprising of Surgeons, Speech and language pathologists, Geneticists, Dysmorphologists and Paramedical specialists.

A. Unilateral cleft of the lip and palate

The treatment protocolfollows age of the patient. At 3 months age, lip adhesion is carried out[13]. At 10 months, lip surgery is carried out. At 18-24 months, palate closure (hard and soft) is done followed by Orthodontic expansion at 5-7 years. Bone grafting is done at 7-9 years. 8 years or later Protraction facial mask is given followed by Maxillary surgical advancement and Lip/ nose revisions technique.[14]

B. Bilateral cleft lip and palate

In such cases, after birth: CBCLP – external elastics is recommended. At 3–4 weeks, lip adhesion surgery is advised. Millard forked flap is done at 6 months of age. At 18-30 months, Von langenbeck repair is done. Buccalcrossbiteis corrected with the help of a quad helix at age of 4-5 years[15].

Fixed palatal retention is attempted at 5-7 years. At 7-8 years, anterior teeth alignment is done followed by bone grafting (secondary).At the age of 9-13 years, full banded treatment is advised. It may be accompaniedby maxillary protraction therapy along with nasaltiprevisionsurgery.

Full Orthodontics is done along with and nasal lip revision at 13-17 years of age. Postsurgical Orthodontics followed by prosthetics andnasal-lip revisions are done at 17-18 years of age.

Treatment sequence of clefts of the uvulae alone and soft palate

Soft tissue clefts are sutured around 3 months. Orthopedic protraction is carried out duringmixed and permanent dentition.

Clefting process and contiguous structures:

A. Skeletal Findings:

(a) Width: Head width is greater than length with orbits further apart than normal. There is a wider maxilla with no crossbites even in adults.

(b) Height: Maxilla on cleft side is smaller than normal, but overall, there is no decrease in vertical facial growth

(c) Depth: Maxilla is placed normally with relation to cranial base. Pre-maxilla is rotated forward & laterally and the protrusion of pre-maxilla increases as age increases.

B. Dental Findings: There is presence of hypodontia, Supernumerary teeth, Microdontia/macrodontia, hypoplasia, natal/neonatal teeth and crossbite in 19% of cases. The teeth adjacent to cleft shows poor palatal support & are susceptible to premature loss. There is delayed eruption of teeth on cleft side.

Effects:

1. Feeding difficulties at birth: Feeding problems arises due to large opening between mouth & nose in case of cleft palate. In case of cleft lip alone problems will arise in efficient sucking. The re are three major concerns:
   - Risk of aspiration because of communication
   - Airway obstruction (Pierre robin syndrome)
   - Difficulty in feeding a child because of nasal regurgitation
2. Hearing difficulties:Hearing defects may be due to sensorineural anomalies and recurrent otitis media.
3. Speech difficulties: Speech pathology may be due to incorrect lip posture, tongue position, velopharyngeal incompetency, abnormal neuromuscular function, abnormal dentition secondary to hearing loss due to sensorineural deficit.
4. Psychosocial issues There is social and emotional adjustment and features of social isolation, obsessive compulsive behavior, lack of cognitive development and school achievement.

Adverse long-term health effects: There are elevated risks for death along with musculoskeletal disorders, autism spectrum disorders and other learning disabilities.

Implications: There is midface retrusion, distortion of dentoalveolar structures, difference in posture and shape of the mandible, crowding of the dentition, missing teeth, concave profile, crossbites.

There are issues like:

1. **Anteroposterior Issues:** The retrusive maxilla along with a normal mandible superimposed on the transverse problem results in a class III tendency.

2. **Vertical Issues:** The position of the mandible varies in rest position and in occlusion. This may generate excessively long or short lower face heights. The functional shift of the mandible results in pseudo prognathism
3. **Transverse Issues:** Crossbites is seen.

Concerns:

In order to minimize the effects of scarring, the various changes that needs to be done include:

a. Biocompatible membranes to inhibit scar tissue formation

b. Epithelial sheets

c. In vivo surgical procedures

Future Perspectives: Information is the quintessential defining factor of this century. It is important to share information among the countries of the world to extend medical benefits equally among developed and developing countries. Japanese Cleft Palate Foundation (JCPF) & the International Cleft Foundation have been established to cater health care needs.Smile train is World's leading cleft charity program, being established in 2000 to help millions of cleft affected families and bring awareness among doctors and medical professionals.

Unicystic Ameloblastoma: An Unusual Case Report

Sreepreeti Champatyray[1], Saurjya Ranjan Das[2], Neeta Mohanty[4], Jagannath Patro[5]

[1]Senior Lecturer, Department of Oral Pathology and Microbiology, [2]Associate Professor. Department of Anatomy, [3]Professor & Head, [4]Research Associate. Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India 751003

Abstract

Ameloblastomas have many microscopic and clinical variations. Typically it has three biologic variants which include solid, cystic and peripheral, out of which 14% to 22% of all cases are unicystic. Rare variantslike granular cell subtype composed exclusively of eosinophilic granular cells present inboth peripheral and inner layers of tumoral islands. This is a unique case of cystic ameloblastoma affecting a 16-year-old male with an unusual radiographic and microscopic pattern. This rare variant will create awareness for oral and maxillofacial pathologists for a proper pathway of diagnosis.

Keywords: *Intraluminal, Mural, Plexiform, Ameloblastoma.*

Introduction

Ameloblastoma is a locally aggressive epithelial odontogenic benign neoplasm, which has several different microscopic variants.[1-3] It is divided into three groups solid, peripheral and cystic (unicystic). The most common location is the posterior mandible.[4,5] Unicystic ameloblastomas are seen in the second decade of lifemore often in younger patients. The large lesions may cause a painless swelling of the jaws which is often asymptomatic.[5] Unicystic ameloblastoma is classified into the mural, luminal andintraluminal (plexiform) based on microscopic features. The fibrous wall of the cyst is infiltrated by typical follicular or plexiform ameloblastoma in mural type. The tumor is confined to the luminal surface of the cystin luminal type when one or more nodules of ameloblastoma project from the cystic lining into the lumen is called as the intraluminal type.[4-6] Radical surgery is the treatment of choice for mural ameloblastoma andenucleation is the treatment of luminal and intraluminal ameloblastoma.[4] Granular cytoplasmic changes are seen in the stellate reticulum regions of the ameloblastomatous follicles and interlacing cords and nests and it's a rare variant. In peripheral ameloblastic cells,g ranular changes can also be seen[1,6] this case report aimed to present a rare challenging case of ameloblastomain a 16-year-old male in the posterior aspect of the mandible.

Case Report: A male of 16-year was referred for evaluation of the painless expansion on the left lower jaw region to the Department of Oral and Maxillofacial Pathology of Institute of Dental Sciences On intraoral examination there was a swelling in the posterior area of left mandible extending from 36 to 43 region. On palpation the swelling was, non-tender, bony hard to firm in consistency with eggshell crackling. The radiograph (Figure 1) revealed a well defined cortical unilocular radiolucent lesion with radiopacity extending from 36 to 43 region superiorly till the alveolar ridge and inferiorly to the lower border of mandible and teeth displacement concerning 31, 41,42,43,44,45 region. Given the radiographic feature,it was diagnosed as ameloblastoma. An incisional biopsy was performed under local anesthesia to make a final diagnosis. The routine hematoxylin and eosin (H & E)was done for

histopathologic study. On microscopic examination it showed anepithelial lining with ameloblast like cells over which there was presence of stellate reticulum like cells proliferating into the underlying connective tissue wall in intraluminal and mural pattern many networks of interconnected strands of ameloblast like cells were also present in the connective tissue wall with areas of cystic degeneration at places (Figure 2, 3) and minimal degree of chronic inflammatory cell infiltration.

Figure 1. Welldefined corticated unilocular radiolucent lesion with radiopacity

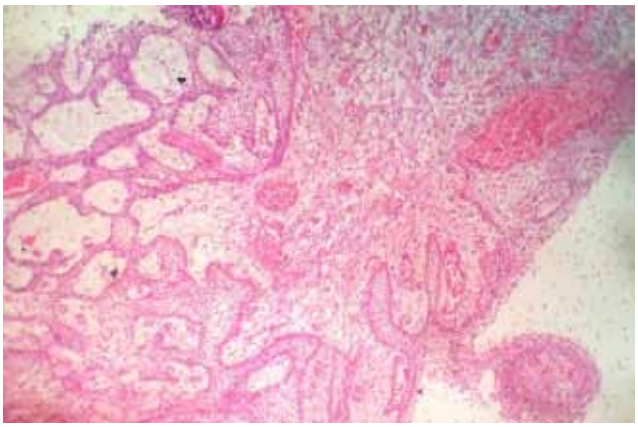

Figure 2. Low power reveals plexiform pattern with mural proliferation

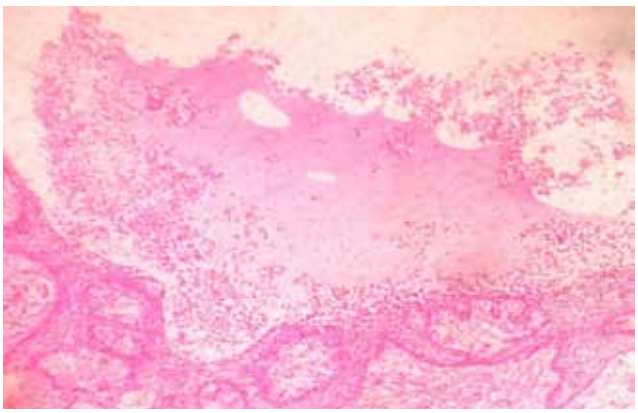

Figure 3. High power reveals plexiform pattern with mural proliferation and luminal variant of ameloblastoma

Differential Diagnosis: Ameloblastoma, Central giant cell granuloma (CGCG) Odontogenickeratocyst (OKC), Calcifying epithelial odontogenic tumor (CEOT).

Discussion

Ameloblastoma is a locally aggressive odontogenic benign, neoplasm which accounts for 1% of all cysts/ tumors of jaws with variable clinical expression and 18% of all odontogenic neoplasms.[6,7] Ameloblastoma is classified as per the WHO system of 2003, based on differences inbiologic behavior, treatment plan and recurrence rate as follows:

(1) Solid/multicysticameloblastoma,

(2) Unicysticameloblastoma,

(3) Peripheralameloblastoma,

(4) Desmoplasticameloblastoma.[7].

6% of ameloblastomas are unicysticameloblastoma which is a rare type of ameloblastoma. It usually occurs in the age group of 15–20 years, with about 50% of the cases occurring in the second decade of life as in our case[8,9]. The male to female ratio of 1.5:1. More than 90% are located in the posterior region of the mandible, the parasymphysis region, the anterior maxilla, and the posterior maxilla[9].

Three pathogenic mechanisms for the evolution of Unicystic Ameloblastoma was proposed by Leider et al.[10].

(1) During the development of the tooth, the epithelium of enamel is reduced which is associated with ameloblastic transformation with subsequent cystic development.

(2) Ameloblastoma arises in the neoplastic ameloblastic epithelium in which there is the temporary non-neoplastic stratified squamous epithelial lining.

(3) When a solid ameloblastoma undergoes cystic degeneration with subsequent fusion of multiple microcysts and develops into unicystic lesions.

Histologic subclassification by Phillipsen and Reichart are described by[7]

Subgroup 1—luminal;

Subgroup 1.2—luminaland intraluminal;

Subgroup 1.2.3—luminal, intraluminal and intramural;

Subgroup1.3—luminalandintramural

Here the present case reveals a swelling in the left lower jaw region of a 16-year-old male radiographically unilocular radiolucency with radiopacity with histopathologic compatibility with intraluminal and mural variant of plexiform pattern.

Conclusion

Unicystic ameloblastoma can be diagnosed based on clinical, radiological, histopathologic, and CT features Recurrence rate was high, especially when the ameloblastic focus penetrates the adjacent tissue from the wall of the cyst. Radiographically, unicystic ameloblastomas show a single large unilocular radiolucency whereas most of ameloblastomas show multilocularity, Unicystic variant of ameloblastoma with aggressive histologic features can be successfully treated with marsupialization with subsequentenucleation, and its an alternative to resection.

Management of Mandibular Molar Having Sub-Gingival Caries by Root Amputation: A Case Report

Naomi Ranjan Singh[1], Shashirekha Govind[2], Swapna Kumari[3]

[1]Senior Lecturer, [2]Professor & Head, [3]Tutor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Conservative management of a tooth has always been the primary option for a dental clinician in the management of severely decayed teeth. Therefore instead of going for the extraction or elaborate and expensive treatment such as implant-supported prosthesis procedures like root amputation/resection and hemisection can be opted to salvage these compromised teeth for longer period of functioning. Root amputation is a procedure of removing the root portion of the multirooted tooth that has been affected with subgingival caries, periapical pathology, or any other defects. This article describes a case report of root amputation in mandibular molars.

Keywords: *Root amputation; Root canal treatment; Mandibular molar.*

Introduction

The increasing awareness of patients to maintain proper oral hygiene and preserving teeth for prolonged periods, have led to the treatment and restoration of teeth that once would have been extracted. Assessment of endodontic and periodontal problems related to the tooth is vital before selecting the case. Various strategies have been used to restore such mutilated tooth such as Root amputation/Root resection, Hemisection, and Bicuspidization. Root amputation is a minor surgical procedure in which an affected or questionable root/ roots of a multirooted tooth are removed at the level of furcation keeping the remaining crown and roots intact for function, whereas in Hemisection the entire tooth is divided and the affected part is removed and in Bicuspidization, the crown is equally divided at the center of the furcation, making the furcation area into a more manageable interdental space.[1,2]

Root amputation and Hemisectionare often valuable procedures once the tooth in question encompasses a high positional worth. The following comprises endodontic indication for root amputation: severe root fracture, undermined furcation areas due to caries, root resorption, root perforation hindering adequate access to the root canal for chemomechanical procedures.[3,4] This article describes a root amputation procedure in mandibular molar.

Case Report: A male patient of age 58 years reported to the Department of Conservative Dentistry and Endodontics with the chief complaint of pain in the lower, left, posterior region, for two months. After a thorough medical and dental history, clinical examination revealed Class II (disto-occlusal) caries in the first molar that extends subgingivally and tooth had mild tenderness on percussion with grade I mobility and furcation involvement. Radiographic examination (Figure-1) revealed, caries extending till the coronal-third of the distobuccal root with vertical bone loss surrounding the distobuccal root and involving the furcation area. The bony support of mesial root appeared intact but radiolucency was seen in the periapical area of mesial and disto-lingual root. So, the diagnosis was primary endodontic lesions with secondary periodontal involvement. The treatment plan was root amputation of

the distobuccal root followed by prosthetic rehabilitation which was informed to the patient and consent was taken.

After administration of local anesthesia, root canal treatment was initiated under rubber dam isolation (Figure-2) and obturation of the mesiobuccal, mesio-lingual, and disto-lingual canals was done followed by access restoration. A mucoperiosteal flap was reflected to expose the distobuccal root, and root amputation was done using a long shank tapered fissure bur with a vertical cut towards the furcation area (Figure-3). The separation was confirmed by passing a probe. A straight elevator was used to luxate and the distobuccal root was removed from the socket (Figure-4-6). Debridement and irrigation with normal saline of the socket were done sufficiently followed by flap repositioning and suturing with 3-0 silk non-resorbable interrupted sutures. Analgesics and antibiotics were prescribed for one week. The patient was recalled after seven days and sutures were removed. The patient was again recalled after a week for crown preparation but as he went out of state and lost communication, the subsequent treatment procedure was never completed.

Discussion

Success of the root amputation is mostly dependent on proper case selection which again depends on various factors such as: Accessibility of root furcation (for easy separation), Adequate bone support for the remaining root, Local factors (tooth anatomy, crown–root ratio, tooth mobility, severity of attachment loss, and occlusal relationships), Patient factors (oral hygiene status and caries index, health and medical status, cost and time) and finally Clinician factors (proper case selection, diagnostic, treatment planning and clinical skill).[5]

In the present case report, root amputation of the distobuccal root was planned as caries had extended sub-gingivally only to involve the coronal third of the distobuccal root along with the furcation involvement, and as it was observed after the removal of the affected root, the remaining structure of the tooth appeared sound clinically as well as radio-graphically along with more than 50% of bone support. Hence a proper prosthetic rehabilitation which was planned, would have been sufficient to reinforce the remaining tooth structure.

The survival rate of root resection therapy as reported by Blomlöf et al, showed 83% survival rate at 5 years dropping to 68% at 10 year recall time, to which the authors stated, even after the diseased root being removed, this procedure inadvertently create a weak zone for aggravating factors such as caries and overhanging restorations to affect these resected teeth and cause further breakdown.[6] Ruiz et al in his study found endodontically treated teeth with periodontal disease to possess a high risk of developing apical periodontitis than teeth without periodontal disease.[7] Therefore a multirooted teeth with more than 50% of bone support around the remaining roots after root resection has a higher chance of survival compared to teeth with less than 50% bone support.[3]

Root fracture is found to be the most common cause of failure after root resection procedures and to reduce the incidence of fractures, sufficient rehabilitation with indirect coronal restoration has proven to have a positive effect on fracture resistance of such root-resected teeth. (8) In certain cases, the survival of these resected teeth can be enhanced by including them as a bridge abutment or splinting them to the adjacent teeth.

Even though root amputation, hemisection, bicuspidization is a successful treatment option in cases where furcation involvement is seen, it is associated with disadvantages as well. The surface of the root that are grinded in the furcation area are more susceptible to caries if not restored subsequently.[5] In the current case report, the tooth might have failed as the patient did not follow up for the prosthetic part of treatment showing his part of negligence making the overall treatment unsuccessful.

Conclusion

Management of teeth with endodontic as well as periodontal problems has always been a challenge to the clinicians. Endodontic, surgical, and restorative work implemented over some time has proven to increase the longevity of such mutilated teeth. And at last, it will be futile if the patients are not informed well about the comprehensive treatment plan and the significance of each step, before initiating the treatment, as they need to give time and be patient, which is the key to the success of the treatment.

Teledentistry: A Mini Review

Siddhant Behera

Post Graduate Trainee, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be) University, Bhubaneswar 751003, Odisha, India

Abstract

Oral health matters. Teledentistry is defined as the collective use of technology to address oral health issues at a distance. The practice teledentistry could possibly be ideal for underprivileged population in remote places where access to oral health services is limited. Teledentistry specifies oral health care assistance through consultation, diagnosis, prevention, treatment using audio, video and data communication. The use of Information and Communication Technologies (ICT) for the exchange of data and information in dentistry, providing health services in situations where it is necessary to overcome geographical, temporal, social and cultural barriers is called teledentistry.

Keywords: *Teledentistry, Telemedicine, E-health, Information and communication technology, Oral health.*

Introduction

Foundation of teledentistry is deeply rooted in telemedicine. The use of telemedicine was initiated for rural population in disadvantaged areas. An equitable and economical paradigm of oral health care is required to increase the opportunity in providing viable dental services to the poor, particularly those living in isolated regions[1]. Government policies have persistently pushed the health practitioners, offering financial enticements, to consider job opportunitiesin rural locations. But, providing ample clinical guidance and support to the newly recruited personnel is a tough task. Thus, teledentistry can be used as a mode of providing access to specialist advice and education, which was previously unattainable[2].

Global Scenario

Oral diseases are definitely amongst the most prevalent global public health problem. Oral health pathologies are the most widespread on a global scale and have serious repercussions on general health[3]. The untreated dental caries of succeedaneous dentition, in particular, accounts for 2.4 billion individuals worldwide which is almost 35% of the entire population[4]. Other oral health issues, namely, cancer of lips and oral cavity, periodontal disease and tooth loss have severe consequences which affect the quality of life of an individual[3]. It has already been acknowledged that oral health issues are a matter of grave concern for the low and middle income countries [LMICs] in terms of social, economic and commercial growth[3].

The United States, Department of defense Total Dental Access venture is considered as the pioneer project in teledentistry[5]. Since its inception in 1994, a sequential shift in technological advancement is eminent. From the use of plain old telephone system [POTS] to the world wide web at present. A series of other technologies have also been used in the interim period, such as fax machines, file transfer via satellite and integrated services digital network [ISDN].

The substantial findings of the previous literature in teledentistry reveals a promising future towards bridging the rural-urban gap of dental health care opportunities. The several key findings of updated literature are presented in the following tables.

Table 1: Substantial findings of the previous literature in teledentistry reveals a promising future towards bridging the rural-urban gap of dental health care opportunities.

Reference	Study Design	Context	Key Findings
Teoh et al.[6] 2018 AUSTRALIA	Economic analysis	Teledentistry in providing specialist care for cleft patients in rural area.	In comparison to face-to-face consultation, teledentistry is a prospective cost-effective alternative.
Carrard et al.[7] 2018 BRAZIL	Exploratory study	Tele-diagnosis of oral lesions via web-based platform to specialized oral medicine teleconsultants.	Tele-diagnosis is an efficient and feasible pathway in detecting lesions of oral cavity, thereby improving standard of primary health care services.
Estai et al.[8] 2018 AUSTRALIA	Cost minimization analysis	Cost comparison between tele-screening and traditional screening approach in school children from different regions.	In a context of limited resources, tele-screening assists in diminishing the inequities by shifting available resources towards high risk children.
Tynan et al.[9] 2018 AUSTRALIA	Mixed method comparative study	Integrated platform combining teledentistry and oral health therapists for residents of aged care facilities.	This integrated setting was beneficial to high care residents with pre-conditions such as dementia and other cognitive or physical disabilities. Added advantage of increased support and training opportunities for staff members.
Pacheco et al.[10] 2018 BRAZIL	Action research	Information and communication technologies for professional training in dentistry.	Teledentistry services can endorse, through its specific tools, information, exchange of knowledge and experiences to develop and improve its services.
McLaren et al.[11] 2017 UNITED STATES	Retrospective study	Teledentistry in predicting accuracy of actual treatment modality in a rural paediatric set up.	Live video teledentistry in paediatric consultations are reasonably accurate as well as effective intervention for extensive dental needs with complex treatment modalities.
Giraudeau et al.[12] 2017 FRANCE	Accuracy study	Oral telehealth communication performed by a dentist and a nurse, to find their disparity in diagnoses.	Although oral teleconsultation is not as accurate as conventional oral screening, it is adequate for providing an appropriate diagnosis. However, 63% of the recorded diagnoses turned out to be wrong.
McFarland et al.[13] 2017 UNITED STATES	Quantitative descriptive study	Formative evaluation and effectiveness of teledentistry program in a rural location.	Statistical data evaluation offered critical feedback to program administrators. Tele dentistry has the potential to improve oral health outcomes, especially for rural and underprivileged populations.
Estai et al.[14] 2017 AUSTRALIA	Cost minimization analysis	Cost savings from a teledentistry model.	Annual reduction in cost of teledentistry program was considerably lesser than conventional face to face dental screening, in rural areas as well as urban areas. This marked reduction of expense was reflected due to the low remunerations for dental therapists, and the cost savings of travel and accommodation.
Kruger et al.[15] 2016 AUSTRALIA	Descriptive cross-sectional study	Australian dental practitioners.	General dental practitioners had optimistic view and have supported the model of teledentistry and its integration into modern dental practices.
Roxo-Gonçalves et al.[16] 2016 BRAZIL	Assessment study	Teledentistry for diagnosis of oral lesions by dentists and non-dentists.	Good capability in distinguishing the nature of oral lesions. E-learning may develop the knowledge essential for detection of oral cancer.
Blomstrand et al.[17] 2012 SWEDEN	Cross-sectional study	Tele consultations against simple referrals.	Highly effectual oral health care and correct diagnosis provided at the correct place as part of the health service is an economical and effective way to organize health services.

Reference	Study Design	Context	Key Findings
Skelton-Macedo et al.[18] 2012 BRAZIL	Descriptive study	Teleassistance applications for adding to professional actions refining the quality of oral care.	Introducing information and communication technology in day to day dental practice is advantageous. However, protecting the confidentiality of information relating to patients is a matter of concern.
Bradley et al.[19] 2010 NORTHERN IRELAND	Descriptive study	Application of teledentistry in oral medicine in a community dental service.	Use of teledentistry for triage referrals, could be a substitute to the management of referrals of elderly patients having oral diseases.
Berndt et al.[20] 2008 UNITED STATES	Case control series study	Teledentistry to provide interceptive orthodontic services to disadvantaged children.	Real time supervision by an orthodontist is a feasible approach to reduce the severity of malocclusion in disadvantaged children when referral is not possible.
Chen et al.[21] 2007 UNITED STATES	Case report	Specialized dental care from a distance.	The assessments, diagnoses, and advocated treatment plans were comprehensive and similar to routine dental clinic visit. However, 61% of visits were of similar time duration as a regular in-office appointment.
Mandall et al.[22] 2005 UNITED KINGDOM	Randomized controlled trial	Screening new patient for orthodontic referrals using teledentistry.	An effective scheme for positively identifying appropriate new patient for specialist orthodontic treatment. Thus, eliminating inappropriate referrals and saving time.
Stephens et al.[23] 2002 UNITED KINGDOM	Questionnaire study	Attitude of orthodontists of United Kingdom in offering advice to general dental practitioners.	A majority of orthodontists encourage the teledentistry model to make their opinion more accessible to general dentists and subsequently to the patients.

Indian Scenario

A considerable improvement in oral health has been noticed over the years. However, an unequal development in the prevalence and severity of oral diseases in the urban civilization compared to their rural counterpart is a matter of concern. World Health Organization [WHO], ideally proposes a dentist to population ratio of 1:7500. According to World Health Statistics- 2014, the ratio was 1:10000. In 2004, dentist-population ratio in India was 1:30000[24]. But in 2004, India had one dentist for 10000 individuals in urban areas whereas one dentist for approximately 250000 individuals in rural areas. This indicates, three-quarters of the total dentists are clustered in the urban areas where only one-quarter of the country's population reside[25].

Periodontal diseases are the most prevalent oral health care issue in India. In age groups 12, 15, 35-44 and 65-74 years, the prevalence of periodontal diseases reported were 57%, 67.7%, 89.6% and 79.9%, respectively [26].

Introduction to teledentistry in India shall propel the health care system as it will serve as an effective adjunct and a potential cost-effective tool in a low-resource setting. A few studies have been conducted in India and there is a vast scope for future research in this field.

Table 2: Studies related to Teledentistry in India.

Reference	Study Design	Context	Key Findings
Avula et al. [27] 2015 INDIA	Descriptive study	Potential of tele-periodontics.	Better patient supervision over geographic limitations. Prospects of oral health education.

Reference	Study Design	Context	Key Findings
Boringi et al. [28] 2015 INDIA	Cross-sectional study	Awareness of teledentistry programs.	Most of the dental professionals lacked enough knowledge and understanding.
Purohit et al. [30] 2017 INDIA	Cross-sectional study	Teledentistry as a tool to screen for dental caries among 12 years old school children.	Teledentistry and clinical examination findings were equivalent. This study set up provides evidence that teledentistry can be used as a feasible tool for consultation and treatment planning.
Vinayagamoorthy et al. [29] 2019 INDIA	Cross-sectional study	Efficacy of a remote screening model for oral potentially malignant disorders.	Based on direct clinical examination and WhatsApp image examination, both examiners concluded similarly on distinguishing a lesion as normal or abnormal. But there was a substantial disagreement in exact diagnosis.

Conclusion

The demand for oral health care is mounting, with the cost rising simultaneously[1]. Even though teledentistry has not been an integral part of dental care services, it is definitely a tool which is worth developing to encourage access to care for the isolated populations. World Health Organization suggests that telemedicine should be amalgamated to the day to day practice of dental surgeons across the globe as a public health equity tool.

Polymers Used in Dentistry: An Overview of Literature

Rasmita Samantaray[1], Abhijita Mohapatra[2], Sitansu Sekhar Das[2], Krishna Nanda[1], Sneha Bharadwaj[1]

[1]Postgraduate Trainee, [2]Professor, Department of Prosthodontics, Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The expanding use and enthusiasm for dental polymer aren't just ascribed to the brilliant surfaces of polymers yet besides their ideal mechanical and organic properties, minimal effort and simplicity of dealing with while preparing for a wide scope of utilizations. Polymers, for example, acrylic acid copolymers are utilized as a dental adhesive; polylactic acids are utilized for dental pulp & dentin recovery and bioactive polymers are utilized as advanced drug delivery systems. The article aims to audit the writing on the headways in the utilization of PMs in dentistry.

Keywords: *Denture base polymer,Polymeric composites, Bonding Agents*

Introduction

Before the introduction of acrylic polymers to dentistry the principle polymers used was vulcanized rubber. Polymers introduced in 1937 included vinyl acrylics, polystyrene, epoxies, polycarbonates, polyethylene, polyvinyl acetate, polysulfides, polysilicon, polyethers, and polyacrylic acids. The primary use of polymers has been the construction of prosthetic appliances such as denture base. However they are also used in artificial tooth, restoration, cements, elastics, inlay patterns, implants, impression materials, dies, temporary materials, endodontic filling etc.

Polymers are shaped through compound responses that convert an enormous number of low sub-atomic weight (LMW) particles known as monomers into a huge exceptionally high sub-atomic weight chain full-scale atoms known as polymers the structure and morphology of this large scale particle decides if the material is a fiber,an unbending strong or an elastomer.

Table 1. Classification of Polymers

Based on the nature of monomer	Homopolymer
	Copolymer
Based on the nature of monomer	Linear
	Branched
Based on Spatial arrangement	Addition
	Condensation

Dental uses of polymers:

The various uses of polymers in dentistry are as follows:

- "Prosthodontics"-"Denture bases and teeth, delicate liners, custom plate, impression materials, core build-up materials, temporary restoratives, establishing/luting materials, and maxillofacial prostheses".
- "Operative Dentistry"- "Dentin bonding agents, cavity fillings, resin and glass-ionomer cements, pit and fissure sealants, bracing materials and veneers".
- "Orthodontics"- "Brackets, bracket holding adhesives and cements and spacers".
- "Endodontics" - "Gutta-percha, root canal sealants and elastic dams".
- "Equipment"- "Mixing bowls and spatulas, mouth guards (athletic gear) and defensive eyewear".

Properties of Polymers:

Mechanical and Physical Properties of Polymers: The blend of polymer creation, chain length, spreading, cross-connecting and nuclear heading can convey a grouping of properties. To address the issues of various dental applications, these features are controlled to make a decent property. These properties can be assembled into four interrelated groupings: "Mechanical, Rheological (Flow), Dissolution and Thermal".

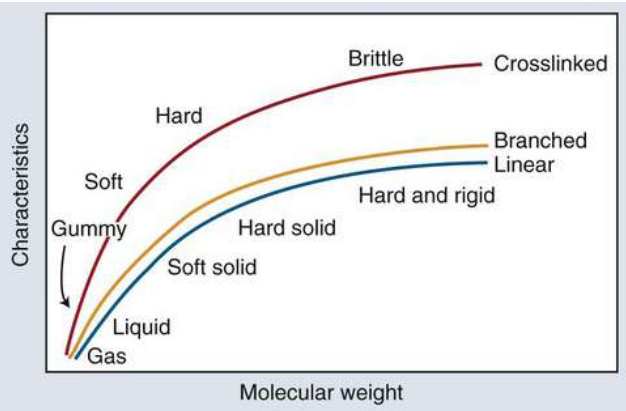

Fig. 1: Rigidity,strength and melting temperature increases with increase with molecular weight and chain length(courtesy-Phillips science of dental material)

Mechanical Properties—Deformation and Recovery: When forces are applied to the polymer they produce stress which causes materials to deform or stretch from its original shape and size (i.e, undergo strain) via either "elastic strain, plastic strain or a combination of elastic plus plastic strain".

- "Plastic strain"- Plastic strain is irreversible distortion that can't be recovered and realizes another, unending shape as the eventual outcome of slippage (flow) among polymer chains.
- "Elastic strain"- Is a reversible,versatile strain that is quickly and completely recovered when the pressure is wiped out, as the aftereffect of polymer chains uncoiling and afterward pulling back.
- "Viscoelastic strain"- Is a mix of both adaptable and plastic deformation, yet simply the flexible part is recovered when the weight is decreased.

Rheometric properties: The rheometry or flow behavior of rigid polymers involves a mix of elastic and plastic deformation followed by elastic recovery after the stresses are removed. This combination of elastic and plastic changes are called viscoelastic property.

The length of the chain,cross link numbers,temperature, and rate of force application determines which type of behavior dominates.

- Plastic flow- Irreversible strain conduct that happens when polymer chains slide more than each other and get moved inside material bringing about perceptual distortion.
- Elastic recovery- reversible strain behavior that occurs in amorphous regions of polymers when randomly coiled chains straighten and then recoil like springs.

Solvation and Dissolution properties: Polymers are usually slow to dissolve the salvation characteristic is very sensitive to polydispersity,cross linking,crystallinity, and chain branching the following characteristic properties exhibited by polymer which is relevant in dentistry-

- The longer the chains with high molecular weight the less is the solubility of the polymer.
- Polymers engross a solvent and soften, but they never dissolve.
- The cross-connecting of the chain forestalls chain detachment and retards disintegration and exceptionally cross-connected chains can't be broken down.
- Elastomers swell more effectively than plastics.
- Absorbed molecules spread the polymer chain within the polymer thus facilitating the slippage of chains and this property is called plasticization.
- The swelling of dental polymers affects the fit of dental polymeric prosthesis.

Thermal properties: The property of a polymer changes with change in temperature and composition,structure, and molecular weight. Thus higher is the temperature the softer and weaker the polymers become. Polymers can be formed into desired shapes using a type of polymeric material used. According to its thermal setting polymer can be divided into thermoplastic polymers and thermosetting polymers.

Thermoplastic polymers: Soften on heating and hardens on cooling. The rmoplastic polymers are made up of branched or linear chains and they soften when heated above the "glass transition temperature(Tg)". Eg-polyamides (nylon), acetal resins, epoxy

resins,impression compound,polystyrene, polycarbonate resins, polyurethane, and acrylic.

Thermosetting polymers: Thermoplastic material undergoes a series of chemical changes and hardens when heated above the glass transition temperature. The y don't soften again on reheating. The y usually are cross-linked in this state and don't melt.Eg-PMMA.

Applications of polymers in dentistry-

Denture Base Material: "Most denture bases and acrylic teeth are manufactured utilizing (polymethyl methacrylate) PMMA".Pmma is much of the time utilized because of its different preferences like low cost,biocompatibility,ease of processing,stability in oral condition, and worthy esthetics.How ever the properties of Emma is upgraded by joining numerous fillers and fibers.

Soft Lining Materials: These are predictable materials that are made to set between the denture and the oral mucosa to lessen torture and misery achieved by hard dentures. These materials are also applied in maxillofacial remaking as obturators". Delicate (soft relining) covering materials are classed in two sorts: delicate acrylics and silicone rubbers.

Warmth or room temperature polymerized methacrylates with included plasticizers, hydrophilic acrylic polymers, silicones, and elastomer/methacrylate copolymers are commonly used as soft lining materials. A fundamental essential is a glass temperature underneath 37 °C, with the ultimate objective that the polymer remains sensitive in the oral pit. The polymers should be biocompatible, nondisturbance to oral tissues, have palatable mechanical quality, and have low fluid take-up.Soft acrylics show extraordinary attach to PMMA dental replacement bases exactly as expected in any case the joining of plasticizers adds to, the cementing over some interval and they furthermore experience the evil impacts of tremendous water take-up. There is a creating stress over the use of Phthalate plasticizers, as a result of their hurtfulness. Silicones experience the evil impacts of nonappearance of cling to the acrylic dental replacement bases and have a low assurance from tear.

Some silicone delicate liners acclimatize a great deal of fluids and water take-up of hydrosilanized silicone rubbers is influenced by included substances, for instance, hydrophobic or hydrophilic silica and is related to the dissolvability of the additional substance, increasingly conspicuous dissolvability offering climb to a drawn-out water take-up with greater deviation from customary dispersal qualities.

Dental Composites: Dental composites are tooth-colored filling materials made out of "engineered polymers, particulate ceramic fillers, polymerization promoters and coupling agents". The y are logically being used as helpful materials set clearly, in an indirect route or as concrete, inbonded rebuilding efforts. Dental composites are provided as single paste details likewise named "visible light cure(VLC) materials and as two paste for the self-cure systems".

Dentin Bonding Agents: Other than GIC, bulk filling material don't adhere to tooth and Dentine bonding agents give an extraordinary joining to tooth structures just as the new age materials similarly permitting bonding between composite resins and substrates, for example, base metal combinations, solidified amalgam, cured composites and porcelain. Dentine bonding agents can be considered to incorporate three segments:"a primer, a coupling agent and an unfilled resin" critical to obtain an exact impression followed by its adaptable recovery and mechanical quality.

All the more as of late, a helpful cement was blended that contained three operators: "a QAM named dimethylaminododecyl methacrylate (DMADDM) with antibacterial movement, nanoparticles of silver (NAg) and NACP for remineralization". There was no lessening in dentin bond quality from one day to a half year of when put in water, while the commercial control bonding agents lost quality generally 33% of its dentin bond quality at six months.bonding agent demonstrated a drawn-out sturdiness in dentin bond quality.

Impression Materials: Various strategies in restorative dentistry require a precise imitation cast of the oral soft and hard tissues to construct appliances outside the mouth; a couple of models being dentures,crowns and bridges, and orthodontic appliances. Impression materials are placed in the oral cavity in a plastic or fluid state which in this way experiences a progression of chemical reaction. The flow properties are critical to get an exact impression followed by its adaptable recovery and mechanical quality. Impressions are much of the time put away at room temperature and exposed to high tensile stress on expulsion from undercut regions. Eg-natural polymers agar-agar,silicone impression material, polyethers, polysulphide.

Peek and Peak: PEEk (polyetheretherketone) is an artificially produced polymeric material and the most critical agent of polyaryletherketone (PAEK). This is a somewhat crystalline, thermoplastic high temperature-resistant, high-performance plastic with a softening temperature of 334°C. In this manner, PEEK can be utilized in pressurized pressure frameworks like the "for 2 press" framework, while the industrial facility squeezed items can be prepared with various cutters and utilized in "computer-aided design/CAM"technology.

PAEK is a tolerably new gathering of high-temperature thermoplastic polymers involving a key sweet-smelling fragrant atomic steel by "ketone and ether". The manufactured structure of polyaromatic ketones gives soundness at high temperatures (more than 300°C), making it incredibly charming for current applications. Before the completion of 1990, PEEK had created as the key thermoplastic polymer and was used to supersede metal parts in the orthopedics. PEEK can without a very remarkable stretch be adjusted by including various materials carbon fiber expansion may assemble the versatile modulus to 18 GPa. The carbon-braced PEEK module is contrasted with the cortical bone and the dentin. The versatility of PEEK resembles that of bone, polish, and dentin in this way making it a perfect material for interminable prosthetic modifying endeavors.

Bio HPP: Bioactive PEEK with ceramic filler (Bio-High Performance Polymer) is a piece of the "PEEk" family and is applied in medical procedures since a significant time allotment. In light of its incredible soundness, its optimal cleaning properties, and its low plaque affinity, BioHPP is commonly phenomenal for definite prosthetic recoveries fabricate. "The biopolymer has a modulus of adaptability closer to the human bone and this reality improves the chewing performances. BioHPP (High-Performance Polymer) is an inventive thermoplastic polymer reliant on PEEK". It was made and upgraded for dental use. It contains ceramic microparticles for better cleaning of the reclamations. These ceramic fillers have a size of about 0.3-0.5 microns and have 20% of the hard and fast volume of BioHPP.

BioHPP is as close as conceivable deep down, on account of its coefficient of versatility (around 4 GPa). This is significant in implant treatment in situations when winding powers may happen. The biting pressure is transmitted as tenderly as could be expected under the circumstances, and the danger of fracture is decreased, because of the BioHPP modulus of flexibility near that of the spongiose bone.

BioHPP is especially appropriate for patients with sensitivities because the solvency of the polymer in water is low <0.3 ìg/mm^3. Studies exhibit high protection from abrasion. BioHPP can be an option in contrast to chromium-cobalt dental alloys (Cr-Co) since it is lighter and doesn't cause erosion. BioHPP developments can be built utilizing both current CAD/CAM innovation and standard wax substitution innovation.

Application of Bio-HPP: Removable Partial Dentures, Crown And Bridge Fabrication, Individual Implant Abutments.

Fig-2: BIO-HPP as framework

Polymers in Implantology: The osseointegration of cpi/Ti implants used for dental, craniofacial, and orthopedic explanations behind existing is related to their course of action and surface harshness. Rough surfaced implants increase osseointegration and biomechanical stability".Implant surface treatment systems join "Ti plasma-splashing,grit blasting,acid etching, anodization and calcium phosphate coatings. A perfect situation is fundamental for embed osseointegration. The diminished oxygen obsession from the poor vasculature at the embed surface interface propels the advancement of host-cell-related electrons as free radicals and proton destructive that can engage disease and irritation causing implant failure. To give a decent ideal condition for osseointegration and overcoming the issues related toTi inserts, surface alterations can be performed using great fiber-reinforced and complex fillers/included substances including hydroxyapatite or antimicrobial circuit by method for thermoset polymers. The polymer/carbon-fiber composite conveyed powerful osseointegration. The rmoset polymer cross-section and carbon strands

make covalent bonds outfitting strong bone structure support with mind-blowing osseointegration. The utilization of anti-infection containing nanofiber put together polymeric films concerning dental implants has been explored to limit implant failure,particularly in periodontally undermined patients.

Conclusion

Plastics are employed successfully in many dental applications. Their properties make them valuable especially in the construction of dentures, plastic teeth, and impression materials. Plastic filling materials have not been successful because of their high coefficient of thermal expansion and lack of bonding to tooth structure. Perhaps the biggest improvement in filling materials would be the development of a satisfactory cavity liner that bonds to tooth structure and is impervious to the mouth fluids. If such a liner were available, the need for a filling material that matches the thermal expansion of the tooth would be less critical. With advancement in higher physical and mechanical properties of polymers, it is now used along with implants and also bridge and crown prosthesis. Although the economical issues cannot be ruled out with this improved material.

Non-Habit Induced Oral Cancer: A Review

Diksha Mohapatra[1], Neeta Mohanty[2]

[1]Post-Graduate Student, [2]Professor & Head, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

The purpose of this article is to review non-habit induced oral cancers in India and study its interrelationships and risk factors on the health of an individual. Oral Cancer is a major issue related to the health of an individual inevery country around the world and has a wide variation in the global burden of the disease. It is a noteworthy issue regarding public health in India and accounts for 30% of the total cumulative cancers reported across the country. Consumption of tobacco and alcohol leads the etiological factors responsible for causing Oral Cancers, but, at times non-habit induced oral cancers have also been recorded. This article focuses on the various etiological factors responsible for causing oral malignancies in individuals having no history of alcohol and tobacco-related habits and highlights their interrelationship and pathophysiology responsible for causing malignancies.

Keywords: *Oral Cancer, Carcinogens, Pathogenesis, Carcinogenic, Metastasis, Tumerogenesis, Exposure.*

Introduction

Oral Cancer is a major issue related to public health inevery individual country around the world and has a wide variation in the global burden of the disease. Incidences in India and South-east Asia ranks highest in the world with Oral Cancer ranking amongst the top three cancers in the Indian sub-continent.[1] In the head and neck region, the Oral cavity is the predominant site of primary malignant tumors, and oral cancer is the prime cause of morbidity and mortality amongst all cancers in India. Oral Cancer is a noteworthy issue regarding public health in India and accounts for 30% of total cumulative cancers reported across the country, with a prevalence rate as high as 20 out of 1,00,000 people having carcinoma of the oral cavity.[2]

In western countries, the tongue and floor of the mouth are the predominant regions of oral cancers due to smoking tobacco and alcohol consumption habits. On the contrary, cancers of buccal mucosa, alveolus and retromolar region are the predominant sites in the Indian subcontinent due to the habit of chewing tobacco and areca nut.[3]

Consumption of tobacco and alcohol leads the etiological factors responsible for causing Oral Cancers, but, at times non-habit induced oral cancers have also been recorded. Poor oral hygiene, ill-fitting dentures, sharp cusps, sharp crowns and bridges, hereditary predisposition, racial and demographic factors, chemical carcinogens, radiation, viruses like Human Papilloma Virus (HPV) infections, etc have now been found responsible playing a role in the pathogenesis of Squamous Cell Carcinoma of head and neck region. The most common reason behind younger generations acquiring non-habit induced Oral Squamous Cell Carcinoma is a genetic predisposition, viral factors such as Human Papilloma Virus (HPV) and Epstein–Barr virus (EBV), immune-suppressive conditions, Fanconi's anemia, and occupational exposures.[4-6]

Etiology: Hereditary and Demographic Factors: The risk of developing cancers in genetically linked

relatives of cancer patients is three times higher than non-genetically linked control groups. Incidences of occurrence of nasopharyngeal cancers in the southeast asian population are higher as compared to other regions of the world.[7] Similarly occurrence of carcinomas can also be influenced by geographical and environmental factors like mineral content in water, diet, climate changes, etc.

Chemical Carcinogens: Directly or indirectly the human body comes in contact with various chemicals that can be carcinogenic and can induce carcinogenesis or tumorigenesis in an individual. Polycyclic aromatic hydrocarbons like benzanthracene, methylcholanthrene, etcpresent in tobacco, smoke, air pollutants or industrial oils can cause skin cancer, oral cancer and lung cancer in an individual exposed to these carcinogenic agents. Aromatic amines like beta-naphthylamine, benzidine and azo dyes used as food coloring agents can be a potential causative agent of oncogenesis. Carcinogenicity of chemical agents is dose-dependent and multiple-dose exposure can have the same oncogenes as compared to single-dose exposure. The mutagens bind to DNA, RNA, or cytoplasmic proteins within the cell and initiate miscoding errors during cell replication. These mutagens interact with the genetic substances of the cell and cause mutagenesis, ultimately affecting clonal proliferation.[7]

Physical Carcinogens: Radiation like UV radiation from sunlight, UV lamps, and ionizing radiation like X-rays, alpha-radiation, beta-radiation, gamma-radiation, or radioactive isotopes have the potential for inducing mutagenesis and even killing a cell. The radiation-induced mutation is generally irreversible and depends upon various factors like a dose of exposure, a period of exposure, type of radiation, number of cells exposed to the radiation, etc.[7]

Biological Carcinogens: In certain cases of reported non-habit induced Oral Squamous Cell Carcinoma, not only chemical or physical carcinogens, but the presence of variousbiological carcinogens like Human Papilloma Virus (HPV), Epstein - Barr virus (EBV), and Herpes Simplex Virus are also seen playing a prime role in promoting cancers.[8-10]

HPVis one of the major etiological factors in non-habit induced Oral Squamous Cell Carcinoma cases reported worldwide. Cases of Human Papilloma Virus infections have also turned up at several areas in the human body like the anus and genital tract, urethra, skin, larynx, mucosa lining the trachea and the bronchus, nasal passage, maxillary sinus, frontal sinus, sphenoid sinus, ethmoid sinus and oral cavity.[11,12] High-risk prototypes of the Human Papilloma Virus, HPV-16, and HPV-18 have been recognized as being capable of transforming epithelial cells in the upper respiratory tract into cancer cells.[13] HPV infection plays a major role in the causation of cancer of the pharynx, but it has also been recognized as an etiological factor behind cancers of the Oral Cavity. Oral HPV infection may be associated with different precancerous lesions of oral cavities like leukoplakia, erythroplakia, oral lichen planus (OLP), nicotine stomatitis, oral submucous fibrosis (OSMF), and tobacco pouch keratosis.[14-16]

HPVbelongs to an age-old known family of pathogens that were known to cause infection of the epithelial tissues in organisms belonging to the family of amphibians, reptiles, birds, and mammals. This cluster of DNA viruses forms a discrete Papovaviridae family, which encompasses Papillomaviridae and Polyomaviruses. HPV can be phylogenetically put into genera like alpha, beta, gamma, mu, and nu, different species, and 150 types out of which 120 types are fully sequenced. About 80% to 90% of viruses in the same species split similar biological properties like tissue morphology, disease illustration, and pathogenicity. The life cycle of the virus is initiated through micro lesions in the epithelium of the human body and is recognized byspecialized distinguishable programs of squamous epithelial keratinocytesthat have been infected, where virusessynthesis DNA and their expressions occur through capsid proteins. Basal cells are directly infected from the Virions released from the stratum corneum and stratum granulosum throughthe synthesis of capsid proteins as well as activation of late and early promoters.[14,17, 18]

If clinical features are observed, HPV-associated tumors can be distinguished as a shape somewhat resembling a strawberry-like exophytic lesion, most commonly seen at the base of the tongue or can also be seen in the tonsilar region and poorly distinguishable histopathological findings, as well as cystic changes, are seen in metastatic lymph nodes of head and neck region present near the tumor.[15-21]

Epstein-Barr virus is a double-stranded DNA containing oncogenic human herpes virus, also known to be the first human tumor-causing virus.[19,22,23] It can appear in individual showing no visible symptoms and

persist for a lifetime as a latent infection.[22] Presence of EBV have been reported in various epithelial cell malignancies, like, nasopharyngeal Carcinomas, so it can also be a potential etiological factor behind various malignancies of the oral cavity.[24] Studies have also shown that Epstein-Barr Virus is also engaged in various B-lymphocyte induced cell malignancies, like Burkitt's lymphoma and Hodgkin lymphoma.[22,23] Epstein Barr Virus malignancy is linked with various proteins in the viruses that controlthe proliferation of the cell, immune response as well as apoptosis of the cell. Latent Membrane protein help in activating the signaling pathway, whereas the nuclear antigens of EBV help in gene expression.[20] However, Epstein-Barr Virus affecting Carcinogenesis of Oral mucosal remains uncertain, because various techniques like PCR, nested PCR, RT-qPCR, IHC, and ISH, are used for detecting the virus, and sensitivity and specificity of the tests varies according to the techniques which have been used, leading to different interrelations between Epstein-Barr Virus infection and Oral Squamous Cell Carcinoma.[21,]

Non-Habit Oral Cancer in Females: Studies suggest the occurrence of non-habit induced oral Carcinoma has a higher incidence rate in female gender as compared to males.[23] The cancer cells derived from head and neck carcinomas show estrogen metabolism genes, especially estradiol in tongue carcinomas. Several studies have also indicated an alteration in the level of various hormones like Follicle-Stimulating Hormone (FSH), Luteinizing Hormone (LH), prolactin, and testosterone in the bodies of female patients reporting with non-habit induced Oral Squamous Cell Carcinoma. The exact role of estrogen behind Oral Carcinoma occurrence is still under research scrutiny and should be studied further to shed light and extract the etiology behind the presence of estrogen receptors in non-habit induced head and neck cancers in the female body.[24]

The Oral Cavity is exposed to various forms of trauma either through ill-fitting dentures, sharp cusps, impinging dental restorations, and root pieces. Chronic irritation to the soft tissues due to the above-mentioned causes can progress towards the emergence of reactive oxygen species (ROS) and reactive nitrogen species (RNS) from various inflammatory cells like lymphocytes, macrophages, etc. When the body's defense mechanism falls behind and concentration of free radicalslike Superoxide Radical (O_2), Hydroperoxyl Radical (HO_2), Hydroxyl Radical (OH), Nitric Oxide (NO), Nitrogen dioxide (NO_2) exceeds the body's antioxidant levels, a mutation occurs in the parent cells leading to carcinogenesis. Ill-fitting dentures serve as a source of chronic irritation and trauma to the buccal mucosa and can be an etiology behind the occurrence of Oral Carcinomas in older generations due to possible synergistic effects of long-standing trauma and delayed DNA repair mechanism.[17]

Conclusion

From various studies, it has been seen that non-habit induced Oral Squamous Cell Carcinoma tends to have a negative nodal status and a tumor size which seldom exceeds T2 (STNMP staging). STNMP is a newly introduced system for giving the notation of intra-oral carcinomas and it is completely different from all previous TNM staging in that along with the conventional notation including tumor (T), node (N), and metastasis (M) which is in generalused in cancer staging, but, an additional notation of site (S) and the pathology (P) have also been considered. The two new additional features have been conceded as a prime factor in estimating the prognosis of the patient. The phenotype of non-habit associated Oral Squamous Cell Carcinoma is generally a well to moderately differentiated carcinoma. When compared the expression of p53 in non-habit associated Oral Squamous Cell Carcinoma shows a significant decrease in its expression than habit induced carcinomas. This suggests a good response to radiotherapy and cancer management procedures and thus an improved overall prognosis. However, a low prognosis rate is seen in non-habit induced Oral Squamous Cell Carcinoma patients due to delayed treatment and medical management as well as lack of awareness amongst the population over the issue.

Restoration of Anterior Tooth with Extensive Coronal Tooth Loss with Custom Metal Cast Post: A Case Report

Sneha Bharadwaj[1], Abhilash Mahapatra[2], Sangram Panda[3], Krishna Nanda[1]

[1]Post Graduate Trainee, [2]Professor, [3]Associate Professor, Department of Prosthodontics, Crown, Bridge and Implantology, Siksha O Anusandhan (Deemed to be University), Institute of Dental Sciences, Bhubaneswar

Abstract

The success of an endodontically treated tooth, when most of the coronal structure is lost, not only depends on the quality of Endodontic treatment but also its post-treatment coronal rehabilitation. This can be achieved by retaining a core with a post holding the final fixed prosthesis. In cases where the bulk of the natural crown is lost, a post and core with Endodontics treatment help to improve fracture resistance. Therefore it is of great importance that an apt post system is chosen depending on the clinical condition of the tooth to be restored. When a large amount of tooth structure is lost or if an insufficient ferrule is present, a custom cast post and core is indicated. This paper elaborates on a case report depicting restoration for central incisor using custom cast posts followed by PFM crowns.

Keywords: *Anterior Tooth; Extensive Coronal Tooth Loss; Custom Metal Cast Post.*

Introduction

Teeth undergo extensive loss of coronal tooth structure after Endodontics treatment and the reason could be either fracture, a pre-existing restoration, or a large access cavity preparation. In such a condition opting for an apt post Endodontics restoration method is of great importance and can be very challenging.[1] The choices are between direct or indirect restoration for smaller defects, partial or full coverage crowns for relatively larger cavities, and also whether there is a requirement of placement of post. If it is decided upon the placement of post, the type of post needs to be opted too, whether a prefabricated or a cast custom post. According to Franklin Weine, the success of most of the Endodontically treated teeth depends on the post Endodontic restoration and not on the endodontic treatment itself.[2]

Corresponding Author:
Sneha Bharadwaj

e-mail: ginger.sneha@gmail.com

Post Endodontic restoration and its choice depending on factors like the remainder coronal structure, position of the tooth and its functional requirements, esthetics, patient's age, and the periodontal health of the tooth.[3] Endodontically treated anterior teeth, without any discoloration can be restored with composite resin if the loss of tooth structure is moderate to low. This will provide a good coronal seal and the fracture susceptibility will be reduced.[4,5] Composite restoration can also be chosen when the anterior teeth have the cingulum or the incisal edge intact with a couple of proximal carious lesions[6] in the Endodontically treated tooth is found to be discolored, bleaching can be done paired with indirect or direct veneers. When coronal tooth structure is considerably lost (<50%) in a root canal treated tooth, it is essential to decide whether to opt for direct restoration or it needs to be restored with full coverage crowns. This depends on the amount of occlusal load on the tooth and the position of the tooth in the arch. Any tooth that is root canal treated and is found with crack lines, mesial or distal caries or cervical abrasion is recommended for placement of intra radicular posts. This provides for better retention on the core and the final restoration with improved fracture resistance.[7] Anterior teeth with more than 50% tooth structure loss, post, and core followed by fullcoverage restoration are mandatory.[8]

When there is a requirement for placement of posts, various options are ranging from the conventional custom cast post to newer fiber posts. Placement of fiber posts requires less time and also the evidence from the laboratory and clinical experience of technicians and dental professionals respectively emphasis on the use of fiber posts. This does not conclude that custom cast post is a matter of past, as they are a better option when there is extensive loss of tooth structure and if there is a need to change in angulations of the core. In this case report, we present a case where it requires the restoration of maxillary incisors by custom cast post with porcelain fused to metal crowns.

Case Report: A Female patient of age 76 years reported to the department of prosthodontics. She had been referred to our department from the department of endodontics post endodontic treatment of both the upper central incisors. She reported a history of trauma on the left central incisor which led to it being fractured from the cervical third of the tooth. The right central incisor was grossly decayed. The patient underwent Endodontics treatment for both the central incisors. The patient gave a drug history of antiplatelet therapy. Intraoral examination revealed 11 to be restored temporarily and 21 with Ellis Class 3 fracture. 21 had undergone such extensive loss of coronal tooth structure that barely the natural crown was visible.

Figure 1. Left central incisor with class 3 Elli's Fracture

The rest of the upper arch revealed severe attrition. The lower arch had undergone complete rehabilitation with porcelain fused to metal crowns where various crowns had lost the ceramic coating over them. There was a general loss of vertical dimension of occlusion and the patient showed a deep bite.

The intraoral periapical radiographs concerning the central incisors revealed that the canals of both incisors were well obturated with no periapical abnormality. After the patient was thoroughly examined, the treatment plan was to restore 11 with composite and place a custom cast post for 21 followed by porcelain fused to metal crowns for both the incisors. As there was not enough crown structure to preserve a ferrule for final prosthesis the patient was referred to the Department of Periodontics for the clinical crown lengthening procedure.

The patient returned to the department after one week. The right central incisor was restored with composite and prepared to receive porcelain fused to metal crown. The tooth preparation was done in such a manner that angulation of the core is inclined more in the buccal direction to provide for clearance on the palatal side as the patient has severe deep bite. For 21, post space was created leaving at least 5 mm of Gutta-percha to preserve apical seal using upto size 3 of the Gates drill. This was confirmed using a radiograph. A ferrule was prepared on the remaining tooth structure.

Figure 2. Custom Cast Post

The canal space was lubricated with petroleum jelly and the impression of the post space is made with light body elastomeric material. Provisional restoration is made and luted with zinc oxide eugenol cement over 11, and the post space of 21 was blocked with cotton pellets.

Figure 3: Cementation of custom cast post and preparation of ferrule w.r.t 21

Figure 4: Tooth preparation of 11

The impression is poured with Class III gypsum material and the wax pattern is fabricated for custom cast post and core. It is invested immediately and casting is done.

This cast post and core (Fig.2, Fig.3, Fig.4) was cemented onto 21 with glass ionomer cement. The final impression is made with light body elastomeric impression material for fabrication of porcelain fused to metal crowns for both the central incisors. The provisional restoration is placed back. Shade selection was done under natural light. Final porcelain facing metal restorations are tried, glazed and cemented with glass ionomer cement.

Figure 6. Cementation of Porcelain facing Crowns

Discussion

The prognosis after an Endodontic treatment of the tooth greatly depends on the post-treatment restoration and little on the endodontic treatment itself,though together with good endodontic treatment and good restoration success rates are seen to be as much as 91.4%. [9]

The post is indicated to aid in the retention of core in a tooth with reduced coronal tooth structure.[10,11] When an anterior tooth has undergone a minimal amount of tooth loss, it can be conservatively restored with bonded restorative materials.[12] In such cases,the post is of not much benefit as the tooth structure is sound it can increase the risk of nonrestorable failure.[13-15]

After an anterior tooth undergoes root canal treatment, the remaining tooth structure is pretty thin and reduces further if indicated for a crown. Anterior teeth are subjected to lateral and shearing types of forces

and after restoration, it should be able to withstand these forces. also, the small pulp chambers are not supportive in providing adequate retention and resistance. and the pulp chambers are too small to provide adequate retention and resistance without a post. Therefore in most cases, placement of post becomes necessary.

As a wide array of post systems available in the market and depending on the case, it is necessary to opt for the best type of post by weighing the advantages and disadvantages of all post systems during treatment planning.

Cast post and core have been the standard for many years and clinicians are still using these as it is advantageous in various situations. In cases where multiple teeth require post and core, to increase efficiency, one impression is made and they are fabricated in the laboratory instead of placing a post in and buildup in each tooth separately as a chair-side procedure. When there is a requirement in the change of angulation for the final restoration to match the adjacent tooth, as in cases of mild proclination, cast post and core can be given.[16]Cast posts are also indicated when there is the minimal residual coronal structure of the tooth, as in mandibular incisors with not enough bulk of tooth to provide anti-rotation features during tooth preparation. These posts are easily retrievable if the tooth requires endodontic re-treatment. Cast posts are capable of confirming to the canal morphology and hence can be used in different types of canal configurations like oval or elliptical.

These have fallen from favor over time because for it to be installed there is a need for two appointments, temporization, and a laboratory fee. On the other hand, according to Gomez Polo et al, cast metal posts have shown higher survival rates over10 years.[17] There have been reportsof a high rate of success with these post and core systems.[18,19] and the research till now is not entirely in favor of other post systems as there are still many unanswered questions.

A 2mm ferrule can increase the fracture resistance of a root canal treated anterior teeth, irrespective of the post system implied or the type of crown to be given. The reason for increased fracture resistance can be credited to the improved stress distribution.[20]The ferrule is a ring of sound tooth structuresthat envelope by the cervical third of the crown. The crown restoration braces the tooth around this ferrule to enhance the integrity and longevity, provides resistance and retention form on the endodontically treated tooth. It helps to transfer the occlusal forces vertically to the periodontium as the artificial crown and root act as one unit. The more is the modulus of elasticity of the post better is their performance. In the absence of ferrule, a cast post with high elastic modulus preferred, since there is less available tooth structure for bonding.[21-23]

The material of the post is not responsible for its fracture resistance and mode of failure. Instead, they are a result of various mechanical properties interacting with each other. But cast posts are preferred in cases where the integrity of the tooth is compromised in the cervical region or has been extensively destructed due to caries of fracture, especially when it is difficult to obtain a ferrule. In the present case, 11 had sufficient clinical crown structure, whereas in 21 the clinical crown was greatly reduced hence rehabilitation of the tooth was planned by placing custom cast posts followed by a metal-ceramic full-coverage crown. As there was insufficient ferrule for the tooth, it underwent the procedure for clinical crown lengthening of about 1 mm. In such conditions, periodontal surgery like gingivectomy with alveoloplasty or orthodontic extrusion becomes mandatory to obtain a ferrule.[24,25] Though all-ceramic crowns are the best option for full coverage restoration in Anterior teeth due to their aesthetic superiority, Porcelain facing metal crown restorations opted to mask the discoloration of the cast core. Also, there was not much clearance on the palatal side due to severe deep bite. This lead to the choice of Porcelain facing metal crown instead of full metal-ceramic crowns.

Conclusion

There are various post systems available today and the selection of the suitable system is greatly influenced by the clinician's knowledge of the indications and contraindications depending on the case and the amount of sound d tooth structure remaining. We should be well versed in the advantages and the disadvantages of these post systems to make a wise choice. In cases with reduced coronal tooth structure, custom cast metal post and core is recommended. Esthetics, other than function, is of great concern when considering the restoration of Anterior teeth.

Rehabilitating Occlusion with a Guiding Flange Prosthesis in a Patient with Mandibular Resection: A Case Report

Abhilash Mohapatra

Post Graduate Trainee, Professor, Department of Prosthodontics, Crown, Bridge and Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Defects with the discontinuity of the mandible following a segmental mandibulectomy present a major challenge for rehabilitation. These challenges include correction of deranged mandibular movements, disfigurement, and esthetics, correction of functional difficulty seen during swallowing,speech and articulation, and also of surgical side deviation of the remainder mandibular structure. The following case report elaborates on the prosthodontic rehabilitation of a patient with the help of a device named «Guide Flange Prosthesis»which isindicated to correct such manifestations seen after hemimandibulectomy.

Keywords: *Rehabilitating Occlusion; Flange Prosthesis; Mandibular Resection.*

Introduction

Mandibular defects present a great challenge for its rehabilitation. When there is a unilateral defect of mandible due to trauma or surgery,there is mandibular deviation towards the surgical site and the mandibular occlusalplane rotates tend to inferiorly. It also causes extrusion of maxillary teeth eventuallyresulting in a lack of occlusion and altered maxillomandibular relationships[1]. Extensive involvement of osseous and soft tissues, loss of sensory and motor innervations, and scar tissue formation after hemimandibulectomy radically compromise the prosthetic prognosis.

Most severe mandibular deviation & dysfunction is caused mainly when there is extensive loss of soft tissue which can occur from tight wound closure, radiation therapy, and the ones that require radical neck dissections[2].

The mandibular deviation can be reduced by retaining the patient's neuromuscular system. The basic objective is for the muscles to reprogram themselves andattain an acceptable interocclusal relationshipfor the remainder of the mandible, so that all opening and closing movements are mostly in control of the patient. These include early corrective mandibular movement therapy, physiological exercise programs, and removable partial dentures for partially edentulous and complete denture prostheses for completely edentulous patients along with all possible modifications in an occlusal scheme to compensate for deviation[3].

Cantor and Curtis have classified the mandibular defects into 6 categories:[4]

Class I: Mandibular resection involving alveolar defect with preservation of mandibular continuity.

Class II: Resection defects involve loss of mandibular continuity distal to the canine area

Class III: Resection defect involves loss up to the mandibular midline region

Class IV: Resection defect involves the lateral aspect of the mandible, but are augmented to maintain pseudoarticulation of bone and soft tissues in the region of the ascending ramus.

Class V: Resection defect involves the symphysis and parasymphysis region only, augmented to preserve bilateral temporomandibular articulations.

Class VI: Similar to class V, except that the mandibular continuity is not lost.

Prosthetic rehabilitation with conventional prostheses such as mandibular based guidance restorations, and palatal based guidance restorations or implant-supported

prostheses have been advocated for the correction of mandibular deviation[5,6]. A Guiding flange prosthesis (GFP) is a mainly a mandibular prosthesis designed in a manner to achieve a neutral mediolateral position of the mandible but is not made tomake consistent repetition of this position for mastication[7,8]. A guiding flange prosthesis can be either removable or fixed. Removable prosthesis gets support from both teeth and tissues. So it cannot be retained intraorally if only a few teeth remained in the sectioned mandible.

Case Report: A male patient aged 45 years, reported to our department with the chief complaint of reducing chewing capacity due to the inability in intercuspation of teeth and deviation of the jaw. The patient presented with a history of tobacco chewing for 10 years,10 times/day, and was diagnosed with early squamous cell carcinoma involving left buccal mucosa and mandibular alveolus. The patient underwent hemimandibulectomy on the left side 4 months ago with PMMC flap reconstruction for the defect. Radiation therapy was completed a month before.

Fig. 1: Patient showing deviation of mandible towards the side of the defect and inability to occlude on the normal side

Extraoral, the symptoms included facial asymmetry, deviation of the lower third of face towards the left on mouth opening, decreased mouth opening, left corner of the mouth drooping downward, angular cheilitis. The patient was unable to guide himself into occlusion (Fig.1). Intraorally, he presented with left mandibular defect distal from the midline, with surgical skin graft on the resected side, and missing teeth that include 31-37, and 25-27(Fig. 2). The patient was partially edentulous with Kennedy's Class II for both maxillary and mandibular arch. Orthopantomogram revealed the absence of the mandible distal to the midline. The case was diagnosed as Cantor and Curtis Class III mandibular defect. The treatment plan decided was mandibular guide flange prosthesis to aid in the correction of mandibular deviation.

Fig. 2: Hemimandibulectomy on the left side with missing molars in the upper arch. Reconstruction was done with a PMMC flap

Fabrication of Prosthesis:

- Primary Impression for the mandible was made using astainless steel edentulous stock tray made which was trimmed on the side of the defect and irreversiblehydrocolloid (alginate).
- The primary impression for the maxillary arch was also made using an irreversible hydrocolloid (alginate).
- Casts were retrieved by pouring Type III gypsum material into the obtained impressions.
- The patient is trained and guided into occlusion and a bite registration record is obtained.
- The obtained casts are articulated on a mean value articulator based on the recorded bite registrations.
- A stainless steel Orthodontic wire of 19 gauge, was used to fabricate a sub-structure for the modified Guiding Flange prosthesis.
- C clasps were fabricated on the first premolars and Adams clasp on first molars of the first quadrant of the maxillary cast.
- Another C clasp is fabricated on the first premolar and Adams clasp on the first molar of the fourth Quadrant of the mandibular arch.

- The wire was also used to fabricate a crib by bending it into zig-zag fashion for the length extending from the distal of the second premolar to the medial for the second molar of the fourth quadrant.
- The clasps are stabilized on the cast using modeling wax on the lingual side of the mandibular cast and palatal side of the maxillary cast
- The casts are coated with two layers of separating media.
- Using cold cure clear acrylic, the buccal vestibular flange is acrylic, for both upper and lower cast.
- After that lingual and palatal flange is fabricated using cold cure acrylic.
- The crib is stabilized in an incline along the buccal aspect of the mandibular first molar manually keeping the maxillary arch in articulation and then it is acrylic.
- The upper and lower fragment of the guiding flange prosthesis is removed from the cast and trimmed to not leave any sharp edges.
- Finishing and polishing was done for both the upper and lower fragments of the Guiding flange prosthesis
- Stability and retention are observed after the prosthesis is tried into the patient's mouth. (Fig. 3)
- Thus a smooth gliding flange surface is to achieve to guide the remaining portion of the mandible to a definite closing point to attain adequate occlusion.
- The Flange height should be such that it can guide the mandible into occlusion without any hindrance. This remains practically within the limit of the height of the buccal vestibule.
- The prosthesis was finally inserted into the patient's mouth and he was informed of all post-insertion instructions.
- The patient seems to be pleased with the overall performance of the prosthesis.

Fig. 3: Insertion of the Guiding Flange Prosthesis leading to a reduction in deviation of the mandible and proper intercuspation

Discussion

The extent and site of a mandibular tumor denote the amount of resection of the mandible, which could be from marginal, through segmental or Hemi, subtotal, or total mandibulectomy. When there is the unilateral loss of continuity of mandible, there is the deviation of the remaining segment of the mandible towards the side of the defect. This also leads to inferior rotation of the occlusal plane. The cause of this deviation is due to the loss of muscles and tissues during the surgical excision[9].

Figure 4: Maxillary component of the guiding Flange prosthesis with stabilizing plate to prevent orthodontist movement of the maxillary teeth.

Figure 5: Mandibular fragment of the guiding flange prosthesis with a crib as an inline plane to guide the mandible into occlusion

On segmental removal of the mandible, reconstruction is recommended immediately to preserve the facial symmetry and mastication ability of the patient. There have been various surgical techniques and Prosthodontic rehabilitation techniques, which with time have advanced, to help the patient improve function and esthetics but still 50% of these patients report with impaired masticatory function[10, 11. The] most common treatment options for patients after hemimandibular resection are palatal based guiding restorations, lower arch removable guide flange prosthesis maxillo-mandibular fixation, and/or implant-supported prosthesis. Amongst these, the most recent and recommended advancement in facial reconstructive surgery is osseointegrated oral and dentofacial implants, that may adequately rehabilitate oral cancer patients, helping them to return to a healthy, productive life. An implant-supported prosthetic rehabilitation cannot be considered since no bone graft [12]was used.

For healing to complete and the osseous graft to be accepted, it requires an extensive amount of time. Therefore, any definitive treatment should be delayed in the best interest of the patient. But during this period, there is a contraction of tissues leading to a gradual increase in difficulty to manage the defect prosthetically. A Guiding Flange prosthesis during this initial healing period helps to reduce the deviation of the mandible and improve the efficiency of mastication. This is achieved as the mandibular muscles get reprogrammed to establish a good occlusal relationship for the residual mandible[13].

Guiding flange prosthesis and any removable partial denture similarly attain support, the primary sources being the residual alveolar ridge and the remaining natural teeth. The best approach would be the placement of multiple clasps distributed widely, but the presence of natural teeth determines their placement. The rigidity of retentive elements should not be more than necessary, but it increases with a decrease in the number of teeth involved[14].

The mandibular guiding flange (Fig. 4) device fits generally over the good natural teeth in the mandibular arch, opposite the side of the defect (base-plate), and is attached with a guide plane (flange splint). From the buccal flange of the mandibular fragment of the prosthesis, a crib extends vertically into the buccal vestibule, contacting the buccal flange of the maxillary fragment of the prosthesis and buccal surface of the opposing maxillary teeth. This extension aids the mandible to properly position itself in the mediolateral direction and hence aids in vertical chewing. No or very little lateral movement is provided by this device[12,15]. This guide plane helps to accomplish centric occlusion during mastication as it is necessary for every patient to maintain it for the sake of attaining basic harmony[16].

To maintain esthetics of this patient during mandibular movements, the mandibular Guiding Flange Prosthesis was fabricated in transparent self-cure acrylic resin and all the wire substructure comprising of retentive wire components were deliberately kept distal to the mandibular canine to minimize the prosthesis display. To prevent palatal orthodontic movement of the maxillary teeth by the force generated by the buccal flange against them, a stabilizing plate was provided for resistance. The maxillary stabilization plate and all its wire components (Fig. 5) were also placed distal to the canines leading to their minimum display and maximize esthetics. The prosthesis must not extend into the junctionof the graft and the normal tissue as it can affect the healing[17.]

The Guiding Flange Prosthesiscan be considered equivalent to a training device for a patient with deviated and deranged mandible to successfully and consistently repeat the mediolateral position. In some patients, there may be some stress generation when the use of the device is continued for a longer period. All such stresses should be carefully monitored. If the reprogramming of muscles is achieved and the patient can occlude on his own, this device can be discontinued.

Conclusion

A long-standing segmental hemimandibulectomy without early intervention presents a challenge during rehabilitation due to a lack of hard use support and loss of muscles during excision. Therefore such patients require as early Prosthodontic intervention as possible to maintain function and esthetics. Mandibular guiding flange prostheses are utilized on an interim basis. However, a definitive mandibular guidance prosthesis with a metal guiding flangeis recommended after healing has complete and the patient can guide himself into intercuspation with the help of this device. This will lead him to successfully correct the deviation and achieve acceptable occlusion for normal mandibular function and mastication.

Serial Extraction: A Review

Sulagna Pradhan[1], Sushant Mohanty[2], Sonu Acharya[3], Sonali Bhuyan[1], Mrinali Shukla[1]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Professor, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003,Odisha, India

Abstract

Serial extraction or eruption with guidance is a pre-planned, premature extraction of certain primary teeth to create space that has been compromised. It is followed by the extraction of certain permanent teeth to maintain the proper proportion of tooth size and dentoalveolar bone space. However, this procedure is challenging as it requires in-depth clinical knowledge and skill. This article provides essential insights to the clinicians to identify and categorize the cases meticulously for serial extraction, apply both theoretical and practical aspects of growth and development, and diagnose the alarming signs of primary crowding in early mixed dentition period.

Keywords: *Serial Extraction, Primary Teeth, Mixed Dentition, Developing Malocclusion.*

Introduction

Serial extraction is fundamentally based on the concept that in certain cases the orthodontists face a challenging situation such as limited space between the arch length and total tooth material. Hence, it is crucial to enlarge the basal bone, so that all the teeth get proper accommodation. To tackle such discrepancy, one has to be skillful enough in both clinical diagnosis as well as basic knowledge regarding the growth and development of teeth so that the dental deformities can be promptly rectified while balancing the proper esthetics[2].

History of Serial Extraction: Serial extraction has remained an attractive procedure for the dentists since the 18th century. Two French dentists, Bunon and Bourdet were among the pioneers who explained that the extraction of more than one uneven teeth can enhance the aesthetic of the rest. Paisson was the first to recommend the procedure to relieve the crowding and align the teeth. Robert Bunon in 1743, in his publication"Essay on Diseases of Teeth", first wrote about the importance of early extractions. Linderer (1851)[5] suggested that the primary canines should be stripped or removed to accommodate the lateral incisors followed by the extraction of 1st premolar as to provide sufficient space for the eruption of molars. From the 1850s, for nearly two centuries, there was no marked improvement to the concept of serial extraction. However, after the second world war, a new era of modern serial extraction was established by many dedicated dentists such as Kjellgren of Sweden, Hotz of Switzerland, Heath of Australia, and Nance, Hoyd, Dowel and Mayne of the United States. Despite working independently during the period of compromised communications because of the second world war, Kjellgren and Hotz reached a common conclusion of the extraction sequence.

In 1929, Kjellgren coined the term "Serial Extraction" to describe a procedure where certain deciduous teeth were extracted followed by the extraction of permanent teeth to facilitate an uninterrupted eruption of the rest of the teeth. In 1940, Nance presented illustrated his technique of "progressive extraction" and has been called "Father of Serial Extraction philosophy" in the United States. In 1941, Rudolf Hotz suggested the

e-mail: pradhansulagna30@gmail.com

term "Guidance of dental eruption by extraction" or "Guidance of eruption". As per him the term "guidance of eruption" is self-explanatory and comprises of all measures available for tooth eruption.

Overview of Dental Development:

1. **Incisor Liability:** The term "incisor liability" was first coined by Warren Mayen. It is defined as the difference between the amount of space needed for the incisors and the space available. In maxilla, it is 7.6 mm while in the mandible it is 6 mm. However, there is individual variation in incisor liability
2. **Inter-dental spacing:** In young patients, the interdental gap may vary from 0 to 10.0 mm(average 5.0 mm) in the maxillary arch, whereas in the mandibular arch, it fluctuates from 0 to 6.0 mm (average 3.0 mm). Lack of space is an obstacle for achieving proper alignment.
3. **Inter-canine width change:** During mixed dentition, the arch widens in between the primary caninesas compared to the primary dentition. Maxillary inter-canine widths coincide with the period of exchange between late mixed dentition to early permanent dentition but mandibular inter-canine width changes a little mostly after 10 years of age.
4. **Arch-length changes:** The total arch length from the mesial surface of the left permanent first molar to the opposite side changes over time. Normally mandibular arch length decreases while growing.

Why serial extraction is essential?: Dental crowding is one of the most prevalent malocclusions which occurs either due to deficient arch length or limited bone space or extra tooth material. To overcome this, we have to either reduce the tooth size or expand the dental arches. As there are chances of relapse even after the expansion of alveolar basal bone so the following factors should be taken into consideration. Physiologic tooth movement: Human dentition shows a physiologic tendency to move towards an extraction space. Thus by specific extraction of some teeth the remaining teeth which are in the process of eruption are influenced by the natural forces into the normal occlusion.

Indications: "When a pedodontist sees a child 5 or 6 years of age with all the deciduous teeth present in a slightly crowded state or with no spaces between them, with a fair degree certainly, that there will not be enough space in the jaw to accommodate all the permanent teeth with proper alignment" (Lysell 1960). The reason behind the need of serial extraction are early loss of primary teeth, arch length and tooth material discrepancy, lack of interdental spacing, lingually placed lateral incisors, unilateral primary canine loss and midline shifting, mesially erupting canines concerning lateral incisors, the mesial drift of buccal segment, flaring,ectopic eruption, ankylosis, etc, gingival recession on labially tipping incisors, ectopic eruption of permanent maxillary first molars resulting in early exfoliation of deciduous second molars

Contra Indication: Serial extraction should be avoided in certain conditions which include congenital absence of mandibular second premolars, mild to moderate crowding, deep or open bites, cleft lip and palate cases, spaced dentition, anodontia/oligodontia, midline diastema, dilacerations, Class 1malocclusion with minimal space deficiency, reverse overjet, deep bite,open bite, rotation, gross malposition, crossbite and severe class 2,3 of dental/skeletal origin.

Benefits: A surgical procedure not only affects the target tissue but also the tissue around the target. Some of the advantages of serial extraction are like reduced duration of the treatment & future appliance therapy, less psychological trauma experienced by the child, more utilization of physiologic force to achieve a normal occlusion, cost-effective, and chances of caries is decreased as better oral hygiene is achieved.

Drawbacks: It needs proper clinical visualization and judgment. The treatment duration can exceed the expected time frame necessitating multiple visits to the orthodontist. Hence, a high degree of patience and cooperation is needed from the patients. Sometimes it may develop tongue thrust and mandibular permanent canines may erupt ahead of 1st premolar into extraction space of the first primary molar, impacting premolar which leads to a strenuous extraction."Serial extraction has both its pros and cons but the pros outweigh all the cons"

Diagnostics Tools: Case history, Clinical assessment, Intraoral periapical radiographs, Orthopantomography, Cephalometric analysis, Intra and extraoral photographs, Study models, Functional analysis Mixed dentition space analysis are a must to diagnose a case of serial extraction.

Treatment Planning

Selection of Teeth for Extraction:

1. Primary canine: The four deciduous cuspids are extracted so that optimum space can be created for the alignment of the teeth and lingual crossbite of interiors can be avoided.
2. Primary 1st molar: 1st primary molars are extracted for the uninterrupted eruption of first premolars. But in this process, the rate and amelioration in crowdingis decelerated.
3. Erupting 1st premolar: When the upper permanent canine is erupting it is advisable to remove the first premolars as it is the essential step of serial extraction. The n it should be rechecked if the teeth are sound and healthy enough to continue the process and relieve of crowding to justify the extraction of 1st premolars.
4. Enucleation permanent canine buds provide maximum distal translation of which is not required in some cases because it protrudes the chin.

Procedure: There are several method of execution of serial extraction. The method of choice is dependent on each individual. The techniques are described below

Dewel's Method (CD4): In 1978, Dewel suggested a 3-step technique of serial extraction which is still popular and even being used nowadays.

Step 1: This step comprises of removal of primary cuspids which results in the creation of space for the normal alignment of the incisors. At the age of 8-9 years, this step is executed

Step 2: At the age of 9-10 years, this step is carried out i.e., almost exactly after 1 year primary first molars are extracted to speed up the eruption of first bicuspids.

Step 3: In this step, the erupting first premolars are removed to make some space for the permanent canine to erupt into the spaces that have been vacant by the first premolars.

A modified DEWEL'S method is applied to some cases where the first bicuspids are enucleated at the time of removal of primary molars mostly in the lower arch as the canines follow the regular erupting pattern.

Tweed's Method: In 1966, Tweed recommended that all primary molars should be extracted by the age of 9 years followed by the removal of the first bicuspid and the primary cuspid.

Nance Method: The procedure followed in this technique is the same as that of the Nance method. It suggests the removal of the primary molars followed by the extraction of the first bicuspids and deciduous canines.

Grewe's Method: Grewe's method of serial extraction usually focuses on the planning of extraction patterns for a variety of clinical cases.

Moyer's Method: Central incisor region is prone to crowding. In that case, Moyer's method is recommended.

Step 1: All primary lateral incisors should be extracted to prevent the malalignment of the central incisors.

Step 2: Then after 7-8 months, all the primary canines are extracted to permit space for the accommodation of central incisors.

Step 3: This step includes extraction of all primary first molars which further accelerates the eruption of first bicuspids.

Step 4: In this ultimate step, all the first premolars are removed after 7-8 months so that speedy and uninterrupted eruption of canines can occur.

Role of Pedodontist: In serial extraction, pedodontist and orthodontist should have mutual understanding for treatment planning. A pedodontist should observe the problem, provide appropriate treatment planning for serial extraction,convince the patient or parents, and refer the case to the orthodontist for future correspondence.

Conclusion

Serial extraction is a matter of time, patience, proper implementation of knowledge and clinical skill for accurate diagnosis, and most importantly follow up. Along with this deficient arch length,the amount of crowding, and health of the remaining hard and soft tissues must be considered. The objective of this technique is to intercept the developing malocclusion at an early mixed dentition period so that further malocclusion can be interrupted. Although this procedure does not eliminate the need for comprehensive orthodontic treatment, however, it can lessen the duration of treatment. Treatment can't be avoided for midline diastema, root parallelism,

incisor angulation, and other malalignments. Thus serial extraction helps in rectifying these irregularities to some extent.

Crowns in Pediatric Dentistry: A Review

Sonali Bhuyan[1], Susant Mohanty[2], Antarmayee Panigrahi[3], Mrinali Shukla[1], Sulagna Pradhan[1]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Reader, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University),Bhubaneswar 751003, Odisha, India

Abstract

Dental caries is the most common chronic disease of childhood. To treat such severely destructed teeth is a challenge for most pediatricians because of three important considerations-patient's behavioral management, tooth structure preservation, and satisfaction of parents. Various efforts have been made for full coverage restorations in pediatric dentistry. Every material has its own merits and demerits. Various options available nowadays are stainless steel crowns and its various forms like strip crowns, zirconium crowns, etc.

Keywords: *Crown, Pediatric, Stainless Steel, Caries.*

Introduction

According to the WHO report, 2003 60% to 90% of school children are affected by dental decay in industrialized countries.[1] Nowadays different techniques and method are available for primary teeth restoration. Stainless steel crowns have been used for restoration since 1947 when it was first introduced by Rocky mountain company but familiarized by Humprey and Engel. But they have been recommended where pulp therapy has been performed or where other restorations are likely to fail. Despite all the biggest drawback of stainless steel crown is–poor esthetics.[3] This article aims to discuss the advancements regarding restorations of full coverage in pediatric dentistry.

Pre-Formed Metal Crowns: These were referred to be an acronym of SSC. It was first described by Engel followed by Dr. William Humphrey in 1950.[4] The metal used in preformed crown was soon transformed to nickel-chromium and nowadays also popularly named as preformed metal crown (PMC).

Indications (Use In Deciduous Teeth)[5]: Stainless steel crowns are preferred in these situations as procedures like pulp therapy as a restoration for prevention, extensive decay in primary tooth, as an abutment for a denture or space maintainer in children requiring general anesthesia for dental treatment should be given consideration, in severe bruxism, in rampant and recurrent caries, inherited or acquired enamel defects,as part of a space maintainer. Advantages are durability is similar to that of the deciduous tooth, it protects the remaining tooth structure which was weakened by excessive caries removal, less technique sensitive,cost effective, and has a low failure rate. Disadvantages are Unesthetic due to metallic appearance andcannot be used in partially erupted tooth. Different types of stainless steel crowns according to shape are as follows:

Untrimmed Crowns: These crowns are neither trimmed nor contoured. It is time-consuming and requires a lot of time for adaptation. Example – Rocky mountain.

Pretrimmed Crowns: These crowns have straight, non-contoured sides. These are designed to follow a line parallel to the gingival crest. They still need some trimming and contouring.

Precontoured Crowns: These crowns are festooned and are also pre-contoured, though a minimal amount of festooning and trimming may be required. Example–Ni-Chro Ion crowns and Unitek stainless steel crowns

Open-Faced Stainless Steel Crowns: he crowns which are preformed though are the most reliable and durable restoration for a primary incisor but have poor aesthetics. To take advantage of its strength and to make it attractive, the cosmetically prominent aspect of the crown should be cut away by the dentist, enough of luting cements to be removed and the void is filled with bonded resin composite.[6]

Success of Open Face Stainless Steel Crown is by:

- Using dentin bonding
- Helps bond resin to teeth tissue.

Phosphoric acid etching: A porous and rough structure layer on remaining glass ionomer cement. Holding tags are formed by unfilled resin, and thus bonding occurs.

Advantages: Appearance is a lot more appealing than the plain metallic appearance of the stainless steel crown.

Disadvantages:

- Time-consuming procedure
- Metal margins can still be seen
- Lifespan is short
- Poor color stability under oral conditions.

Preveneered Stainless Steel Crown: Preveneered stainless steel crowns are more appealing because they have the combined effect of the durability of conventional stainless steel crowns and esthetics of composite resin. A variety of mechanical and chemical bonding approaches retain esthetic veneers on stainless steel crowns. Initially, these were developed for primary anterior only but later were also designed for primary molars. Different types of PVSSCs available depend on the use of facing attachment to the SSC, clinicians ability to crimp crown[8],shades available, and crown length.

Advantages: Good esthetics with relatively short operating time. Durability is long. It can be used with ease where moisture condition is difficult.

Disadvantages: PVSCCs have more thickness than conventional SSC due to the addition of resin,which results in more extensive tooth preparation for proper fit and occlusion.[9] It is more expensive so not cost-friendly. Dentists don't have many options on resin shade, so at times supplied crowns look artificial.[9] Crown forms that are tried in,cannot be sterilized under pressure with high heat, as such treatment will destroy the resin layer. These crowns have overly convex appearance so re-shaping is required,which takes additional laboratory or clinical time. Multiple approximating crowns are difficult to place in people with loss of space due to bulk or crowding. Inflexibility and brittleness seen on resin facing material has a tendency of breakage when subjected to heavy force.

Polycarbonate Crowns: In pedodontic practice, most common lesions which occur are due to nursing bottle caries. More severely carious teeth require either composite crowns, stainless steel crowns, or polycarbonate crowns. Polycarbonate crowns are 'temporary crowns given as fixed prosthesis to primary anterior teeth which are likely to get exfoliated in future'. These are linear polyesters of carbonic acids. These are termed as thermoplastic resins as exhibit high impact strength and rigidity and can be molded into solids by pressure and heat into the required form. Esthetically these were appealing but disadvantage being brittle and no resistance against strong abrasive forces.

Polycarbonate Crowns Include:

- 3M ESPE Polycarbonate
- Kudos polycarbonate crowns
- PedoNatural Crowns

Uses: Extensive caries requiring full coverage restorations like nursing bottle syndrome. It can be used in fractured or malformed teeth,in discolored teeth, in teeth requiring restoration after pulpotomy or pulpectomy procedures.

Contra Indications: Bruxism, Deep bite, Abrasion

Zirconia Pediatric Crown: These are crowns made of zirconia and donot contain metal. These are utilized for a variety of computer-aided manufacturing/computer aided design restorations, including framework/ hand veneer,implant abutments, full-contour fixed prosthodontics. Though zirconia is widely being used for permanent dentition but primary dentition it is a new restorative material. Zirconia has demonstrated superior corrosion-resistant, high wear resistance, and excellent biocompatibility. Some of the commercially available pediatric zirconia crowns are: E Z Pedo Crowns, NuSmile Crown, Cheng pediatric crowns, Kinder crowns.

Strip Crowns: Strip crowns were first introduced

in 1979 by Webber et al. These are crown forms filled with composite and are bonded onto the tooth and the crown form is then removed. These are considered to be the most popular and esthetic restorations for deciduous anterior incisors. Although esthetically appealing, but its retention depends on the amount of tooth structure remaining after excavation of caries. This is the first choice of most clinicians as it can be easily repaired if the crown fractures or chips off. This is but technique sensitive.

Figure 1. Strip crowns

Pedo Jacket Crowns: Use of pedo jacket crown is similar to that of celluloid crown form, except for thepedojacket is made up of a tooth-colored copolyester material, which is filled with resin and left on the tooth after polymerization instead of being removed.

Disadvantage: It can neither be contoured nor aligned with a high–speed bur used for finishing as it will cause the material to melt onto the bur[11]. It is available in only one shade, which is very white, so shade matching of correspondent, non-restored tooth is challenging.

New Millenium Crowns: These are similar to pedo jacket crowns only for it constitutes laboratory –an enhanced composite material made of resin and bonded to the tooth. The crowns are esthetic and even can be trimmed and reshaped with a high-speed bur. These crowns are more susceptible to fracture or crack if forced into a preparation that has not been reduced adequately.

Advantage: It is highly esthetic and parenteral satisfaction is high.

Disadvantages: Technique sensitive and for successful treatment, proper isolation, and achievement of hemostasis are required.

Figure 2. Pedo Jacket Crowns

Indications: It can be used in discolored primary incisors. Also indicated in multisurface or extensive caries in deciduous incisors. Fractured incisors following trauma can b restored with these crowns**.** In developmental defects like Amelogenesis imperfect[12], these crowns can be used.

Contra Indications: Not adequate if excavation of caries results in less remaining tooth surface area. Not indicated in impinging deep bite and in the presence of periodontal disease.

Nusmile Crowns: These were introduced in the year 1991[13]. Used when a full-coverage restoration is required for longevity and to protect the remaining tooth structure. They are available in 2 forms Nusmile Signature and Nusmile ZR.

Advantages: These are anatomically correct, color-compatible tooth colors, can be easily placed,less time consuming,less technique sensitive, and durable. It has color stability.

Cheng Crowns: These were developed by Peter Cheng in the year 1982. These are crowns with a facing of pure resin which makes them stain resistant. These can be used for both anterior and posterior teeth. Advantages are less time consuming,less technique sensitive,require a single patient visit,less patient discomfort, and is stain resistant.

Dura Crowns: These preveneered crowns are esthetic and can be placed with poor moisture or hemorrhage control. These are made up of high-density polyethylene veneered crown.

Advantages:

- Facial and lingual surfaces may be crimped.
- Easily festooned
- Easily trimmed
- Full knife-edged margin capabilities

Kinder Crowns: These are known for providing shades that appear natural and good contour for the patient. These were introduced in 1989. Kinder crowns are known for their finely feathered margins, scientifically developed shades, incisal edge. They come as zirconia Kinder crowns or a preveneered Kinder crown and are available for anterior or posterior teeth.

Figure 3. Kindler crowns

Pedopearls: These are aluminum crown forms having a coating of a tooth-colored epoxy paint. These are relatively softer and may cause the epoxy paint to wear off in areas of heavy occlusion. As they are softer can be easily crimped and cut but durability is poor.[14]

Conclusion

This article throws light onto various aspects for restorations of full coverage in pediatric dental practice. There isa wide range of articles and materials to rehabilitate carious lesions but each has its advantages and disadvantages. Research is still going on different crowns and materials to be used for full coverage .clinicians have used these above-mentioned crown for decades with success. The choice of material depends on clinician preference, skill,functional and esthetic needs of the child and parent.

Zygomatic Implants: A Review

Sanchari Sinha Roy[1], Subrat Kumar Padhiary[2], Satyabrata Patnaik[2]

[1]Post Graduate Trainee, [2]Professor, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Zygoma implants (or zygomatic implants) vary from traditional dental implants in that they attach in rather than maxilla (upper jaw) in the zygomatic bone (cheekbone). They can be used where the consistency or quantity of maxillary bone is insufficient for normal dental implant placement. Inadequate maxillary bone volume can be due to bone resorption as well as maxillary sinus pneumatization or a mixture of both. The required bone height for typical implant placement in the upper jaw posterior area should be approximately 10 mm to ensure appropriate implant survival. Where there is inadequate bone available, bone grafting procedures and sinus raising procedures should be done to increase bone volume. Procedures for bone grafting in the jaws have the downside of extended care, limiting denture wear, the morbidity of donor surgical site & graft rejection.

Keywords: *Zygomatic implants, maxillary bone.*

Introduction

People having a chief complaint of the missing tooth are sacrificed in the function of chewing, problems related to speech, esthetic look, and being self-confident in social gatherings. However, this is not something new in this profession. Dentistry is the first oral care professionals to improve from the invention of osseointegration by Per-Ingvar Branemark who was first to place implants inside the oral cavity in the year 1965, has become the genuinely acceptable modality of procedure in patients, who has lost their teeth: implant can be used as a substitute.[1] Modern dentistry aims to reimburse patients' to oral health in a predictable manner. The partial and complete edentulous prosthesis may not be able to recover normal form & function, esthetics, comfort, or speech.[2]

Accessing Quality of Implant: The benchmark for evaluating implant quality is mobility & pain. Probing depths might help to find any local disease or pre-existing thickness of tissue before the implant was inserted. When there is an increase in depth of probing it signifies bone loss, hyperplasia of gingiva, or hypertrophy. Loss of bone is best valued with probing depths than with IOPAR. Implant quality factors were established by Jarnes and modified by Misch in an implant quality scale that not only assesses the implant health-disease but affects the treatment and prognosis of the existing conditions.[2] Due to lack of internal bone (cortical & cancellous) stimulation and non-physiologic crestal bone loading, it causes of an atrophic edentulous maxillae's continuous resorption. The result is not being able to use a conventional full denture prosthesis.[3] A collection of strategies like composite or complex grafting with bone and Le Fort osteotomy to an easy procedure as sinus bone augmentation have a different success rate. Such treatment protocols have a separate surgical treatment and often requires one to two month of healing or even more, before placement of the implant. The substitute for such a stage-wise method requires the **zygomatic implant** invented by Branemark. [4]

The zygoma implant is a length-extended (30–52.5 mm) machined titanium screw which is inserted via the crestal bone(i.e palatal) part of the posterior (resorbed) maxillae trans-antrally inside the compact bone of the zygoma. Moreover, 2 or 4 conventional screws are inserted in the maxillae (anterior part). Starting support of these screws is assured by its contact with four bony cortices (Fig-1).

1. At the crestal ridge.
2. The floor of the maxillary sinus.

3. The sinus roof.
4. The superior border of the zygoma.

It has been reported that the zygoma implant gives posterior maxillary support when the surrounding bony structures don't permit implant insertion. The adjunct to the implant is an augmentation of bone graft (sinus lifts and on-lay grafts) along with the cost of their attendant, dis-comfort, prolonged treatment time, and high chances of complication rate. The zygoma screw is suggestive in instances like:

When the entire maxillary (edentulous) arch is associated with advanced posterior resorption which will need graft otherwise. Two or preferably four anterior implants are required along with both bilateral zygoma implants. In partial or incomplete maxillectomy individuals where more implants might be inserted in other areas i.e pyriform sinus, rims of the orbit, palatal shelves, or pterygoid plates to provide anchorage to cross-arch stabilization. [3]

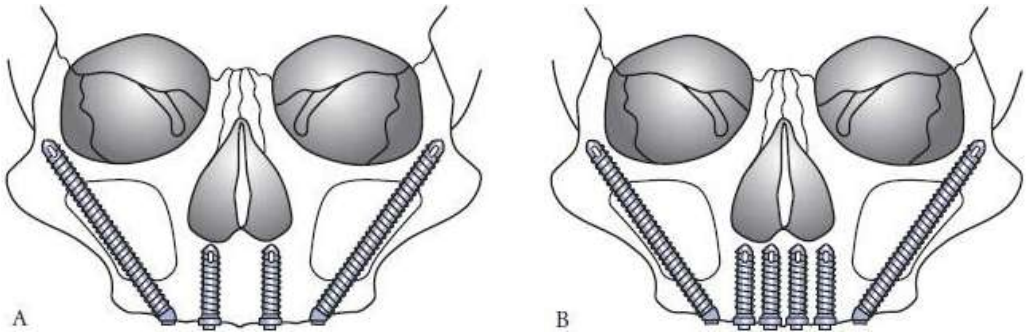

Figure 1A. Pictorial representation of recommended zygoma and standard implant fixtures cross-arch stabilization and fixed restoration. B. Diagramatic representation of zygoma and implant fixtures for restoration with cross-arch stabilization and fixed restoration.

Indications & contra indications: The zygoma implant is usually preferred in candidates having moderate to severe atrophy but it can be thought of as a beneficial choice in patients with or without any significant atrophy, requiring posterior maxillary implant support.

1. Moderate Atrophy.
2. Severe Atrophy.
3. Syndromicpatients e.g ectodermal dysplasia patient presents with partial anodontia.
4. Acquired & congenital defects. E.g cleft palate, rhinectomy usually required after malignant tumors of the nose.[13]
5. Partial edentulism.
6. Immediate loading.

Contra Indications:

1. Any sinus pathology.
2. Systemic diseases.
3. Zygoma implant is not required where there is adequate bone in the maxilla to facilitate implant placement in positions & numbers which can help in retention of a prosthetic appliance.
4. Where there is no enough pre-maxillary bony anchorage, for 2 stable implants with the best potential longevity. The volume and condition of the anterior bone of the maxilla are determining factors on which differential diagnosis often depends rather than existing posterior maxilla whether the edentulous patient may be suitable for this procedure.

Medical Evaluation: Medical history includes those medical conditions most likely to influence implant treatment decisions. The physical examination consists of a hands-on evaluation and recording of the patient's vital signs. The second, section (Laboratory Evaluation) reviews those laboratory tests of interest to implant dentistry. The evaluation includes a complete blood count (CBC), sequential multiple analysis (SMA), and bleeding disorder tests. The third section relates the medical and dental implications of the common systemic diseases found in implant patients, which have the greatest impact on implant dentistry.[5]

Pre-surgical assessment

Both physical and mental stability of the patient is required to withstand the surgical procedure approximately 2 hours long and to endure deep intravenous sedation or general anesthesia. Adequate mandibular range of motion of the patient is needed for proper access while the placement of fixtures 30-52.5 mm long transpalatally in the region of the zygomatic buttress. The placement of the zygoma fixture may be hindered in the presence of opposing mandibular teeth. In the case of deep sedation, local anesthesia in the mandibular arch, as well as in the surgical site itself, is advisable.[6]

Radiographically using an image-guided oral implantology system (IGOIS) is introduced including the framework, 3D-reconstruction, preoperative planning, registration, and the motion tracking algorithm to transfer the preoperative plan precisely. With the help of stereolithography technology, fabrication of the jaw model and a surgical drill guide with skeletal support is done referring to the finalized treatment plan. The main objective is the creation of an individualized drill guide that is suitable for the patient's bone profile. A CAD/CAM program utilizes the contour of the bone and the 3D information of the planned drill course for designing the drill guide. The drill guide is then made by using stereo lithography. Before performing the surgery, and intended simulatory operation is performed on the stereolithographic maxillary model using the surgical drill guides.[7]

Current trends in clinical dental implant therapy involve using endosseous dental implant surfaces embellished with nanoscale topographies. Existing data supporting the role of nanotopography have shown crucial steps in osseointegration can be modulated by nanoscale modification of the implant surface. Nanoscale modification of titanium endosseous implant surfaces can change the cellular and tissue responses that may be beneficial for osseointegration & dental implant procedure.[9]

Surgical Protocol: General anesthesia or deep intravenous sedation offers the best option for the zygoma implant placement surgery. Administration of local anesthesia- maxillary nerve blocks, vestibular infiltration and infiltration or percutaneous blocks laterally and superiorly to the zygomatic notch (just lateral to the orbital rim) should be done. When the surgery is performed with sedation, a bilateral inferior alveolar nerve block can be advantageous as it ensures adequate access because of the significant retraction of the lower lip, tongue, and mandible.[10]

A crestal incision is made in the region of the first molar-second premolar slightly to the palatal aspect of the ridge. It is placed from the right to left maxillary tuberosity regions and bilaterally releasing incisions are given at the incision ends. Sufficient full-thickness mucoperiosteal flap is reflected to expose the lateral maxilla which aids to visualize the zygomatic buttress from the crestal ridge to the superior surface of the zygoma at the zygomatic notch, just lateral to the orbital rim. To avoid tearing of the flap while retracting, the anterior maxilla is exposed till piriform rims, which facilitates the placement of the conventional pre-maxillary implants. A "slot" window is created vertically on the lateral wall of the maxillary sinus in close approximation to the height of the zygomatic buttress.[11] The slot is prepared with a fissure bur, generally a 703 or 702, in a straight surgical handpiece. The prepared slot on the lateral wall of the sinus should be parallel to the planned course of zygoma implant placement which lies just medial to it. The extension of the slot should be from close to the floor of the sinus just superior to the planned site of implant installation to near the sinus roof. The window is prepared by the surgeon for the direct visualization of the implant placement, passing of all drill preparations, and instrumentations. During the slot preparation, the Schneiderian membrane is removed from the sinus wall to facilitate better visualization and to prevent its interference at the time of site preparation and implant installation.[12]

For the incremental preparation of the planned site, a series of long drills are used. The length of the zygoma implant varies from 30 to 52.5 mm. The diameter of alveolar one-third and apical two-thirds is 5 mm and 4 mm, respectively. To enhance the visualization and aid in the position of the surrounding structure, a customized zygoma retractor with a toe-out tip is placed in a position over the zygomatic notch through the entire procedure of slot preparation. There is a midline marker on the retractor parallel to the site preparation which assists in the orientation of the drills in the proper direction. To complete the site preparation, these drills are used sequentially- 2.9 mm diameter long twist drills, 2.9 mm-3.5 mm pilot drill, and 3.5 mm twist drill. Direct visualization of the implant insertion is done through the slot preparation on the lateral wall of the sinus.[12]

Insertion of the implant is done along with substantial irrigation. The implant should be in the same plane as that of the drills during the implant placement to enable the engagement of the implant in the preparation site at the body of the zygomatic bone. On engagement of the apical portion of the implant 2-3mm into the dense zygomatic bone, the handpiece will come to a halt after the adequate preparation of the site. To complete the installation of the implant, a manual driver is employed when the handpiece comes to a stall. Determination of the proper abutment platform angulation is done with the help of the placement of a screwdriver into the screw head of the implant carrier and placing it until the screwdriver becomes perpendicular to the crest. It is then followed-up by the removal of the implant carrier and placement of a cover screw.[13] 2-4 regular platform (Mark III or Mark IV Nobel Biocare) implants are inserted in the pre-maxillary region following the installation of the zygoma implants. Subsequently, repositioning of the flap and suture placement is done. Relief is given in the maxillary denture by making it hollow at the site of implant emergence and relined with the tissue conditioner. The impression of the implant level is made before the closure. This facilitates fabricating a rigid bar which will be placed at the second stage of the surgery around six months later.[14]

Prosthetic Procedure:

Healing Phase: The existing or the provisional maxillary denture can be remodeled for immediate use for preserving the patient's esthetic. Significant limitations may be noted in the case of functional use like alteration in retention or masticatory ability, but an alternative of having teeth through the entire treatment process is usually far more pleasing than the interim periods of no prosthesis that accompanies many graft procedures.[15]

Protective splinting: On combining with splinting and cross-arch stabilization, the strength these implants provide is one of their unique features. If they are utilized or loaded independently, it is perceived that the off-axis load transfer can be pernicious and feasibly ineffective for the maintenance of osseointegration. It is recommended to take some precautionary measures to hinder the independent transfer of the stress from the base of the denture to the implants individually promptly following stage II surgery, or uncovering of all implants with abutment connections. A gold bar measuring around 2 mm in diameter is contoured accordingly so that it's in contact with a set of gold cylinders which are affixed to the abutment analogs on the cast. With the help of a micro-welding device, the soldering of the bar and the cylinders together can be accomplished and the fabrication of passive protective splint can be achieved within a short period. Within the next day usually, the bar splint is delivered and the denture is hollow ground for complete seating without the interference of the bar. An absolutesoftliner can be appliedat this time tothemaxillaryprosthesisfor the enhancement of retention and comfort. If the patient is not wearing a maxillary prosthesis, bar splint may not be necessary but in the case where constant denture wear is advisable, the bar splint protocol should be followed.[4-6]

Final prosthesis construction: After an adequate period of healing, final impressions can be taken which is usually after 3 to 4 weeks. With approved wax-up silicone putty indexes are made which are then used to provide a matrix for creatinga metal bar structure. After the evaluation of passive fit and esthetics in the second try-in appointment, with heat polymerizing resin the prosthesis is processed. Using appropriate screws and screw torques to provide even and complete seating, the delivery is accomplished.[7,8]

Discussion

The complete restoration of the severely atrophied maxilla along with the implant placement is a challenge faced by both the surgeons and the prosthodontists. In the case of exclusive conventional implant placement in this condition, the insertion of the implant requires extensive bone grafting and usually also involves sinus upliftment and onlay grafts with a larger amount of donor's bone. The important considerations are to be taken involve the inconvenience of the patient, prolonged duration of the treatment, potential complications, lower rates of implant success, donor site morbidity, and cost. This is further complicated by the patient's inability to wear a prosthesis for an extended period—a factor that hinders many patients from pursuing the treatment. Avoidance of bone grafts if not indicated, shortened treatment duration, no requirement of the donor sites, and the continuous use of transitional prosthesis by the patient are the perks of zygoma implant rehabilitation. As a result, greater patient compliance is achieved while furnishing the patient with a stable, well-tolerated, and esthetically accepted removable or fixed prosthesis at the time of treatment completion.[11-15]

The benefits for the consideration of the zygoma implant include the following:

1. Reduced or entire elimination of the donor site morbidity.
2. Markedly reduced or eliminated the treatment duration.
3. Survival of the bone grafts and consolidations are into considerations.
4. Reduced the total number of implants to support the prosthesis.
5. Relatively economical mode of treatment and less invasive than other alternatives.

The disadvantages include the following:

1. It's a demanding surgery— well trained technical skills are required. Experts capable of dealing with any surgical situation or complications that might arise should perform the surgery.
2. The risk to injure adjacent structures- orbital contents, orbit, lacrimal apparatus, infraorbital nerve, the facial nerve.
3. Chances of postoperative sinusitis, although relatively less than with the sinus liftprocedures.
4. Failure of the fixtures—although it is rare, more difficult to retreat the access. General anesthesia or deep sedation is required as with all properly planned and executed implant prosthetic surgery, it also requires extensive coordination between the surgeon and the prosthodontist before commencing the treatment.

Ideally, at the time of surgery, the prosthodontist should be available. Similarly, the prosthetic requirements andtechniques of fixture positioning and final restoration should be familiarized by the surgeon. Finally, the important steps of the procedure and its ultimate success include education of the patient, preparation, assessment, and informed consent. Before initiating treatment, patient understanding should include the need for meticulous oral hygiene and maintenance. Proper understanding and appropriate use of the zygoma implant, provides an alternative for several patients with atrophic edentulous maxillae.[11-15]

In conclusion, we recommend zygoma implants in the atrophied edentulous maxilla for the following reasons-

1. The rate of successful osseointegration is greater than 96% for the zygoma implant.
2. Decreased surgical interventions for the patients.
3. Does not require bone harvesting or grafting as a necessity.
4. Decreased overall operating and working time for the surgeon.
5. The surgery of a zygoma implant can be accomplished within the office setting.
6. Precise placement of the zygoma implant platform on the crest of the maxillary ridge permits the access screw hole of the zygomaimplant to surface in the central groove of the first molar.
7. There is no requirement for any angled or custom made abutments in the final restoration.
8. No additional restorative dental or laboratory time is required in comparison to the traditional implant techniques.
9. The entire laboratory and prosthetic charges for the zygoma implant rehabilitation are comparatively equal to or less than conventional implants.
10. Relatively the expense of zygoma implant therapy is quite economical than the grafting procedure for the patient.

Platelet-Rich Fibrin: An Update

Prachi Khuntia[1], Rashmita Nayak[2], Saurav Panda[3], Abhaya Chandra Das[3], RinkeeMohanty[4], Sharmistha Das[1]

[1]Post-Graduate Trainee, [2]Professor, [3]Reader, [4]Professor & Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

The development of bioactive surgical additives to regulate the inflammation and increase the speed of the healing process is one of the great challenges in clinical research. In this sense, platelet-rich fibrin (PRF) appears as a natural and satisfactory alternative with favorable results and low risks. The following review attempts to summarize the relevant literature regarding the technique of using PRF, focusing on its preparation, advantages, and disadvantages of using it in clinical applications and its updates. PRF alone or in combination with other biomaterials seems to have several advantages and indications both for medicine and dentistry, due it is a minimally invasive technique with low risks and satisfactory clinical results.

Keywords: *Blood Platelet; Fibrin; Platelet-Rich Fibrin; Hard Tissue Regeneration; Soft Tissue Regeneration.*

Introduction

Platelets are generally produced in the bone marrow by the megakaryocytes and their sizes vary from 2–3 μm in diameter. They are consists of several granules, mitochondria, and canalicularsystem. The re is also another structure known as theα granules which are oval or round in shapes with diameter 200 to 500 nm which is covered by a membrane (Figure 1 : Platelet). These create a mass storage of proteins that are vital for wound healing, including platelet-derived growth factor (PDGF), transforming growth factor (TGFb), and several others. The fusion of αgranulewith the platelet cell membrane occurs after activation. This again leads to the formation of bioactive proteins. Then these proteins allow them to bind with the target membrane or cells. After the attachment, intracellular signal proteins are activated. This ultimately creates a gene expression sequence which leads to cell multiplication, collagen synthesis, and new cell production.[1]

Figure 2 : Platelet Concentrates

Platelet Concentrates: PRF was first introduced by Ross et al in 1974 and it was also discovered that there are presence of several growth factors in PRF (Figure 2 : Platelet concentrates).Platelets play an important role in both the bleeding control and wound healing. From the early 90s, there are discoveries regarding numerous blood-related growth factors which can accelerate the wound healing procedure.[1]

Classification[1]:

1st Generation–PRP (Depending on the presence or absence of leukocytes and the activation or not of the PRP) Mishra et al, 2009

- Type 1, PRP is a L-PRP solution
- Type 2, PRP is a L-PRP gel
- Type 3, PRP is a P-PRP solution
- Type 4, PRP is a P-PRP gel

2nd Generation–PRF (Based on their fibrin architecture and cell content) Dohan Ehrenfest 2009

- Leukocyte poor or pure platelet-rich fibrin (P-PRF)
- Leukocyte and platelet-rich fibrin (L-PRF)-Choukroun's PRF
- Leukocyte poor or pure platelet-rich plasma (P-PRP)
- Leukocyte & platelet-rich plasma (L-PRP)

History of Platelet Concentrates:

Fibrin sealants: It was first available in the market since the late 1970s in Europe. Fibrin sealants or 'fibrin glues' are derivatives of plasma which helps in the blood coagulation process by the formation of a fibrin clot. The y are currently used as topical hemostaticagents. Widely used for flap closure in aestheticzones. As there is enhanced risk in cross-infection, nowadays tissue sealants are produced from the patient's plasma.[2]

Pure PRP or Leucocyte-Poor PRP: This is prepared without the addition of leukocytes, it results in low-density fibrin clot.[2]

Leucocyte-Rich Fibrin and Pr: Products are preparations with leucocytes and with a high-density fibrin network.[2]

Pure Prf or Leucocyte-Poor Prf: Preparations are without leucocytes and with a high-density fibrin network. Unlike pure PRP or PRP containing leukocytes, these products cannot be injected and exist in an activated gel form.[2]

Leucocyte-Rich Fibrin and Prf: Products are preparations with leucocytes and with a high-density fibrin network.[2]

Leukocyte and platelet-rich fibrin (l-prf)-choukroun'sprf

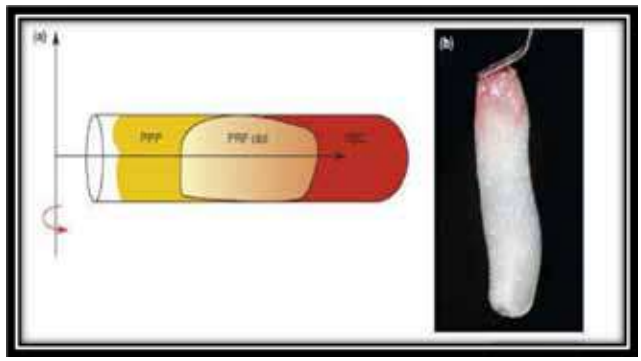

Figure 3 : Choukroun's Prf

PRF was first introduced by Choukroun et al, 2001 (Figure 3 :Choukroun'sPRF).

The procedure of making PRF uses neither anticoagulant nor bovine thrombin.[4]

Prf Protocol: Choukroun et al. in France produced the PRF by taking up venous blood (around 5 ml) in 2 test tubes without any addition of anticoagulant and the tubes are then centrifuged at 3,000 rpm, (approx. 400g) for 10 min, which creates 3 distinct layers.[4]Upper straw-colored acellular plasma, red-colored lower fraction containing red blood cells (RBCs), and the middle

fraction containing the fibrin clot. The upper straw-colored layer is discarded and the middle fraction is collected, which is PRF.[4] (Figure 4 : L-PRF)

Antimicrobial Property of Prf: An in vitro study, it was found that i-PRF has maximum antimicrobial efficacy rather than any other platelet preparations because of its high platelet count.[9]

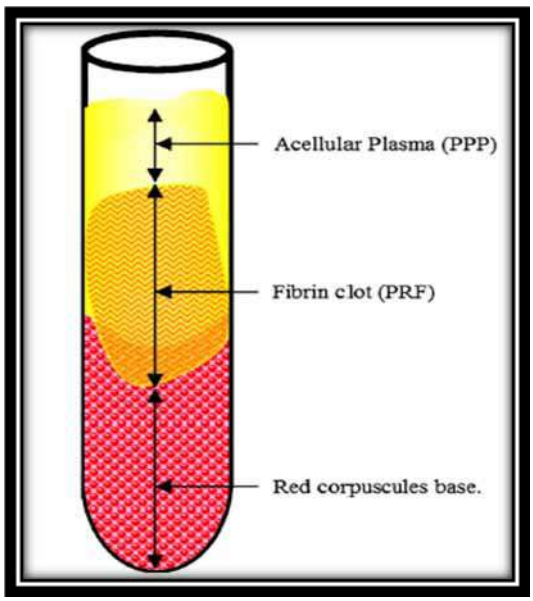

Figure 4 : L-PRF

Importance of Various Parameters for Centrifugation:

Relative centrifugal force, Radius of centrifuge and Rotation per minute: Various authors have reported centrifugal g-force at the PRF clot (referred to as relative centrifugal force (RCF)-clot – location at which the PRF clot is formed), whereas others have utilized the international standard method to report g-force calculated at the bottom of centrifugation tubes (RCF-max).[6]

Biological Differences of Platelet-Rich Fibrin Clots Based on Centrifugation Parameters[6]: PRF clots fabricated at lower centrifugation speeds and times improve growth factorrelease and cellular behavior owing to higher cellular content and growth factor accumulation. PRF clots fabricated at lower centrifugation speeds and times are smaller in size, however, contain more platelets and leukocytes, as well as with more growth factor release. The g-force calculated at the fibrin clot (RCF-clot) is subject to change owing to the centrifugation time – even when centrifuged at the same speed. For these reasons, this method of reporting g-force is inferior in accuracy and not commonly reported internationally. The g-force calculated at the end of the centrifugation tubes (RCF-max) is not subject to these differences – hence, why it is internationally utilized to report g-forces.

PRF Box:

Figure 5 : PRF Box

Figure 6 : PRF Box with PRF

The PRF Box (Process Ltd., Nice, France) is commercially available to prepare the PRF membrane. The PRF clot is placed on the grid in the PRF box and covered with compressor lid which squeezes out the fluid from the clot (Figure 5 : Prf Box). The membranes formed using this method had constant thickness which remain hydrated for several hours and have recovered the serum exudate expressed from the fibrin clots.[4] (Figure 6 : Prf Box with PRF).

Application of PRF:

Socket preservation in case of tooth extraction: A study was performed to check the efficacy of PRF in extraction sockets andthat study showed faster-wound healing, bone regeneration along with the high-density bone formation.[12]

L-PRF block for bone augmentation procedure: The L-PRF block seems a successful new protocol for horizontal alveolar bone augmentation. This procedure is safe, predictable, with a high feasibility and a low morbidity.[7]

L-PRF in intrabony defects: The use of PRF as the sole grafting material seems to be an effective modality of regenerative treatmentfor periodontal intrabony defects at 6 months after the surgery.Greater reduction in pocket depth, more gain in clinical attachment level and greater intrabony defect fill at sites treated with PRF than those treated with open flap debridement alone.[14]

L-PRF in furcation defects: PRF has shown good results in reducing probing depth, improved clinical attachment level, and defect fill. Also, it was proven as an effective regenerative material for treating class II furcation defects.[15]

PRF as a Barrier Membrane in Guided Bone Regeneration: The use of PRF has popularity because it's biological scaffold capable of improving tissue healing. It is always advised to place PRF membranes over-top of the collagen barrier membranes. In this way, PRF membranes can be utilized to speed defect closure, improve soft-tissue wound healing/regeneration, and further bear the added defense component from pathogen-fighting leukocytes capable of significantly reducing the rate of infection and complication.[5]

L-PRF in fenestration and dehiscence: Guided tissue regeneration in combination with platelet-rich fibrin can successfully be used to treat fenestrated root apices. Satisfactory healing of the gingival fenestration defect with excellent color, texture match with the surrounding area along with the keratinized tissue formation emphasizing the importance of using PRF as a membrane in esthetically demanding areas.[16]

L-PRF application in delayed implant placement: A study showed that PRF may improve the post-insertion stability of dental implants during the time of healing.[17]

L-PRF in implant placed in sinus lift: It was seen that sinus floor elevation can be done by PRF placement alone as a regenerative material. The potential clinical implications for this inexpensive and autologous material are promising. Treatment approach with PRF was effectuation active in treatingthe peri-implant defects.[18]

L-PRF in wound healing: The use of PRF in a case of delayed and complicated healing following subepithelial connective tissue graft harvest action has proved to be effective in reducing donor site morbidity of free gingival grafts.[13]

Figure 7: Titanium-PRF

Titanium-PRF[3]: A new method for the formation of L-PRF was introduced in which normal test tubes are replaced by titanium test tubes which can omit the silica particles from dry glass. This new formulation is known as T-PRF which is a modified PRF. The material itself forms an adhesive oxide layer and quite popular because of its enhanced property of osseointegration in dental implants (Figure 7 : Titanium-PRF)

Usage of different materials for blood processing during PRF preparation[3]: Tunali & co-workers used medical-grade titanium tubes to produce PRF and called it T-PRF. On examination, it was observed that T-PRF samples have more organized structure and integrity compared to the L-PRF samples. Reddy et al, 2018 concluded that T-PRF helped in the treatment of intrabony defects by showing radiographic defect fill.

Advanced PRF[10]: For creating A-PRF, slow speed(1500 rpm) for a longer duration (14 mins) is used in vacuum sterile glass tubes. Enhanced B- & T-lymphocyte entrapment, more even distribution of platelets, neutrophils. The number of platelets is significantly more in A-PRF and is better deployment of resident monocyte, macrophages, and lymphocytes. Clinically, this would be beneficial as it would translate into an increased amount of growth factor and cytokine release. Pinto & co-workers demonstrated that A-PRF protocol produced lighter, shorter, narrower clots with

light polymerization and more squashed bodies. A-PRF application has proven more effective than PRF for reduction of probing depth,CAL as well as increasing bone fill.

Advanced PRF + (A-PRF+)[19]: Fujioka- Kobayashi & co-workers in 2016 formulated this combination by reducing both RPM and centrifugation time (1300 rpm for 8 minutes). The authors argued that decreased centrifugation time would lead to the production of more viable platelets in the PRF matrix. When they assessed the PRF produced by this protocol to L-PRF and A-PRF in terms of growth factor release, biocompatibility & cellular activity, they observed that A-PRF+ demonstrated the highest release of PDGF, TGF- β1, EGF and IGF. Also, in culture, gingival fibroblasts exposed to A-PRF+ revealed significantly higher levels of PDGF, TGF-b, and collagen-1 at three and seven days measured in terms of mRNA expression.

Injectable PRF (I-PRF)[19]: Injectable PRF (i-PRF) formulation is one of the recent development. For producing i-PRF, blood-filled test tubes without anticoagulants are centrifuged 700 rpm (60 g) for 3 minutes. Another set of authors has proposed a similar protocol where they centrifuge plain blood in non-coated test tubes at 2400-2700 rpm for around 2 minutes. The supernatant is collected and they have named it concentrated growth factors (GCF).Used along with bone grafts for regenerative purposes as it forms a gel-like consistency. Mixing the bone graft with i-PRF also gives the benefit of growth factor release at the recipient site. It was also seen that by mixing PRF clot, i-PRF and bone graft combination has shown improved efficacy in regeneration.

PRF Lysate: A novel preparation of PRF based products is the PRF lysate. In this, after PRF preparation, it is incubated at 37°C in a humidified atmosphere of 5% CO2/95% air and the exudate thus collected has been referred to as PRF lysate.[19]

Current Updates (Recent Studies Carried Out by Different Authors): Miron et al in 2019 revealed a new method for the preparation of PRF, rather than using normal centrifugation technique, a horizontal method is used which can result in higher platelets/leukocytes. The y have also shown a 10 fold increase in the platelets and leucocyte count by utilizing only 0.3–0.5 mL of sample. Tsujino et al, 2019 suggested that tube types and centrifugal speeds affect the types of growth factors that are released over the periodand the retention of those factors in the periodontal defect. Along with that, they also added that even though silica-coated testtubes are easily available, they should not be used to avoid health hazards. Wang et al, 2019 showed that combining L-PRF with bone marrow stem cells has the potential to replace the normal human bone structure.

Conclusion

PRF as a biologic surgical additive has been successfully used for varied applications in dentistry. Technological advancements in the field of PRF have paved the way for the versatility in the applications of the platelet concentrates. Therefore, in the future, more advances can be expected in the field of PRF which will be beneficial in different aspects.

Combating Risks in Dentistry During Covid-19 Pandemic

Sukanya Mishra[1], Manoj Kumar[2]

[1]Post Graduate Trainee, [2]Associate Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha "O" Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

The year 2019- 2020 has given rise to a menace in the form of Corona Virus Disease, which within no time has turned into a pandemic, affecting every corner of the world. It has disarranged the day-to-day lifestyle of the society, economy, employment, trade, hunger, etc. Dentistry is also one of these, affected by the pandemic, and has caused heavy financial loss for the dental personnel, along with delay/halt in the dental treatment to a massive population in need. When eradicating the disease has become a question, it is better to live with the disease and restrain the risks of transmission in the dental operatory by following few crucial and mandatory steps like proper hand hygiene, maintaining social distancing, creating awareness, fumigating the operating rooms and surfaces etc. This review article thus elaborates the expedients a dental surgeon should follow to combat the risks of transmission of this fierce disease during dental interventions.

Keywords: *COVID-19, Dentistry, Infection, Transmission, Risk.*

Introduction

Coronavirus disease is caused by a new type of virus SARS-CoV-2 i.e. severe acute respiratory syndrome coronavirus 2 which, as the doctors evince, can trigger infection of the upper respiratory tract (sinuses, nose, and throat) and lower respiratory tract (trachea and lungs) as well.[1] It is also namedas COVID-19 owning the full form–Corona Virus Disease, 2019. It is declared a worldwide emergency/the global pandemic by the World Health Organization (WHO). Alike SARS-COV, SARS -COV-2 also uses the same host receptor, namely human angiotensin-converting enzyme 2 (ACE2).[2]

Signs and Symptoms[3]: On an average, the patient becomes symptomatic after 5-6 days of infection from the virus, to manifest it might require up to 14 days too. These are, fever, dry cough, tiredness, which are the most common symptoms of all. Less common symptoms are aches and pains, sore throat, diarrhoea,headache, a rash on skin, conjunctivitis, loss of taste or smell. And the serious symptoms being, "difficulty in breathing or shortness of breath, pain in the chest, loss of speech or movement."

Coronavirus and Dentistry: The COVID-19 virus spreads via droplet transmission, especially from person's cough or sneeze. Transmission can be through:

Direct Contact: When an individual is in close contact, i.e. within around 1 metre with COVID-19 patient, and the patient has not covered their face when coughing or sneezing.

Indirect Contact- surfaces and clothes act as reservoir for the infected droplets. Therefore, touching the infected surfaces and applying those hands on the eyes, mouth and nose, can transmit the disease.

For human-to-human transmission, saliva plays a crucial role. Aerosols can, hence, be a source of transmission for dentists, and they may unknowingly get exposed, especially when patients are in incubation period of Covid-19 or choose to not reveal that he/she is

e-mail: manojkumar@soa.ac.in

positive.[4] Of all the procedures, scaling and handpiece-based procedures are the ones generates highest droplets or aerosols, putting the operator at maximum risk.[5]Moreover, the characteristics of the dental clinical setup and basic measures followed to prevent cross contamination with infection are not adequate to stop the transmission of Covid-19.

Prevention of Transmission:

Hand Hygiene[6]: It is considered as the most compelling procedure, one should inculcate in its habits, to decrease the transmission risk of the microorganism. This reinforcement is due to, as stated earlier, SARS-CoV-2 persists for few hours lasting till several days on the surfaces. The persistence although depends on the humidity as well as temperature of the environment and the texture of the surface.[7] Hand hygiene is taken care of by using hand washing and hand sanitizing measures.

Procedure of hand washing: This should be done for around 20-30 seconds.

Wet hands using water

↓

Scrub the hand properly with soap

↓

Rub the hands palm-to-palm.

↓

Interlace fingers by keeping right palm over left hand's dorsum and vice versa.

↓

Following this, rub by interlacing fingers palm-to-palm.

↓

Rub the backs of fingers to the opposing palms with fingers interlocked.

↓

Rub the left thumb in rotational motion with the right palm and vice-versa.

↓

Following this, continue rotational rubbing, backwards and forwards with clasped fingers of right hand in left palm and vice-versa.

↓

Rinse hands in running water.

↓

Close the tap using the elbow.

Hand sanitization–Effective, Rub-in hand disinfectant with composition of propanol and ethyl-hexadecyl-dimethyl ammonium ethyl sulphate, commercially available as **Sterillium** can be used. Hygienic Hand Disinfection: Rub Sterillium well over clean, dry hands and nail grooves for 30 seconds.Surgical Hand Disinfection: Rub Sterillium well over clean, dry hands, grooves and up to elbows for 3 minutes.[8]

Personal Protective Equipment (PPE)[9]: This includes gloves, masks,protective gowns and goggles as well as face shields. This provides a protective canopy to the skin and mucosa from infected blood and droplet secretions. The respiratory route is the primary mode of transmission and hence and N-95 mask or other masks with particulate respirators are recommended for daily practice in dental operatory.[10] The maximum limit to which the PPE can be worn is 6 hours and apart from the operating instruments and surfaces, nothing else should be touched.[11] The equipment should be changed after every patient/procedure.

Social Distancing: The front office staffs in the waiting room area should maintain as much distance possible, with the patients. The payment procedures, consent form fill-up, feedbacks etc should be done digitally. Apart from this, the seating arrangement in the waiting area be such that at least 3 feet/1 metre distance should be maintained between everyone. Masks should be made mandatory. Care should be taken to not keep more people waiting and provide them appointments for the next day, to avoid the room from getting congested.[12] Avoid touching other persons, like handshaking, shoulder tapping etc., as much as possible.

Operatory Asepsis: operatory surfaces that are repeatedly soiled are best protected with disposable covers (barriers), that can be discarded after each treatment.

For"dental unit trays, paper, plastic film or surgical pack wraps (paper or towels) should cover the entire tray."[13]It is better to minimize or avoid the procedures that produces aerosols and if not, use of high-speed ejector should be done. Anti- reflux equipped handpieces can also decrease the cross-contamination.

Waiting Room Sanitization: Each surface that comes in touch of the infected person/operator, say for example magazine, chairs, doorknobs, tables etc., is a potentially infection risk surface. It is therefore crucial to use alcoholic disinfectants frequently, to sanitize the surfaces along with the air conditioning system.

Unit Dose Concept: Unit dose concept was introduced with purpose to minimize cross contamination. It basically refers to dispensing of amount of materials sufficient to accomplish a procedure, prior to patient contact.[14]

Patient Awareness: No measures taken can be fruitful, if the patients themselves are not aware of the seriousness of the disease. Hence, initiatives can be taken by the dentists to clue-up the patients about the disease, its harm, steps to prevent it from spreading to others and themselves. Advertisements, leaflets, projecting videos, coaching them with hand washing techniques and hand sanitizing techniques etc. are the few ways to develop awareness. It is also important to provide patients oral hygiene instructions and educate them the importance of proper and regular brushing as well as flossing, and balanced diet, so as to avoid the oral diseases from developing and the need to run to a dentist.

Patient Management During Covid-19 Crisis: During the outbreak of COVID-19, emergency procedures should be considered for treatment, ensuring limit of contact between the individuals. However, this cannot go on for long and there is a need to restore the normalcy and keep the work in progress. Therefore, in response to ethical decision-making process for treatments, the interventions in dentistry can be divided into categories:

Emergency Interventions: Fatal conditions that needs immediate treatment can be ruled out by managing with minimally invasive procedures and along with least/ no aerosol production. Uncontrolled bleeding, facial bone trauma, compromising the patient's airway, cellulitis or a diffuse soft-tissue bacterial infection with intra-oral or extra-oral swelling that potentially compromises the patient's airway comes under emergency category.

Urgent interventions: "Severe dental pain from pulpal inflammation, biopsy, pericoronitis or pain in the third molar, tooth fracture resulting in pain or causing soft tissue trauma, avulsion/luxation surgical post-operative osteitis, dry socket dressing, abscess, or localized bacterial infection resulting in localized pain and swelling, dental treatment required prior to critical medical procedures, gingival irritation, comes under this category." Here too, attempt should be made to complete the procedure in one or least number of appointments with least generation of aerosols.

Non-urgent interventions- These are the elective procedures and can be postponed according to the need of the hour or treatment can be provided to minimum number of patients to decrease the exposure risk. This includes, general oral examinations, recall appointments, routine scaling and root planing, preventive restorations, orthodontic procedures, treatment of asymptomatic teeth, or any aesthetic dental procedure.

To curb the risk of cross- contamination, disposable devices and instrumentation can be made use of. The load of virus in the saliva of the patient can be reduced by providing prophylactic mouth rinse of 0.23% povidone-iodine, for 15 seconds before any procedure.[15]

Rubber dam isolation can also be used to check the spread of microorganisms.[16]

Although not feasible, extraoral radiographs in place of intraoral, can be taken to reduce salivation and transmission risk.

It is advised not to prescribe Ibuprofen for pain management in suspected/confirmed cases of COVID-19, though strong reason is not yet specified.[17]

Also, it is important to follow procedures like temperature scrutiny of the patients along with strict protocols should be followed, making it mandatory to use masks and sanitizer by every visiting patient.

Conclusion

The fundamental of treatment of COVID-19 is to follow containment measures. This is how in the countries like China and South Korea, there is an exponential decrease in the development ofnew cases. Till the pandemic is under control, it is merely possible to avoid providing dental treatments, specifically keeping in mind the ethical and financial issues. Therefore, dental personnel can act according to the above-mentioned steps and decrease the risks of COVID-19 transmission. Also, for vulnerable age groups like older adults and paediatric patients, new guidelines should be imposed as soon as possible, for their management.

Liquid Biopsy: A Tool for Detecting and Monitoring Oral Carcinoma

K. Laxmi Sushmita

Postgraduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral squamous cell carcinoma is frequently occurring malignant tumour of the H & N (head and neck) region; with a rising oral cancer burden despite attempts of prevention, delay in diagnosis leads to loco-regional spread and poor prognosis. Hence there is an utmost need for biomarkers which could lead to early diagnosis of oral carcinoma. In the quest for innovative and early diagnostic aid, liquid biopsy is evolving as animportant tool in diagnostic oncology. A liquid biopsy also called a dynamic biopsy or fluid phase biopsy is a non-invasive analysis of non-solid biological tissue predominantly blood. Malignant tumours release different biomolecules into body fluids that have the potential to be used as biomarkers for diagnosis, prognosis, and therapy selection. As the clinical application of Circulating tumour DNA (ctDNA), circulating tumour cells (CTCs), & exosomal miRNAs are quite significant they have acknowledged colossal attention have acknowledged gigantic consideration. Evaluation of the circulating biomarkers has made it easy for unique therapeutic methodologies and meticulous medicine. An increasing amount of studies have indicated that application of these biomarkers intended for detecting, therapeutic scheduling, reaction observing and prognosis management. Even though these novel biomarkers can deliver widespread series of conceivable clinical applications yet there arenot any authenticated circulating biomarkers which have been unified into the clinical practice for oral carcinomas. This article is a brief review of the various biomarkers used in liquid biopsy as well as about tumour educated platelets.

Keywords: *circulating tumour DNA (ctDNA), circulating tumour cells (CTCs), Exosomes. Next-generation sequencing, tetraspanins.*

Introduction

Liquid biopsy is a potential revolution in the carcinoma diagnostics which not only helps in detecting the tumour but also monitors the progression of the disease. As a result of the novel biotechnologies and diagnostic potential, it has emphasized the restrictions of present sampling method; out-dated biopsies and minor operating techniques are invasive, indicted with impending problems, occasionally cannot be repeated and executed when clinical circumstances have deteriorated or when a tumour is unreachable. Additionally, the genomic profile of biopsy tissues delivers a tumour profile restricted to a particular period, and may also show the genetic heterogeneity of manytumouralsubclones. These boundaries of the standard technique of biopsy are quite evident in monitoring the evolution of the ailment during follow up. Because of these drawbacks in currentages, the research is being focussed more on the cells that are circulating in the blood which not only helps us in knowing the location of cancer but helps use in monitoring the progression of the disease.Circulating cell-free DNA fragments get separated from apoptotic or necrotic cancer cells are labelled as circulating tumour

DNA and exosome specifically, these are encapsulated subcellular structures which contain proteins and nucleic acids released by tumour cells.

Liquid biopsy mainly focuses on the segregation of these tumour cells from the peripheral blood smear. The insufficiency of nucleic acid, as well as difficulty in differentiating among normal and tumour nucleic acids, have been overcome by using next-generation sequencing techniques, which helps in precisely detecting the genetic and epigenetic aberrations. It presently offers high specificity, permitting the assemblage of healthy and reproducible data in a simple and non-invasive way by a blood sample. Even now in 21st-century liquid biopsy procedure is not carried out routinely.

Reasons for opting liquid biopsy:

Following are the reasons for considering liquid biopsy over the standard method of biopsies:

1. It aids in understanding the spatial and temporal heterogeneity of cancer.
2. Necessitates less quantity of blood to carry out the investigation
3. It is minimally invasive
4. Helps in quickrecognition of cancer.
5. Actual time observing for therapeuticreactions and resistance could be performed by repeated analysis
6. Shorter turnaround time for genotyping.

Why not tissue biopsy?: It is invasive, lacks representation of the complete variety of malignant clones, multiple sampling is not feasible and despite all these drawbacks, it is still the gold standard in understanding the characteristics of the tumour.

Circulating Tumour Cells (CTCs): There has been tremendous development in isolating the tumour DNA from the heterogeneous components of blood due to the advancements in biotechnological applications since it was first discovered in 1869. Circulating tumour cellsget separated from primary or secondary tumour sites; they circulate in the blood and are accountable for distant metastasis. CTCs are quite rare and occur at a very low frequency like 1CTC per 10^6 -10^7 leukocytes in the initial stage of diseases. CTCs have irregular morphology & they can differ according to cancer type and stage. Circulating tumour cellscan form anaggregate with primarytumour cells or with fibroblasts, leukocytes, endothelial cells or platelets, with more susceptibility to cause distant metastases.

The key dissimilarities are their outsized size up to 20-30 μm, mechanical plasticity, and dielectric mobility properties in comparison to the blood cells. Successful techniques of isolation are membrane filtration, density gradient stratification dielectric mobility, photo-acoustic & microfluidic separation.[1, 2]. The principal documented function of CTCs is in prognosis; in advancing tumours, scientists have found that the total number of CTCs in a 7.5ml blood sample is expressively related by the prognosis, with a precise cut off value. Cristofanilli et al reported "in metastatic breast cancer the patients with more than 5 CTCs in 7.5ml blood have shorter progression-free survival and overall survival compared with patients with a lesser count".[6] CTCs significantly provide information related to the epigenetic changes occurring in tumour cells. DNA methylation in liquid biopsy has proved to be a prospective biomarker for staging, prognosis.[7]

Circulating Tumour DNA: Mandel and Metais (1948) gave their principal experimental confirmation of cfDNA in blood.It took nearly 3 decades for its application in carcinomas when Leon et al proved that the circulating tumour DNA levels have increased in the pancreatic cancer patients.Till date, various mechanisms regarding how the ctDNAis entering the blood have been hypothesized. In physiological circumstances, circulating free DNA are separated from the apoptotic and necrotic cells by phagocytosis by macrophages and scavenger cells [9,8] in addition tothey can be released by the living cells. In a healthy human being the concentration of plasma cfDNA ranges from < 10ng/ml to> 100ng/ml with a half-life of between 0.16hrs and 2.5hrs. Normal physiological situations such as inflammation, trauma, or exhaustive exercise can also lead to the release of cfDNA but the DNA which are released due to tumour tend to have large fragments as there occurs irregular digestion leading to the formation of DNA fragments with large kilobasepairs.

Exosomes: Exosomes are nano-sized vesicles discharged by cells and evident in the body fluids, such as plasma, urine, saliva or ascites. The se are dissimilar from the extracellular vesicles which usually get separated directly from the cell membrane, likemicrovesicles (50-1000nm in length)apoptotic bodies, exosomes are the last product of the recycling endosomal pathways and originate from intrinsic budding of the plasma

membrane[10]. However, they were formerly regarded as cellular discarded products it is now documenteda key role where they act in intercellular communication reliant on the cargo of functional molecules from donor to distant cells. Many studies have shown that these cells are involved in cancer progression and metstatization. After getting separated from cancer these cells encourage EMT and affect propagation, relocation and attack of tumour cells as well as are supportive to the angiogenesis and institute an immunosuppressive milieu[16].

Exosomes are evolving as an original chemo-resistance mechanism, chieflyreliant on drug liberation throughvesicle budding, nullification of antibody-based drugs, and exosomes arbitratedtransfer of micro RNAs (miRNA).[15]Exosomes containa lipid bilayer which encompassesboth trans-membrane and non-membrane proteins, as well as noncoding RNAs, mRNAs, and either ss or ds DNA[14]. Concerning proteomic analyses, Exosomes are categorised through a preservedset of proteins autonomous of their cellular origins, such as CD63, CD81, and CD9 tetraspanins.[10] Nevertheless, the protein configuration of exosomes coarselybear a resemblance to originating cells, thereforesignifying an exosomal cell-type or tissue-specific signature.[12] It has been established that definite RNA transcripts are augmented up to 100 times in exosomes paralleled by the donor cells, therefore backing up active packaging.[11] Various procedures are established to resourcefully gatherexosomes from bodily fluids. The present protocols follow the vesicle detachment concerning the biophysical characteristics, which includes the dimension, morphology and density, whereas others are based on the immune-affinity captured.[16,3] Till now the regularly followed protocol adopts series of centrifugations with an increase in speed to eliminate cellular debris and greater plasma membrane-derived vesicles, following this procedure is the sedimentation of EXOs by ultracentrifugation.

Tumour educated platelets: This is the newer concept that is being considered in liquid biopsy. Platelets are not educated by the tumour but they form the first cell type that interacts with a tumour which leads to change in their mRNA profile. Since platelets are available abundantly in the blood it does not need high sensitisation techniques to isolate them in comparison to the circulating tumour DNA or exosomes.

In the last decade, there was much appreciation for the involvement of platelets to the immune system of the body in health and certain diseases including cancer too.[4] They are regarded as "scanning soldiers" of the immune system, in that way detecting the existence of bacteria inflowing the bloodstream, lymphocyte cross-communication, and then regulating immune cell extravasation [14]. In cancer patients, the platelets function on tumour resident cancer cells as well as the tumour cells that have entered the bloodstream. Initially, platelets generate an environment supporting the neovascularisation by providing the tumour with various pro-angiogenic factors like VEGF, PDGF and b-FGF and stimulates expression of the factors[15]. Then, platelets reduce the apoptosis of tumour cell and anoikis and induce the switch of epithelial mesenchyme in tumour cell with direct physical interaction and discharges of TGFb molecules[17].Consequently, a significant contribution to the metastatic process is done by the capacity of platelets to safeguard tumour cells in motion from the normal immune response.

Then, there is the formation of a cell fibrin platelet aggregation encircling the CTCs which provides mechanical protection, and it transmits major histocompatibility complex class I to CTCs, which results in supplementary safeguardin contradiction of natural killer cells. Current lab-on-a-chip microfluidic methodexaminationdiscovered the occurrence of animpending CTC sub-population with heightened platelet coverage and perhaps platelet-mediated defence. On activation, platelets can discharge numerous growth and pro-angiogenic issues[3], and after these issues are unconfined at a metastatic niche, a tumour-stimulating growth microenvironment is generated[4] Therefore, platelets are an essential constituent of the tumour microenvironment and are deliberated asignificantfeature of oncology as they contribute to tumour initiation, tumour progression, and therapy response. Attention has been rehabilitated in cancer avoidance facilitated by daily use of aspirin, a provocative topic spanning many years. Aspirin canconstraintumour-intrinsic cyclooxygenase activity, which mayregulate intracellular signalling ways and the local inflammatory response, and platelet-resident cyclooxygenase activity, which can affect procedures such as platelet activation and aggregation.

Challenges: Since it is still an emerging study there many obstacles that we need to overcome for this technique to be used routinely. Following are the challenges that we face presently:

1. We still lack in recovering huge amounts of analytical samples from the liquid biopsy.
2. Detecting genes translocation and RNA expression data is a puzzling task.
3. We cannot identify those early-stage cases.
4. To recognise the fundamental modifications that recognise or resistant tumour cell clones.
5. Justification and reproducibility of molecular and computational data.
6. Dispersion and application of liquid biopsy on anenormous scale as repetitive analysis.
7. The decrease in mutational/expressional data complexity.

Future Aspects:

1. High throughput assaying such as multiplex digital PCR and expression array.
2. Advanced genomic method having higher sensitivity to recognise any mutations occurring in matched ctDNA and tumour tissues
3. Enhanced understanding of dynamics of the biology of CTCs, exosomes and ctDNA release.
4. Calibration and logical authentication of techniques for liquid biopsy
5. Overview of cheaper biotechnology and computational software.
6. Using this software to implement the databases for a gigantic amount of data.

Gingival Diseases in Children and Adolescents

Sulagna Pradhan[1], Sushant Mohanty[2], Sonu Acharya[3], Mrinali Shukla[1], Sonali Bhuyan[1]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Professor, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Gingival diseases are prevalent in both children and adolescents. These diseases may or may not be associated with plaques, maybe familial in some cases, or may coexist with systemic illness. However, gingiva and periodontium receive scant attention as the primary dentition does not last for a considerable duration. As gingival diseases result in the marked breakdown of periodontal tissue, and premature tooth loss affecting the nutrition and global development of a child/adolescent, precise identification and management of gingival diseases is of paramount importance. This article comprehensively discusses the nature, spectrum, and management of gingival diseases.

Keywords: *Gingival diseases; children and adolescents; spectrum, and management.*

Introduction

Children are more susceptible to several gingival diseases, paralleling to those observed in adults, though vary in numerous aspects. Occasionally, natural variations in the gingiva can masquerade as genuine pathology.[1] On the contrary, a manifestation of a life-threatening underlying condition is misdiagnosed as normal gingiva. Hence, it is crucial for dental professionals to acquire expertise and diagnostic skills to identify the diseases in childhood before it turns out to be a catastrophe.[2]

Anatomical Consideration: Gingiva of children and adults differ anatomically. Gingiva of the primary dentition usually appears pale pink, but paler than that of adults. The marginal gingiva has rich vascularity but comprises fewer connective tissues. The thinner, reddish epithelium with mild keratinization may be misdiagnosed as inflammation. Lesser variability in the width of the attached gingiva in the primary dentition results in fewer mucogingival problems. The interdental papilla is broad buccolingual, and narrow mesiodistally. The junctional epithelium associated with the deciduous dentition is thicker than the permanent dentition. Gingival sulcular depth in children varies from 1 to 2 mm, which is shallower than that in adults.[3]

Epidemiology: Previous investigations have revealed the frequent occurrence of gingivitis of various intensity in children and adolescents. These investigations illustrate that the universality of severe forms of periodontal pathologies is fewer in the younger population as compared to the adults. Al Bandar and colleagues in 1996 evaluated a substantial number of adolescents in the United States and reported the existence of gingivitis in 82.1% of the participants. Several other studies from other parts of the world reported comparable results. Epidemiological studies indicate that loss of periodontal attachment and supporting bone at different locations can be recognized in 1% to 9% of 5 to 11year-old, 1% to 46% of 12 to 15-year-olds(juvenile periodontitis) and as low as 2.75% of 16-17-year-olds (chronic periodontitis). When a broad mixture of the population was taken into consideration, reports revealed

e-mail: pradhansulagna30@gmail.com

a fewer universality of periodontitis among pediatric and adult patients. Many investigators have proclaimed that higher plaque quantity and fewer inflammation in children as compared to young individuals. However, physicians recognize that the tissue destruction related to the periodontal pathologies in children and adolescents are generally self-healing and less prevalent compared to that in the adults.[4-7]

Classification of Gingival Diseases:

A. Gingival Disease Associated With Plaque

1. Without Local Contributing Factor

Plaque Induced Gingivitis: The presence of plaques is the prime mover of this pathological entity. Dental plaque usually builds up more briskly in the 8-12 years age group compared to the adults. However, gingivitis in the pediatric population is typically less severe than in adults with the same plaque level. Inflammation is generally restricted to the marginal gingiva with insignificant depletion of bone or connective tissue attachment in the majority of the cases. Red, linear inflammation accompanied by underlying chronic changes including swelling, augmented vascularity, and hyperplasia. Bleeding and deep pockets are not common findings in children. The greatest intensity of gingival inflammation exists in patients aged 14-16-year. Aggressive plaque control is recommended along with gingivectomy or gingivoplasty as per the condition.[8,9]

2. With Local Contributing Factor

(a) Eruption cyst and hematoma: Erupting teeth are frequently related to a variety of dentigerous cyst known as eruption cyst. These cysts have circumscribed swellings and are usually translucent and fluctuant. The presence of blood in the cystic cavities imparts a purple/deep-blue discoloration to the circumscribed swelling, described as eruption hematoma.[10]

(b) Eruption gingivitis: Emergence of primary teeth into the oral cavity is often associated with gingival inflammation. Malalignment of the erupting teeth and/or neglected oral hygiene may exaggerate the inflammation. However, optimal occlusion of the tooth subsides the inflammation. It may reappear in the 6-7 years of age group when the permanent teeth set to erupt. This develops, as the coronal contour of the tooth provides limited protection to the gingival margin during the initial stage of an active eruption. Additionally, frequent gingival food impingement is also contributory. Hence, plaque control should be taken seriously before it culminates in pericoronal abscess or leads to pericoronitis.[11]

(c) Gingivitis secondary to the orthodontic appliance: Effective brushing of the interproximal tooth is hampered during fixed appliance therapy. Accumulated plaques have a subgingival shift generated by the tipping movement which is virtually out of reach of the bristles. The gingival changes occurring in the first two months of appliance placement is temporary and largely reversible.[12]

(d) Gingivitis associated with mouth-breathing: Oral tissue undergoes dehydration as an effect of frequent mouth-breathing, resulting in inflammation of the gingiva and halitosis. This should be addressed with appropriate oral hygiene, moisturizing the tissues, use of the oral screen to protect the tissue during sleep, planning a comprehensive treatment protocol with orthodontics, and otolaryngology consultations.[13]

(e) Other elements: Excessive overjet and overbite, nasal blockage, partially exfoliated, loose deciduous, malaligned tooth, chipped off sharp edges of partly cavitated and decayed teeth can usually lead to gingival inflammation.[14]

B. Gingival Diseases and Systemic Factors:

1. Effect of Endocrine Alterations

(a) Puberty gingivitis: Pubertal gingivitis or steroid hormone-associated gingivitis is described as aggravation of gingivitis by pre-pubertal and pubertal alterations in sex hormone levels. This can be justified by estrogen and progesterone upsurge in the gingival tissues leading to vasodilatation and proliferation and increased susceptibility to inflammation. The interrelationship between elevated levels of the gonadotrophic hormones and pubertal gingivitis is noticeable from the fact that gingival inflammation peaks prior in girls (10-13 years) than in boys (13-15 years). According to in vivo evidence, P. intermedius is associated with the elevated levels of plasma estrogen and progesterone, suggesting that P. intermedius thrives on these hormones for nutrients. It is markedly distinguished by conspicuous inflammation, bluish-red appearances, swelling, and overgrowth, prominent bulbous interproximal papillae of anterior segments which are precipitated from local irritating factors

that would normally evoke a relatively benign gingival reaction. Management of puberty gingivitis should be targeted towards professional prophylaxis, elimination of all local irritants, restoration of carious teeth, and nutritional monitoring to ensure a sufficient nutritional status. Occasionally, the fibrotic transformation of the gingival swelling warrants timely surgical debridement.[15]

2. **Gingivitis Associated with Leukemia:** Leukemias are malignant diseases resulted from the proliferation of the WBC-precursors. Leukemia may have an acute or a chronic presentation and may be associated with one of the WBC precursors such as granulocytes (myeloid), lymphocytes, or monocytes. Acute leukemias are prevalent under the age group of 19-years. Acute lymphoblastic leukemia is common in the first decade of life. Factors that have been suggested in the etiology are radioactive rays and chemical damage, inherited risk factors (for example, Down's syndrome), immune-compromised state, and viral ailment. Gingiva appears as swollen, glazed, and purplish-deep-red in color accompanying hemorrhage. The swelling may emerge as a scattered expansion of the gingival mucosa, and overgrown augmentation of the marginal gingiva, or a distinct lump like interdental papillary mass. The texture is reasonably firm, but there is a propensity towards friability and bleeding, either involuntarily or on trivial provocation. Indolence, restlessness, painful throat, pyrexia, recurrent dermatological manifestations, purpura, cervical lymphadenopathy, splenomegaly, hepatomegaly, and petechiae are common signs.[16-18]

3. **Associated with Nutritional Deficiency**

(a) Gingivitis associated with nutritional deficiency: Several lines of evidence indicate an association of hypervitaminosis and mineral deficiencies with periodontal diseases. Scurvy, which emerges due to hypovitaminosis-C culminates in the reduction of collagen synthesis or the production of abnormal ones. Oral scurvy manifests with painful gingival swelling, edematous and spongy gingiva, and hemorrhage, either spontaneously or with a slight provocation. A combination of vitamin C deficiency and poor oral hygiene contributes to a painful version of gingivitis known as scorbutic gingivitis. It has additional signs that include ulcerative gingivitis, malodor, the fast formation of the periodontal pocket, and tooth damage.

C. Effect of Medications: Drug-induced gingival overgrowth: Gingival hyperplasia is an established side effect of several medications which include phenytoin (anti-convulsant), cyclosporine (immunodepressant), nifedipine, verapamil, and amlodipine (calcium channel blocker and anti-hypertensive). Gingival hyperplasia was described in 30% of patients receiving cyclosporin (Seymour & Heasman 1992), 50% of patients receiving phenytoin (Hassell 1981), and 15% of patients receiving the above-mentioned calcium channel blockers (Lederman et al. 1984, Pernu et al. 1989, Seymour et al. 1994). The gums look normal during the neonatal period but start to enlarge with the eruption of the primary teeth. This pattern of gingival hyperplasia typically starts as a nodular bulge in the interdental papillae before growing extensively to intrude the marginal gingival and labial tissues. The mouth is predominantly affected in the anterior side, but occasionally it affects the incisal and occlusal surfaces of the teeth. Histological hallmarks of this condition include epithelial acanthosis, higher fibroblast quantity, and enhanced collagen synthesis. Mechanical and chemical plaque control method are essential for the improvement of oral hygiene. Besides, professional scaling and root planning are warranted to eliminate the local contributing factors. On occasions, gingivectomy and gingivoplasty are recommended so that the patient can be esthetically sound which ultimately enhances the hygiene. Patients' physiciansshould be consulted to discuss the drug side effects so that other safe therapeutic avenues can be explored at the earliest.[17]

B. Non-Plaque Induced Gingival Diseases

Bacterial

(a) Acute necrotizing ulcerative gingivitis (ANUG): ANUG is also recognized as Trench mouth or Vincent's disease and is caused by *Borrelia vincentii*. ANUG has a greater prevalence in developing countries than in developed countries, and children are more frequently affected compared to adults. India has up to 2/3rd of the cases affecting the children in the first decade of life. ANUG is described by punched-out crater-like ulcers in interproximal gingiva coated with a grayish-white pseudo-membrane, which may expand to encompass marginalgingiva. It sometimes presents with deep pockets as a result of extensive gingival necrosis and crestal alveolar bone destruction.Patients

commonly report excruciating pain, a distinctive metallic taste, spontaneous gingival bleeding, and halitosis. Low-grade fever, swollen lymph nodes, restlessness, myalgia, loss of appetite are the frequent accompanying symptoms. Simultaneous local and systemic therapy is required to manage ANUG. The initial step should be professional scaling and root planing along with the debridement of necrotic tissue.Patientsare encouraged to maintain a proper diet andoral hygiene. Oxidizing mouthwash (e.g., chlorhexidine) mayserve to improvemicrobial stability. Five-day therapy with penicillin or erythromycin is usually recommended. Metronidazole can be administered for the speedy recovery of symptoms.[12-15]

Viral

(a) Acute herpetic gingivostomatitis: This self-limiting disease occurs due to Herpes simplex virus (HSV-1) infection. Pediatric patients younger than 6-7 years are chiefly affected. It is characterized by a scattered, reddish, and glazed appearance of the gums and the neighboring tissues. Varying grades of swelling, spontaneous gingival bleeding, disjunct spheroidal gray vesicles that eventually burst and develop into ulcers with an erythematous, raised, nimbus like edge and a depressed yellowish or grayish-white central part are also recognized.[18]

Fungal

(a) Acute candidiasis (Thrush, Candidiasis): It arises due to the overgrowth of the fungus *Candida albicans*. Children frequently develop acute candidiasis after prolonged local antibiotic therapy. The lesions appear as elevated, furry, white patches, which can be taken out easily to produce bleeding of the underlying surface. For infants and very young children, daily administration of Nystatin suspension (1 ml, 4 times/d) is recommended. Clotrimazole suspension is also highly effective.

(b) Linear gingival erythema (LGE): It is clinically described by a reddish, linear band of 2-3mm width on the marginal gingiva presentedas petechiae-like or disperse erythematous changes on the attached gingiva which may be associated with profuse hemorrhage. It might be limited to less than two teeth but it is frequently a generalized gingival pathology.[13-15]

Congenital Anomalies:

(a) Congenital Epulis(Gingival Granular Cell Lesion): It is an uncommon gingival tumor of unknown histogenesis that grows commonly in newborns, especially on the maxillary alveolar ridge. On presentation, the area of concern (gum pad) typically is firm, pink, smooth swelling of the gingival, and usually seen as gingival hyperplasia. Considerably large-seized growths may elevate the upper lip. The teeth which have not emerged into the oral cavity are typically unaltered and can be visualized in MRI.[15]

(b) Congenital Gum Synechiae: This rare malformation is identified by innate adherence between various parts of the oral apparatus. It leads to trouble in breathing soon after birth. Prompt treatment is advocated involving the excision of alveolar bands. If left untreated, it may result in TMJ ankylosis, restricted jaw movement and overall growth may also be interrupted (restricted feeding).[16]

Traumatic Lesion:

(a) It occurs accidentally in our daily practice and the inflammation or swelling lasts only for a transient period. Factitious gingivitis (*Gingivitis artefecta*) is a self-inflicting injury of gingival that could be habitual, accidental, or psychological. Soft tissue injury by bitting unknowingly, faulty brushing techniques, idiopathic trauma, tissue laceration while replacing orthodontic components, chewing abrasive foodcan result ina mucogingival recession or local inflammatory reaction. Management includes removal of irritation source, habit, rectification, and wound dressing. Psychological or psychiatric consultation may be beneficial in severe cases.[17,18]

Gingival Diseases Due to Heredity:

(a) Hereditary Gingival fibromatosis (HGF): This benign condition is marked by a gradually progressive gingival enlargement. The commonest variety, HGF, is usually familial and has an autosomal dominant mode of transmission. Another rare type has been referred to as elephantiasis gingiva or hereditary hyperplasia of the gums. It manifests asnon-hemorrhagic, firm, leathery which advances slowly upon eruption of permanent dentition involving attached, marginal and interdental gingiva. This may be complicated by esthetic or

functional issues such as a malaligned tooth, delayed retention of primary teeth, and delayed eruption of a permanent successor. Removal of hyperplastic tissues by conventional gingivectomy may be a treatment modality.

Amalgam Tattoo: Although it is a very unusual condition, it is manifested as a grayish-blue-black appearance on the oral mucosa (typically on the lower gums) due to the accidental diffusion of dental amalgam into the soft tissues. Occasionally, it is misdiagnosed as melanoma.

Gingival Findings Associated with Systemic Disorders:

(a) Infectious mononucleosis: Epstein-Barr virus (EBV) is the causative organism and it primarily affects children and young individuals. Patients chiefly complain of fever, sore throat, and enlarged lymph nodes, but malaise, fatigue, headache is also present. The abnormal findings include gingival bleeding, palatal petechiae, ulceration of the gingiva, and buccal mucosa (White, 1998).

(b) Chickenpox: Varicella-zoster is the reason of chickenpox primarily affects individuals who are less than 15 years old. Although the location of lesions in the oral cavity is variable, palate, gingiva, and buccal mucosa are commonly affected.[18-20]

(c) Herpangina: The causative pathogen of herpangina is the Coxsackie group A virus. It characterized by plentiful small vesicles that further form small ulcers made up of a gray-floor and inflamed border. The location of these ulcers is quite predictable like the tongue, palates, oral mucosa, and the posterior pharyngeal wall. These ulcers are typically painless and recede within a few days to a week.[18-20]

(d) Hand-foot and mouth disease: The bulk of cases of hand, foot, and mouth disease can affect not only the infants but also the preschooler ranging from 5 months to 5 years of age. Both the Coxsackie group A as well as group B are implicated in this disease. The signs and symptoms are identical to that of herpangina but culminate in dysphagia due to sore mouth. This disease commonly heals and abates within 1-2 weeks.[18-20]

(e) Wegner's granulomatosis: This vasculitis originally presents with marked alterations in the gingiva. Erythematous enlargement of the gingiva associated with this disease is often described as strawberry gingivitis.

(f) Kindlers syndrome: This condition is characterized by the presence of poikiloderma, cutaneous neonatal bullae, acral atrophy, and photosensitivity. Oral lesions similar to desquamative gingivitis can also be part of the manifesting symptoms. Traditional non-surgical periodontal management can be useful for treating gingival manifestation.[18-20]

Conclusion

Gingival diseases have a wide prevalence and these can affect all the age groups. However, the common myth is that gingival diseases affect only adults. Through this review, we reinforce that gingival diseases can be troublesome in children as well. Inadequate awareness about any signs and symptoms involving the gingiva in toddlers and young ones would jeopardize the periodontium in grown-up individuals. As prevention is better than cure, it is important to streamline patient education, and parent counseling to have regular pedodontic gingival assessment to maintain a healthy oral cavity in childhood.

Maxillary Hollow Obturator for Rehabilitation of Palatal Defect: A Case Report

Krishna Nanda[1], Gopal Krishna Choudhury[2], Pradyumna Kumar Sahoo[3], Rasmita Kumari Samantaray[1], Sneha Bharadwaj[1], M. Krishna[1]

[1]Post Graduate Trainee, [2]Professor and Head, [3]Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Intraoral defects may be congenital or acquired are most commonly seen in the maxilla. These are usually large openings in the palate or the peripheral structures along with palate. Patients with acquired maxillary surgical defects very commonly appear with lingering functional disabilities and cosmetic disfigurement. One of the most acquired jaw defects among all is a patient suffering from oral cancer. The aim to treat this entity is to give a comfortable, cosmetically acceptable prosthesis that can restore the impaired physiological activities i.e deglutition, speech, and mastication. An obturator is very much promising for this type of complaint. Obturatorsprimarily close more specifically seal the defects to restore the above-mentioned patients' basic needs and as well as aesthetics when it is concerned. This article presents a case report describing the technique for fabricating a hollow bulb obturator in a hemimaxillectomy patient.

Keywords: *Hollow obturator, Maxillary defect, Rehabilitation, Aramany Classifications.*

Introduction

Defects of the maxilla are more often formed by surgical removal of benign or malignant tumors, to trauma or infectious causes or oral cancer. Prosthodontics is the specialty of dentistry,which deals with restoration and rehabilitation of maxillofacial defects. Complete and sometimes partial surgical removal of tumors in the maxillary region can lead to chewing, phonation,aesthetic, and functional disorders.[1] The aim is to fabricate obturator prosthesis which seals tissue openings of the palate and contiguous structures and improves the quality of life by recuperating of course aesthetics and also deglutition, speech, mastication. Rehabilitation and re-establishment of functions by prosthesis of patients with maxillary defectsis divided into three phases and each having altered objectives. The initial phase of the treatmentis called surgical obturation and entails the placement of prosthesis during the surgical procedure. It primarily helps to restore and maintain oral functions at the time of immediate postoperative period.[2]

The second phase is called the interim obturation, and it allows the tissue to heal. The interim obturator is usually fabricated 2 to 6 weeks after the surgery and it is held in reserve till the final prosthesis is made.[3-5] The third or last phase of treatment is the fabrication of definite obturator which is made 3 to 6months after the surgery when the site is well healed.[6,7] Hollow obturator is one of the best treatment options for rehabilitation and re-establishment oforal function and aesthetic. There is numerous way of fabricating the hollow obturator. All these techniques propose to provide a lightweight prosthesis that is well accepted by the patient. The open bulb obturator provides the benefit of easy cleans facility, but the accumulation of moisture necessitates frequent cleaning. One piece of hollow bulb obturator can be

e-mail: krishnananda09@gmail.com

fabricated by refilling the hollow portion using materials like salt, sugar, sponge, polyurethane foam, and gas injection using argon gas. Some times nondetachable screw cap may also be used to coat the opening made to serve the sugar or salt.[8,9]

Case Report: A 62 years male patient from Berhampur, Odisha came to the Department of Prosthetics and implantology, IDS, Bhubaneswar, Odisha with the chief complaint of missing teeth in upper left back tooth region and closure of the defect in the same region. On eliciting the history of presenting illness hemi maxillectomy has been done to cure the squamous cell carcinoma of the left half of palate, 3 months back from the reported date.

On further interrogation,the patient gave no relevant past medical history. He was a chronic gutkha chewer, 4-5 times per day, for 10-15 years approx, placement of the gutkha in the left buccal mucosa. But he discontinued the habit since he was planned for the surgery. He was well oriented to the time, place, and person and all the vitals were in the normal range. On examination, there is partially edentulous from 13 to 17. The patient has generalized attrition. The left palatal arch distal to 12 is showing erythematous area with erythematous border. Tissue healing of that part is satisfactory. It is encountered that the defect is the Armani class II maxillary defect in the left palatal arch.

Impression Procedure:

Figure 1: Intra oral pictures of maxillary defect.

Before making the primary impression patient's mouth was cleaned thoroughly with a salinecoated wet gauge. Then a small piece of the wet gauge with saline was put deep inside the defect to prevent naso-oral communication. Then the primary impression was made using alginate. The primary cast was made and a special tray was fabricated. Border molding was done using a green stick compound. And the final impression was made using elastomeric impression material. The master cast was thus, obtained over which denture base was fabricated. Jaw relation was done. Teeth arrangement was done by using monoplane teeth due to generalized attritionand tried in the patient's mouth. 3 C clasps were made by 21 gauge orthodontic wire with the help of Adam's and universal pliers. One clasp was placed around the left lateral incisor and the other two were placed around the right canine and first molar respectively. Then these clasps were sealed along with the trial obturator over the master cast. Then wax-up was done properly.

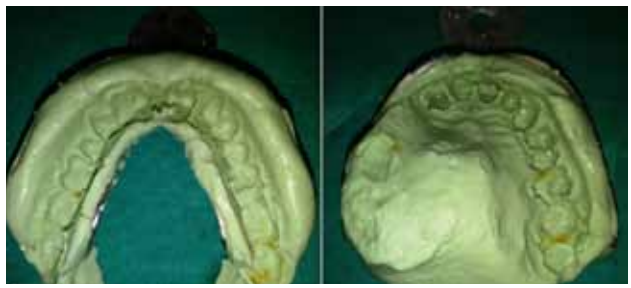

Figure 2. Primary impression of maxilla and mandible

Figure 3. Final impression

Processing Technique: The whole trial denture assembly was flasked and dewaxed. Upper and lower part of the flask was cleaned and wiped properly. Separating media was applied properly in both parts. Heat cure acrylic powder and liquid were mixed in a porcelain cup according to the manufacturer's instruction. Previously depending upon the size of the defect salt was kept for the packing procedure. When the dough stage reached one layer of acrylic material was placed along the floor of the defect. Then salt was put over it and again wrapped by acrylic material and packed properly by a clamp.

It was left for bench cooling. Then salt was vaporized during the curing procedure inside the waterbath. After cooling down the flask, the obturator was retrieved and cleaned properly. Holes were made in the lid for easy cleaning with the round bur. The obturator was finished and polished.

Discussion

"In 1978 the late Dr. Mohammed Aramany presented the first published system of classification of postsurgical maxillary defects. He divided all defects into 6 categories based on the relationship of the defect to the remaining teeth and the frequency of occurrence of the defect".[10]

Class I. Curved Arch form and Linear Arch Form: "The class I category represents the classic maxillary resection defect where the hard palate, alveolar, ridge, and dentition are removed to the midline. This unilateral defect is the one most commonly seen in the maxillofacial rehabilitative practice". "The linear design is used for the class I defect when there are no anterior teeth present or when one does not desire to use the anterior teeth. The remaining posterior teeth are usually in a relatively straight line."

Class II: "Class II includes arches in which the premaxilla and the premaxillary dentition on the contralateral side are maintained. A single, unilateral defect is located posterior to the remaining teeth."

Class III: "Class III involves a midline defect of the hard palate and may include a variable portion of the

soft palate as well. The dentition is usually preserved, making this obturator prosthesis design simple and effective."

Class IV: "Class IV situations involve the surgical removal of the entire premaxillae, leaving a bilateral defect anteriorly and a lateral defect posteriorly. There are often a few remaining posterior teeth located in a relatively straightline, creating a unilateral linear design problem where leverage cannot be used to an effective degree."

Class V: "This situation involves a bilateral posterior surgical defect located posterior to the remaining teeth. Many or all of the teeth are present anterior to the defect. Labial stabilization and the use of splinting, especially of the terminal abutments, is desirable."

Class VI: "The class VI defect is a rare surgical creation. Most often it results from a congenital anomaly or trauma such as an automobile accident or a self-inflicted wound that removes the entire premaxillae (and may include a portion of one or both of the maxillae), leaving a single bilateral defect located anterior to the remaining teeth."

Maxillectomy results in a sudden change in the physiological process creating oronasal and oroantral communication. An obturator provides a simple reconstructive solution for separating oronasal communication, reducing the difficulties associated with swallowing, mastication, supporting the facial soft tissues, re-establishing speech and providing immediate dental restoration, without the need for second surgery.[11]

The remaining teeth and their location and number will determine the type of retainer to be used. Retainers that are properly designed help to reduce stress to the abutment tooth. Hence, while designing the clasp assembly, basic principles such as passive placement, encirclement and stabilization should be followed. However, in cases with large palatomaxillary defects, the stability and retention of the obturator could be significantly compromised because of the diminished bone support or if terminal abutment tooth is absent, for long-term clasping. There are different types of retentive aids that are used for the conventional hollow-bulb obturator prosthesis such as magnets and snap-on (friction type) attachments, acrylic buttons, retentive clips and implants. Implants reduce prosthesis movement, prevent rotation and encourage axial loading. Obturators retained using implants and cast metal framework will be of a different design and their weight may change accordingly. In this particular case, the patient was not willing to have further surgical procedures or to bear the additional cost involved. Obturator with open lid inserted intraorally.[12-14]

A heavy obturator prosthesis exerts continuous stress affecting the health of the tissues and resulting in discomfort. The weight of the prosthesis should be minimized to reduce dislodging forces. The most commonly used material for the fabrication of obturator prostheses is heat cure acrylic resin because of its durability and compatibility with tissues. A hollow-bulb obturator fabricated by the open lid technique is a lightweight prosthesis that not only extends effectively into the defect area but can also be easily tolerated by the patient. It is hygienic and increases speech intelligibility.[15]

Conclusion

In patients with maxillary defects, surgical procedures cannot provide satisfactory cosmetic and functional rehabilitation. These are compromised people who require physical as well as psychological rehabilitation through a multidisciplinary approach.A good result will depend upon the correct diagnosis and well-made treatment plan. Obturator satisfies the functional and psychological needs of the patient and aneffective treatment modality. This case report discussed the prosthetic treatment of acquired maxillary defect with one obturator.

Mode of Actions of Bisphosphonates in Dental Implant Procedure: An Overview

Krishna Nanda[1], Gopal Krishna Choudhury[2], Rasmita Kumari Samantaray[1], M. Krishna[1], Sneha Bharadwaj[1]

[1]Post Graduate Trainee, [2]Professor and Head, Department of Prosthodontics, Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Bisphosphonates (BP) are the most commonly used drug forthe past few years for the treatment of various types of bone disorders and malignancies**.** Osteonecrosis of the jaw (ONJ) is most devitalizing but still not has been properly acknowledged as of now. These drugs suppress bone turnover by decreasing osteoclastic activity**.** This article points in featuring the key and pharmaco-physiological system of activity of both N2 and non N2 bisphosphonates on bone and activity of bisphosphonates on dental implants, particularly their commitment in success of the implant and the present suggestions and rules for implant treatment in patients who are on bisphosphonate therapy**.** This article also includes the prevention and management for decreasing the cumulative IV bisphosphonate dose, stoppage of bisphosphonates before any invasive dental treatment, and in ONJ using serum beta-CTX-1 in assessment of risk. "Drug Holiday" for the invasive dental procedure is incorporated as well.

Keywords: *Bisphosphonate, Dental implants, osseointegration, osteonecrosis, BRONZ.*

Introduction

"Bisphosphonates (BP)",since years is been used to treat diseases such as "osteoporosis, Pagets' disease, hypercalcemia in malignancy, osteolytic lesions of multiple myeloma and bone metastasis associated with breast, prostate, lung and other soft tissue tumours". Their mode of action is osteoclastic inhibition and synthetic biochemical modification of bone resorption.[1]

There are two method of drug intake, oral and intravenous route. Systemic administration i.e. (Intravenous) bisphosphonates, is more potent than orally administered. The potency of the drug does not depend upon the mode of delivery rather depends upon the existence of the N-H group to the basic P-C-P structure. Due to the good binding affinity to the minerals, they are appropriate therapy for skeletal disorder where bone metabolism is high. It decreases osteoclastic actions by stimulating osteoblasts and afterward suppresses bone remodeling and turnover. N2 containing and non N2 containing are the two varieties of BP.[2]

According to some hypothesis, action of BP on the oral mucosa, specifically to the oral epithelium, keratinocytes, macrophages and fibroblasts is impaired oral wound healing.[30-35] Ill-fitting dentures cause BRONZ of the jaw without any surgical injuries, which further hinder angiogenesis continuing to avascular necrosis.

Many side effects are also reported due to long term use of BP, which may be a matter of concern regarding the safety issue of the drug. Patients, who are prescribed with BP may require implant therapy. Therefore it is necessary to know the effects of these drugs on osseointegration and implant survival & success rates.[3,4]

History of BP: BP was used in the textile, fertilizer and oil industries when it was synthesized in Germany

in 1865. In an in vitro study,Herbert Fleisch and colleagues found the role of inhibition of inorganic pyrophosphates (PPi) for the dissolution of calcium phosphate in plasma and urine. Severe mineralization defects of the skeleton were found in 1964 due to high PPi levels in urine. An in vivo study has shown that the compound prevented ectopic calcification; it did not have any effect on resorption of bone and normal mineralization. Pyrophosphate used in scintigraphy and dental calculus as therapy. Bisphosphonates have empathy for mineralization of bone, it additionally represses the arrangement and conglomeration of calcium phosphate crystals as PPi.Early studies indicate that bisphosphonates also can inhibit the dissolution of hydroxyapatite crystals. It is discovered in the early 1990s the potency of the drug is mainly depend upon the Nitrogen compound present in its structure.[5]

Chemical Confugaration Nitrogen Containing BP: The drug potency is increased by the alteration in the chemical structure that is the peripheral or side chain of the central carbon atom and N2 group in the R2 position and it is also done by adding alkyl and amine groups to R1 side chain for chain elongation. This helps to maintain the calcium-binding affinity through the OH group in the R1 position.When hydroxyl or amino group present in one side chain, it increases Ca binding affinity, due to tridentate conformation.[6]

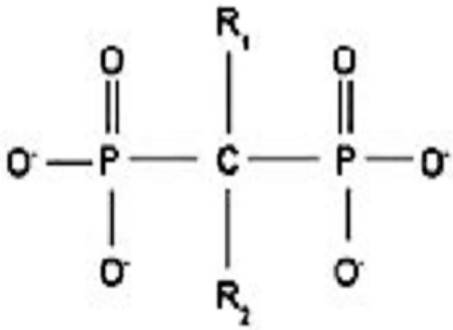

Figure 1. Bisphosphonate

Mechanism of actions: Osteoclastic bone resorption is inhibited by osteoclast-mediated BP internalization due to which there is decreased osteoclastic activity. Two types of mechanisms are there, one is cellular, and the other is biochemical. They help in decreasing skeletal resorption and turnover.

Non-N2 containing bisphosphonates (Cellular Mechanism): First-generation BPs (clodronate and etidronate) resembles to the PPi. They reverse the activities of aminoacyl-tRNA synthases through metabolically incorporated into nonhydrolyzable cytotoxic ATP analogs as pyrophosphate. The derived metabolites which should consist of β, γ-phosphate groups of ATP, but it contains P-C-P structure, which is non-hydrolyzable. These metabolites get accumulated intercellularly, which inturn hinders the functions of osteoclast. They interrupting with mitochondrial ATP-translocases resulting in osteoclastic cell mortality. So the cell death of osteoclast due to BP causes resorption of bones.[7]

N2-containing bisphosphonates and "Mevalonate biosynthetic pathway" (Biochemical): In the mevalonate pathway, farnesyl diphosphate and geranylgeranyl diphosphate proteins are biosynthesized. The amide group-containing BPs are inhibitors of the biosynthetic pathway. In the case of post-translational prenylation of small GTPases such as Rho, Rac, RAS, the above proteins are required. The Rho and Rac proteins are activated through geranylgeranylation, so that it helps organize the cytoskeleton and ruffling of the cell membrane. The "ruffled border" is important because it helps in the attachment to bones and destroys the bone tissue. When the ruffled border diminished, then automatically it turns into osteoclastic cell death. Ultimately there is a reduction in bone turnover. N2 containing bisphosphonates create disruptions in osteoclastic functions, the morphology of cells and cytoskeleton, which fails in the sealing zone and ruffling of membrane, apoptosis and also trafficking of vesicles.[8]

According to **Elliott Ballantyne** Sealing zone consists of

1. Ruffled border
2. The basolateral domain
3. The functional secretory domain

Prolonged Effects of BPs: BPs has long-term effects on decreasing bone turnover. Some BPs (eg. alendronate and zoledronate) act more prolonged than others (etidronate and risedronate). The rate of resorption and fracture is less even after the discontinuation of the drug for a longer period. Also the disadvantages of the drug may take a long duration to go away. BPs are inserted in the skeleton, which are liberated in future cycles of resorption. It implies prolonged and steady removal of all BPs from the bones. Some study reveals that the elimination of alendronate in humans is so slow that it can take up to 12 years. [9,10]

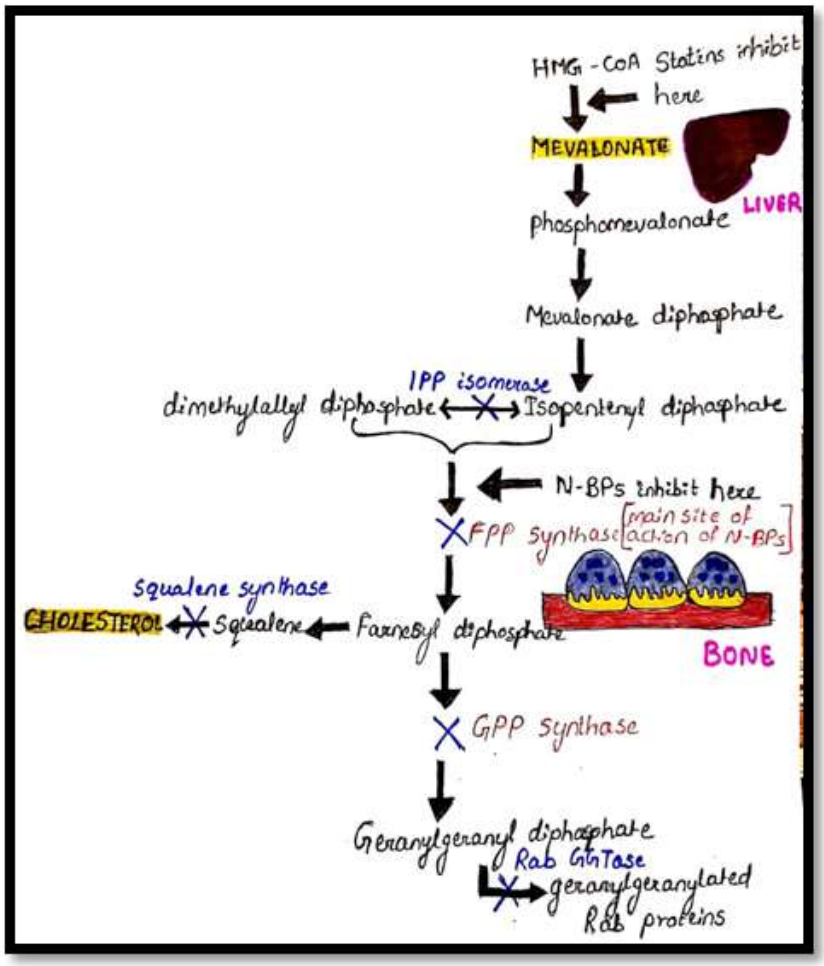

Figure 2. Mevalonate biosynthetic pathway

Why BP Deposition is higher in Jaws: Bisphosphonates are useful for metabolism in bones of the body however in the event of BRONZ of the jaw the most common site is in the maxilla and mandible. It is said that the thinner the mucosa over the bone, the higher the rate of deposition of the drug. So, jaws containing less than 5mm mucosal layer are more favourable than the other bones of the body.

As indicated by certain investigations that the alveolar crest get remodeled at a higher rate of 10 times quicker than the tibia, 5 times quicker than the inferior border of the mandible and 3 - 5 times the rate of the mandible at the Inferior Dental canal and jaws and collect a higher rate of concentration of bisphosphonates because of the alveolar ridge remodeling at rapidly.[11]

Effects of BP in "Angiogenesis and vasculogenesis": For the local immunity, tissue homeostasis and regeneration, sufficient blood supply and new vascularisation is fundamental. The veins in bones and the cells in the endothelium are significant in bone development and resorption. The Angiogenesis and vasculogenesis both are different.

Angiogenesis is defined as "the sprouting from pre-existing vessels of mature endothelial cells". Vasculogenesis is "the formation of new primordial vessels from bone marrow-derived, circulating endothelial progenitor cells". [12]

Some studies concluded that the N containing bisphosphonates like zoledronate inhibits angiogenesis. In some in vitro studies after using human umbilical cord vascular endothelial cells (HUVEC) it is found that zoledronate inhibits the production of HUVEC and it is dose depending upon the dose. Zoledronate inhibits integrins (α5β3 and α5β5), which helps in the

formation of a blood vessel by endothelial cell adhesion and migration.

In some in-vitro studies, it is mentioned that the endothelial cell proliferation and migration are become impaired after administration of zoledronate. RANKL is suppressed resulting in deterioration cellular mechanism by bisphosphonates. [13]

Tissue healing around the implant: Fundamentally wound healing process around dental implants is significant and important for implant to survive. It involves delicate tissue recuperating and hard tissue mending around the implants.After osteotomy and placement of an implant, the delicate soft tissue ought to be sutured appropriately with the goal that it must seal the blood coagulation and save the zone from bacterial colonization. There should not be any tension present in soft tissue during primary wound closure. A series of processes goes on during healing at the implant site like the development of blood clot, fibroblast, macrophage activity, and epithelial proliferation which is associated with primary osteoid formation, called primary stability of the implant. [14]

As there is suppression of endothelial cell proliferation and interruption in angiogenesis and vasculogenesis the tissue healing around the implant becomes delayed after administration of BP.Primary stability is one of the key factors for the survival of the implant.That is why in case of a patient taking BP the survival of the implant is a questionable matter. [15]

Failure of implant: Failure of an implant can be defined as "the first instance in which the performance of an implant fails to meet the criteria for success". The indication like implant mobility, vertical bone loss greater than 0.2 mm, bleeding pockets that are greater than 5 mm are observed when evaluated clinically. Implant failure is further classified as early or late failures, depending on whether they occur before or at abutment connection or after occlusal loading following the prosthetic restoration. Early implant failure results due to the inability of the implant to establish an intimate bone contact. Evidence says BP interrupts in osseointegration by the formation of fibrous connective tissue around the implant results in early failure. Late failures occur during functional loading and cause periimplantitis. BP has a significant role in late failures as well as it is compromising the wound healing.[2]

Laboratory Marker: During bone formation, resorption and turnover C-telopeptides (CTx) fragments of collagen are liberated. Because BPs decrease CTx levels, it is also well believed that evaluating serum CTx levels is a reliable indicator for risk assessment. The "CTx test, also known as C-terminal telopeptide and collagen type 1 C telopeptide is a serum test obtained in laboratories or hospitals.[16]

Oral Bisphosophonate Use >3 Years

1. Physician approval to discontinue bisphosphonates 3 months before sugery and 3 months after sugery ("drug holiday").
2. Determine serum CTx levels during initial consultation and immediately before surgery; CTx levels must be >150 pg/mL before proceeding with surgery.
3. Detailed informed consent for bisphosphonate-associated osteonecrosis.

Oral Bisphosophonate Use <3 Years without Clinical or Radiographic Risk Factors

1. Serum CTx level must be >150 pg/mL.
2. Proceed with surgery with detailed informed consent for bisphosphonate-associated osteonecrosis.
3. If serum CTx level <150 pg/mL, institute a physician approved "drug holiday"; continue monitoring every 3 months until CTx levels >150 pg/mL.

Oral Bisphosophonate Use <3 Years with Clinical or Radiographic Risk Factors

1. Physician-approved "drug holiday" for 3 months.
2. Serum CTx level must be >150 pg/mL to proceed with detailed informed consent for bisphosphonate-associated osteonecrosis.
3. If serum CTx level <150 pg/mL, continue monitoring every 3 months until CTx level >150 pg/mL.

Figure 3. According to Carl E Misch Protocol, suggestions and assessments for patient taking oral BP

CTx Value (pg/mL)	Risk for Osteonecrosis
300-600 (normal)	none
150-299	none to minimal
101-149	Moderate
< 100	High

Figure 4. Laboratory Risk Assessment

Discussion

A Review of this literature throws light on relative risk associated with the use of bisphosphonates and implant therapy**.** There are many case report and literature which expresses that utilization of bisphosphonate medication may promptly lead to failure of implant therapy in patients especially those accepting intravenous bisphosphonate treatment, while another review contemplates have shown that there might be a danger of osteopathology in patients getting oral bisphosphonates and dental implant treatment. According to **BRONJ** "it is a potential complication that may lead to implant failure. It is also important to distinguish that implant failure may occur without the presence of any clear pathology due to a loss of osseointegration in patients being treated with this group of drugs. This is believed to be the result of reduced bone turnover due to diminished osteoclastic activity".[17] "In the first reported case series it has found the occurrence rate of BRONJ was at about 70% after tooth extraction or other dentoalveolar surgical procedures such as periodontal surgery and dental implant placement."

According to **Vescovi et al**. "36.2% rate of incidence of BRONJ in a non-surgery triggered group compared to 63.8% rate of incidence in a surgery triggered group. [63] They also stated that intravenous bisphosphonate therapy for underlying malignant disease is an absolute contraindication for the placement of dental implants, whereas implants can be placed in patients receiving oral bisphosphonates for those treated for osteoporosis". [18]

According to **Elliott Ballantyne** "the association between oral bisphosphonate therapy and dental implant failure". [2]

In a systematic review by **Javier Ata-Ali et al**, it was discovered that the position of dental implants in patients treated with bisphosphonates doesn't decrease the implant success rate. On the contrary, it can't be said that such patients are not without difficulties and hazard evaluation. Therefore it is decided by the singular premise".[19]According to **Hom-Lay Wang et al** "bisphosphonates may play a role in wound healing and suggested that if there is compromised healing it can be successfully treated with systemic antibiotics, local microbial mouthrinse and aggressive defect management". [20]**Yip JK et al** 2012 did a study and found that the use of oral bisphosphonates at the time of implant placement was associated with dental implant failure. Specifically, the use of bisphosphonates among women were almost three times greater than other counterparts.[21]

According to **A Cheng et al** "placement of implants in patients on bisphosphonates does carry a small but defined risk. The long-term management strategy for the patient's underlying condition needs to be discussed with the patient's medical practitioner and informed consent of the risk needs to be provided. Patients with previously placed implants who subsequently are placed on the bisphosphonates need to be carefully monitored. Aggressive surgical salvage procedures are best avoided as these will probably decrease failure".Thought of bisphosphonate tranquilize occasion or elective clinical administration of their bone disorder ought to be talked about with the treating clinical expert and after that implant treatment ought to be effectively carried out. [22]

Conclusion

It is concluded that patients taking bisphosphonates by intravenous method should not be considered for the placement of dental implants. Patients under oral bisphosphonates can be chosen for the dental implants but before the surgery the protocol has to be followed.

The Etiopathogenesis of Myofacial Pain Dysfunction Syndrome

Subhalaxmi Kar

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

This article presents a review of revisiting the Etiopathogenesis of myofacial pain dysfunction syndrome. This article concentrates on the appropriate evaluation, causes and management of MPDS. Myofacial pain is one of the significant and common reasons for the orofacial pain that originate from the myofacial trigger point. Patient with myofacial pain dysfunction syndrome also complains of a chronic musculoskeletal pain on which pressure on a sensitive muscle or point cause pain.

Keywords: *Myofacial pain dysfunction syndrome, Orofacial pain, Trigger point, Musculoskeletal pain.*

Introduction

Myofacial pain dysfunction syndrome is an order characterized by pain and dysfunction of masticatory muscle as well as the skeletal muscle and the trigger zones. The trigger zones are sensitive in nature and palpable. Myofacial pain dysfunction syndrome is defined as pain originates from the myofacial trigger point in skeletal muscles.MPDS is the most common form of temporomandibular disorder. It is the common cause of orofacial pain. MPDS is a psychological disorder that involves masticatory muscles, skeletal muscles, limitation of jaw movements, sensitivity in touch."TMJ pain dysfunction syndrome", first described by Costen (1934), which included Tmj dysfunction, facial and head pain. The term 'Myofacial pain dysfunction syndrome, first coined by Laskin (1969). Myofacial pain can arise in skeletal muscles such as those in the head (commonly muscle of mastication), neck, lower back, and shoulder.[1-3]

Abnormal occlusion – a person can modify the pathway of closer in case of painful and potentially damagingcontact. This corrective movement of the mandible, during the closer, may lead to muscle strain and spasm resulting in abnormal pressure on the Temporomandibular joint.

Prosthetic problem – according to many authors' faulty partial and complete dentures, bilateral loss of molar teeth, over closer and increased vertical dimension in partial or complete dentureleads to TMJ dysfunction. There is also a change in myotatic stretch reflex in the above mentioned condition.

Orthodontics problem – malocclusion leads to TMJ dysfunction.

Emotional problem – in this case, patients show over behavior or overreactingon food habits, to care for teeth which give rise to TMD (Temporomandibular disorder). At the same time, oral habits are quite dangerous and can cause damage or persistent pain. A behavioral change like anxiety due to dysfunction of ANS(Autonomic nervous system).[1-3]

Psychophysiologic theory – The signs and symptoms of pain dysfunction syndrome are due to masticatory muscle spasm. Tenacious myospasm also can cause 2 other changes in the body, namely degenerative arthritis and contracture degenerative change. Degenerative arthritis arises from constant jaw function with abnormal condyle position contracture degenerative i.e. Muscle

change that accompanies long period spasm. Spasm maybe start by muscular overextension which gives rise tooral habits, dental restoration, tooth loss, denture irritation, adenture wearer.[1-3]

Etiopathogenesis: - Primarily energy is released during muscle contraction then there is an initiation and acceleration of lactic acid, which in turn effectuate coin in osmolality consequence in the reduction of the pH. It makes the muscle receptor susceptible to impule excitation as their censorious firing level is damaged. The lactic acid itself causes effusion and infusion of bradykinin, histamine and serotonin and another amine into the region by the decreased in pH, it leads to pathological musculardisturbance, then this specific zone of muscular disturbance are called as 'trigger zone' or hypersensitive area from which impulse the CNS and cause referred pain.[4]

Clinical Feature:

1. Unilateral, dull pain in the or preauricular region
2. Tenderness in the muscle of mastication.
3. Tender on palpation
4. Restricted mouth opening(opening of mandible)
5. Mostly occurs in the mandible with a more female predilection.
6. The pain continues in episodes of several times a day.
7. Gradually it raises due to increased emotional stress and increased intraarticular pressure in joints.
8. Due to myalgia, arthralgia masticatory pain occurs.
9. Mostly Pain occurs in the preauricular region but can be radiated to the temporal, frontal, and occipital region.
10. The patient complains of difficulty in chewing and restricted mouth movements.
11. Patients also complain of nose rubbing, clicking, grinding, and popping snapping sounds on mandibular movements.
12. The patient also complains tinnitus (ringing in the ear) or toothache or otalgia (pain in-ear). The cause behind tinnitus is that loss of bilateral molar leads to distal condylar movement and puts direct pressure on the Eustachian tube with impaction on the auriculotemporal nerve which is responsible for the ear symptoms.
13. The patient also focuses on hearing loss, myospasm other problems parafunctional habits, such as bruxism, clenching, extensive attrition, ridging of the buccal mucosa, malocclusion.
14. Pain aggravated by movement of the mandible.[1-4]

Management of MPDS: The management of myofacial pain requires a multifactorial approach. It is a long term procedure that takes time to recover. The patient should be calm and keep patience for recovery. The management can be done in two ways –Nonsurgical management & surgical management[5]

Nonsurgical Therapy:

1. Re-educate the patient about the disorders.
2. Reassurance the patient has to be assured of the character, sign, and symptoms of the myospasm.
3. Diet and rest- hard and chewy food should be avoided and the patient should be aware of resting jaw rather than postural movements like clenching, swallowing, or gridding.
4. Thermal therapy- laying a hot moist towel, electric heating pad over the symptomatic area is helpful to reduce pain. It should remain in the place for 10-15 min.

Supportive Therapy: There are two types of supportive therapy are: pharmacological therapy and physical therapy.[6]

Pharmacological Therapy:

- Pain control analgesics- salicylates, morphine,paracetamol, aspirin.
- Anti-depressants- monoamine oxidase inhibitor, lithium carbonate and caffeine.
- Anti-inflammatory agents – salicylates (aspirin)
- Propionic acid (ibuprofen), acetic acid (indomethacin),oxicam, fenamic acid, aryl acetic acid derivative (diclofenac sodium).
- Anxiolytics agent – Benzodiazepines such as lorazepam, diazepam and oxazepam are commonly used.
- Muscle relaxants- chlorzoxazone, meprobamate, methocarbamol and cyclobenzaprine.[7]

Physical Therapy: Physiotherapy may help in such cases and that infection and all are for the second option. There are many kinds of physiotherapy are available e.g. Stretch and spray, ischemic, pressure, soft pressure, continuous massage. Physical therapy can alsoadd electrical stimulation therapy which includes:

- Electro galvanic stimulation (EGS), is a periodic electrical impulse that is applied to the muscle, creating repeated involuntary relaxation and contraction, which cause increases in blood flow to the muscle.

- Trance cutaneous stimulation (TCS), is an electrical nerve stimulation (TENS)that stimulates the A-delta fibers and prevents pain from c- delta fibers by using electric current.[8]

Other Therapies:

1. Hydrotherapy- It is one of these therapies where the patient's cooperation is most important. Patients should understand the procedure and follow the hypnotist's suggestion. This results in muscle relaxation.
2. Acupuncture- it is the simple and effective pain control method skilled by inserting needles into appropriate joints at an appropriate surface called meridians. This therapy (acupuncture) gives relief from pain rather than remove the basic cause.
3. Restoration- Faulty restoration may lead to interactive contact. So the overfilled restoration should be removed. And the occlusion should be checked properly.[8-10]

Surgical Therapy: Surgical management is the rarest treatment of choice where long term results are disappointing. They are:

a. Condylotomy- it meansthe displacement of the head of the condyle, which moves slightly forwards and medially. The procedure is carried out without disturbing the joint capsule and intracapsular structures.[8-10]

b. High condylectomy- this is done when all other conservative forms of therapy have failed and other examination results in extensive proliferative changes or erosion of the condylar head. Basically in this procedure is based on the elimination of condylar articular pathology and surgical reduction of the hight of the condylar head.

c. Meniscectomy- the most acceptable method in which articular disc is removed from the TMJ. After removing the articular disc there is a relief of symptoms due to cutting off the capsular nerve supply and tightening the capsular ligament by post-operative fibrous scarring.[8-10]

d. Myotomy- selected myotomy of the temporalis or masseter muscle via an intraoral method is helpful in the management of pain dysfunction syndrome.

e. Arthroscopy- is the least invasive surgical technique for myofacial pain dysfunction syndrome. It has the potential of successful surgical outcomes with the minimal sequel.

f. Botulinum toxin A (Bt A) injections. It is one of those expensive and intensive means of treatment. This may helpwhen dystonia is a major factor. This method is successfully used to treat having both recurrent TMJ dislocation and excessive clenching.[8-10]

Conclusion

This is important to know about the etiology and the proper diagnosis of MPDS before treating this. The management should be properly done which includes conservative management as well as surgical management. The patients should take rest and have patience. MPDS is self-limiting if etiological factors are erased. Conservative management includes medication, jaw exercises, physical therapy, injections, etc. surgical management should be considered if the pain is not subsided by conservative management. After all of the above efforts, more research is still required. It includes lavage and lysis technique which results in an increased range of motion improvement of joint function and reduction of pain. Better management of the patient who is suffering from this syndrome. The proper management of myofacial pain dysfunction syndrome should be done in the early stage of the disease.

Salivary Glands: A Brief View on Types, Anatomy & Histological Features

Tariq Soyab

Post Graduate Trainee, Department of Oral Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, 751003, Odisha, India

Abstract

Salivary glands are crucial organs playing a vital role in the secretion of saliva in the oral cavity. During its morphogenesis a sequel of coordinated movements that are developmental processes occurred and the interaction of mesenchyme and epithelium generating the ductal system and secretory units. Salivary glands consist of major and minor glands that play different roles in saliva secretion. The maximum cell types of salivary glands are innervated by parasympathetic and sympathetic nerves. Histologically serous acini and mucous acini cell types can be seen with a network of the ductal system which includes striated, excretory and intercalated ducts, the external carotid artery maintain the blood supply of major salivary glands and the role of vasculature supply remaining unclear regarding the maintenance of saliva secretion which needs further investigation. The article throws light on its different types, its histological features, and its ductal system.

Keywords: *Salivary glands, serous acini, mucous acini, Ducts.*

Introduction

The human salivary glands are the major ones for maintaining the homeostasis of the oral cavity. They secrete saliva which is a multi-functional fluid that gives salivary electrolytes providing antibacterial property and help in mucosal lubrication which in return protecting the oral mucosa and teeth surface. Various types of enzymes are also secreted by salivary glands. The saliva secretion is very crucial in maintaining the oral hygiene and keeps the oral cavity moist. Reduction in the saliva may occur due to different reasons which involve loss of gland or degeneration and SG includes three pairs of glands i.e. parotid, submandibular and sublingual glands.

Corresponding Author:
Dr. Md. Tariq Soyab
Post Graduate Trainee, Department of Oral Maxillofacial Pathology& Microbiology, Institute Of Dental Sciences, Siksha O Anusandhan University (Deemed to be University), Bhubaneswar, 751003, Odisha, India
e-mail: soyabtariq21@gmail.cm

These are considered major salivary glands and they are responsible for 90% of saliva secretion and rest are secreted by minor salivary glands. Minor salivary gland comprises of 600-1000 glands distributing through the whole oral –cavity. As these minor salivary glands, only less than 10% of saliva but they provide an important role in the main lubricant of saliva because of its mucous and protective components. The adult salivary glands include specialized cells which are acinar cells and myoepithelial cells that contribute to the secretion of saliva into the ducts.[1] Intercalated ducts are first structures that receive the initial secretion which is then conveyed to striated ducts, where changes occurred in several electrolytic between the extracellular matrix and the fluid salivary through the plasma membrane.

Classification of Salivary Glands:

- Based on its location and size – A. Major salivary glands B. Minor salivary glands

The major salivary glands are further classified into– parotid gland, submandibular gland, sublingual gland.

These all are located outside the oral cavity and the secretion reaches the mouth by the ductal system.

- Based on the types of secretion- A. Serous secreting glands-example such as parotid glands, von Ebner's gland.

B. Mucus secreting glands- examples such as glands of Blandin and Nuhn, glosso palatine glands.

C. Mixed glands- Such as submandibular gland & sublingual gland.[2]

Major Salivary Glands:

- Parotid Gland - The word originates from Para which means around and otic means ear. It is the largest salivary gland among all. It is characterized by serous cells as it is purely serious. It weighs about 15 grams.

Anatomy- The superficial part of this gland is present in front of the ear and the deepest portion lies or filling the retromolar fossa. The artery supply includes the external carotid artery, maxillary artery, and superficial temporal and posterior auricular artery. Facial nerves supply this gland with the union of the superficial temporal and maxillary vein.

Duct- Parotid duct which is also known as **Stenson's duct** crosses the masseter and then pierces the buccinators and then opens into papilla at buccal mucosa which is present opposite to the maxillary second molar. The duct sizes 4-6mm in length and 5 mm in the diameter. The blood supply is provided by ECE and veins drain into the external jugular vein. The lymph first drains into parotid notes and then t upper deep cervical lymph nodes. The parasympathetic fibers, sympathetic nerves, and sensory nerves are associated with the parotid gland. [3]

- Sub-mandibular Gland- This is the second-largest gland and is also known as the submaxillary gland. It is a mixed type of gland which includes both serious and mucous acini but the serous units are found to be dominating as compared to mucous units.

Anatomy - The superficial part of the gland lies in the digastric triangle and the deepest part is associated with or deep to mylohyoid and superficial to styloglossus and hyoglossus. They are supplied by the facial artery and the veins drain into a common lingual or facial vein. The lymphatic drains into the deep cervical and jugular group of nodes.

Duct- The important excretory duct includes the **Wharton's duct** that runs forward above the mylohyoid muscle which lies just below the mucosa and floor of mouth. It opens on the carnucula sublingual and lateral to the lingual frenum. The secretomotor pathway playing a crucial role in its nerve supply. [4]

- Sublingual Gland –This is the smallest salivary gland and weighs about 2gram. It contributes to the 2.5% secretion of total saliva.

Anatomy- It lies at the anterior part of the floor of mouth, which is just between the mylohyoid muscle and mucosa. It opens in the oral cavity by a series of small ducts i.e. duct of rivinus and opening along sublingually fold which opens through a large duct known as **Bartholin's duct.**

The blood supply is provided by sublingual and submental arteries and its lymphatic drains into the submental lymph nodes. The nerve supply including parasympathetic supply consisting of the facial nerve reaching the gland by the submandibular ganglion and lingual nerve and in sympathetic supply includes postganglionic fibers coming through the plexus on the facial artery.[5]

Minor Salivary Gland: The minor salivary gland ranges between 600-1000 in number and playing a crucial role in protecting and moistening the oral mucosa. It is present in the submucosa throughout the oral cavity. This gland is rich in anti-bacterial protein and rich in mucin and consists of secretory immunoglobulin.

Von Ebner's lingual Serous Gland- It is present in a tongue that opens in the circumvallate papillae on the dorsum of the tongue and also in the foliate papillae on another side of tongue. This gland secretes digestive enzymes and also proteins which play an important role in the taste process. [6]

Development of Salivary gland:

It includes different stages in the development of salivary glands, as follow:

- Stage 1 (Bud formation) – This stage starts with the proliferation of oral epithelium into the ectomesenchyme that is underlined and a thin basal lamina that separates the bud from the underlined mesenchyme and the epithelium interaction with condensing mesenchyme is responsible for gland formation.
- Stage 2 – This stage includes the formation and growth of epithelial chord. As the proliferation of epithelial buds in the underlined mesenchyme gives

the formation of epithelial cords and the MES also starts proliferating this is around the glandular epithelium. Basal lamina is found to be playing a vital role in influencing the differentiation and morphogenesis of the salivary glands.[7]

- Stage 3 - It includes the initiation of branching in the terminal part of the epithelial chord. The epithelial chord proliferating and ending with branch into bulbs.
- Stage 4- In this stage the cleft formation occurs and the ECM deposits within the clefts and the connective tissue component which is present below the epithelial chord forming capsule and surrounding the entire gland. The hypothesis including the interaction of epithelial-mesenchymal. Growth factor b which is transformed by fibroblasts growth factor family and their receptors. The stage notices the contraction of actin filament at the apical and basal ends.
- Stage 5- (Canalization):- In this stage the formation of lumen takes place at the distal ends of the chord and then it takes place in the proximal end and the central part in the last. The lumen develops in the terminal buds before that they form within the ducts. In this respective stage the apoptosis occurs of centrally placed cells and the proliferation of inner and outer layers of the epithelial chord occurs with the fluid secretion by ductal cells that increase the hydrostatic.
- Stage 6- (Cytodifferentiation)- In this stage which follows the formation of the lumen within terminal buds in which the epithelium including the two layers – the inner cells differentiate into the mucous or serous cell and the outer cells differentiate to myoepithelial cells which are present in and around the secretory and intercalated ducts. The result gives the main excretory duct which formed by epithelial bud portion that is close to the oral cavity as well as the secretory end piece forms by the distal portion.

Histology of Salivary Gland: The histology includes the acinar units, ductal system & connective tissue.

The acini is the basic functional unit of the salivary gland and the secretory unit is formed by serous cells, mucous cells, and myoepithelial cells. The cells in acini rest on a basement membrane and the central lumen which is star-shaped due to extension of the lumen between the cells resulting in intercellular canaliculi. The mucous acini have larger lumen as compared to serous acini and the continuing central lumen forming the excretory duct i.e. ductal system.[8]

Serous Cells- Morphologically it is pyramidal in shape with a broad base in the basement membrane and apex focusing toward the lumen. Finger-like extensions are noticed between the adjacent cells which are known as intercellular canaliculi which increase the size of cells of the luminal surface. The apical cytoplasm showing the secretory granules that are 1mm in diameter. The secretory granules including the zymogen granules and the glycolate proteins are stored in a vacuole. The desmosomes and adhering junction holds the adjacent cell and thus helps in cell signaling. The gap junction allowing the passage of ion and small molecule in between the cells.

Mucous Cells- the structure showing the apex of cells appears to be empty except for the thin strands of cytoplasm resulting in a trabecular network. Compressed nucleus and the rims of cytoplasm present against the base of the cell. Oval or flattered in shape nucleus can be observed which is located just above the basal plasma membrane. Large amount of secretory product is accumulated by mucous cells in the apical cytoplasm.[9]

The mucous secretion differs from serous secretion by two ways, which includes:

1. As they have less or no enzymatic activity and crucially serving the lubrication and protection action of oral tissues.
2. The ratio of carbohydrate to the protein is higher and a greater amount of sialic acid and often sulfated sugars is present.

Myoepithelial cells: These are the contractile cells attached with secretory end pieces and intercalated ducts of the salivary gland. These cells are similar to smooth cells but are derived from epithelium. They are located between the basal lamina and the ductal cells. Desmosomes connect the myoepithelial cells plasma membrane to the basal membrane of parenchymal cells. They are spider-like cells having nucleus flattened with flat perinuclear cytoplasm and secretory and duct cells are embraced by long branching process. Their appearance gives basket cells as basket cradling the secretory unit. The immunofluorescence studies indicating the presence of actin and myosin. A regular pulsatile movement of the entire unit occurs. These cells containcytokeratin

filament and actin filaments. This helps it to identified immunohistochemically. The function of these cells includes the acceleration of the initial outflow of saliva and contributing to secretary pressure in the duct. It also reduces the back permeation of fluids and supports the underlined parenchyma. Recent research has shown that myoepithelial cells playing a role in the signal to the secretory cells and protecting the salivary gland tissue. These cells also produce several proteins that have a tumor suppressor activity like as angiogenic factors that provide a barrier in fighting against the epithelial neoplasms. [10]

Ducts: The different ducts involved as- Intercalated ducts which are the smallest – striated ducts i.e. intralobular – excretory ducts (interlobular). The ducts play a main role in modifying saliva by the secretory and resorptive process. The intercalated ducts replace the damaged cells in the striated ducts. The striated ducts which are lined by tall columnar epithelial cells and the nucleus is placed centrally. Eosinophilic cytoplasm shows prominent striations at the basal end of cells, helping in the absorption of sodium, and excretion of bicarbonate and potassium. The excretory duct includes two layers which are mucosa and connective tissue adventitia. The transformation of stratified squamous epithelium from cuboidal occurs by ductal epithelium slowly.[11]

Connective tissue elements: These cells include macrophages, mast cells, fibroblasts, plasma cells, and fat cells. These cells are embedded in ground substance consisting of proteoglycans and glycoprotein. These elements tissue forming the capsule for gland and dividing the gland into lobules.[12]

Conclusion: Salivary gland which secretes saliva contains digestive enzymes like lingual lipase and amylase, these enzymes start breaking the food in the oral cavity or mouth and the chewing process the food mixes with saliva, thus starting the mechanical process of digestion and in return produces a bolus that can be swallowed down the esophagus entering into the stomach, wherein the stomach the gastric phase of digestion takes place. Thus saliva helps in food digestion and maintains oral hygiene by keeping the oral cavity moist and reducing it to dry to prevent the infection in the mouth. There are different disorders relating tothe salivary gland that includes sialolithiasis, sialadenitis, and many more. A disease known as Sjogren's syndrome results in the dry mouth, which is a disorder of salivary gland, that often occurs with lupus and rheumatoid arthritis.

Blue M–Healing with Oxygen

Sukanya Mishra[1], Manoj Kumar[2], Rinkee Mohanty[3], Abhaya Chandra Das[2], Saurav Panda[2], Gatha Mohanty[4]

[1]Post graduate Trainee, [2]Associate Professor, [3]Professor and Head, [4]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha "O" Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

Studies reveal that, world's two-third of population suffers from chronic form of oral diseases and wounds. The principle etiological factor behind is a polymicrobial complex, which initiates the increase in the formation of reactive oxygen species e.g. per hydroxyl radicals, peroxyl radicals, aryl peroxyl radicals etc. These ROS may cause damage to protein, lipid and DNA at sub molecular level. To combat these microcosmic reactions, a revolutionary inventiveness for optimum oral health was carried out by a European based company in the form of a product, Blue-M. This acts as a continuous supplier of oxygen and by perfusion of this oxygen, it enhances healing of wound. It further aids in collagen synthesis, angiogenesis and is comprehensively Osseo inductive as well as anti-inflammatory in nature. Thus, this review aims at understanding the obligatory functions of oxygen and the biology behind neutralization of inflammation as well as to recognize the essential benefits of this novel product, which in near future, after numerous studies, may even be used as an effective anti-microbial agent without developing resistance.

Keywords: *Blue-M, Nascent oxygen, Wound healing.*

Introduction

Wound healing is a dynamic nexus of processes, which has inflammation, granulation and maturation phases in it. When it comes to the specialization of oral cavity, occurrence of wounds and inflammation are common. There is accumulation of dental plaque accompanied with enhanced hostinflammatory response as well as inflammation of gingiva.[1] This, in long term, leads to onset of inflammation of bone and other peri-radicular tissues. This can also be associated with other oral problems like mucositis, ulcerations, bad breath etc.

Apart from maintenance of oral cavity by eradication of microbes,to accelerate the healing of these wounds, ample amount of oxygen is required.

Lately,unconventional mouthwashes and gels, containing oxygenating technology has been introduced (Blue M, Europe), having anti-microbial and anti-inflammatory properties. It prevents formation of plaque biofilm as well as promotes teeth whitening, and improves the rate of wound healing.[2]

Role of Oxygen in Wound Healing: Gingival wounds, as known, involves healing as well as phagocytosis of microbial intruders. "Professional phagocytes of our innate immune system increase their oxygen consumption through the inducible activity of NADPH oxidase (NOX) that generates oxygen and hydrogen peroxide." These oxygen-derived metabolites release Reactive Oxygen Species(ROS), that are potently antimicrobial but which may also cause damage by destroying surrounding tissue and cellsby substantial damage cellular phospholipid, nucleic acid, protein, carbohydrate, and enzymes. These events are

investigated in phagocytes (neutrophilic and eosinophilic granulocytes, monocytes, and macrophages). Exposure of these cells to any of a large number of stimuli activates a ''**respiratory burst**,'' caused by an activation of the plasma membrane-bound NADPH oxidase. Approximately 98% of the oxygen consumed by wound neutrophils, is utilized for respiratory burst.[3]

Topically applied oxygen gas increases the partial pressure of oxygen of the superficial wound tissue. Interestingly, topical oxygen treatment was associated with higher VEGF expression in the wound edge tissue. Pure oxygen is known to induce VEGF. Deliberate hyperoxygenation recruits endothelial progenitor cells to the wound, increases vascular endothelial growth factor (VEGF), and promotes angiogenesis.[4]

Hydrogen peroxide enhances collagen mRNA abundance and other cytokines and growth factors depend on oxygen supply. Another role of oxygen is to support one or more needs of growing vessels such as hydroxylatingprolinerequires oxygen to convert procollagen to collagen.[5] In addition to having this antibacterial property, oxygen is also an antifungal and antihistamine substance.[6]

Therefore, to briefly summarize, oxygen is essential for

- Production of collagen
- Wound tissue epithelialization
- Neovascularization
- Phagocytosis
- Mortification of necrotic wound tissue

Composition of Blue-M and its Basis:

1. **Sodium Perborate:** Key active component and is required for plaque control and facilitate wound healing. Sodium perborate itself doesn't exert any action rather, it reacts with saline and produces nascent oxygen. Since we know that the use of high concentration hydrogen peroxide disinfectant damages the wound tissue, due to production of increased number of free radicals. However lower concentration (<0.15 %) of hydrogen peroxide, when present continuously, is deleterious to pathogenic bacteria only, without causing damage to healthy cells. Hence, acts as a steady source of active oxygen.[7]

2. **Honey[8]:** For plaque control. Basically, honey is phytochemical and has antibacterial characteristics. Its wound healing aspect is attributed to liberation of proinflammatory cytokines i.e. macrophages and monocytes from the neighboring cells.It even exhilarates the production of IL-1β,IL-6 and TNF-α from Matrix metalloproteinase- 6 cells and peripheral blood monocytes. Moreover, Type II arabinogalactan proteins are identified in honey, having immune modulatory characteristics, due to its endotoxin content, which again has stimulatory effect on monocyte family to release TNF-α.

   Honey contains antioxidants that breaks the inflammatory cycle by scavenging the reactive oxygen species. Anti-inflammatory effect of honey is also due to inhibition of COX-2 and inducible NO synthase expression. An in-vitro pilot study has shown that Blue-M mouthwash solution is comparatively effectual than chlorhexidine and is annihilates unicellular as well as multicellular (biofilm) microorganisms.[9]

3. **Xylitol:** Also, for plaque control. Unlike glucose, the classical acid forming bacterial, contained in dental plaque cannot metabolize xylitol as a nutrient. This result due to conversion of xylitol into xylitol 5-phosphate (X5P) once the bacterial cells ingest it and xylitol inhibits acid production. Therefore, xylitol halts the growth of *S.*mutans and S. sobrinus.[10]

   This mechanism credits to retarded cell to cell adhesion of bacteria and polysaccharide production which amounts to less bulk of plaque biofilm and the biofilm is also less sticky.

4. **Methyl Salicylate:** A salicylic acid derivative, this product has been used since long as a constituent of mouth rinses in combination with essential oils (Listerine). It even comes in the group of non-steroidal anti-inflammatory drugs and therefore, also has mild analgesic property. Known to have antisepticand anti-inflammatory effect, methyl salicylate is one of the active ingredients of Blue-M.[11]It acts by disrupting the cell membrane and inhibiting its enzyme activity. Its slight minty characteristic further acts as an add on to the product's flavor.

5. **Lactoferrin:** Acts as bone growth accelerator. From the group of transferrin, there is another iron-binding glycoprotein, Lactoferrin. Apart from being

present in the secondary granules of neutrophils and epithelial secretions, lactoferrin is also readily available in breast milk. This pleiotropic factor has eloquent immunomodulatory and antimicrobial facets. Lactoferrin triggers the differentiation and multiplication of Osteoblast-Like Cells.[12] Therefore, this increased number of osteoblasts has the capacity to orchestrate and mineralize new bone and can also pause cell death. Lactoferrin Inhibits Osteoclastogenesis i.e. even though it directly doesn't affect the osteoclasts' ability to resorb bone but decreases thepotency of precursor cells to produce osteoclasts.[13]

Mechanism of Action of Blue-M: The basic mechanism of Blue-M is controlled delivery of active oxygen i.e. hydrogen peroxide to the site of treatment.

This occurs when Sodium perborate comes in contact with water, it creates a chemical process of hydrolysis, the end products being hydrogen peroxide and boric acid. Hydrogen peroxide further reacts with saline and releases nascent oxygen.

Method of Application

Few elementary steps are followed:

(i) **Preparation and treatment step:** The fundamental procedures like examining the treatment site clinically, taking radiographs and preparation of patient is done. Once the treatment has begun an acute wound is formed. On this wound the gel is applied and left for 2 minutes. The area is then flushed with saline. The previous step is again repeated but now the gel is left as it is in the wound.

(ii) **Patient care:** Patient is instructed to brush twice daily with Blue-M toothpaste. Rinse with blue M mouthwash postoperatively, 4 times a day for 1 minute, for 4 weeks, followed by 2 times a day for 1 minute. In cases of gingival recessions/pockets, use an interdental brush with blue M gel twice daily is recommended.

(iii) **After care:** Follow up period is 2 weeks, 4weeks and 8 weeks. Reevaluation of clinical parameters as well as radiographs are done after 4months and 1 year. This is done to assess the developments in soft/ hard tissue level.

Clinical Indications for Using Blue-M: Gingivitis, periodontitis, periodontal abscess, pericoronitis, periimplantitis, implant treatment and maintenance, halitosis, flap surgeries, endodontic treatments, after tooth extraction, oralmucositis, aphthous ulcer, wound healing, xerostomia.

The products available are Blue M oral gel, mouthwash, fluoridated/non fluoridated toothpaste, mouth spray, oxygen fluid.

Conclusion

Research has shown that nearly all processes in illness can be linked to oxygen deficiency. If we look at the oxygen saturation (pO2 values) of infected or damaged tissue, we find that these values are much lower than they would be in a situation of health. Long-term insufficiency of oxygen saturation will put tissue in what is known as a chronic phase, and no healing is possible thereafter.

The importance of oxygen to the body has long been known, and so oxygen therapy is often practiced nowadays.

Long-term studies on this product can have effective and non-toxic effect on addressing multifactorial infective conditions, without developing resistance to microorganisms unlike antibiotics and can help in accelerating healing process in future practices.

An Eye for an Eye Makes Maxillofacial Prosthodontics Beautiful: A Case Report

Rasmita Samantaray[1], Krishna Nanda[1], Sitansu Sekhar Das[2]

[1]Postgraduate Student, [2]Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Loss of eye causes physical and emotional disturbace in patient. Rehabilitating the missing eye with ocular prosthesis can alleviate their suffering and brings back confidence in them.Maxilla facial prosthesis includes artificial prosthesis that replaces missing part of facial region which are removed/lost due to trauma,congenital defects or any kind of malignancies. Customized occular prosthesis is one of the method of rehabilitating a missing eye. The re are many method and materials used for fabrication of these prosthesis which has already been discussed in many literature,out of which acrylic resins prosthesis provides better esthetics. The y are economical and characterization is possible. This case report describes the use of stock iris and custom made sclera made up of heat cure tooth colored acrylic.Acrylic resin provides various advantages over stock prosthesis by mimicking the natural eye.

Keywords: *Occular prosthesis, Eye prosthesis, Maxillofacial Prosthesis.*

Introduction

Losing a part of the face especially eye can cause severe physical and emotional problems. Loss of eye can be due to malignancies,congenital defect or irreparable trauma.[1] Depending on "seriousness of loss of eye,the surgical management may include one of three approaches"[2]

Evisceration: "Excision of the intraocular contents of the globe,leaving the sclera and sometimes the cornea".

Enucleation: "Removal of the entire globe and a portion of optic nerve from the orbit'.

Extenteration: "Enbloc removal of the entire contents of the orbit including the extra ocular muscles.[3,4]

Custom made eye prosthesis provides "improved aesthetics and fit but usually more time consuming and complicated".

Case Presentation: An 36 year male patient reported to department of Prosthetics, IDS, Bhubaneswar for a prosthetic replacement of missing left eye. His history revealed that he got his left eye eviscerated 4 years ago due to inverter blast. On Examination it was noticed that anopthalmic socket was healthy with synchronous movement. "Adequate depth was present between upper and lower fornices of the affected side of eye for retention of prosthesis". There was a contracture in left eye lid and healed scar in the eyebrow region.

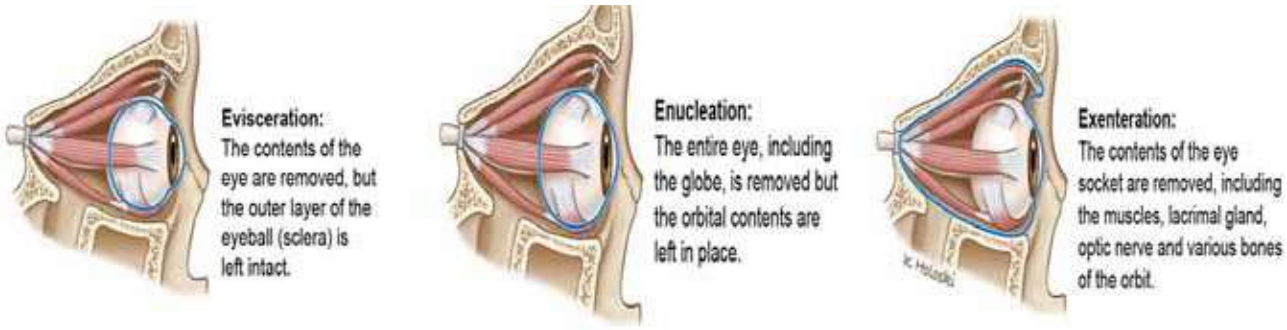

Figure 1.

Figure 2. Left Eye Missing

Technique: Petroleum jelly was applied to the surrounding areas around the eye so that the impression can be retrieved easily. Extra ocular impression was made with alginate (coltene whaledent pvt Ltd) reinforced with simultaneous layering of plaster (BN Chemicals) and Gauge.

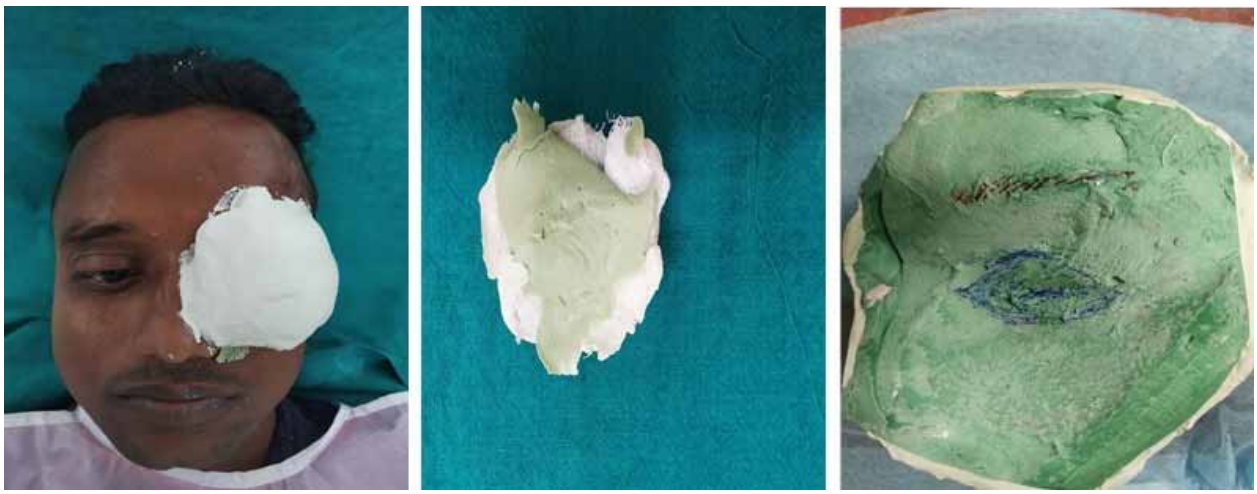

Figure 3. Impression made and cast obtained

After setting of the plaster the whole extra ocular impression was removed and then poured with dental stone (BN chemicals) and cast was retrieved. In the cast spacer of 1 mm was given and a special tray was fabricated using cold cure material (coltene whaledent Pvt Ltd).Fives holes of 2mm diameter was made on the tray. A syringe conformer was attached to the centre of the special trayThe special tray was checked for passive fit in socket and ocular impression was made with light body addition silicone (coltene whaledent Pvt Ltd) by inject through the syringe conformer attached. The patient was asked to make functional movements. After setting of the impression material it was then removed from the eye ball socket. The n the impression was boxed with a paper cup and stone was poured in two layers to obtain a mould. The syringe conformer provided a channel through which molten wax was allowed to flow (maarc,shiva products, mumbai). A commercial available "eye shell" which matched the patients "natural iris" in color and size was selected by matching with the "right eye". The n wax trial was done and position of iris was verified. Flasking and de waxing was done using conventional method. Selected shade of heat cure acrylic resin (coltene whaledent Pvt Ltd) was mixed and packed into the mould and then final curing of heat cure acrylic was done. Trimming and polishing was done. Prosthesis was disinfected. Final insertion of the acrylized prosthesis into the "eye socket" was done and evaluated for esthetics and comfort of the patient. The patient was educated on how to insert and "remove the prosthesis". Regular follow up appointments was scheduled along with instructions on maintenance of prosthesis.

Figure 4. Special tray made and final impression made with light body

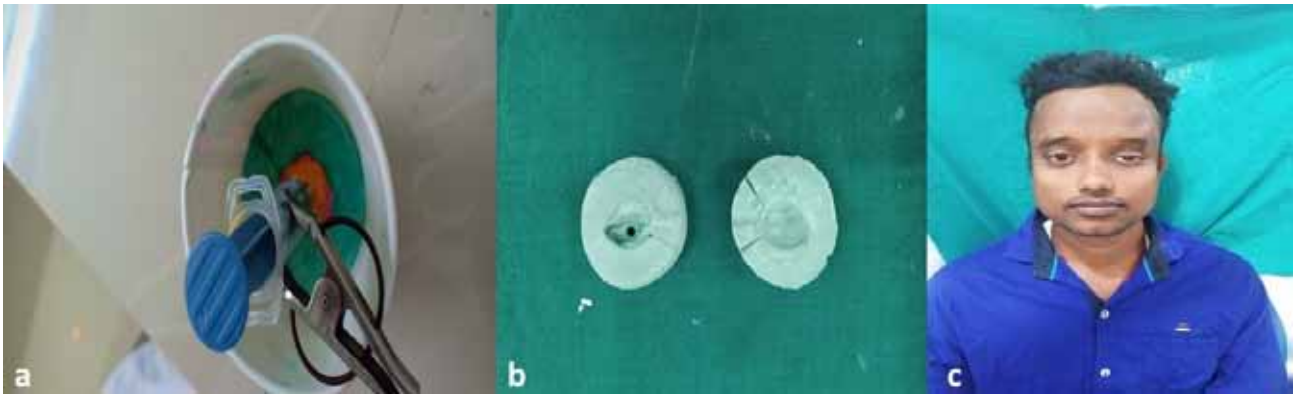

Figure 5. a, b. Final Impression Boxed and Split Cast c. Wax Trial Done

Figure 6. Final Insertion Of Prosthesis

Discussion

Custom made eye prosthesis gives a close contact between prosthesis and tissue bed thus it prevents accumulation of tears and mucous thus incidence of conjunctival abrasion and infection is less. It also provides good esthetic result and retention and stability[5]. Also in custom made prosthesis the iris and the sclera can be painted in accordance with the adjacent natural eye thus making it appear more esthetically pleasing.

Conclusion

Customized occular prosthesis is one of the method of rehabilitating a missing eye. The re are many method and materials used for fabrication of these prosthesis which has already been discussed in many literature,out of which acrylic resins prosthesis provides better esthetics. The y are economical and characterization is possible. This case report describes the use of stock iris and custom made sclera made up of heat cure tooth colored acrylic. Acrylic resin provides various advantages over stock prosthesis by mimicking the natural eye.

Red and White Lesions of the Oral Cavity: An Update

Tariq Soyab

Post Graduate Trainee, Department of Oral Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, 751003, Odisha, India

Abstract

In our oral cavity various pathological conditions have been reported which includes different type of lesions which require a proper diagnostic criteria, clinically correlation including radiographic & histological reports for its diagnosis. In this article we focus on the various types of red and white lesions of the oral cavity which have been classified based on its etiology, variation in structure, appearance, precancerous potentiality & etc. The lesion appears white due to changes in the epithelium which can be caused by an increase in the keratinization of normal keratinized mucosa, keratinization of non keratinized mucosa or thickening of the epithelium. The reduced vascularity or fibrosis of mucosa can also lead to the whiteness of the oral mucosa. The red appearance of the lesion appears because of the inflammation,atrophy, vascular dilation, and purpura or reduced in the keratinization of the oral epithelium. Generally the red and white lesions are benign and a large proportion of the normal population has been affected by it. The most common precancerous condition which comes under these lesions classification is Leukoplakia**.** A proper management of this condition is required to avoid its future complication. All conditions should be properly examined by taking a proper and careful history. However a biopsy is much needed for these conditions to be diagnosed accurately.

Keywords: *Red Lesion, White Lesion, Leukoplakia, Keratinization, Precancerous.*

Introduction

The red and white lesions are most commonly affected lesion in the oral cavity. To understand the various colors of this lesion one has to know, the color of oral mucous depends on the Degree of keratinization, dilation, and concentration of blood vessels, the amount of melanin pigment present in the epithelium and thickness of the epithelium. The whiteness of the oral mucosa can be due to acanthosis, hyperkeratosis, and necrosis in oral epithelium, vascularity reducing in the underlying lamina propria, and accumulation of fluid intracellular or extracellular in the epithelium. Same as the red appearance is caused by enlarged blood vessels, atrophic epithelium, and an increase in vascularisation and a decrease in the number of epithelial cells.[1]

Classification According to the Burkett's 11th Edition:

- **Red and White tissue reactions**
- **Infectious diseases,** which includes
  - Oral candidiasis
  - Hairy leukoplakia
- **Pre Malignant lesions**
  - Oral leukoplakia and Erythroplakia
  - Oral submucous fibrosis
- **Immuno Pathologic Disease**
  - Oral lichen planus
  - Drug induced lichenoid reaction

e-mail: soyabtariq21@gmail.cm

  - Lupus Erythematosus
  - Lichenoid Reaction
- **Allergic Reactions**
  - Lichenoid contact reactions
  - Reaction to dentifrice and Chlorhexidine
- **Toxic Reactions**
  - Reactions to smokeless tobacco
  - Smokers palate
- **Reactions to mechanical trauma**
  - Morsicatio
- **Other red & white lesions**
  - Benign migratory glossitis
  - Leukoedema
  - White sponge nevus
  - Hairy tongue

Infectious Disease:

1. **Oral Candidiasis**:-It is also known as oral thrush. It is caused by yeast *Candida albicans*. The different species of Candida which are responsible for the infection are c. albicans, c. tropicalis, and c. glabrata thus contributing in the 80% of cases. The production of lipases facilitates the penetration of yeasts into the epithelial cells.[2]

   Pathogenesis:

   Yeast cells adheres to host cell

   ↓

   Host cells triggers yeast to hypha transition

   ↓

   Uptake of fungus by host cells through endocytosis

   ↓

   Penetration of fungal active into host cells

   ↓

   Formation of biofilm

Various traits also influence the fungal pathogenicity, which includes Hsps, induction of hyphal formation by uptake of amino acids, and extracellular alkalinization.

Classification includes Acute, Pseudomembranous, Erythematous, and Candida associated lesions such as denture stomatitis, angular cheilitis, and median rhomboid glossitis.

Pseudomembranous Candidiasis: The oral lesions are white, soft and plaques are elevated occurring on buccal mucosa, tongue, gingiva, palate, and floor of the mouth. Acute form belongs to classic Candida infection whereas chronic form is associated with HIV and steroid inhalers. It affects the people who are under medication for prolonged antibiotics and immunosuppressant drugs.[3]

Erythematous Candidiasis: It is also known as antibiotic stomatitis and occurs due to a long course use of broad-spectrum antibiotics, smoking and steroids inhalation. It can occur in any site and it's the only variety of oral candidiasis that is consistently painful.

Chronic plaque-type and nodular candidiasis: It is also known as chronic hyperplastic candidiasis. It is featured by a white plaque. The lesion is firm, white persistent plaques occurring in the lips, tongue, and cheeks. This form is associated with malignant transformation.[4]

Candida-Associated lesions:

I. Denture stomatitis

II. Angular Cheilitis

III. Median rhomboid glossitis

IV. Oral candidiasis associated with HIV infection, Management of following involves:

The treatment of denture stomatitis includes eliminating the predisposing factors, dentures should be kept in antimicrobial solutions and surgical excision.

Angular cheilitis is treated by topical miconazole or a mild steroid ointment suppresses the inflammation.[5]

The treatment of median rhomboid glossitis involves the use of topical antifungal clotrimazole, fluconazole, and topical corticosteroid which includes fluocinonide 0.05% & clobetasol 0.05%.

2. **Hairy Leukoplakia:** This lesion is a corrugated white lesion that occurs on the ventral or lateral surfaces of the tongue. The disease affects mostly the severe immunodeficiency patients. It is the

second most HIV associated lesion. It mostly affects men as compared to females.

Pathogenesis: The marker involves lowering of **CD4+ T- lymphocytes counts.** Greenspan and the co fellows in 1984 reported the first time. It is strongly associated with the Epstein Barr virus. The clinical features involve vertical white folds in the borders of tongue **shaggy orfrayed** appearance. The lesion is bilateral often, asymptomatic and cannot be scraped off. A palisading pattern can also be seen clinically.[6]

Histopathology Features: In the irregular surface severe hyperkeratosis can be noticed with acanthosis. Hairs can be seen projecting from the surface. Balloon cells can be observed in the spinous layer 7 pyknotic nuclei. The important microscopic features involve homogenous nuclear inclusions and EBV can be detected by in situ hybridization or by IHC. The lesion does not require any treatment. However antiviral drugs such as acyclovir, zidovudine is been used and topical application of podophyllin resin 25% solution is used. The malignant transformation is very low.[7]

Pre Malignant Lesion:

1. **Oralleukoplakia:** It is the most common premalignant condition. It is a white patch that can't be characterized pathologically or clinically as any other disease.

Pathogenesis: The cause of Oral leukoplakia is still unknown.

The various etiologic factors of leukoplakia include:- Use of tobacco, hot, cold and acidic foods, beverages, occlusal trauma, syphilis, presence of candida Albicans, sharp tooth, ethanol, and presence of viruses.

Oral leukoplakia is more common in men and it mostly occurs over 50 years of age.

Clinical Findings: It is usually asymptomatic and occurs in the floor of mouth, buccal mucosa, maxillary gingiva, hard palate, lip, soft palate, and lip vermilion. The borders are ragged or smoothly contoured. The mouth is scattered by solitary or multiple plaques. The most common occurring sites or at high risks isthe floor of the mouth and lateral borders of the tongue for malignant transformation.[8]

Classification: Oral leukoplakia can be classified as:

1. **Homogenous leukoplakia:** In this type no red component can be found and is asymptomatic and the lesion is white and consists of well-demarcated plaque. Surface fissures appear as cracked mud.
2. **Speckled Leukoplakia:** This form of leukoplakia consists of both red and white flecks of line.
3. **Erythroplakia:** In this form also a combination of both red and white patches can be observed.
4. **Verrucous Leukoplakia:** It is a lesion where verrucous areas are present. It consists of nodular or exophytic components. The lower gingiva is a predilection site. An aggressive form of this lesion can occur which is called proliferative verrucous leukoplakia in which the reoccurrence rate is high.

Diagnosis: The cause should be eliminated such as sharp tooth or restoration.

If the healing does not occur then a biopsy is must required.

Histopathology: The Features include hyperkeratosis, hyperplasia, and atrophy.

The malignancy rate of oral leukoplakia is between 4%-8%.

Differential Diagnosis of this lesion includes lichen planus, smokeless tobacco lesion, hairy leukoplakia, verruca Vulgaris, lupus erythematous, cheek biting lesion, white sponge nevus, etc.[9]

Management: The management involves first and furthermost to discontinue the habits. Different types of surgeries include cold knife surgical excision, laser surgery are widely used. Chemoprevention is used in the form of topical bleomycin. Antioxidants such as retinoic acid and beta carotene are administrated. Stripping procedure with free grafts is also used.

2. **Oral Submucous Fibrosis:** It comes under the classification of premalignant lesions. It is a chronic disease that is mostly caused by the use of arecanut. It has a high risk of malignancy. The metabolism of collagen is affected by arecanut which leads to increased fibrosis.

Clinical Features: The hallmark diagnosing feature is the Burning sensation in the patient mouth. Excessive salivation, dryness of mouth, generalized inflammation with ulcerations can also be seen. In the cheek and palate small vesicles can be observed. Bands are also

present where pain persists. In the advanced cases of this lesion in the entire oris or mouth orifice circular bands are found, difficulty in swallowing, fibrous bands appearance, difficulty in tongue movement and inability to whistle are observed.

Histopathology: It involves hypertrophic fibroblasts, epithelial atrophy, loss of rete pegs, edema, and dilated & congested blood vessels.[10]

Management It involves furthermost the elimination of habit. In treatment plan vitamin B complex and high proteins and calories should be taken. Glucocorticoids which act as immunosuppressive agents is been used. Local injections of hyaluronidase, dexamethasone, and placental extract are used. In surgical management involving the excision of the fibrotic bands by fresh human placental grafts, followed by the injection of dexamethasone in the advanced cases.

Immunopathologic Diseases:

1. **Oral Lichen Planus:** It is one of the most common diseases. The cause of this disease is still unknown. It can consist of both red and white components with different textures.

The autoreactive T lymphocytes play a vital role in the development of OLP. Severe pruritis is a primary symptom of this disease. The surface is covered by very fine grayish-white lines called **Wickham's Straie.** One of the classical hallmarks of these skin lesions is **pruritic erythematous to violaceous papules**. Koebner phenomenon is associated with this disease. Genital mucosa is the most common extraoral mucosa site. The OLP has different forms which include Reticular Form, popular form, plaque form, Bullous form, Erythemateous form, and ulcerative form.

Histological Features: It includes Liquefaction degeneration, hyper ortho keratosis, and sawtooth appearance of retepegs. Beneath the basement membrane one can notice an eosinophilic band and thickening of the granular cell layer.

Management: It involves the use of Corticosteroids, Calcineurin inhibitors, Tacrolimus, Pimecrolimus Retinoids, Dapson, Mycophenolates Enoxaparin, Efalizumab. The different nonpharmacological modalities include PUVA therapy, Photodynamic therapy, and LASER therapy.

2. **Drug:** Induced Lichenoid Reactions-It is a type of lesion which exhibits similar histopathological features as lichen planus and clinically it is very difficult to distinguish between drug-induced lichenoid reactions and lichen planus. It can be differentiated from the OLP based on drug administration, contact with a metal or systemic disease & when the factor was eliminated, on resolution. The causes include Gold therapy, NSAIDs, Other hypertensives, etc. Clinically ulcerative reaction pattern can be seen and unilateral.[11]

Management: The treatment involves discontinuation of drug and topical steroids are used.

3. **Lupus Erythematosus:** It is an autoimmune disorder, which is chronic. The etiopathogenesis of SLE is not all so clear but some research fin that it is due to the interaction between genetic and hormonal factors, and hormonal exposures. Epstein Barr virus ad cytomegalovirus is commonly associated with this disease. In some researches it has been found that ROS, which is reactive oxygen species, triggers the production of autoantigen and T cells which are involved in the pathogenesis of SLE. Different diagnostic criteria are made for SLE which includes Neurological involvement, arthritis, anti-double-stranded DNA, APLA, ANA are now considered in the inclusion criteria. The management involves the use of corticosteroids, Hydroxychloroquine, Cyclophosphamide, and other immunosuppressive agents are used.

Allergic Reactions: This classification presents:

- **Lichenoid Contact Reactions:** It is a type of hypersensitivity reaction which occurred due to the reaction of amalgam fillings. The most important disguising feature to differentiate between OLP and LCE is **the extensions of lesions.** It is usually asymptomatic. The management includes the replacement of dental materials and the healing period is 1-2 months.
- **Reactions to Dentifrice and Chlorhexidine:** It is a very rare disorder. It is a type of allergic reaction that includes flavor additives such as carvone and cinnamon or preservatives. Clinically both ulcerations and white lesions can occur. The common sites involve buccal, labial, and tongue mucosa. The healing of the lesion is seen after the withdrawal of allergic contained agents.[8-11]

Toxic Reactions: Under this classification;

- **Reactions to smokeless Tobacco:** It is divided into 3 groups; Moist snuff, chewing tobacco, and Dry snuff. It is a white and leathery lesion and gingival retractions can be seen in smokeless tobacco habit. Wrinkles at the site of application can be observed in the mild form. Discontinuation of the habit is the proper treatment regarding this lesion.
- **Smokers Palate:** It is also known as stomatitis Nicotina or Leuukokeratosis. This is a white patch diffused in nature occurring in the Hard Palate. It is usually caused by smoking like cigars or pipe smoking. It is painless and the response of chronic heat forms this patch, during smoking. It has not an increased rate of transferring into oral cancer. Clinically one can observe gray or white nodules and the presence of red dots in the center. In some severe cases dried lake **bed appearance** can be seen in the mucosa. In this lesion a biopsy is not required usually but in some cases where red patches can be seen i.e. Erythroplakia then a biopsy is required. Stopping the habit of smoking can lead to an eradication of patch, but if the lesion persists even after the stopping then a biopsy is required must and leukoplakia condition can be diagnosed in those cases.

Reactions to Mechanical Trauma:

Morsicatio: It is also known as chronic cheek biting. In this trauma the buccal mucosa is injured due to chronic irritation due to repetitive biting or chewing. It is bilateral and the lesion is white with thickened mucosa. Erythema (redness) and ulcerations can also be seen. No treatment is required for this trauma, however if the problem prolongs then one can seek medical attention.[10,11]

Other Red and White Lesions:

1. **Benign Migratory Glossitis:** It is also known as geographic stomatitis. It is more common in females as compared to males. It mostly common in the age group between 20-30 years. Etiopathogenesis includes genetic like B15, DRW6, & CW6, Nutritional deficiency, hormonal and psychological disturbances. Allergy can also be a cause of this lesion. No treatment is required however mouthwash like tantum or benzydamine hydrochloride 0.15% spray can be used.
2. **Leukoedema:** It is a white lesion and occurs frequently in the buccal mucosa. The etiology is still now not clear. Bilaterally in nature and usually asymptomatic. No treatment is required.
3. **White Sponge Nevus:** Canon in 1935 first described this lesion. It is an autosomal dominant disorder. Epithelial keratin gene playing a vital role in its pathogenesis. It is a very rare disorder. Clinically a white lesion with irregular surface can be noticed in the buccal mucosa. The mucosa gets swollen in this disorder like a sponge, hence the name Sponge Nevus. It is benign with no treatment is required.
4. **Hairy Tongue:** The etiology is unknown but the predisposing factors include antibiotics, excess alcohol consumption, poor oral hygiene, immunosuppressive drugs, the microflora in mouth, and oral candidiasis. Clinically hair-like appearance can be seen due to impaired desquamation of filiform papillae. The treatment involves elimination or reduction in predisposing factors.[8-11]

Conclusion

The red and white lesions include different type of lesions and the professional require a skillful knowledge to diagnose and distinguish between these lesions. However clinical correlation plays a very important role in diagnosing apart from histological reports. The malignancy rate is not so high of this lesion except in the cases of leukoplakia or oral submucous fibrosis. Researches are done to know the etiological factors of some of these lesions.

Silver Diamine Fluoride in Clinical Pediatric Dentistry

Sarjana Mishra[1], Susant Mohanty[2]

[1]Postgraduate Trainee, [2]Professor & Head, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Silver diamine fluoride is the most recent advancement in the field of dentistry. Its history dates back to the 1960s and since its invention there was no looking back. People across the globe and different races and cultures have benefitted from SDF. With almost no adverse reactions, pocket-friendly, and highly effective qualities in its stride, SDF has emerged as a powerful tool in caries prevention, especially in a county like India where the oral health of a child is neglected. This review focuses on the history, indications, contraindications, mechanism, and safety margin of SDF as a dental material.

Keywords: *Silver diamine fluoride; Mechanism of action; Oral health, Child.*

Introduction

The field of dental sciences has witnessed plenty of changes to techniques, materials and concepts. With the advent of the 20th Century, a number of researchers began focusing on new materials that could be used to prevent dental caries. Unlike G.V. Black's concept of "extension for prevention", new age concepts focuses primarily on conservation and regeneration. The face of dentistry has changed since the concept of dental caries being a disease and not a lesion has emerged. The more we understood the mechanism of the disease process, the more we, as dentists began accepting a more medical approach towards treating dental caries. This involved the various caries risk assessments of the child patient followed by counseling the patient/parent regarding all the possible preventive methods deemed fit.[1]

One such concept which has gained popularity among dentists and researchers across the globe is Silver Diamine Fluoride (SDF). Since its invention in 1969, it has proven to be an effective and reliable alternative to other invasive treatment options.

History: Silver Diamine Fluoride was first invented by a Ph.D. Graduate named Mizuho Nishino at Osaka University, Japan in 1969.[2] She came up with the idea of using silver as an antimicrobial agent in combination with the remineralizing properties of fluoride. The product that resulted was a substance with additional properties like obliterating dentinal tubules by forming a precipitate, hence reducing dentinal hypersensitivity. Eventually, SDF was approved as a marketable product by the Central Pharmaceutical Council of the Ministry of Health and Welfare of Japan.[1] Since then, it is considered as a cariostatic agent. Toyo Seiyaku Kasei Co. Ltd., Osaka, Japan began marketing this product under the brand name Saforide.

The Food and Drug Administration (FDA) approved to release the first silver diamine fluoride product into the market in August 2014. In October 2016, SDF was awarded as the "breakthrough therapy" of the year, based on its efficacy in arresting dental caries in children as well as in adults. What followed next was the recognition of oral disease as a major medical condition and a serious public health issue.

Mechanism of action of SDF: SDF is a clear liquid product primarily made up of water, 25 % silver,

e-mail: mishra.sarjana@gmail.com

8% ammonia and 5.5% fluoride. This results in a 38% SDF.[3]As the name suggests, Silver Diamine Fluoride contains silver, which acts as an antimicrobial agent, fluoride which contains remineralizing properties and ammonia which helps in stabilizing the solution at high concentrations. SDF was first invented to arrest dental caries and prevent dentinal hypersensitivity. As the carious process begins, the dentin undergoes demineralization leading to exposure of the organic matrix. After applying a preparation of silver diamine fluoride on a carious lesion, the formation of a squamous layer containing silver-protein conjugate occurs. This layer acts as a shield against acid dissolution and enzymatic digestion.[4] Eventually, there is formation of hydroxyapatite and fluorapatite, including silver chloride and metallic silver on the exposed surface of the organic content.[5] Once applied, lesion depth begins to decrease, while at the same time mineral density and hardness increases. SDF promotes inhibition of those proteins which split the exposed organic matrix of dentin: metalloproteinase, cathepsins and collagenases.[4]

Silver ions have anti-microbial and antirheumatic properties. It acts by breaching bacterial membranes and denaturing the proteins, thus inhibiting the process of DNA replication.[6] SDF surpasses all other bacteriostatic medicaments in destroying caries causing bacteria in the dentinal tubules.[7] Silver and fluoride ions can penetrate upto 25 microns into enamel[8] and nearly 50-200 microns into dentine.[9] Carious lesions arrested due to Silver diamine fluoride are nearly 150 microns thick.[10] Lesions that are artificially treated are defiant towards the formation of a biofilm and additional cavity formation, apparently because of the presence of residual silver ions.[11,12] It is found that more amount of silver and fluoride is deposited on demineralized carious dentin as compared to non-demineralized dentin as a result of which, demineralized dentin treated with SDFis better resistant to further caries attack than sound dentin treated with SDF.[13]

Due to the action of Silver ions, some amount of bacteria is killed. When these are supplemented to the living group of bacteria, the silver ions which were present are replenished and reactivated. As a result, the dead bacteria successfully kill the living bacteria as well. This process is coined as a "zombie effect".[14] This explains as to why the silver ions applied to a lesion within a cavity demonstrates sustained antimicrobial activity. While treating hypersensitivity, the application of topical SDF promotes the formation of a squamous protective layer on the exposed dentin matrix, eventually obliterating dentinal tubules.[6] This mechanism of action of SDF is in agreement with the Hydrodynamic theory of dentin hypersensitivity.[15]

Indications:

1. **Active carious lesions:** Both silver and fluoride ions display potential to prevent the formation of cariogenic biofilms. Increased concentration of fluorides can unite to the cellular components of cariogenic bacteria and regulate enzymes that help during glucose metabolism and also sucrose uptake.[16] Simultaneously, silver ions denature the bacterial cell wall, control enzyme activities,sway metabolic processes and hinder the replication of bacterial DNA.[16]
2. **Remineralization:** Fluoride acts as a remineralizing agent of hydroxyapatite in enamel and dentin. This takes place when SDF reacts with hydroxyapatite of teeth forming calcium fluoride and silver phosphate.[5] This calcium fluoride thus formed, is a reservoir of pH regulated fluoride on the surface of the decayed tooth. 38% SDF contains 44,800ppm of fluoride.[8]
3. **For caries prevention:** Topical application of SDF on healthy tooth surfaces prevents caries in children.
4. **Dentinal Hypersensitivity:** SDF promotes obliteration of dentinal tubules thereby reducing hypersensitivity.[18]
5. **Root caries:** Because of the virtue of SDF to arrest active caries, it can be annually applied on cariously exposed root surfaces, without any toxicity.[19]

Contraindications:

1. It cannot be used in patients prone to silver allergy.
2. SDF tends to irritate sensitive open pores. Hence, it cannot be used.
3. SDF cannot be applied to teeth that require endodontic therapy.

Clinical application of SDF: A study of extracted teeth treated by SDF found that the application of 38% SDF increases the remineralization process of initial carious lesions. The University of California, San Francisco (UCSF) designed a clinical protocol for the clinical application to maximize the safety and effectiveness of SDF in clinical settings[20].

1. Counter top and the patient should be covered with plastic.
2. Personal protective equipment (PPE) should be provided for the patient and the clinician.
3. In a dampen dish, take one drop of SDF. Simultaneously take one drop of SSKI in a separate dampen dish.
4. Using a saliva ejector, remove the excess bulk.
5. Isolation of the selected tooth from the tongue and cheek should be done using gauze or cotton rolls.
6. Use petroleum jelly if the affected tooth surface is close to the gingiva.
7. Use a triple syringe or dry cotton to dry the affected tooth surfaces
8. Using a microsponge, bend it, dip it into the dampen dish containing SDF, and squeeze the excess on the side.
9. Apply the microsponge directly onto the affected tooth surface(s).
10. Leave the SDF to soak up for one minute, then wipe the excess material using gauze or cotton roll. (In case of SSKI, use a separate micro sponge and apply onto the affected tooth surface. Repeat for one to three times till no more white precipitate appears. Wait five to ten seconds between the applications. Wipe the excess with cotton/gauze.)
11. After one minute, rinse with water.
12. Discard the used materials into plastic waste bags.

Many clinicians prefer application of SDF first during the initial appointment, then at one and/or three-month follow-up, then at every 3 months.

Side Effects: No adverse event has been reported since the approval of silver diamine fluoride as Saforide which was marketed more than 50 years ago.[21] Silver diamine fluoride causes darkening of carious lesions although it doesn't discolour sound enamel; it will cause some degree of darkening of early non-cavitated carious lesions. It is found that due to the formation of insoluble silver phosphate, the lesion treated with SDF turns black on exposure to sunlight. To surmount this shortcoming, potassium iodide was used after the topical application of SDF.

Maximum recommended dose and safety margin: Calculating the maximum recommended dose and the margin of safety of any drug is of utmost importance. Research conducted in this aspect yielded that an average Lethal Dose orally was 520 mg/kg and 380 mg/kg via subcutaneous route. One drop (25 µL) is sufficient to treat five teeth since it contains 9.5 mg of SDF. Assuming the youngest child with caries would be about 10 kg, 0.95 mg/kg SDF would be required for the child.[23]

Conclusion

Silver Diamine Fluoride has emerged as an exceptional treatment method in the field of dentistry. No material to date has reached up to it in terms of safety, efficacy and affordability. It is primarily indicated as a means of caries prevention for children, especially those who are terminally ill or too weak to be conventionally treated. It halts the disease process. SDF application is recommended twice annually, which surpasses all invasive conventional attempts at caries prevention. In a developing country like India, where the majority of the population cannot afford professional healthcare, this new-age material is a powerful tool that would help reach out to the masses. Children with a high caries burden are advised for SDF application on all teeth until they are restored or exfoliated. More research and refinement with regards to technique needs to be conducted to improve caries prevention modalities and provide quality healthcare.

Distal Shoe Space Maintainer for the Premature Loss of Primary Second Molar in a 5-Year-Old Patient: A Case Report

Sarjana Mishra[1], Susant Mohanty[2]

[1]Postgraduate Trainee, [2]Professor & Head, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Uneventful loss of deciduous second molar, afore the eruption of first permanent molar could lead to unadorned malocclusion due to undesired loss of space in the arch, tipping, crowding of the dental arch and many other dental problems. So, to avoid further occlusal complications, it is desirable to place a space maintainer after successful extraction of the carious primary molar. This case report describes the removal of a primary mandibular second molar, followed by delivery of a distal shoe appliance before the eruption of the first permanent molar.

Keywords: *Distal shoe, primary molars, permanent first molar, crown, eruption.*

Introduction

The idea of a device to maintain space loss due to premature exfoliation in the dental arch was first given by Davenport, in 1887.[1] Space maintainers are "the appliances used to maintain space or regain minor amounts of space lost, to guide the un-erupted tooth into a proper position in the dental arch". The two main types of space maintainers include fixed and removable. The distal shoe space maintainer, also called as Intra-Alveolar Appliance/Eruption Guidance Appliance is a fixed type of space maintainer, which was first developed by Gerber in 1964.[2] It was later modified by Croll in 1980.[3,4] It is primarily given in cases where there is premature exfoliation on the second primary molar, before the eruption of the permanent molar. Since this appliance helps in guiding the eruption of the first permanent molar, it is also called an Eruption Guidance Appliance.

Hicks, in 1973[5], first used cast gold to fabricate this appliance, but it soon grew out of popularity because of its increased cost. After 20 years, Gegenhiemer and Donly,[6] were the first to fabricate a laboratory-prepared distal shoe space maintainer which was already soldered to a stainless steel crown. The advantage of this was it was less time consuming, and the patient had to visit only twice. Clinically, the indications and contraindications as described by Hicks in 1973 are [5]:

Indications:

- Premature loss or extraction of the second deciduous molar before the eruption of first permanent molar.
- Advanced root resorption and periapical bone destruction of the second primary molar before the eruption of first permanent molar.
- A primary second molar with advanced caries that is non-restorable.
- Ectopic eruption of the permanent first molar.
- Ankylosis of the primary second molar.

Contraindications:

- Inadequate abutments due to multiple loss of teeth.

e-mail: mishra.sarjana@gmail.com

- Poor patient/parental cooperation.
- Missing permanent first molar.
- Systemic diseases that affect healing such as Diabetes Mellitus.
- Cardiac anomalies that require antibiotic prophylaxis before dental treatment.

The motive of this article is to describe the management of a premature exfoliation of mandibular deciduous second molar due to extensive caries before the eruption of the permanent first molar using the Roche variety of a distal shoe space maintainer.

Case Report: A male child aged 5 years visited the Department of Paediatric and Preventive Dentistry, with a chief complain of pain in his left lower back tooth region (Fig 1). A proper history revealed that the patient had recurrent pain and swelling concerning the same since 1 month. Medical history was non-conclusive. Dental history showed the patient had previously visited the department for pulpectomy procedure.

Figure 1. 5-year-old patient with pain on the left lower back tooth region

Clinical intraoral examination showed grossly decayed primary mandibular second molar on the left side (75) and a carious primary first molar (74). (Figure 2) The permanent first molar of the same side is yet to erupt. Radiographic examination concluded the perforation of the pulpal floor, inter-radicular radiolucency and root resorption with respect to 75. (Figure 3)

Thus, it was decided that 74 was to be restored using Glass Ionomer cement and 75 was to be extracted and instead a distal shoe space maintainer was to be adapted. The procedure was explained to the parents and informed consent regarding the number of visits and the procedure was taken before the start of the procedure.

Figure 2. Intra-oral examination of 74, 75

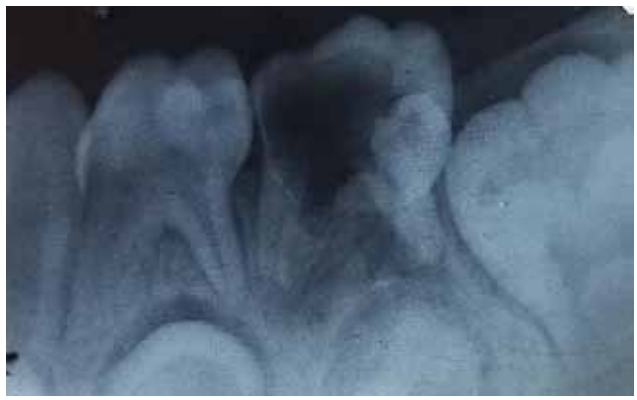

Figure 3. Radiographic examination of carious 74, and grossly decayed 75

Procedure: The primary first molar (74) was excavated for caries and restored using Glass Ionomer Cement. Eventually, it was prepared for a stainless steel crown. After tooth preparation, the crown was adapted and an alginate impression was made. Eventually, the stainless steel crown was taken out and correctly fitted into the impression and stabilised using thin 21 gauge wires, which was poured using dental stone and die stone. (Figure 4) A temporary crown using tooth coloured acrylic was fabricated chair-side and delivered to the patient. Patient was recalled after 4 days.

Figure 4. Alginate impression made and crown seated. Cast poured using die stone with adapted crown.

The distal shoe appliance was fabricated using a 19 gauge stainless steel wire. The Roche variety of distal shoe appliance was fabricated. It consists of a horizontal part of the wire spanning the space and a vertical sub-gingival extension which would be seated approximately 1 mm below the medial most aspect of the first permanent molar. The length of the loop was calculated extending from the distal-most aspect of 74 up to the mesial aspect of the un-erupted permanent first molar using a radiograph. The sub-gingival extension on the loop was scanned using the same IOPA. The wire component of the appliance was fabricated using pliers and soldered to the stainless steel crown.

During the following appointment, the deciduous mandibular second molar (75) was extracted under local anaesthesia and a prior antibiotic coverage. After haemostasis was achieved, the fabricated appliance was seated on the primary first molar and its sub-gingival extension was pushed into the extraction socket with gentle digital pressure. It was seated in such a way that the gingival loop lightly grazes the mesial marginal ridge of the un-erupted permanent first molar. After the position was confirmed using a radiograph, the appliance was cemented in place using Luting type of Glass Ionomer cement (Figure 5). Recall appointments were scheduled after one week, one month and then after every 3 months.

Figure 5. Radiographic and intra-oral images to confirm placement of the appliance.

Discussion

The primary second molar is a crucial tooth in the mixed dentition for the sole reason that it guides the permanent first molar by providing a path for an eruption. The distal surface of deciduous second molar helps to guide the eruption of permanent first molar which has a mesiooccclusion pattern of eruption. Hence, it is very important to preserve the deciduous second molar until the eruption of the permanent first molar. Extraction of the same should not be taken up unless indicated. As a result of premature loss of primary second molar, there could be loss of arch perimeter, which would eventually need complicated orthodontic intervention. The criteria of a successful placement of distal shoe space maintainer is judged by the successful guidance of the un-erupted permanent first molar into the dental arch with no or minimal glitch with the space maintainer, as suggested by Baroni et al[7] and Quidemat et al[8].

Conclusion

The major concern for a paediatric dentist is to try and save the primary second molar before the eruption of the permanent first molar. In extreme situations when that cannot be achieved, there are no other solutions except to extract it. Thus, as a subsequent treatment plan, the fabrication of an eruption guiding appliance is the safest and the best way to prevent crowding and malocclusion. It is cost-effective, less time consuming and patient-friendly method of space management. After the eruption of the permanent first molar, the appliance could either be removed or modified into a crown and loop type of space maintainer by just removing the sub-gingival extension of the loop. Hence, the distal shoe appliance is the best way to prevent serious dental malformations that could occur due to inadvertent early loss of primary second molar.

Tobacco Smoking and Cardiovascular Diseases: A Review

Upasana Dhar[1], Ramesh Nagarajappa[2], Dharmashree Satyarup[3], Marlin Jena[1], Abhilash Mohapatra[4]

[1]Post Graduate Student, [2]Professor & Head, [3]Professor, Department of Public Health Dentistry, [4]Professor, Department of Prosthodontics Crown Bridge and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, India

Abstract

The major risk factor for cardiovascular diseases (CVD) is tobacco use, if we stop use we can reduce cardiovascular disease. Atherosclerosis, which is a main contributor to cardiovascular diseases is formed because of tobacco use. Nicotine is the main addictive substance of cigarette smoke. Its effect on Cardiovascular organs is well documented but when nicotine is taken in the form of patches it effect is very limited. For this reason, Nicotine Replacement Therapy is used for tobacco cessation. Smokeless tobacco is also harmful as they contain nicotine and other chemical components which affect the gastrointestinal tract. Quitting tobacco not only have an immediate health benefit but also improves the psychosocial life of that person.

Keywords: *Tobacco, Smokeless Tobacco, Cardiovascular diseases (CVD), Atherosclerosis, Nicotine Replacement Therapy.*

Introduction

Tobacco chewing or smoking has a grim and unfavorable effect on most organs of the body and is associated with multiple diseases reducing the expectancy and quality of life. Diseases associated with tobacco usage include lung & oral cavity cancer, cardiovascular diseases, emphysema, and bronchitis. Tobacco consumption is considered highly prevalent and an epidemic both in developing as well as developed nations. The prevalence of tobacco usage is more inmen than women in India. Rustic, illiterate & poor section of the society were found to have this habit of smoking as found in a survey done by National Family Health Survey (NFHS)-3, conducted in 2005–06.[1] As it was found by Global Adult Tobacco Survey (GATS) done on persons 15 years of age or older than 34.6% of the adults (47.9% males and 20.3% females) are tobacco users. Of this fourteen percent of the adults smoke (24.3% males and 2.9% females) and 25.9% use smokeless tobacco (32.9% males and 18.4% females).[2] And in the survey done by Global Youth Tobacco Survey (GYTS)[3] on students aged 13–15 years, 14.6% of students were found to be tobacco users. Reports done on morbidity in the age group of 30 – 69 years it was found that one in twenty (5.4%) deaths among Indian women and one in five deaths (25%) among Indian men are because of smoking[4]. India has 11.2% of the world's total smokers. The main organ affected by tobacco use, are cardiovascular system and death due to cardiovascular diseases (CVD) deaths are expected to surge by 12% over the next decennium.[5] Only if tobacco use can be stopped there will be a reduction in the occurrence of cardiovascular diseases (CVD).[6] From 2007 the creation and enforcement of Cigarettes and other tobacco product acts (COTPA) and national tobacco control program (NTPC) by the government has tried to control tobacco usage[4].

The smokes of cigarettesharm numerous parts of the body thus causing diseases and ultimately death. A study done in 2015 found globally one in every ten cardiovascular deaths is attributable to smoking, and the majority of them took place in just four countries one being India. Morbidity due to cardiovascular diseases is measured in disability-adjusted life years (DALYs) and 41% of this that are attributable to daily smoking[7]. The smoke that is coming out while a cigarette is burning is a toxic mix of more than 7,000 chemicals[8] and, when the inspiration of cigarette smoke loaded air is actively or passively done by a human body, it starts interfering with the normal physiological processes of the body. Pumping and delivery of oxygenated blood to the heart and different parts of the body is one of such important physiological process which is mainly processed by heart and lungs in collaboration. As the world is developing technology-wise the urban lifestyle diseases are also increasing. Cardiovascular diseases which claim lives globally, encompasses ischemic heart diseases (IHD), cardiac dysrhythmias, cerebrovascular diseases, peripheral arterial disease and heart failure.[9]

Effect of Smoking on Cardiovascular Health: Fresh air from the atmosphere is oxygen-rich, thus when we breathe in, lungs exchange the oxygen with the impure blood and send oxygenated blood back to the heart and other parts of the body viaan artery. When we breathe in air contaminated with cigarette smoke, the blood carrying this air is dispensed throughout the body thus affecting body parts with the cigarette chemicals. The chief chemicals of tobacco smokeare total aerosol residue abbreviated as tar, carbon monoxide gas, and nicotine toxin. The maximum risk of CVD is posed by the chemicals which are present in cigarette other than nicotine. The nicotine is a highly habit-forming substance and it is associated with escalation in heart rate and blood pressure when inspired. The chemicals that reach the heart and other parts of the body will cause damage[8] and thus cause cardiovascular disease (CVD). The majorcause of all deaths for both men and women in America.[10] is cardiovascular diseases.

CVD is a generic term referring to multiple conditions affecting the heart or blood vessels.[7] Some of these conditions include:

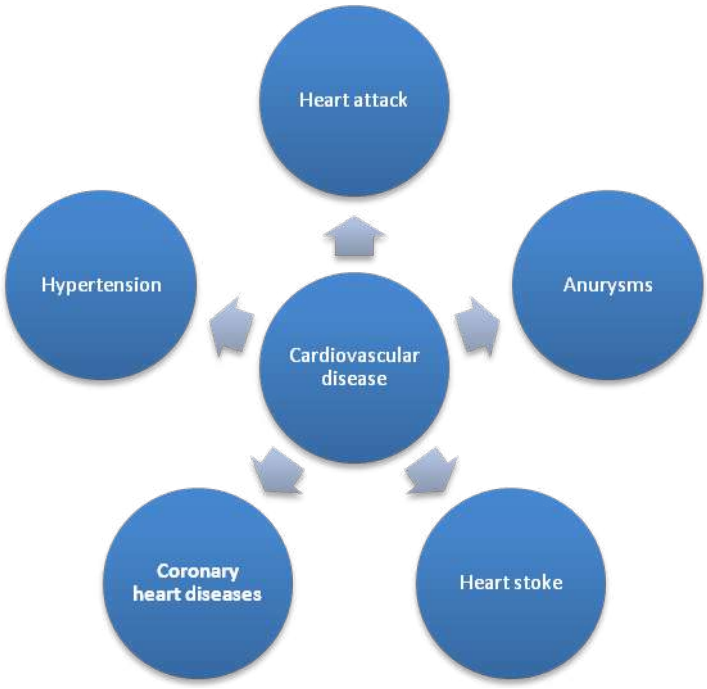

Figure 1. Multiple Condtions Leading To Cardiovascular Disease

The chemical components present in the smoke from cigarette have a seriously damaging effect on heart, its blood vessels and causes cardiovascular diseases by the accumulation of plaques on sides of the walls, the plaques are a sticky substance which consists of cholesterol, calcium, triglycerides, and scar tissue and this plaque

causes a disease called atherosclerosis.[5-7] This plaque formed causes constriction of the blood vessels, which in turn causes difficulty for the blood to flow through the vessels and reach the vital organs like the heart, brain, and lung. When there is a clot in vessels supplying the heart, it leads to heart attack, which may even cause death.[5,6]Some serious cardiovascular conditions that can be an end product of smoking are as follows:

- **Peripheral Artery Disease**: It is a common circulatory problem in which plaque builds up and narrows the arteries and reduces blood flow to your legs. Smoking along with a high amount of cholesterol and fat is the leading cause of this condition. This peripheral artery disease by itself doesn't cause any morbidity but patients with this condition are at higher risk of ischemic heart disease. And it a preventable disease which can be treated by lifestyle modification which includes quitting smoking, healthy eating, and more physical activity.
- **Abdominal aortic aneurysm**: It is a localized enlargement of the abdominal aorta like a small balloon such that the diameter is greater than 3cm. The bursting of an abdominal aortic aneurysm, may cause sudden death. Abdominal aortic aneurysm can be prevented by eating healthy food, exercising daily and avoiding smoking.[8]

Impact of cardiovascular disease caused by tobacco smoking: According to the American Heart Association, CVD accounts for about 800,000 deaths every year,[11]in United states making it the leading cause of all deaths. Of those, nearly 20 percent are due to cigarette smoking.[12] Even in persons who smoke less than 5 cigarettes per day also are at risk of CVD.[12]

Not only smokers even people who are passive smokers are at a risk of cardiovascular disease and ultimately death. There is a 25 to 30 percent increased risk of coronary heart disease in nonsmokers who are regularly exposed to secondhand smoke than those who are not exposed.[12] In fact, according to surgeon general report 33,000 U.S. coronary heart disease deaths per year are caused by exposure to secondhand smoke[13] Passive smokers exposed to cigarette smoke increases the risk of a heart attack..[12,13]

It is time to protect your heart: Smoking is a bad habit and we all must refrain from this habit, for people who have this habit, it is time to quit smoking now as it is said it is better to be late than never and the earlier you do it the better. Once a person gives up his smoking habit, certain changes start occurring in our body:

- Heart rate drops after twenty minutes of quitting smoking.[14]
- In 12 weeks circulation improves and lung function also increases[14]
- The level of carbon monoxide in the blood plunge to normal, allowing more oxygen to vital organs like your heart & brain just after 12 hours of quitting smoking.[14]
- The risk of stroke drops to that of a lifetime non-smoker within five years of quitting smoking.[15]

Conclusions

Quitting tobacco smoking has many immediate and lifelong benefits. By quitting smoking, immediately blood pressure and heart rate normalizes, the destruction process of lungs will stop and the body will try to repair itself. And, after one year of quitting smoking the risk of coronary heart disease reduces to half when compared with a smoker. Socially and frugal, benefits of quitting tobacco, are enormous not only we save our income of not buying cigarettes but also we can protect society from the harmful effect of passive smoking particularly the vulnerable group babies, teens. Nicotine when given as patch or better known as Nicotine Replacement Therapy is neither addictive nor affects the cardiac health. As quitting an addictive habit like smoking cigarettes is difficult, these therapies can be of help and can help us achieve our goal to completely quit smoking. There are some good habits which can help boost our health along with these therapies, they are regular exercise, eating a healthy diet,getting to an ideal body weight, reduce stress, limit alcohol consumption, make sure other health conditions, such as diabetes & hypertension, are under control. Last but not least have 8 hours of sleep and visit a physician regularly for routine check-up after the age of 60.

Quitting tobacco also reduces the impotence, low birth weight, Preterm babies and miscarriage[16].

So to conclude to the prevention of CVD, is directly proportional to smoking, so we should take steps to reduce the proliferation of smoking in the general population particularly in teens. This can be done by urging the government to strongly enforce the laws of restriction of smoking like COTPA & NTPC in public

spaces and enact new regulations to halt the availability of cigarettes to teens.

Immediate Implant Placement in Mandibular Esthetic Zone: A Clinical Report

M. Krishna[1], Priyanka Basu[2], Abhijita Mohapatra[3], Gopal Krishna Choudhury[4], Krishna Nanda[1]

[1]Postgraduate Trainee, Department of Prosthodontics, Crown Bridge and Implantology, [2]Postgraduate, Department of Periodontics and Implantology, [3]Professor, Department of Prosthodontics, [4]Professor & Head, Department of Prosthodontics, Crown Bridge and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In the past two decades' immediate dental implant placement has been considered satisfactory treatment modality. The dental implants can be placed in the fresh extraction sites by simultaneous use of bone graft material. The patient was suggested to go for a treatment procedure for the extraction of and immediate implant therapy. A bonegraft material was used to fill the space between the implant and the sockets along with planning a two-stage surgical procedure to optimize bone healing. When the osseointegration was complete abutment connection was placed with no complications radiographically examination showed a slight marginal bone reduction after 6months of follow-up. The immediate placement of implants helps in preserving the form and contours of the hard and soft tissues, by decreasing the necessity augmentation procedure. It also helps in minimizing the surgical exposure of the patient, reducing the treatment time and also improves the esthetic outcomes.

Keywords: *Immediate Implant Placement; Mandibular Esthetic Zone; Treatment option.*

Introduction

In general, the extraction of teeth often leads to resorption of alveolar bone. The immediate implant placement at the site of extraction might add to the preservation of the alveolar bone during the procedure and also helps in reducing the healing time.[1] The bone-to-implant might be enhanced by the bone-forming activity in comparison to implants placed in a less osteogenic active-site.[2] The early implant placement may result in favorable implant crown ratio, improved esthetics along with preservation of the alveolar structure, and the positioning of implant-fixture in a fresh extraction socket enables in maintaining the bony crest.[2]

According to literature preceding tooth extraction, the predictable loss of alveolar bone is accelerated in the first six months with as much as 40% of the alveolar height and 60% of the alveolar width loss, continuing at a rate of 0.25% to 0.5% per year.[3]As thisresorption of the alveolar ridge has been an inevitable event followed by extraction of a tooth, to prevent this conventional guidelines in the late 1980s advises 8 weeks of socket healing and for remodeling additional 3-6 months of load-free healing, which was believed to be necessaryfor osseointegration.[3,4]There are various advantages of immediate implant placement such as crestal bone preservation, reduction in complex surgical procedures, minimizing the edentulous period, and better patient acceptance.

Simultaneously, the guided bone regeneration (GBR) procedures, that usebone grafts and collagen membranes, are frequently essential in such situations

to correct the peri-implant defects and/or to augment surrounding tissues.[3]

The loss of mandibular incisors is most likely to be frequent maybe because of caries or periodontal diseases.[5] The replacement of such incisors by immediately placed implants is a straightforward, predictable, and minimally invasive procedure. The purpose of this article is to present a case of periodontally compromised anterior teeth associated with bone loss using immediate implant placement combined with simultaneous GBR to correct the defect.

Case report and technique: A 52-year-old female was reported to the department of prosthodontics with localized advanced periodontal disease including mandibular incisors; 32 and 42 exhibiting Class II mobility due to bone loss (Figure 1a). The aesthetic requirement of the patient has been a major concern due to the loss of mandibular central incisors and a mild discomfort on biting due to the mobility of lateral incisors. Medical history was noncontributory. Various treatment alternatives including removable prosthesis, resin-bonded bridge, conventional fixed prosthesis, and implant-supported fixed prosthesis procedures were discussed with the patient. The patient was not willing for a removable partial denture or any interim prosthesis. Based on the patient's desire for a reduced the number of surgical procedures and overall treatment time, immediate implant placement after tooth extraction of 32 and 42 was decided as the final treatment plan.

For the placement of the implant, an adequacy in the volume of bone was determined by the clinical and radiographic examinations. The treatment choice would be the extraction of the tooth nos. 32 and 42 preceding immediate placement of two implants. Postoperative instructions provided include a soft diet for the first six to eight weeks followed by surgery. Informed consent was obtained. Before proceeding into the surgical phase, a diagnostic impression of the maxillary and mandibular arch was made from alginate material along with a bite registration. The diagnostic casts were articulated at the proper intercuspation position and a diagnostic mockup was done to determine the position and the final aesthetic outcome of the implant-supported fixed prosthesis.

The surgical phase was initiated with the administration of local anesthesia (lidocaine with epinephrine 1:100,000), extractions of teeth No. 32 and 42 were performed (Figure 1b, 2a). The desired implant positions to be placed were determined based onthe diagnostic wax-upsurgical guide was fabricated for proper implant placement. Osteotomies were performed to gain access through the site of the extraction socket[5] (Figure 2b). The drilling process progressively ensures the increase in the socket diameter with the utmost use of apical bone to the extraction socket. For the duration of the drilling procedure a finger was placed over the thin buccal mucosa, facilitating close approximation with the labial bone plate, consequently preventing perforation of the bone. Socket curettage was done before the placement of implants.[6] An implant (myriad plus measuring 3.5 mmx13 mm) were placed in 32 and 42 positions (Figure 3a). The implants were placed parallel to the incisal edge of the adjacent tooth with a lingual inclination. Implants were screwed properly into the alveolar bone unless the threads of the implant completely embedded into the alveolar bone and the collar in alignment with the crestal bone. Evaluation of the primary stability of the implants can be verified when there is an absence of rotation on the application of a reverse torque of less than 20N-cm. The snug fit of the implant ensures the prevention of mobility. The clinical stability of implants can be determined by palpation and percussion.[7] Adequate initial stability was obtained when placed with a torque driver at 35 Ncm.[2]A minimum distance of 3mm from the adjacent CEJ was maintained to achieve a normal emergence profile. A localized Guided Bone Regeneration procedure was then undertaken using bone grafts (biooss) along with (platelet-rich fibrin) barrier membrane, followed by placement of interrupted sutures to enable maximum approximation of the soft tissues to the abutment(Figure 3a) This platelet-rich fibrin membrane enhances stability is immediately placed implants when used in guided bone regeneration.[8] The patient was then instructed to follow a intake of soft diet consisting of high nutrient value and postoperative medications like Augmentin and zerodol SP and Pantop D advised for 5 to 7 days, along with a mouth wash, chlorhexidine gluconate (0.2%) twice a day for a week.[9] The patient was recalled for the postoperative follow up for suture removal after a week following the surgery and then called for subsequent follow-ups at their month, six months, and twelve-month respectively.

The stability of the implant was evaluated by tactile perception and fremitus test while the gingival inflammation was evaluated by noninvasive gingival index using Modified Gingival Index (MGI).[6]

The patient was recalled after 3 months for follow-up. Second stage surgery was done and the gingival former was placed (Figure 3b, 4a). After a 2week prosthetic phase was performed in which the gingival formers were replaced with abutments and the final impression was made with polyvinyl siloxane material (Figure 4b). The lab analogs are then placed upon the abutments and sent to the laboratory for the fabrication of the permanent fixed ceramic-metal Fixed prosthesis. After a week metal trying was done followed by loading of the 4unit prosthesis (Figure 5a) Implant protected occlusion was designed to improve the longevity of the prosthesis with adequate aesthetic outcomes. The six-month follow-up examination revealed stable, healthy peri-implant soft tissue with no signs of complications and clinical modifications in soft or hard tissue levels.[10] The patient was also satisfied with the esthetic and functional outcome (Figure 5b).

Discussion

According to Macheti et al in periodontally susceptible patients the rate of survival of immediately placed implants is similar to that of no susceptible patients. For immediate implant placement the anterior mandible proves to be a favorable site for reasons like adequate bone quantity and quality, narrower and shorter tooth sockets than the osteotomy which helps in stabilization of bone beyond the sockets.[9] In anterior mandibular site there is less potential of nerve damage as the inferior alveolar nerve doesnot course in between the mandibular foramina.

The patient was advised to keep caution while eating and instructed to avoid biting with the restoration for at least 4 weeks.

According to literature it has been shown that within a period of three to twelve months most of the major changes occur following tooth extraction with an estimated demonstration of 50% reduction in the buccolingual width. Immediate implant placement following tooth extraction eliminates the socket healing period and thus reduces the occurrence of alveolar bone resorption.[11, 12]

It has been documented that using barrier membrane and different graft material fills the residual peri-implant defects for enhancing the peri-implant bone healing and to achieve a final aesthetic outcome. These barrier membranes may also help in preventing the invasion of connective tissues and the epithelium into the microgappresent in-between the implant and the surrounding bony walls, which ultimately favors bone regeneration.[8] The bone grafts can moreover acts as a spacemaintainer moreover promoting bone formation that can eventually provide better osseointegration.

Conclusion

Based on the literature review, the universally applicable defined criteria for implant success adopted from Bursar et al were the absence of persistent

infection, gingival inflammation, implant mobility, peri-implant radiolucency neurologic signs and symptoms.[15] According to the present report and its outcome, it can be concluded that immediate implant placement may be considered as a viable treatment modality as the treatment protocol showed reduced clinical time in situations that allow an aesthetic outcome. It significantly showed high survival rates that can be achieved with the implants placed in immediate extraction sockets.

Abstract

Laser applied science has been newly introduced into the dentistry to substitute drilling. The 1st dental experience for pediatric patients using laser can be useful from the point of preventive & therapeutic approach. This article approached to educate about laser physics, its components, fundamentals, mechanism of its action, applications, advantages,disadvantages, laser safety & medico-legal aspects of laser specifically concerning pediatric dentistry. Due to their minimal invasion, treatment by laser is well accepted by children. The use of scalpels conventionally, may produce post-operative discomfort & thus, prolonged wound healing. Being safe in use, lasers are an important in-office alternative to treat pediatric dental patients. Hence, lasers use enhances the children's cooperation leading to greater satisfaction by all three i.e. guardians,patient & dentist.

Keywords: *Pediatric laser dentistry; Laser dentistry, minimally invasive approach.*

Introduction

The therapeutic use of light is being used from centuries. LASER is "Light Amplification by Stimulated Emission of Radiation".[1] In 1916 when physicist Albert Einstein explained the stimulated emission theory, the principle of laser came into light.[2] It is an electromagnetic energy with unidirectional and monochromatic unique properties. Today laser has found endless uses in many disciplines of medicine & dental surgery. Laser can serve as a favorable option due to less pain, sound & vibration. Lasers were 1st used for soft tissue incision. The new types of lasers' work on water molecules can be used for the ablation of hard dental tissue as well. It's been used in different fields of dentistry as it has wide applications. Laser is a promising arena towards the "minimally invasive", modern pediatric dental treatments. In the present scenario, the laser provides a safe & effortless alternative for treating children in dentistry. Then dental visit becomes a lot easier for patient, parents, and dentist. Children seem to be more cooperative during dental procedures using lasers, which boost up the quality of care & the method of treatment.

History: A **MASER** is a device that stands for "**Microwave Amplification by Stimulated Emission of Radiation"**, which produces "coherent electromagnetic waves through amplification by stimulated emission & was built by Charles H. Townes, James P. Gordon, and Herbert J. Zeiger at Columbia University in 1953". The laser works by the same principle as the maser, but produces "higher frequency coherent radiation" at visible wavelengths. In 1960, LASER was made from a laser device "known as ruby laser," invented by Theodore Maiman which stands for "Light Amplification by Stimulated Emission of Radiation". Gordon Gould is credited with creating this acronym in 1957.[3] The first application of the laser was used for skin problems diagnosis & treatment and later used in endoscopic surgery & ophthalmology.[4] In ***1965*** "*Stern & Sognnaes's* detailed about this "*ruby laser* "in their study that it could *vaporize enamel* & also thermally *affects* the pulp of the tooth.[5] Patel invented CO_2 *laser* in 1964 that had both soft tissue & hard tissue applications.[6]

In ***1964***Nd: YAG laser was introduced *by* Geusic which remain unnoticeable until 1990. The 1st usage of laser in 'endodontics' was shown by "*Weichman & Johnson"* in the year of 1971*,* for the apical foramen seal, in vitro, by utilizing CO_2 laser.[6] Studies are carried out for future indications. Since then, the clinical applications of lasers continue to increase indentistry.

Laser Physics: A laser machine forms *multiple atoms* that pump out *multiple photons (known as light particles*) all of which line up to form a *concentrated light beam*. Matter consists of *atoms*. Nucleus lies at the center of the atom; which contains *protons & neutrons*. A (+ve) charged is a proton & neutron is neutral. Outside the atom are *electrons* which are (-ve) charged and they are in motion surrounding the nucleus. The conversions are of 3 types which are as follows:[7,8]

1. **Spontaneous Absorption:** In this, an electron alter state to higher state from lower state by absorbing a photon (Figure. 1a)
2. **Spontaneous Emission:** In this, an electron spontaneously releases a photon to shift it to a lower state from a higher state (Figure. 1b)
3. **Stimulated Emission:** In this the electrons transit to a lower state from higher state & release a photon. The incident photon & their released counterparts possessa similar wavelength. This particular wavelength correlates with the energy difference between the two orbits.(1c)

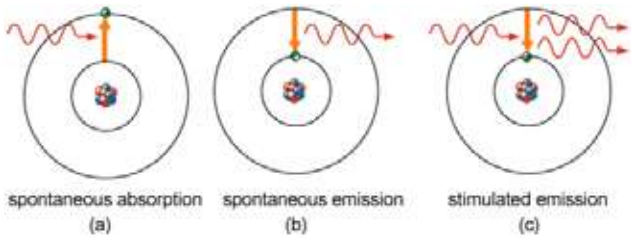

Figure 1. Concentrated light beam (3 types of conversions)

The characteristic of laser-produced from stimulated emission are as follows:[9,10]

1. **Monochromatic:** Single wavelength light is produced.
2. **Coherent:** All photons show similar polarization & produce a very high intensity when they superpose.
3. **Collimation:** It depicts a narrow & powerful emitted laser beam which consists of constant shape & size.
4. **Efficiency:** At low energy state lasers produces the required energy to carry out their specified function.

Amplification: The process of amplification takes place within the laser device. The laser machine consists of a core that is known by the optical cavity that comprises of chemical elements, molecules/compounds which are known by 'active medium'. Lasers are termed after the active medium material, such as after a gas, semiconductor, etc. The optical cavity has two ends. Each end has one mirror which is placed parallel to one another. An electrical coil/Flash lamp is the excitation source for active medium.

Stimulated Emission: In 1900 *Max Planck* introduced the 'quantum theory of physics' which later forms the basis for stimulated emission. Albert Einsteinstated that an "additional quantum of energy traveling in the field of the excited atom that has the same excitation energy level would result in a release of two quanta, a phenomenon defined stimulated emission". These photons further energizes more atoms & it results in the population inversion that causes an increase in numbers of the atoms of the active medium from resting state. And to maintain this excitation, a pumping mechanism is required. At the two ends of the active medium, two mirrors are placed which reflect photons back & forth for further stimulated emission. This consequence travels through the active medium which raises the photon beam power & thus gets amplified.

Radiation: It is the light waves emitted as a distinct form of electromagnetic energy. The short wavelengths, below 300 nm, are described by ionizing radiation. The higher photon energy can penetrate biologic tissue easily & reproduces charged atoms. Wavelengths more than 300 nm possess less photon energy & results in excitation. Thus, it heats the tissue with which they interact. The currently used lasers in dentistry have wavelengths from 500 nm to- 10,600nm.

Fundamentals of Laser: Oral tissues have a distinguishing affinity for absorbing laser energy of specific wavelengths. Hence, the selection of a laser depends on the target that is to be treated. The optical aspect of target tissue forms the basis of laser light interaction in different ways with the intended tissue. These interactions are as follows:[11,12"]

a. **Transmission:** *Laser* energy is transmitted directly through the target tissue without effecting target tissue.

b. Reflection: This property of laser used for diagnostic purposes. It redirects itself off the surface. It is useful for measuring the 'sound tooth structure' in dental caries.

c. Absorption: There is the absorption of laser energy in the target tissue on the application of laser on tissue. Different laser wavelengths have a "different absorption coefficient" with the dental tissue components.

"Lasers primarily interact with dental structures photothermally. The temperature of the target tissue increases as laser light is absorbed & when the tissue reaches 100°C temperature, the intercellular & intracellular H_2O (water) boils, which induces both soft tissue vaporization or likely to explode & disarrange 'hard tissue' (*ablation*).With the continued increase in temperature of 200°C,the tissue gets dehydrated & later burned in the presence of the air (*carbonization*). Carbon is the end product & it absorbs all wavelengths".[13-15]

Laser-Component:

All lasers have the six components which are listed below: Figure 2.

1. Active medium- Materials in the core of the laser, can be gas, solid, liquid, or crystals.
2. Pumping mechanism-It is a primary source of energythatis absorbed by the active medium, that results in the "production of laser".
3. Optical resonator- It has a two-mirrorsystem (one is completely reflective & the other one is selectively transmissive) which amplifies and collimates the developing laser beam.
4. Cooling subsystem- It cools down the heat produced by a laser.
5. Controller subsystem (microprocessor)-It is responsible for controlling power output variation to time.
6. Delivery system- It is dependent on the wavelength emitted."

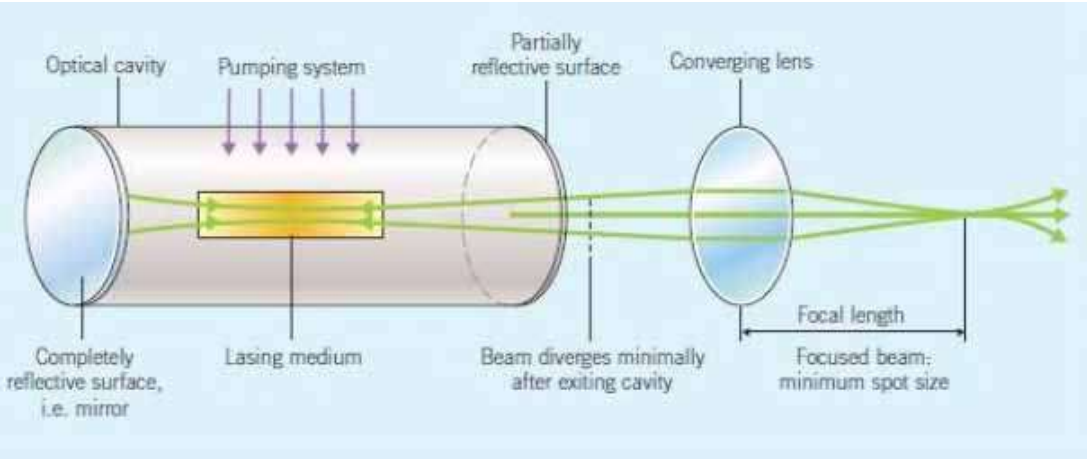

Figure 2. Laser-Component

Various Laser Delivery System: Earlier most dental lasers were having bulkier articulated arms for their delivery systems. But each laser has a distinctive delivery system such as handheld laser, fiber delivery system,articulated arm deliver system & hollow tube delivery system.

Classification of Laser:

"Lasers have been classified in many ways such as[16,17]:

I. According to the wavelength (nanometers)

1. UV (ultraviolet) range – 140 to 400 nm
2. VS (visible spectrum) – 400 to 700 nm
3. IR (infrared) range – more than 700 nm

Most lasers operate in one/more than one wavelength region.

II. Broad classification

1. Hard laser (for surgical work)
   i. CO_2 lasers (CO_2 gas)
   ii. Nd: YAG lasers (Yttrium-aluminium-garnet crystals dotted with neodymium)
   iii. Argon laser (Argon ions)
2. Soft laser (for biostimulation and analgesia)
   i. He-Ne laser ii. Diode lasers

III According to the type of active medium used:

a. Gas lasers:
   - Argon • Carbon-dioxide

b. Liquid:
   - Dyes

c. Solid:
   - Nd:YAG
   - Erbium: yttrium aluminium garnet (Er: YAG)
   - Diode

d. Semiconductor:
   - Hybrid silicon laser

e. Excimers:
   - Argon-fluoride
   - Krypton-fluoride
   - Xenon-fluoride

IV. According to pumping scheme
1. Optically pumped laser
2. Electrically pumped laser

V. According to operation mode
1. Continuous-wave lasers
2. Pulsed lasers

VI. The laser classification system is based on the possibility of damage occurring-
- Class I (< 39mw):No threat.
- Class II (< 100 MW): It could harm a person if he stare into the beam for a long period. The normal aversion response or blinking should prevent from staring into the beam.
- Class III (500mw): It causes permanent damage including blindness.

VII. Based on clinical use
1. Surgical: i. Hard tissue; ii. Soft tissue
2. Non-surgical: i. Diagnostic; ii. Low-level therapy; iii. Miscellaneous photo-activated disinfection laser-based curing light"

Wavelengths Used in Pediatric Dentistry:

Table 1. On basis of active medium, wavelength, clinical uses laser are named accordingly

"Argon laser	**Active medium-**Argon gas **Wavelength used**-488nm (blue) & 514nm (blue green). **Clinical applications-** – Caries detection. – Polymerization of light-activated composite resins, dentin bonding agents, sealants, bleaching gels, light-activated impression materials.
Diode laser	**Active medium-**GaAlAs,InGaAs(semiconductor) **Wavelength used**- 655nm, 800-830nm & 980nm. **Clinical applications-** – Cutting & coagulating gingiva and oral mucosa. – Sulcular debridement.

Laser-Nd:YAG	**Active medium-**A solid garnet crystal combined with rarerare earth elements yttrium & aluminumdoped with neodymium ions. **Wavelength used-**1064nm **Clinical applications-** – Cutting & Coagulating dental soft tissues. – Sulcular debridement
Laser-Ho:YAG	**Active medium-**Solid crystal of YAG sensitized with Cr doped with holmium & thulium ions. **Wavelength used-**2100nm **Clinical applications-** – Used frequently in oral surgery for arthroscopic surgery on the TMJ. – It has many medical applications.
Laser-Carbon dioxide	**Active medium-**A mixture of CO_2, He & nitrogen gases in proportions of 8:7:1. **Wavelength used-**9300nm,9600nm & 10600nm. **Clinical applications-** – Soft tissue procedures such asgingivectomy,gingivoplasty,biopsy, frenectomy. – Coagulation after completion of surgery.
Laser-Erbium family	**Active medium-** Solid crystal of YSGG doped with Er Cr. & solid crystal of YAG doped with Er. **Wavelength used-**2780nm & 2940nm. **Clinical applications-** – Caries removal & cavity preparation. – Bone removal. – Vital & non-vital pulp therapy. – Tissue retraction for uncovering implants.”

Role of Laser in Pediatric Dentistry[18-20]: It contributes to providing a positive dental experience with reduced fear and anxiety for the pediatricpatient. Due to its less invasive nature,children are more cooperative during treatment.

Advantages in Pediatric Dentistry:

1. No anesthesia, no drill
2. Less blood loss.
3. Reduce post-operative edema.
4. Initial healing, rapid regeneration, reduce post sensitivity in restorations
5. Suture, dressing are not required.
6. Less chances of metastasis
7. Sterilization of treatment site.
8. Tooth enamel is less exposed,results in a decrease in caries progression.
9. The patient becomes free of fear & anxiety.
10. Beneficial for medically compromised patients.

Disadvantages:

1. Direct light or reflected light both can harm the eyes of the practitioner as well as the patient.
2. The laser is quite expensive.
3. Need qualified personal.
4. Dental hand-pieces required for finishing, after cavity preparation by laser. Also, it should not be used to fill the cavities present between teeth.
5. It should not be used for the removal of silver restoration or damaged crowns.
6. The possible risk of viral disease transmission from “aerosol” in immune-compromised patients.

Applications

Soft Tissue Laser Uses

1. **Frenectomy and treatment of ankyloglossia:** The abnormally joined frenum on the maxilla/ hyperactive labial frenum both are the cause of spacing between teeth, poor oral hygiene, gingival retraction & continuous trauma during brushing.

Also, the situation with the short & hypertrophic lingual frenum (ankyloglossia) is common in new-borns, which results in remarkable problems in breastfeeding, swallowing & phonation.

2. **Gingival recontouring, gingivectomy, bone surgery & crown lengthening:** In children with gingival hypertrophy, tooth decay that propagated under the gingiva, the laser can be used. It is also used for the gingivectomy, limiting the use of anesthesia. The YSGG was 1st laser used for the bone surgery & crown lengthening to correct deformity & create required the physiologic osseous contours.

3. **Exposure of unerupted tooth & treating pericoronal problems in erupting teeth:** To expose an unerupted or partially erupted tooth for orthodontic bracket or button placement, laser is used.Lasers are used to expose the clinical crown of the involved tooth.

4. **Pulpotomy, pulpectomy of primary teeth using laser:** Laser takes 10s-20s to work in a vital tooth. In non-vital teeth, the laser's success rates are almost the same as that of conventional pulpotomy procedures. In 1999, Jeng-fen Liu *et al*. evaluated the effects of laser pulpotomy in primary teeth and found it clinically successful in a 6 months followup visit except one.

5. **Direct, indirect pulp capping of young permanent teeth using laser:** CO_2 laser is used for direct pulp capping as it controls hemorrhage and sterilizes the exposure site which facilitates better placement of calcium hydroxide paste at the exposure site. Laser energy has an obtundent and sedative effect on inflamed pulpal tissue which led to its use in indirect pulp capping procedure.

6. **Laser in wound healing:** Low-level laser treatment promotes wound healing.

7. **Laser in diagnosing pulp vitality:** Laser Doppler flowmetry is a non-invasive method of diagnosing pulp vitality.

8. **Laser in disinfection of root canal:** Laser used in root canal disinfection during root canal treatment and irrigation of the canal with 5.25% sodium hypochlorite or 14% EDTA is carried out during laser irradiation.

9. **Laser in tooth bleaching:** When the laser light hits bleaching gel, it produces heat thus the oxidation process becomes accelerated resulting in the whitening of the tooth surface.

10. **Laser in pediatric tooth preparation:** Biolase is used for pediatric tooth preparation. This eliminates the need for local anesthesia & increases the micromechanical bonding with resin cement as it producesmore roughness on prepared tooth surfaces.

11. **Hypertrophic lesions:** Diode laser is particularly recommended in oral soft tissue surgery, specifically regarding benign lesions.

12. **Lasers used in pain management:** "LLLTdrop the concentration of chemical agents such as histamine, acetylcholine (Ach) etc., all of them are pain mediators. They inhibit the concentration of ACh, a pain mediator, through increased acetylcholine esterase activity & hence, used for the treatment of dentin hypersensitivity."

13. **Herpes Labialis & Recurrent Aphthous ulcers:** Laser brings immediate relief to the "aphthous ulcer" lesion or shorten the duration of the" herpes labialis" lesion.

Hard Tissue Uses:

1. **Removal of caries, old restoration, and cavity preparation:** Lasers are used for carious tissue removal, results in the preservation of tooth-healthy tissues.Cavity preparation with the use of laser in children for enamel & dentin removal seems very reasonable, because it eliminates the injury to lip, tongue due to lip bite & tongue bite which are frequent problems with children.

2. **Pit and fissure sealants:** The lasers can clean & sterilize the enamel fissures. Laser can be used for fistulotomy, cleaning & conditioning of pits & fissures before sealant application.

3. **Diagnodent and caries detection:** Diagnodent is the device has also the ability to show decays in early stages that are not seen in radiographs. Laser fluorescence at a wavelength of 655 nm is effectively used for the detection of occlusal hidden caries and occult lesion in primary and permanent teeth.

4. **Prevention of dental caries:** Laser heat effects and the creation of micro openings and small cracks facilitate the penetration of fluoride. It seems that the simultaneous use of laser & fluoride is the best method of carious lesions prevention.

Dental Laser Safety[21,22]:

The aspects of laser safety are:

1. The assembling procedure of the laser instrument,
2. Right mechanism of the device &
3. Personal protection of patients as well as operating squad from laser.

Medico-Legal Aspects of Laser in Dentistry[23]: Conventional soft tissue surgery with a dental laser is accepted in dentistry & covered under insurance policies. Informed consent must be routine & a part of the general consent form that all patients, guardians read & sign before the start of dental treatment. It is highly suggested that each practitioner take a course."

Conclusion

Its use in pediatric dental procedures is well accepted. Its minimal invasiveness allows pediatric patients to be cooperative during dental procedure. Lasers in dental practice present remarkable accuracy, pain-free, quick healing & safety. Although its effectiveness in the diagnosis of dental caries, prevention of caries, endodontic management of deciduous and permanent teeth, and different softtissue procedure is well documented, further research regarding its efficacy in pediatric dental procedure is still needed.

Cancer Associated Fibroblasts (CAFS) and their Indispensable Role in Tumor Microenvironment: An Update

Shubhangi Pareek[1], Swagatika Panda[2], Neeta Mohanty[3]

[1]Post Graduate Trainee, [2]Professor, [3]Dean and Head, Department of Oral and Maxillofacial Pathology and Microbiology, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Cancer-associated fibroblasts commonly known as CAFs which have a modified phenotype as compared to normal fibroblasts are exclusively present in the tumor microenvironment surrounding the tumor mass. They play inevitable roles in tumor initiation, progression, invasion, and metastasis. The constant cross-talk present in between the cancer cells and CAFs is responsible for the maintenance of such a malignant environment. Thus,they may prove to be efficient targets in the field of cancer therapeutics which may yield excellent results. This review throws light upon their much evident roles in carcinogenesis as well as how the mechanisms driven by them may be targeted in therapeutic interventions.

Keywords: *Cancer-associated fibroblasts, CAFs, tumor microenvironment, tumor stroma.*

Introduction

A tumor mass is composed of malignant epithelial cells as well as groups of nonmalignant cells. These non-malignant or non-cancerous groups of cells include fibroblasts and myofibroblasts, endothelial cells and lymphatic networks, pericytes, immune regulatory cells, and cytokines in the extracellular matrix (ECM) (1). This mass of stromal cells along with the ECM constitutes the tumor microenvironment. Tumor microenvironment, in turn, governs the tumor progression through stages of initiation, progression, and metastasis (2).

One such subpopulation of cells is of the cancer-associated fibroblasts (CAFs) which is a group of fibroblasts having a modified phenotype of myofibroblasts. These are the same as the myofibroblasts which are transiently present during fibrosis and wound healing, the only distinguishing characteristic feature is that they are present and remain almost activated throughout, at the site of the tumor (2). An ideal microenvironment is maintained by these CAFs and they also undergo the required biological and morphological changes for tumorigenesis and its progression. These can serve as essential therapeutic targets for the treatment of cancer.(3, 4)

This review highlights the recent trends associated with CAFs and aims towards a better understanding of their role in the advancement of tumors. Additionally, the interaction between the malignant cells and tumor microenvironment for the scope of identification and development of potential anti-cancer therapy has also been analyzed.

Distinguishing Nature of CAFs: "The origin of CAFs comes from a variety of cells, majorly from fibroblasts while other sources include epithelial cells, endothelial cells, adipocytes, pericytes, or mesenchymal stem cells[1-5] CAFs are identified in the stroma using specific molecular markers and also distinguished easily as large spindle-shaped cells often showing resemblance to myofilaments of smooth muscle.[6] The biomarker most commonly used is α-smooth muscle actin.[7] Some

of the other biomarkers less commonly expressed by these activated fibroblasts that have been detected with the help of immunohistochemistry includes FAPα (fibroblast activation protein α) a cytomembrane protein, vimentin, PDGF receptors α and β, podoplanin-a, S-100, FSP-1 (fibroblast specific protein), and IGFBP7 (Insulin-like growth factor-binding protein).[8,9]. Moreover, with techniques like microarray gene-expression analysis, there has been a better understanding of the nature of CAFs and more knowledge about their role in oncology has been gained. Many studies done on paired CAFs and normal fibroblast cell lines have identified a total of 46 differentially expressed genes which further encoded for paracrine factors released in the tumor microenvironment. The genes expressed were regulated by the TGF-β signaling pathway, and some of them include intercellular-adhesion molecule 1 (ICAM1), THBS2, MME, OXTR, PDE3B, B3GALT2, EVI2B, COL14A1, GAL, MCTP2 and Integrin α11 which were used to form a prognostic signature of CAFs in non-small cell lung cancer (NSCLC).[10,11]

Fibroblast Activation Induced by Tumor: Whenever there is metastasis of tumor cells to a different organ, natural fibroblasts are reinforced by them into the tumor mass. Once reinforced, they undergo phenotypic activation into cancer-associated fibroblasts under the influence of genetic as well as epigenetic changes that are either self-regulated or regulated by tumor cells themselves. Nonetheless, the precise mechanism of this activation is still not clear.[12]

"TGF-β, EGF, PDGF, FGF2, CXCL12(C-X-C motif chemokine ligand 12) are some of the chemokines involved in the activation of these fibroblasts which are secreted by the cancer cells and other stromal cellswhile other factors involved in their activation comprises of cell-cell communication with adhesion molecules like ICAM1 and vascular-cell adhesion molecule 1.[13,14]"

"A large group of miRNAs often regulate the conversion of natural fibroblasts into CAFs by undergoing upregulation or down regulation. Various differentially expressed CAFs have been listed in figure 1.[15-18]"

Figure 1: Regulation of miRNAs in CAFS

Initiation of Tumor Growth, Angiogenesis, Metastasis and Chemoresistance by CAFS:

(a) Tumor growth: Aconstant interplay between the abnormal increase in malignant cells and alterations in the tumor microenvironment is the probable cause for tumor growth and the induction signals for this neoplastic initiation are usually derived from CAFs.[19,20]

A variety of cytokines have been known to be produced by these CAFs that alter the malignant biological nature. These mostly include classical growth factors, EGF, hepatocyte growth factor (HGF), novel CAF-secreted proteins [secreted frizzled-related protein 1, and IGF like family member (IGF) 1 and 2], and membrane molecules (integrin α11 and syndecan-1) which possess either the ability to upgrade the migratory and invasive properties of tumors or directly and indirectly induce their growth as well as survival.[21]"

Previous studies have demonstrated that chemokines secreted by CAFs into the microenvironment allow for the recruitment of bone marrow-derived cells (BMCs) and immune cells. In oral squamous cell carcinoma (OSCC), CCL2 expression in CAFs is upregulated, promoting the production of endogenous reactive oxygen species (ROS) in oral cancer cells (OCCs). Subsequently, ROS induces the expression of cell cycle regulatory proteins in OCCs, and advocates OCC proliferation, migration, and invasion. Altogether, these chemokines and cytokines create a suitable microenvironment allowing for the proliferation and metastasis of cancer cells.[22-24]"

(b) Activation of tumor angiogenesis by CAFs: There is an increased production of vascular endothelial growth factor (VEGF) in the tumor microenvironment. The increased levels of VEGF are responsible for tumor angiogenesis and lymphangiogenesis. The main source of VEGF is the CAFs through the activation of the PDGF receptor pathway. Additionally, the induction of BMC's by PDGF leads to the formation of endothelial channels. Endothelial stability is then maintained by the entry of pericytes along the walls of the vessels by the action of subunit B of PDGF. Therefore, promoting angiogenesis.[25-27]

(c) Nagasaki *et al* reported that cancer cells stimulate the secretion of IL-6 from fibroblasts, subsequently inducing tumor angiogenesis. IL-6R neutralization antibody inhibited IL-6 signaling and tumor angiogenesis by inhibiting the interaction between the cancer, and stroma. This finding suggests that IL-6 is a novel target for anti-angiogenesis therapy.[28]

(d) Role of CAFs in mediating Tumor metastasis: There is much evidence about the metastatic role of CAFs in tumor genesis but their role in lymphatic and distant metastasis is still doubtful. The transformed phenotype (mesenchymal) of these CAFs is considered to increase the metastatic potential of the tumor cells as compared to the normal fibroblasts of epithelial origin which restrict metastasis.[29-31]

(e) YAP, regarded as the trademark feature of CAFs is a transcription factor that plays evident parts in matrix reinforcement, invasion as well as angiogenesis by controlling distinct cytoskeletal proteins (anillin, myosin, etc.) and also via the production of inflammatory cytokines (NF-KappaB) thus leading to carcinogenesis. Additionally, CXCL12 and IGF1 are also generated by CAFs which in turn initiate the AKT signaling pathway. Tumor cells in this CXCL-2 enriched microenvironment within bone marrow further initiate metastasis (34).Evidence about the reduced expression of miR-148a amongst CAFs and the resultant increase in the WNT10B gene because of activation of the Wnt activity leading to elevated migration of endometrial cancer cells has also been reported (40). Other miRNA's involved in migration and invasion includes reduced levels of miR-26b and miR-320 in human breast cancer, downregulated miR-15 and miR-16 in prostate cancer.[32-36]

(f) Resistance to anti-cancer therapy induced by CAFs: The development of chemoresistance is consideredto be a rare feature of CAFs and they can be easily targeted for potential anti-cancer therapies but a contradicting part is played by the fibroblasts in helping the tumor cells bypass these treatment modalities as explained under.[37]

(i) "PDGF: Solid tumors exhibit the property of an elevated interstitial fluid pressure that is IFP in the centermost portion as compared to the remaining portion of the tumor tissue. As a result, the drug infiltration into the core of tumor tissue is cut down and the probability of survival of these malignant cells is increased. Thus, the chemotherapeutic regimens are designed to reduce this IFP and increase

the drug penetration up to the center of the tumor. One such regimen includes targeting the tyrosine kinase receptors and PDGF present in different malignancies like STI571 in anaplastic thyroid carcinoma, targeting of which causes a reduction in IFP and elevated Taxol intake and reduced tumor growth.[38-41]"

(ii) **"HGF:** Data demonstrates that the presence of fibroblasts secreting HGF confers resistance to therapy. Besides, HGF can activate MET, which is expressed on cancer-initiating cells (CICs) through paracrine signaling.[42] This can sustain typical CIC properties, including long-term self-renewal, ultimately leading to resistance to anti-EGFR therapy. Subsequently, there is the restoration of cell proliferation and rescuing of cells from G_1 phase arrest, and apoptosis through restimulation of the MAPK and AKT signaling pathways.[43] Notably, this effect is inhibited by suppressing MET activation with PHA-665752, a highly specific MET kinase inhibitor, or by knocking down MET expression using RNA interference."

(iii) **"Chemokines:** Many chemokines present in the tumor stroma play an evident role in the maintenance of chemoresistance. One such chemokine is CCL2, recruited by immune cells into the tumor microenvironment and is responsible for resistance against many drugs. Moreover on treatment with CCL2 inhibitor, there is enhancement of the anti-tumor potency of paclitaxel and carboplatin therapy. CAFs can induce CCL2 production through signal transducer and activator of transcription 3 (STAT3) phosphorylation, and in turn, CAF-derived CCL2 promotes cancer progression by regulating cancer stem cells through activation of the Notch signaling pathway (46). Hence, chemokines, including CXCL12, may act as promising targets for cancer therapy, alone or in combination with other cytotoxic drugs.[45,46]

(iv) **"Interleukin family:** An important inflammatory cytokine mainly secreted by CAFs is IL-6 which is involved in growth and invasion of tumor cells through activation of STAT3. Thus, IL-6 is responsible for the survival of tumor cells and also induces their relapse.[47]

(v) **"Other factors:** Some of the other fibroblast-derived proteins like WNT16B and B1 which are secreted in the tumor microenvironment are responsible for conferring chemoresistance against many drugs. WNT16B reduces apoptosis induced by chemotherapy drugs and thus targeting WNT16B may reverse chemoresistance. Group protein B1 present in the tumor microenvironment, performs paracrine signaling on neighboring cancer cells, which has been suggested to induce chemoresistance in breast cancer.[48]"

Loop of Interaction: A constant communication present between the malignant cells and CAFs in the tumor stroma is responsible for the development of a malignant microenvironment as well as the advancement of cancer. This interplay between the two components is initiated by a complementary signaling activity of stromal components such as cytokines and other factors of the extracellular matrix. Platelet-derived growth factor (PDGF) is secreted by neoplastic cells which in turn governs an increase in the population of fibroblasts and further production of IGF I and II. These IGFs initiate tumor cell proliferation as well as the production of more PDGF.[49](49).

Production of matrix metalloproteinases (MMPs) by CAFs further accelerates the invasive potential by destroying the ECM (50), further resulting in secretion of growth factors from fibroblasts like HGF, keratinocyte growth factor, IGF-1 and IGF-2 which also stimulate proliferation of tumor cells.[51-53] Thus, these positive feedback loops governed by signaling pathways result in boost up of signaling molecules, elevated numbers of tumor cells and as a consequence resistance to tumor therapy. A better understanding of these processes may prove to be helpful in the evolution of more targeted therapies that may inhibit such feedback looping mechanisms."

Suppression of the Feedback Loop: A Potential Target in Cancer Therapeutics: Such techniques targeting the association between fibroblasts and tumor cells are yet to be exploited practically, but apparently, their definite benefits cannot be ignored. This idea of targeting the loop mechanism can be implemented either by direct suppression of fibroblastic markers or by inhibition of CAF related paracrine growth factor signals.

(a) **"Direct suppression of fibroblastic markers:** Targeting the FAP membrane protein which is extensively expressed on CAFs can suppress the growth of tumor cells.[54] FAP protein induces tumor growth and division and therefore targeting the associated antibodies like FAP5-DM1 inhibits

tumor growth in xenograft models of head and neck cancer in vivo.[55]"

(b) "Inhibiting paracrine signaling of fibroblasts: This involves targeting the various pathways like PDGFR, VEGFR, FGFR which further inhibits MAPK and Akt signaling pathways in endothelial cells and prevents angiogenesis as well as initiates apoptosis. Additionally, targeting the HGF/MET signaling pathway has proven to be of therapeutic value in various cancers. Furthermore, suppressing the TGF-β pathway which is responsible for myofibroblast differentiation, has resulted in a considerable reduction of tumor growth and lastly the use of matrix metalloproteinase inhibitors (MMPIs) as anti-cancer drugs is still undergoing research.[56-60]"

Conclusion

One of the most important aspects in the field of carcinogenesis is the various roles played by cancer-associated fibroblasts which have much research and studies in their evidence. They promote carcinogenesis through their multifarious nature and mechanisms and can be exploited as promising marks in the field of cancer therapeutics.

Design of the Questionnaire: Fundamental Principles

Swati Patnaik[1], Shakti Swaroop[2]

[1]Associate Professor, Department of Public health Dentistry, [2]Assistant Professor, Department of Orthopaedics, Institute of Medical Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, Odisha, India

Abstract

The most critical aspect of investigative process, is the development of questions that correctly assess public perception, knowledge and behaviour. Precise random sampling and high answer rates are lost, if the information obtained is based on ambiguous or partial questions. Hence, in order to establish effective steps, a series of substantial questions are formulated and compiled in form of a Questionnaire.

Keywords: *Questionnaire Designing; Principles; Public health.*

Introduction

The design of the questionnaire is complex, because surveys can ask questions on various subject areas in varying degrees of detail and questions can be asked in various ways.[1] It is amulti-stage process that requires attention to several details at once. Researchers are also often keen to measure change over time and thus must pay attention to the measurement of opinions or behaviours in prior surveys.[2] Survey preparation is a key step, to assess how people respond to individual questions and in total. Surveyors have approached questionnaire design as an art, but substantial research over the past 30 years has shown that there is a lot of science involved in the development of a good survey questionnaire. In this paper, we discuss the shortcomings and best practices in the design of questionnaires.[3, 4, 5]

Question development: Developing a survey questionnaire involves various steps. The first is identifying what topics will be covered in the survey. Surveyors want to track changes in people's attitudes, opinions and behaviour over a period of time.[6] Change or variations in data is usually measured by asking questions at two or more proposed intervals. The cross-sectional design, the most common in public opinion research, surveys different people in the same populace, at multiple points in time. The panel or longitudinal design, often used in other types of social research, surveys the same people over time.[7,8]

When assessing the time-based improvements, it is necessary to retain the words of the question and regard the position of the questionnaire to deliver a similar result as when previously used. All the survey reports include a top-level questionnaire that provides the exact words and sequence of the question, together with the results of the current poll and the previous polls in which the question was asked.[9]

Open- and closed-ended questions: Some of the main decision-making factors that can affect how questions are answered is, whether the it is asked as an open question or whether respondents are answering themselves or whether they are asked to choose from a list of responses.

Structured closed questionnaires have the advantage of being focused and pertinent to the study objectives, easy to administer, uniform, pre-coded and thus easy to analyse in a short time. They are preferred in medical studies.[10]

Open-ended questionnaires are useful for social and anthropological investigations. Such questions permit the interviewee to discuss openly and thoroughly, but

they can vary from the subject. At the end of the test, they need special coding, so that the research time is longer. Researchers will sometimes conduct a pilot study using open-ended questions to discover which answers are most common. They will then develop closed-ended questions that include the most common responses as answer choices. In this way, the questions may better reflect what the public is thinking or how they view a particular issue.[11,12,13]

When asking closed-ended questions, the choice of options provided, how each option is described, the number of response options offered and the order in which options are read can all influence how people respond.[14]The order of responses categories will affect how people answer closed questions in addition to the number and choice of response choices. Research indicates that respondents select things that are heard later on in a list more frequently in phone surveys (the "recency effect").[15]Due to concerns about the effects of the category order on responses to closed-ended questions, many sets of response options is programmed to be randomized (when questions have two or more response options) in order to ensure that options are not put in the same order for each respondent.[16] Randomization of response items does not eliminate order effects, but ensures that this type of bias is spread randomly.[17, 18]

Questions with ordinal response categories – those with underlying order (e.g. excellent, good, only fair, poor OR very favourable, mostly favourable, mostly unfavourable, very unfavourable) – are generally not randomized because the order of categories conveys important information to help respondents answer the question.[19] Generally, these types of scales should be presented in order to make it easy for respondents to place their responses along the continuum, but the order can be reversed for some respondents. Again, reversing the order does not eliminate the recurrence effect, but distributes it randomly across the population.[20]

Question Wording: The choice of words and phrases in a question is critical in expressing the meaning and intent of the question to the respondent and ensuring that all interpret the question the same way.Even small wording differences can substantially affect the answers people provide.

A considerable amount of research has been conducted to assess the impact of different ways of asking questions and how to minimize differences in the way, respondents interpret what is being asked. The issues related to the wording of the question are numerous which can be adequately addressed in this short space of time. This paper discusses some of the important issues to consider in the development of survey questions:[13, 17, 21]

First, it is important to ask questions that are clear and specific, and that each respondent will be able to answer. If a question is open-ended, it should be evident to respondents that they can answer in their own words and the type of response they should provide (an issue or problem, a month, number of days, etc.). Closed-ended questions should include all reasonable responses (i.e., the list of options is exhaustive) and the response categories should not overlap (i.e., response options should be mutually exclusive).[12,13]

It is also important to ask only one question at a time. Questions that ask respondents to evaluate more than one concept (known as double-barreled questions) are difficult for them to answer and often lead to responses that are difficult to interpret. It would be more effective to ask two separate questions, one about domestic policy and another about foreign policy.[22]

In general, questions that use simple and concrete language are more easily understood by respondents. It is especially important to consider the education level of the survey population when thinking about how easy it will be for respondents to interpret and answer a question. Double negatives (e.g., do you agree or disagreethat dental treatment is traumatic) or unfamiliar abbreviations or jargon (e.g. NAD or no abnormalities detected) can result in respondent confusion and should be avoided.[22]

One of the most common formats used in survey questions is the "agree-disagree" format. In this type of question, respondents are asked whether they agree or disagree with a particular statement. Research has shown that, while comparing the better educated and better informed, the less educated and less informed respondents have a greater tendency to agree with such statements. This is sometimes called an "acquiescence bias" (since some kinds of respondents are more likely to acquiesce to the assertion than are others). A better practice is to offer respondents a choice between alternative statements. [12, 18]

One other challenge in developing questionnaires is

"social desirability bias." People have a natural tendency to want to be accepted and liked, and this may lead people to provide inaccurate answers to questions that deal with sensitive subjects.[23] Research has also shown that social desirability bias can be greater when an interviewer is present (e.g., telephone and face-to-face surveys) than, when respondents complete the survey themselves (e.g., paper and web surveys).[11]

Question Order: Once the questionnaires have been created, attention should be directed towards the order of the questions. The placement of a question may have a greater impact on the outcome than the specific choice of words used in the question.[24]

When determining the order of questions, surveyors must be careful how the initial questions may have unintended effects on how respondents reply to the questionnaire. Researchers have shown that the order in which questions are asked can influence how people respond; earlier questions – in particular those directly preceding other questions – can provide a context for the questions that follow. (these effects are called "order effects").[21,24]

One kind of order effect can be seen in responses to open-ended questions. Research surveys generally ask open-ended questions about national problems, opinions about leaders and similar topics at beginning. If closed-ended questions that relate to the topic, they are placed before the open-ended question, so that respondents are much more likely to mention concepts or considerations raised in those earlier questions while responding to the open-ended question.[13,14]

There are two main types of order effects on closed opinion questions: comparison effects, where the order results in greater differences in responses and assimilation effects, where the responses in their order are more similar.[25] Assimilation is done if two questions are answered more consistently and/or closer together. When tracking patterns over time, the order issues are of particular importance. Therefore, care should be taken to ensure every time a question is posed that the meaning is identical. Any changes detected over time can be clarified by adjusting the context of the topic.[26]

A questionnaire, like a conversation. It should be categorised by topics and unfolded in a logical order. It is often helpful to begin the survey with simple questions, so that respondents will find it interesting and engaging in order to help for establishing rapport and motivating them to continue the survey. Throughout the survey, an effort should be made to keep the survey interesting and not overburden respondents with several difficult questions right after one another. Demographic questions such as income, education or age should not be asked at the beginning, unless they are needed to determine eligibility for the survey or for routing respondents through particular sections of the questionnaire. Although it is best to precede such items with more interesting and engaging questions.

Pilot tests and focus groups: Pilot tests are used, to determine how a survey population sample responds to the questionnaire. For a pilot project, surveyors typically contact several individuals to examine possible variations within groups. Further, the complete implementation procedures (eg contact notes, benefits, callbacks) are evaluated through pilot test for several surveys. Pilot tests are usually conducted sometime before the survey is carried out to allow more adjustments to the questionnaire or procedure. Pilot tests are especially useful as researchers check new questions or make major adjustments to questionnaires, evaluate new approaches or different forms of carrying out surveys like the Census.[27]

Focus groups are somewhat different from pilot projects because people address the survey subject or answer specific questions in a group environment, often in person. The survey involves individual people or a group. Focus groups may be especially helpful to collect information prior to creating a survey questionnaire to see which topics affect people, how people are aware of a subject area and how people perceive questions (particularly how the topic or question can affect answers in different ways). Focus groups can be used for some projects in conjunction with the survey questionnaire to give people the opportunity to speak more deeply or intensely about subjects than possible in the interview.[28]

Pre-tests: The pre-testing with a small number of people in the survey community is one of the most important ways to decide whether interviewees' answers are as intended and influenced by the order of the questions. The pre-test is conducted using the same protocol and environment as the survey and is usually performed after the questionnaire and procedures are completed. Pre-test information is crucial as final survey questionnaire decisions are made.[29]

Conclusion

A successful survey requires a well-designed questionnaire. Nevertheless, the researcher must establish his own sense of "effective design" because no questionnaire theory is there to direct them. A good questionnaire helps directly to accomplish the study goals, offers reliable and complete details. It is simple to answer, sound analysis and interpretation is accessible for both the interviewer and the respondent in a precise format. To concise, the initial information is determined by organising various parameters and constraints, to define the target respondents and a methodology to follow in order to reach them. Furthermore, the contents of the questions are determined to form a precise and on-point questionnaire, maintaining an appropriate length. Thus the its pre-tested and the final questionnaire is produced.

Periodontal Microsurgery: An Evolution in the Progression

Aseema Samal[1], Manoj Kumar[2], Rashmita Nayak[3], Anurag Satpathy[3], Abhaya Chandra Das[2], Gatha Mohanty[4]

[1]Intern, Institute of Dental Sciences, Siksha "O" Anusandhan Deemed to be University, Bhubaneswar, India, [2]Associate Professor, [3]Professor, [4]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The main purpose of this article is to provide a review of the challenges that are often faced in conventional surgery and how magnification has become an integral part of modern dentistry. The objective is to incorporate magnification for a minimally invasive periodontal microsurgery. This procedure requires clinical expertise and training. Different procedures ranging from GTR, crown-lengthening and root coverage to implantology and many diagnostic procedures are aided by periodontal microsurgery. In this challenging new era of technology, it claims to give more predictable therapeutic results with rapid healing and also improved cosmetic results whereas in other hands conventional surgery provides less visual acuity,delay in healing along with ergonomic problems.

Keywords: *Periodontal Microsurgery, Microscope, loupes.*

Introduction

Optical magnification has broadened the horizons of dentistry. The main aim of surgical intervention is not only a minimally invasive procedure but also to preserve the maximum amount of function of the organ. Periodontal microsurgery is reaching new heights of precision using loupes and surgical operating microscope. It emphasizes more on increasing visibility,minimize trauma and improve surgical results with the help of and microscalpelsmicro suture.

History: In 1876, a German physician Saemisch introduced loupes in medicine. A variety of magnification is there for surgeons ranging from simple loupes to prism loupes and most importantly the surgical microscope. Each of them has its pros and cons. It is now believed that magnification has more to do rather than just corrective vision. "In 1979, Daniel[1] defined microsurgery in broad terms as surgery performed under magnification using a microscope. Serafin described microsurgery as a methodology–modification and refinement of existing surgical techniques using magnification to improve visualization, with applications to all specialties."[2]

In 1981[3] Apotheker and Jako first introduced a commercial operating microscope to dentistry. At the annual meeting of the American Academy of Periodontology in 1993,it was subsequently conferred by Shanelec and Tibbetts on periodontal microsurgery. As treatment philosophy, microsurgery involves 3 important principles:

1. Advancement of motor skills thereby improving surgical ability
2. Passive wound healing with accurate apposition of the wound edge
3. Proper microsurgical instrumentation and suturing to reduce trauma to tissues.

Microsurgical Triad: There are 3 basic advantages provided by operating microscope i.e. illumination,

magnification and increased surgical skills. Illumination of the field plays a crucial part in microsurgery. Clinicians who use loupes usually need a headlamp to compensate for the reduced amount of light passing through loupes. Essential criteria require while taking in consideration of accessory lighting source which includes quality, and brightness of the light and ease of focusing and directing the light within the field of view of the magnifiers and ease of transport between surgeries.

Magnification is the second most important criterion of the microsurgical triad. There are various types of magnifications available for surgeons ranging from simple loupes to prism telescopic loupes and surgical microscope. Each of them has benefits and drawbacks. The principle of optics needs to be understood that governs magnification systems to improve the accuracy of clinical and diagnostic skills. "Decrease in field of view and depth of focus should be taken into consideration as magnification increases which is a major problem with dental loupes and operating microscope."Microsurgery is an advanced surgical technique, which is defined as surgery performed under magnification of 10× or more which is performed under a surgical microscope.[4]

Magnifying Loupes: They are most commonly used for magnification in periodontology. They are primarily dual monocular telescopes with side-by-side lenses convergent to focus on an object."The magnified image formed by its convergence is called a Keplerian optical system."Despite being widely used, there is a major flaw in comparison with a microscope. The clinicians need to converge to get the operating view which leads to eye strain, fatigue, and also vision impairment with prolonged use of ill-fitted loupes. 3 types of Keplerian loupes are mostly: -

1. Simple loupes
2. Compound loupes
3. Prism loupes

1. **Simple Loupes:** They consist of a single pair of side-by-side meniscus lenses and are limited to two refracting surfaces. Greater magnification can be obtained by increasing lens diameter and size. The size and its weight make it impractical for magnification beyond 1.5x. Spherical and chromatic aberrations are limitations of simple loupes. The shape of image and object color being viewed is also distorted due to this.[5,6]
2. **Compound Loupes:** They use multielement lenses with intervening air spaces to gain additional refracting surfaces.[7] Magnification can be increased without increasing the size and weight of the lens of lengthening the distance between the lenses. Along with this, a special optical feature that favors clinicians while selecting magnifying lenses is that it is achromatic. Hence it negates the chromatic aberration of the paired lens to produce a color correct image. However above 3x they become obsolete.
3. **Prism Loupes:** They are the leading loupes of optical magnification that employ Schmidt or "rooftop"prisms to elevate the light path using a series of switchback mirrors between the lenses.[8] Shortened barren of loupes provide improved magnification, wider field depth, longer working distances and also larger field views than other loupes. However, the heaviness of these loupes with magnification up to 4x makes headband mountings table and comfortable. Recent advances in these loupes are the incorporation of coaxial fiber optic lighting into the lens to enhance illumination.

Magnification range of surgical loupes: Dental loupes have a limited range of magnification ranging from 1.5x to 6x. The loupes less than 3x are usually inadequate for visual acuity necessary for the clinicians. Due to excessive weight, small field of view, shallow focal depth surgical loupes of magnification more than 4x are not practical in use. In some periodontal procedures, prism telescopic loupes with magnification 4x provide an adequate combination of magnification, field size and depth of focus. However, the surgical microscope offers much higher magnification and superior optics than any optical systems mentioned.

The surgical Microscope: Due to its extended range of magnification with superior optical performance and its greatest flexibility it has taken over the surgical loupes. Over 70-80% of periodontal microsurgery is performed under 10x-20x using a surgical microscope whereas under 6x-8x enhanced motor skills are acquired during microsurgery training sessions. Its design is based on Galilean optical principles and uses an inclinable binocular eyepiece which enhances maneuverability. "It incorporates fully coated optics and achromatic lenses with high resolution and high contrast stereoscopic vision. It uses Coaxial fiber-optic illumination produces an adjustable, uniformly illuminated, bright, and shadow-free circular spot of light that is parallel to

the optical viewing axis." It has better visualization of farther reaches of oral cavities, including into some subgingival pockets, angular defects, and root surface irregularities. Both provide enhanced vision and better ergonomics by increasing working distance. To reduce postural problems and eye strain in dentists there is an increase of 6-8 inches in working distance.[10]

Drawbacks include are:

1. As magnification increases there is a restricted area of vision and loss of depth of field.
2. Visual reference points are lost.
3. To avoid errors in instrument and suture placement,extra time is needed to achieve an experienced team approach.
4. Physiological tremors need to be controlled.

Ergonomics in microsurgery: While operating clinicians should be in a comfortable and relaxed state of mind and posture. A stable instrument-holding position and mental focus are needed for precise controlled movements of fingers. Finger movements are controlled by long flexor and extensor muscle. Physiologic tremor is unwanted movement and can be reduced by stabilizing the wrist and ulnar surface off forearm on a flat surface, angled in a dorsiflexion position at approx.20 degree.[11] To perform efficient and deliberate movement the operator should be erect with both feet flat and thighs parallel to the floor. Pen grip is mostly used or the internal precision grip which provides better stabilization than other hand grips due to tripod effect formed by the thumb, index and the middle finger which holds the instrument and the thumb and index finger are in contact with the underlying middle finger. Proper instrumentation is necessary for surgical intervention. The handle of the instrument should be round for better manipulation yet traction to execute fine controlled rotating movement. The most accurate rotary suturing movement of hand for a human body can perform is from 2 o'clock to 7 o'clock. Persistent practice of alternative positions around 360 degrees will result in better skills and good microsurgical results.

Microsurgical Instruments: The smaller instruments are used for high precision movement and minimize tissue trauma. The length of approx. 15cm is adequate for an average-sized hand to hold on to the instrument in a pen grip. The circular cross-section of the instrument used allows smooth rotational motion whereas the rectangular design does not allow such precise manipulation and hence not ideal for microsurgery.[12] The working tips are generally used that are quite smaller than those of regular instrument. They are manufactured under magnification to high tolerances to provide consistent manipulation to tissues. The surface of the instrument is usually colored to prevent unfavorable metal flare under the microscopic light. Each of them is around 15-20g in weight to avoid muscular fatigue of hand. The needle holders need to have an accurate working lock which should not exceed beyond a force of 50g (0.5N) as the precision is reduced in low locking forces and cause tremors in high locking forces. Titanium made instruments are stronger and lighter and non-magnetized than the stainless steel but are expensive and are resistant to distortion if properly cared for. A microscalpel holder, needle holder, micro-scissors, micro-forceps and elevators are the basic set of microsurgical instruments. To achieve wound healing by primary intention small size and sharp knives are used to place clean, non-ragged incision. The sharpest needles, spatula needles (6.6mm long with 140 degree) with microchips with reverse cutting-edge needles and taper tip are generally in practice to minimize tissue trauma and early tissue regeneration.[13,14]

The choice of suture needle size is crucial for atraumatic tissue passage. The most commonly used suture is 4-0 suture on a three-eight circle FS-2 reverse cutting needle. Most of the sizes range from 6-0 to 9-0.Among various suture materials, non-absorbable monofilament sutures are preferred and should be removed at the earliest biological time as they are bacteriostatic and non-inflammatory e.g. Vicryl® Plus (Ethicon®, Norderstedt, Germany). An ideal suture material is sterile,less reactive and resistant to shrinkage in tissues. It should be strong enough until wound healing to withstand its stress. The chord distance is an important component of needle design. It's the distance between the cutting point and the swaged end and radius is the arc of its circumference. The arc determines the ease of passing a suture between adjacent teeth. Also the angle of entry (less than 90degrees), bite-size (approx. 1.5times the tissue thickness) determines the proper wound approximation. Suturing plays a significant factor for a successful treatment. Though it takes motor skills and dexterity but through the visual guidance aided by the microscope knot tying requires minimal time. In microsurgery, the entry and exit of the needle should be perpendicular to the tissues and at equal distances. Under a microscope, with the help of instrument ties,the

microsurgical needle holder in the dominant hand and tissue is picked in the non-dominant hand using proprioception.[11] The best surgical knot is achieved with the surgeon's knot followed by a square knot. Integrity or strength is lost by adding excess ties to the knot. Well tied knots ensure there is no microinjury under function.

Uses of microsurgery in periodontics: Periodontal microsurgery has broadened the horizons of dentistry by descending the conventional surgery by its attempt to reduce surgical trauma and hence give better therapeutic results.

1.**Root preparation**: Root surface debridement is an important criterion for periodontal therapy. Clinical and research studies demonstrated that with stereo microscope there in better visual access and hence effective in root planing. It is reported that under illumination, root instrumentation is effective along with less postoperative pain and improved healing index.[15,16] Moreover, using micro ultrasonic instruments of size as small as 0.2-0.6mm in diameter and variable power settings(25,000-40,000 cycles per second) allows deep pocket cleaning and reduces the chances of over-instrumentation of the root surface.[17] All surface of instrument have active working sides and requires minimal water supply. The clinician could differentiate the calculus from the surface and biofilm to the microscopic level, hence morphological contours are determined for the working end to angle accordingly during instrumentation.[18]

2. **Minimally invasiveperiodontal surgery (MIPS) for regeneration:** Recent studies have found that clinical effectiveness for periodontal regeneration of intrabony defects is better through the microsurgical approach. Further more, treatment of isolated or multiple intrabony defects with increased accuracy and minimal trauma. There is no much significant differences of probing depth, clinical attachment level gainwith treatment of intrabony defects treated with MIPS than those with conventional surgical approach.[19] Isolated interproximal defects are ideal for bone grafting using MIPS while contra indicated for generalized horizontal bone loss and multiple interconnected intrabony defects. In MIPS, for proper debridement of the periodontal defect and root surfaces, a new operating microscope (Varioscope®)with appropriate illumination which allows visualization of defect easily from different angles.[20] It has also known to minimize marginal tissue recession and improved esthetics. Recently, a new microsurgical technique named "Entire Papilla Preservation" to maintain wound stability and limit the exposure of regenerative biomaterials such as bone grafts and enamel matrix derivatives.

3. **Periodontal plastic surgery:** Esthetic improvement is the major indication for mucogingival surgery. To restore normal gingival or alveolar mucosa anatomy, several surgical procedures including pedicle grafts and free soft tissue grafts are performed. This also includes rotational flaps(e.g., laterally sliding flap or double papilla flap) or without rotation or lateral movement(e.g., coronally placed flaps). This technique is used along with the membrane barrier using GTR as a treatment of root coverage. Subepithelial connective tissue graft is obtained from the palate by a "trap door[20,21] approach can heal rapidly and is less invasive and can restore wide recession defects. Root coverage grafting is easier through autologous grafts due to their rapid revascularization.Many interdental papilla augmentations could have a better outcome using proper microsurgical procedures.

4. **Microsurgery in implants:** Surgical microscope aids in indirect visualization of sinus membrane and minimize the chance of perforation through it and hence applied in sinus lift procedures. Also, implant failure and peri-implantitis management can be performed with more precision. Although there is no strong evidence of less postoperative pain following extraction and implant placement, its rationale suggests that microsurgery causes less trauma and rapid healing and postoperative morbidity.

Conclusion

With training and motor skills, an average periodontal microsurgeon can produce better-crafted work than the proficient conventional surgeon. Though it is technique sensitive but requires less time to produce promising clinical results and have more patient acceptance. Despite having applications and benefits microsurgery it also has many drawbacks that include limited vision, loss of depth of field and arduous learning curve with the high initial cost of setup.

Dental Management of Children with Special Health Careneeds: A Review

Fungbili Mahilary

Intern, Institute of Dental Science, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Children with special needs for health care (SHCN) management causes uncertainty and anxiety among health practitioners like dentists as it involves advanced skills gained through special training, enhanced understanding, accommodative measures and resources. A quest was undertaken to find revised and evidence-based guidelines and alternatives for the dental care available to SHCN children. Such guidelines will help dentists determine some suitable dental treatment and also help other medical practitioners recognize the need to ensure good oral health for children with SHCN and the value of collaboration with dental practitioners.

Keywords: *Special health care needs; Behaviour; Sedation; General anesthesia; Dental caries.*

Introduction

The American Academy of Pediatric Dentistry (AAPD) describes special health care requirements as "any physical, physiological, neurological, sensory, behavioral, cognitive or emotional disability or restricting disorder requiring medical treatment, involvement in health care and/or the employment of specific services or programs." The condition can also be genetic, hereditary or developed by illness or environmental causes, consistent with the AAPD, and may place limits on the performance of daily life-maintenance activities or severe restrictions during large lifetime operations. Yet, despite offering such assistance, many professionals often find it difficult. Such difficulties may vary from an absence of formal experience, uncertainty, potential ergonomic limitations, routine adjustments within the consulting room requiring physical modifications and special equipment, to the shortage of scientific expertise.[1] Moreover, it's common for patients with different levels of cooperation, a problem or perhaps an impediment of the dental treatment in an outpatient setting. Thus, health care professionals can reduce barriers using different techniques Special care dentistry is the dental care provider dedicated to the particular needs of patients with worsening medical conditions or behavioral or cognitive disabilities that need treatment outside traditional method. Patients with intellectual, emotional or physical disorders are often at greater risk of oral and dental illnesses. Thereafter, behavioral treatment method must be used first, but within the case of failure, sedation is another to the patient that's to not undergo anesthesia.[2]

Parents with SHCN children spend more money on dental services that healthy children need, a substantial barrier to access to oral care is taken into account. The purpose of this article was to scan the review for up-to-date and proof-based guidelines and usable and affordable dental management approaches with SHCN, help dentists in selecting the correct dental management and assist other medical professionals in identifying the same need.[1]

Mental Retardation: Definition-"Mental retardation is a common neurodevelopmental condition characterized by substantially impaired intellectual and social functioning"–American Mental Deficiency

Corresponding Author:
Fungbili Mahilary

e-mail: mfungbili@gmail.com

Association (1983). Mental retardation has a new name "Intellectual disability" or "Intellectual Developmental Disorder or General Learning Disability". The sizeable subaverage is known as I.Q. Around 70 or below on a standardized intelligence scale.[4,5]

Table 1. Classification of special health care needs children[3]

Frank and winter (1974)	According to Agerholm	According to Nowak (1976)
• Blind or partially sighted • Deaf and partially deaf • Educationally subnormal • Epileptic • Maladjusted • Physically handicapped • Defective of speech • Senile	• **Intrinsic category:** The handicapped condition cannot be eliminated/separated/improved significantly in the child. e.g. cerebral palsy, mental retardation • **Extrinsic category** The handicapped condition may be made better with strategic meticulous care. Social deprivation is an example.	• Physically handicapped • Mentally handicapped retardation • Congenital – cleft lip and palate • Convulsive- epilepsy • Communication-deafness • Systemic- hemophilia • Metabolic- juvenile diabetes • Osseous disorder- rickets • Malignant disorder- leukemia

Table 2. Classification of Intellectual Disability[5]

Types	IQ ranges
Mild Mental Retardation	50-70
Moderate Mental retardation	35-50
Severe Mental retardation	20-25
Profound Mental retardation	<20

Dental Findings[6,11]:

- Damaging oral habits is a problem for some intellectually disabled individuals. Specific behaviors include bruxism; breathing of the mouth; thrusting of the tongue; self-injurious actions such as picking on the gingiva or chewing the lips; and pica–consuming items and substances such as dirt, cigarette butts or pens.
- Dental Caries- Incidence is the same as normal children but the occurrence of untreated caries is higher than usual children.
- Periodontal Disease - Medicines, malocclusion, several disabilities and poor oral hygiene lead to increase the risk of periodontal disease in mentally impaired people (6).
- Malocclusion occurrence in persons with intellectual disabilities is equivalent to that found in the general population
- Missing permanent teeth, retarded eruption and hypoplasia of enamel are even more prevalent in Intellectual Disabilities.
- Trauma and Injuries-In people with intellectual disability, TRAUMA, and Injuries occur to the mouth through falls or accidents.
- Owing to the various drugs, increased plaque and calculus formation that contribute to poor oral hygiene, salivary flow is altered further contributing to halitosis.
- Speak disability due to early teething delay.

Dental Management 3:

- Such kids can have a shorter period of maturity too. Such kids can have a shorter period of maturity too.
- These two main objectives were accomplished by the following:
- Familiarisation (Desensitisation) - To that his anxiety and fear of objects around him that might be unfamiliar to him by getting acquainted with the dental office environment, the apprehensive child patient needs to be desensitized.
- Effective communication-–It's necessary to make the child understand the proceedings through clear and uncomplicated verbal contact. These are used successfully in Mentally Retarded Educable (EMR) and Mentally Retarded Trainable (TMR).
- Active Listening.
- Short appointment time.
- Structuring and scheduling–Care must be given at times when in the early part of the day the dentist and the operator are both less exhausted.

- Positive Reinforcement–A social or material reward will positively reinforce the child's interpretation of conduct which is beneficial during the operation.

Down syndrome (trisomy 21): Down syndrome, or Down's syndrome, also known as trisomy 21, is a genetic disorder characterized by whole or part of a single copy of chromosome 21. The most severe abnormality in human chromosomes is the Down syndrome. It occurs every year in about 1 in 1000 babies born.[8-10]

Dental Findings[7]:

- Periodontal disorder: Nearly all children with Down's syndrome have moderate to extreme periodontal disorder.
- Xerostomia: Dry mouth, normally caused by oral coughing and other drugs (anticonvulsants, sedation).
- Infection: Fissured lips and tongue that lead them to the region's oral candidacies, aphthous ulcers and wounds.
- Hypotonia: Such disease that affects muscles in different areas of the body.
- Difficulties with oral hygiene and brushing: Few people with Down syndrome will brush and floss easily, while others need assistance.
- Dental abnormalities: This disorder is very common in patients with Down's syndrome, including enamel hypoplasia, microdontia, impacted teeth, crowded teeth, missing teeth and malformed teeth.
- Malocclusions: a prognathic Class III occlusal relationship, Posterior crossbite, and anterior open bite.
- Macroglossia, Delayed eruption of teeth, Sleep apnea, Dental Caries, Halitosis, Speech difficulties

Dental management[12]:

Table 3. Prescribed medications based on symptoms

Symptoms	Medication	Side effects
Seizures	Anti-convulsant (Dilantin)	Gingival hyperplasia
Hypertension	Calcium channel blockers	Xerostomia

Behavioral Management:

- Pre-(person/phone) plan before the first appointment to discuss special patient needs. Speak best about this-knowing the child to the parents or the caregiver.
- Timetable patient rendezvous early in the morning or best time of day.
- Speak to the parents or caregiver to assess the level of mental and cognitive ability of the patient, and describe each treatment at a level that the patient can understand.
- Using the quick, concise directions and talk to the patient directly.
- Reduce stimuli such as hustle and bustle that can make it difficult for the patient to comply.
- Start the oral examination slowly, beginning with fingers first. When this is a success, continue to use dental products.
- When implementing new instruments or techniques, use the Tell Show-Do approach.
- The cooperative behavior is compensated by positive verbal strengthening.
- Improve faith and continuity between the dental personnel and the patient.

Cerebral Palsy: Cerebral palsy is a category of chronic movement and posture development disorders that cause restriction of activity, due to excessive progressive disorders that developed in the developing fetus or autistic child brain.[13]

Dental Findings[3]:

- Malocclusion prevalence rate was recorded between 59 and 92 percent, with the overwhelming majority of malocclusion categorized as Angles Class II with increased overjet and overbite, unilateral cross-bite and open bite associated with irregular oral habits is twice as common.
- Rodrigues CAM et al.found that the incidence of dental trauma was (36.3 percent); the most severe trauma (89.1 percent) was enamel fracture.
- In several studies a high prevalence of bruxism has been confirmed in individuals who have Cerebral palsy.
- Higher prevalence of the periodontal condition.
- Ferreira de Camargo et al. found that the occurrence of caries in kids and teens with CP is strong, but Quintela M et al. concluded that in both dentitions, cerebral palsy individuals are less likely to have caries than subjects in comparison groups.

- Dental erosion is prevalent in patients with Cerebral palsy.
- In children with CP the sequence of eruption was almost close to normal. Except for the second premolar and the second molar, showing delayed eruption.
- Lin et al. found a high frequency of developmental enamel deficiencies in children with CP {Enamel hypoplasia (25.9%), opacity alone (3.7%), and mixed deficiencies (opacity and hypoplasia)}.

Dental management[3]:

The reason for the treatment involves three aspects:

- Intellectual maturity and willingness to cooperate: Based on this measure, children are graded as educable, trainable and untrainable.
- Postural compliance in the dental chair: the manifestation of increased muscular rigidity, hyper-contractility, uncoordinated movement, and ataxic gait that compromise the child's compliance with a dental chair.
- Preventive care: Requires good oral hygiene habits, instruction and knowledge of the caretaker's oral hygiene habits, application of fluoride and sealant, as well as regular examination

Some Considerations: A patient who is using a wheelchair should be treated in the wheelchair itself. The patient must be balanced and held as security in the midline of the dental chair, with arms and legs as close to the midline. The patient's upper and lower limbs will not be pushed into an uncomfortable position. Patient choice should be essential. A choice of two adapted radiographic techniques is available to reduce extreme gag reflexes which may occur in children with cerebral palsy: one is the 45-degree oblique head plate, and another is the reverse bitewing (buccal technique). Working as effectively as possible must be on the operator, and reducing the exhaustion of the muscles involved.

Dental management while doing Dental Treatments

The therapeutic needs must be prioritized (preventive, conservative, surgical) as follows:

- Preventive treatment involving the regular scaling/ cleaning and application of fluoride, as well as the positioning of sealants.
- Restorative treatment that involves both primary and permanent endodontic and restorative care.
- Surgical treatment including extractions of the tooth, gingivectomies, biopsies and other mild oral surgery.
- It could be suggested and appropriate to recommend some relaxation exercises or even physical help, so that the dental treatment runs out un-eventually. Both of these advocate limiting movement, which must be used to prevent patient movement from obstructing dental assistance. This strategy often prevents patient "escape attempts," while shielding the work team as bites from potential traumas and injuries. Based on clinical experience with journalists, below are a few suggestions:
- 'Holding therapy' is a child-friendly physical support strategy that stays in the lap of the person responsible for stabilizing the trunk and arms while supporting the patient (Figure 1).

Figure 1. Holding therapy

The "knee to knee" position is ideal for 1-3-year-old children. The technique consists of placing the child on the dentist's and the person responsible's hands, each reaching the knees and creating a kind of hammock (Figure 2).

Figure 2. Knee to knee position

The procedure in which the auxiliaries carries the head of the patient should be extended to patients of all ages. The auxiliaries support the head of the patient to stabilize or sustain it (Figure 3).

Figure 3. Auxiliary sustaining the patient's head

Such method can be used for short dental visits in which, as mentioned above, preventive, restorative and/or surgical treatments can be performed before the pharmacological restraint attempt.[14,15]

Conclusions

For a person with SHCN, oral and general health care needs "specialized knowledge acquired through additional training, as well as increased awareness and attention, adaptation and accommodation beyond what is considered normal".[15]Children with special health care needs get a substantially greater incidence of dental diseases due to lack of oral health education, exposure to treatment, and prevention measures such as fluoride supplements and dental adhesives for their caregivers. Children with special health care needs have also considered oral health low relative to otherwise healthy children in terms of their dentition status, periodontium of their treatment needs and dentofacial defects. Many children with mild to moderate developmental disorders may be treated with limited modifications in a dental clinic. A well-trained team of professional dentists, fair parental participation in difficult care plans, and knowledge of the level of child development for daily language skills and attention will also enable the patient to cope with the care better. By delivering comprehensive school-based services (along with oral hygiene programs to help children develop skills), delivering fluoride supplements and sealants, and providing health and nutritional guidance, the dental team will seek to improve oral hygiene. Educational videos that show both children with SHCN and healthy children with a variety of materials can be useful in teaching them oral protection. Routine oral healthcare preparation is much more critical for children with SHCN than for healthy children because of the complications of the condition and the chronic nature of the disease.

Chondroblastic Osteosarcoma: A Review

K. Kiran Kumar Patro

Intern, Institute of dental sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

The main purpose of this article to present a review on chondroblastic osteosarcomaand its prevalence in the different jawbones of the body. The word osteosarcoma mainly refers to a group of heterogeneous malignancies that involves bone formation or it can also results due to mesenchymal tissue with evidence of osteogenic disparity. It has been reported around 25% of the pattern of the chondroblastic osteosarcomas represents neoplasms.

Keywords: *Osteogenic sarcomas, chondroblastic osteosarcoma jaw, bonetumors.*

Introduction

Sarcoma is procured from the Greek word "SERX" which means "Flesh''.A sarcoma is a type of cancer that arises from the transformed cells of mesenchymal origin. These are primary connective tumors.[1]

Osteosarcoma is the most common type of cancer that primarily affects immature bone. It is the most common type of cancer and has a more male prediction ratio. Osteosarcoma occurring in the orofacial regions is extremely sparse, noticing around 1 % of all head and neck region and 7% of all osteosarcomas occurring in the body.[2]

Types:

The different types of osteosarcoma are:

Central:

- Lowgrade-parosteal;
- Intermediate-periosteal;
- Highgrade- Dedifferiatelyparosteal

Surface:

- High-grade 1.Conventional; 2. Telangiectatic; 3. Small cell; 4. Epithelioid; 5. Osteoblastoma-like; 6. Chondroblastoma-like; 7. Fibrohistolytic; 8. Giant cell-rich
- Low grade: 1.lowgrade-central; 2.fibrous dysplasia-like

Intracortical:

Gnathic:

Extra Skeletal:

- High grade
- Lowgrade

Depending on who classifies the chondroblastic osteosarcoma as a histological entity illustrious by the major occurrence of the chondroid matrix, which marks in the direction to give you an idea about an elevated degree of hyaline cartilage as well as is intimately associated through the non-chondroid elements like osteoid, bone matrix.[3]

Epidemiology, genetic factors and risk factors: Osteosarcoma is a condition which occurs in both children and adolescence group of people but it is found that it culminates more during the second decade of life. The occurrence rate in children and juvenile age group mostly variety stuck between 3.5 to 4.2 cases

Corresponding Author:
K. Kiran Kumar Patro
Intern, Institute of dental sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India
e-mail: kiranpatro156@gmail.com

per million inhabitants per year at the same time as the rate in old aged group of individuals is found less .i.e. approximately 1 to 2 cases per million population per year and it is found that middle age group of individuals shows around 1.5 to 4.6 cases per million population per year (25-60) years. Among the risk factors for osteosarcoma, fluoride exposure is found to be the predisposing factor for causing bone cancer. Later no evidence was found clearly regarding this factor.[4]

The exact cause is still unknown but several risk factors are been identified. It is been found that it has arisen from the hereditary multiple exostoses and diseases like Paget disease, fibrousdysplasia, etc. The re are different types of osteosarcoma of jawbones and they can be classified mainly into two groups-

a. Primary

b. Secondary

The cause of the primary subtype of osteosarcoma is still unidentified .but it has been predicted that it may take place due to possible risk factors like genetic as well as environmental factors in addition to the genetic predisposing factors includes the hereditary form of retinoblastoma .i.e. gene alteration,Li-Fraumeni condition. i.e. P53gene transformation, Rothmund – Thomson syndrome. The cause of the resultant subtype of osteosarcoma arises as of the late sequel to craniofacial irradiation, Paget's disease as well as fibrous dysplasia. And it is found that it mainly occurs in grown-up group of patients.[5]

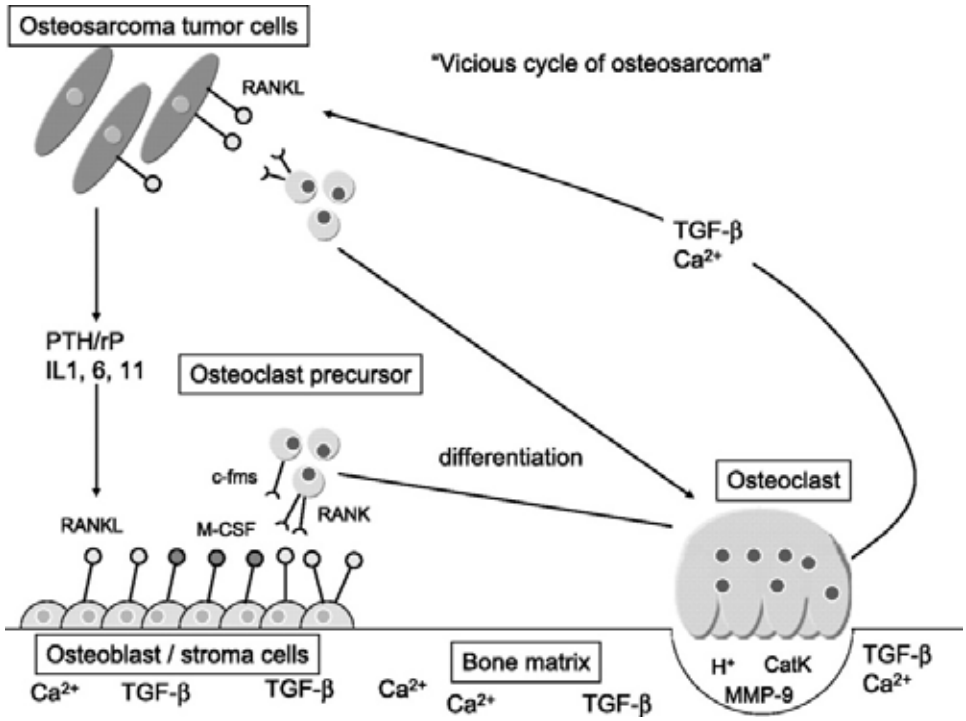

Figure 1. Vicious cycle of osteosarcoma

Clinical Features: It mainly occurs in the age groups of 20-40 years with predominance in males as compared to females and has a higher occurrence in the posterior mandible as compared to the mandible. In some cases, it has been found that the maxilla and mandible are involved with equal constancy. Sites that often participate in the mandible are at symphysis and the sites that mainly involve in maxilla are the alveolar ridge, palate, sinus floor etc.[6]

These lesions can be purely osteolytic, purely osteoblastic,or mixture of both. Common signs and symptoms include pain,swelling, or both in some cases. Lymphadenopathy is also found where there is unusual focal and regional lymph nodes involvement. The essential microscopic criteria to detect are the direct production of osteoid cells by malignant mesenchymal cells. In addition to these osteoid cells we find the tumor cells producing chondroid type of material and the

different fibrous connective tissue. Other complaints include numbness, facial dysphasia, mobility of the teeth, trismus, headache, nasalcongestion, inability of mouth opening, etc. But it is found that some patients have no prodrome at present time but their tumors can be located incidentally by radiographic imaging.[7]

At first parading, metastatic infection is accessible around 4- 5% of the patients. This occurs in a reduced amount in the patients among appendicular skeleton osteosarcoma. The lungs are the most habitually implicated sites of our body.[8]

Investigations: Radiography plays a major role in the initial diagnosis and it is seen that the classic radiographic presentation of osteosarcoma includes Sunray/Sunburst appearance. And this sunburst appearance arises due to osteogenesis of tumor cells. But the extent of the tumor in both hard and soft tissue is been better appreciated in the CT Scan, MRI imaging, Angiogram which mainly detect the vascular displacement and the relationship of the vessel to the lesion and the same time it also helps to determine the vascularity of the involved tumour.[9]

Immunohistochemical characterization plays an important role in the diagnosis of osteosarcoma which includes mainly the osteonectin and osteocalcin-osteocalcin is specific for osteoblast cells but osteonectin is not specified for osteoblasts and the other biomarkers that are used apart from osteonectin and osteocalcin are cytokeratin, P53, P16, Ki67, CD99, S100, caveolin-1, etc. Some laboratory standards like lactate dehydrogenase, alkaline phosphate serum levels possibly will be escalated in a small number of collections of patients. Even though they do not keep up a correspondence with disease proportions, exceptthey may have anegative prognostic importance.[10]

Codman's Triangle: It is formed primarily in the angle between the elevated periosteum and the cortex's underlying surface.

In many cases, CORTICAL BREACH is commonly observed. Histologically, there is the presence of belligerent malignant mesenchymal cells that produce undeveloped bone. And the stroma mainly consists of malignant connective tissue with anaplastic spindle cells surrounded in the mesenchymal parenchyma.[11]

Chondrosarcoma comprises of cartilage along with varying degrees of cellularity and maturation. It is found that normal chondroid lacunar formation is visible, but this feature may be rarelyseen in poorly differentiated tumors. The tumor can be often seen in globule growth patterns with thin fibrous connective septa-separated tumor lobules.

The central areas of the lobules show the highest degree of maturation. Calcification or ossification may occur within the chondroid matrix. Neoplastic cartilage may be replaced by bone-like normal endochondral ossification.[12]

It can be divided into 3 histopathologic grades of malignancy and this grading system is well correlated with the growth rate of tumors and the prognosis of extragnathic skeleton chondrosarcomas.

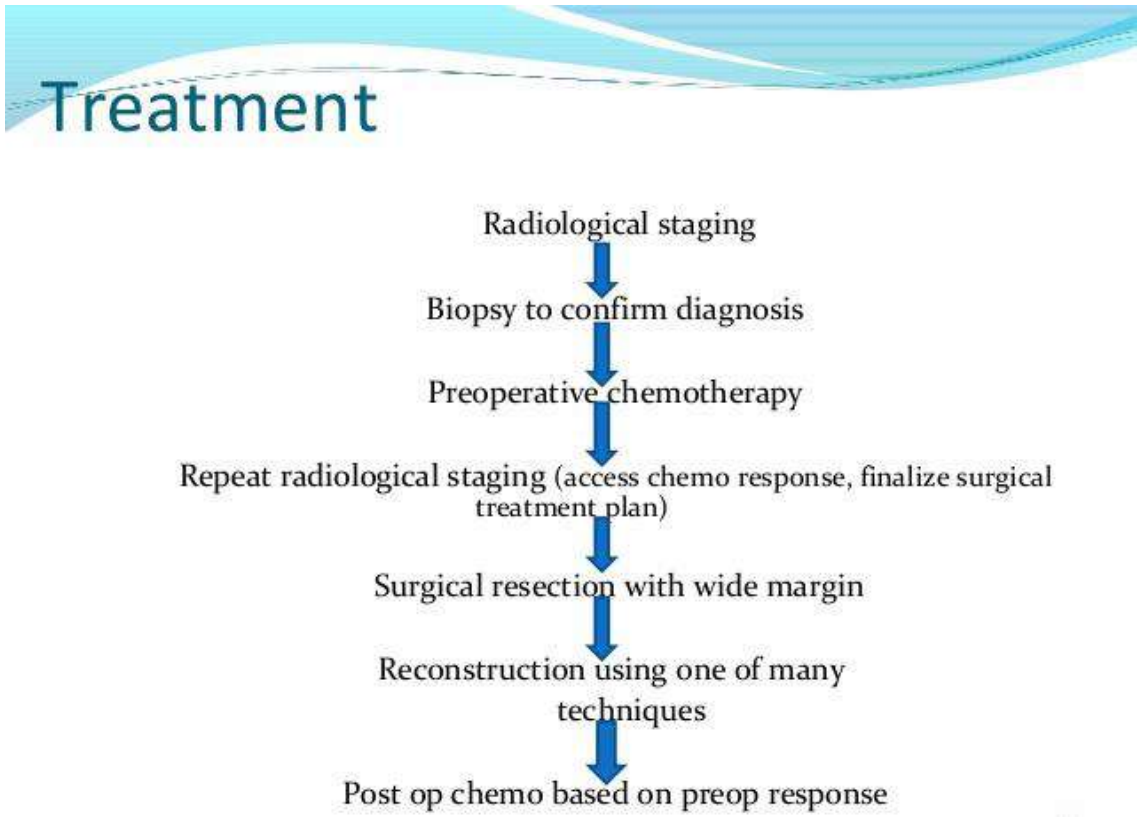
Grade I: Chondrosarcomas powerfully bear a resemblance to the manifestation of chondromas, consisting of the chondroid matrix as well as chondroblasts displaying no more than a slight deviation of normal cartilage outer shell. The cartilaginous matrix calcification or ossification is prominent, as well as the mitosis is rare.

Grade II: Chondrosarcoma shows a larger portion of moderately sized nuclei and increased cellularity, especially in the lobules with a less prominent hyaline matrix. However, the mitotic rate is low.

Grade III: Chondrosarcoma is exceedingly cellular with may show prominent spindle cell propagation mitoses may be important. Simply identifiable cartilaginous matrix containing lacunae cells may be scarce. Eventually develop into higher grade osteosarcoma with poor prognosis.[13]

The different histopathologic variants are as follows:

1. Conventional type-osteoblastic, chondroblastic, and fibroblastic osteosarcoma
2. Telangiectatic/osteolytic type osteosarcoma
3. Diminutive cell osteosarcoma
4. Low downgrade central osteosarcoma
5. Periosteal osteosarcoma
6. Periosteal osteosarcoma
7. Secondary osteosarcoma
8. Elevated grade surface osteosarcoma
9. Extraskeletal osteosarcoma



The prognosis feature is mainly evaluated by the Enneking system which for the most part evaluates the histological grade of the tumor (G), the extent of the primary tumor (T) as well asmetastasis to the close by lymph nodes or other concerned organs (M).

Amongst all the diverse histological types as well as subtypes chondroblastic type is more impervious to treatment and exhibits unfavorable prognosis. Whereas we can find Fibroblastic types that have a rather better prognosis and as well as responds to the treatment.

Treatment: The management is finished with a permutation of therapies together with surgery, chemotherapy as well as radiation therapy. However, they have to undertake three months of chemotherapy, acknowledged as neo-adjuvant therapy previous to surgery if the patient is originated to have high-grade tumors.[14]

Surgery: As these cases for the most part lies in the skeletal orientation, surgery is a central component of osteosarcomas treatment too in the head as well as neck region. The modality of the management, principles of the surgical management largely depends on the position of the tumor, the dimension of the tumor. Obtaining disease-free resection margins is of course dictatorial, to keep away from the risk of local reappearance. on the other hand, this objective is even extra complicated to reach when dealing through the head as well as neck osteosarcomas, as resecting few millimeters, more often means imperil significantly functional structures, through a noticeable reduction in the patient's quality of life. While in the intraoperative strength of mind of resection margins might represent a useful tool in other head as well as neck malignancies. Intraoperative pathological examination does not consent for the evaluation of bone margins. In the meantime, only soft tissue margins can be evaluated through the intraoperative consultation. It is found that the best management results is been obtained when the criteria .i.e. the histopathologic evaluation, biopsy of the desired site and the extent of the neoplasm is been determined, before the treatment. Multimodal mode of treatment is indicated or we can say that the best analeptic option is when we are dealing with the high grade of osteosarcomas but only alone surgery can be done if the neoplasm comes under the low grade, parosteal and central group of osteosarcomas. Provided if the metastatic potential of the neoplasm is found to be absent.[15]

The treatment procedure can be understood as follows:

Conclusion

Chondroblastic osteosarcomas of the mouth remain "Delphic''. Anamount of difficulty associated with their diagnosis as well as treatment is yet to be determined. True synchronous multicentric osteosarcomas of the mouth are tremendously uncommon but like other osteosarcomas of the jaw, have a successful result. The palliative resection modality of the management in such lesion through difficult however can show the way to an enormously enhanced quality of life in addition to may even offer the window for cure. Bountiful studies have been reported that the molecular pathogenesis of the osteosarcoma as well as the related biomarkers associated with means of the tumor. Even though many studies are exceedingly favorable as well as there has been no upgrading in the reoccurrences along with survival rates of osteosarcoma. Our facts and data of the pathway caught up in sarcoma genesis deficient, as well as new perceptiveness are enthusiastically awaited in the perspective of developing a forceful target therapy to come together with surgery.

Deleterious Oral Habits and Management in Pediatric Patients: A Review

Fatma Shaghaf

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Habit is the constant and unconscious repetition of an act. Children (usually infants) frequently acquire oral habits that can be temporary, if continued can be permanent & harmful to dental occlusion and supporting structures. This article aims to throw lights on harmful habits, its cause, side effect and treatment available, as ignorance of these habits can cause facial abnormality; hence Dentists play an important role in the identification and removal of habits.

Keywords: *oral habits, Bruxism, Digit Sucking, Nail Biting, Tongue Thrusting, Mouth Breathing, Lip Sucking.*

Introduction

Oral Habit most commonly seen during infancy as it is part of normal development. It usually fades away with time. If not, then it is a matter of great concern as it can cause serious dentoalveolar changes. It is usually associated with several etiologies out of which psychology is common and important. Hence, if a patient complains of habit understanding the associated deep-rooted psychology and management is very important for Dentist.[1]

Oral habits is justified as a frequent or constant practice which is fixed due to frequent repetition

Oral Habits are classified in several headings by following scientist:

According to William James (1923): Useful habits such as nasal breathing/harmful habits such as thumb sucking.

Corresponding Author:
Fatma Shaghaf
Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: fshaghaf@gmail.com

According to Kingsley (1956): Functional Oral Habit like mouth breathing/Muscular Habit like tongue thrusting/Combined Muscular Habit like thumb and finger habit/Postural Habit like chin propping.

According to Morris and Bohanna (1969): Pressure Habit like lip sucking/Non Pressure Habitlike mouth breathing/Biting habit like lip biting.

According to Finn (1987): Compulsive/ Noncompulsive.

According to Klein (1971): Empty or unintentional Habit/Meaningful or intentional habit.[2]

Bruxism: The word bruxism is derived from the word 'la bruxomaine' coined by Marie Pietkiewicz (1907). It is a repetitive movement disorder of mandible which is characterized by unconscious clenching and grinding of teeth. This type of Parafunctional movement is important for dentist's knowledge as it is used to detect the reason behind broken restoration, tooth damage such as tooth fracture or any temporomandibular disorders. Bruxism is of two types Nocturnal bruxism/Sleep Bruxism which occurs in sleep and Diurnal Bruxism/Awake Bruxism which occurs when the patient is awake. Sleep bruxism is of two types of primary or idiopathic (occurs without any medical reason), secondary or iatrogenic (may be caused due to use of the drug).

Etiologies associated with bruxism are psychosocial factor (emotional stress), pathophysiology factor (illness, trauma, smoking, medication), genetic factor (offspring of people with bruxism have more chances), local factor (faulty restoration, calculus, malocclusion), systemic factor (a nutritional deficiency, intestinal parasite infection).[3-6]

Clinical Feature: Bruxism affects the anatomy, morphology and dental occlusion. It causes mobility of teeth, hypersensitivity, pain in facial muscle,restricted mouth opening, pain in the temporomandibular region (frequent headache), tooth fracture, damage to the dental prosthesis and dental fillings.[3-6]

Treatment: There is no such accepted treatment available for bruxism as it is not life-threatening hence conservative treatment is recommended. Eliminate the causative factor. Awake Bruxism can be reduced by habit modification training or use of small chewing gum as a reminder in the molar region. Sleep bruxism can be reduced by sleeping without pillow i.e. flat on back, occlusal splint and dental guards can be used. Medication such as benzodiazepines, beta-blockers, dopamine agents, antidepressants, anticonvulsants, muscle relaxants can be used to treat Bruxism.[3-6]

Digit Sucking: Digit (Thumb, finger) sucking is the most common type of non-nutritive sucking habit. It is defined as positioning of digits at varying depths of the oral cavity. This habit started during the 29th week of gestation continues till 2-3yrs of age after which children usually stop this habit on their own. If this habit continues it can cause malocclusion and can also alter the shape of a digit.

Two theories are involved to explain the etiology of digit sucking, emotional theory and learned behavior theory. Emotional theory is explained by Sigmund Freud according to him finger sucking is a type of pleasure in which a child derives from excitation of oral erogenous routes. If infants sucking needs are not fulfilled this habit become fixation, later continuation is known as regression. Fixation and regression are features of emotional disturbances. In recent times learned behavior theory is the most favored theory, according to this theory sucking is a natural desire in infant and digit sucking is caused due to excess sucking urge because of efficient breast/bottle feeding by nutritionally proficient mother. Emotional and physical stimuli, such as hunger,boredom, stress, pleasure and other disability are the main cause behind the continuation of this habit.[7-11]

Classification: Subtelny (1973) has classified types of digit sucking into 4 types:-

Type A-(50%) of children place the entire thumb or digit inside the oral cavity witha pad of the thumb is a place such that is pressing the palate. Anterior teeth of the maxillary and mandibular region are in contact.[7-11]

Type B-(25%) of children place the whole thumb inside the mouth but it is not in contact with the vault ofthe palate. Only anterior teeth mandibular and maxillary region are in contact

Type C- (18%) of children place thumb just beyond its first joint, there is no mandibular contact thumb is in contact with maxillary incisor.

Type D-(6%) of children doesn't fully place thumb inside the mouth, only thumbnail is in approximate contact with mandibular incisors.[7-11]

Etiology: Type of malocclusion during digit sucking depends on several factors such as the position of the digit, related oro-facial muscle, the position of the mandible during sucking, facial and skeletal design, intensity frequency and duration of force applied.

Clinical feature: Prolong Digit sucking can cause damage to facial structure, dental structure and digits involved in sucking. Maxillary changes due to a long time sucking habit areoverjet of the maxilla,increased maxillary arch length,reduced width of palatal arch, increased angle of sella-nasion-point A. Effects on the mandible include proclination of the mandibular incisors,increased distance in intermolar region and reduced angle of sella-nasion-point B. Other dental deformity includes increased overjet, reduced overbite, and crossbite in posterior tooth region. Digit deformity can be caused in chronic sucking patients.[7-11]

Removal of psychological reason, engagement of the child in various activities to divert the mind, adequate duration of breastfeeding, use of dummy or pacifiers can reduce the thumb sucking habit.[7-11]

Management of thumb sucking involve following therapy according to Pinkham:

Preventive therapy (Hughes): Feed the child enough in a natural way such that his feeding needs are fulfilled.

Psychological Therapy: This habit usually acquire by those children who lack parental care, love and proper care. Hence dentists and parents need to carefully handle the situation with proper understanding and without shaming and punishment. Positive reinforcement or positive reward system should be used to modify behavior. Dunlop's beta hypothesis is the best way to break the habit. According to this hypothesis conscious and purposeful repetition can stop the habit. The child is asked to stand with the mirror and suck his/her digit looking at self, this procedure is very productive when a child is repeatedly asked to perform this act whenever he sucks thumb. Dr. Dragan Antolo's book named 'The Little Bear Who Sucked His Thumb' is also a positive and pressure less way of removal of habit as a child relates himself to bear and willingly quit the habit. [7-11]

Reminder Therapy: They are of two types chemical and mechanical. Chemical therapy includes the use of bitter-tasting or bad odor chemicals such as quinine, asafetida, castor oil, red pepper in volatile liquid, commercially available femite (Denatonium benzoate) in thumb. Mechanical therapy includes mechanical restrains applied to hand, wrist, thumb to quit habit examples of mechanical restrainers are Thermoplastic thumb post (Allen in 1991), ace bandage system, use of long sleeves nightgown, three-alarm system introduced by Northan and Gellin (1968).According to them when the child putsa finger in mouth and feels the tape its first alarm when a child feels the pin which is tied with a bandage in the elbow is second alarm lastly when bandage gets tightened serves as a third alarm.

Appliance Therapy: They are of two types

Removable Appliance: Palatal crib, oral screen, hay rakes.

Fixed Appliance: Quad helix, bluegrass appliance, modified bluegrass appliance.[7-11]

Nail Biting: Nail-biting is also known asonychophagia is the most common stress-relieving oral habit seen in both children and adults. Nail-biting habit is due to anxiety which usually develops after sucking age. It includes biting of nail or its surrounding soft tissue and cuticle. This habit starts after the age of 4 and attains its peak in 4-6 yrs and get stable during 7-10yrs of age again triggers in adolescence. It is not a pernicious habit hence it does not cause malocclusion. Somehow, attrition of lower incisors can be seen in rare cases as the force applied in nail-biting is similar to mastication yet quitting this habit is necessary as this habit is socially unacceptable. Operational definition of Nail Biting is "putting one or more fingers in the mouth and biting on the nail with teeth"

The etiology of nail-biting is controversial some studies believe it is due to behavioral disorder or anxiety while others deny this theory. It occurs due to boredom,emotional stress or successor of thumb sucking.

Clinical features include attrition of incisal edge, rotation of teeth, crowding, resorption of apical root, gingivitis, fracture (in severe cases). Other feature includes damage to the cuticle, inflammation of nail bed, bacterial infections.

Management includes behavioral modification and physical barriers. The patient must be treated with a little more attention, love, affection, and comprehension. Chewing bubble gum can be an alternative when patients feel the urge to bite nails. The application of olive oil or bitter-tasting preparation might annoy the young patient. Educating the child and creating awareness is the best way to quit this habit.

Tongue Thrusting: Tongue thrust is defined as the movement of the tongue tip in the forward direction between the teeth to touch the lower lip during swallowing and speaking, so that the tongue becomes interdental. This habit is most commonly seen during infancy and subsides after a certain age. It can be Physiologic (normal tongue thrust swallow during infancy), Habitual (presence of habit even after the rectifying the malocclusion), Functional (adaptive behavior developed to achieve an oral seal), and Anatomic (person with macroglossia).[12, 13]

Etiology: According to Fletcher following factor may cause development of tongue thrusting

Genetic factor: anatomic or neuromuscular deformity in head and neck region e.g.: macroglossia, hypertonic orbicularis oris activity, position of lingual frenum *Learned behavior:* It is an acquired habit hence following condition such as improper bottle feeding, prolonged thumb sucking, prolong tonsillar infection and upper respiratory tract infection, prolong tenderness of gums or teeth can alter the swallowing pattern and can cause tongue-thrusting habit.[12, 13]

Classification of tongue thrust according to James. S. Barner and Holt:

Type 1: Non-deforming tongue thrust

Type 2: Deforming anterior tongue thrust. (2a) anterior open bite, (2b) proclination of anterior teeth, (2c) posterior crossbite.

Type 3: Deforming lateral tongue thrust. (3a) posterior open bite, (3b) posterior crossbite, (3c) deep overbite

Type 4: Deforming anterior and lateral tongue thrust. (4a) anterior and posterior open bite, (4b) proclination of anterior teeth, (4c) posterior crossbite. [12, 13]

Clinical feature: Intraoral clinical feature includes: proclined upper anterior, retrocline lower anterior, anterior open bite, posterior crossbites, bimax protrusion (complex tongue thrust)

Extraoral feature includes: Doligocephalic face, increase lower anterior facial height, incompetent lip seal, speech deformity can also be seen

Management: This habit is vanishes once permanent teeth erupt by age of 8-9 yrs. mayo functional therapy, speech therapy, subconscious therapy or orthodontic treatment is required to correct this habit. Several exercises can also be performed such as lemon candy exercise, 4s exercise, whistling, counting from 60-69, yawning, gargling, water holding exercise, lip exercise.

Following Removable orthodontic appliances are used:

Modified Hawley's Appliance: acrylic is cut on anterior hard palate region, crib or rake is attached on the anterior side this increases anchorage and cribs act as a reminder to the tongue.

Oral screen: it acts as a barrier to the tongue, corrects open bite, arranges the maxillary anterior teeth. Ring attached in oral screen helps in Lip muscle exercise.

A fixed orthodontic appliance includes Nance palatal arch (acrylic button type).[12,13]

Mouth Breathing: Breathing is the vital function of the human body, usually done through the nose. Breathing through the mouth instead of the nose is considered as abnormal breathing habit. Merle suggested the name oro-nasal breathing. It's the most common habit among children as well as adults. Mouth breathing due to an acute illness, cold is not of main concern. Chronic mouth breathers who completely depend on their mouth or people with medical conditions like sleep apnea are of main concern. It shows the child needs additional medical involvement or retraining on breathing easily through the nose. According to Finn mouth breathing can be obstructive, habitual, and anatomical.[15,16]

Etiology: Airway obstruction (enlarged turbinate), defect on the intranasal region (tumors, deviation of the intranasal septum, bony spurs), hypertrophy of pharyngeal lymphoid tissue, infection or inflammation in the nose (nasal polyps, chronic allergic steatitis), birth abnormality (cleft lip, cleft palate, tongue tie), abnormal facial musculature due to former habit like thumb sucking.[15, 16]

Clinical Feature: General side effects include pigeon chest deformity, hoarseness voice, poorly developed sinuses, decrease sense of smell. Extraoral features like adenoid face, gummy smile, short upper lip, narrow nostrils, dryness and crack in lips can be seen. Intraoral symptoms are proclination of maxillary anterior, generalized spacing, gingivitis, posterior crossbite.[15, 16]

Treatment for mouth breathing depends on its underlying cause. It should be treated as early as possible patients with nasal congestion should use nasal spray. Surgery like Tonsillectomy, Sepatoplasty, and Adenoids removal is advised. Dentists prescribe the use of orthodontic appliances such as oral screen, chin cap and activator.[15, 16]

Lip Sucking/Lip Biting: Child might occasionally suck their lip when anxious but some suck and bite their lip as deleterious habit which might cause soreness and redness of lip below the vermillion border. This case occurs almost in all cases of lower lip.[17,18]

Etiology: It is caused due to physical causes such as malocclusion, TMJ disorder. Physiological disorder includes fear, stress, anxiety or body-focused repetitive behavior (BFRB). This is also caused due to hyperactivity oh mentalis muscle.[17,18]

Clinical Feature: It causes protrusion of maxillary incisor, retrusion of mandibular incisor, generalized spacing in the upper arch, crowing in the lower anterior arch. Lip will appear red, chapped, irritated below vermillion border. Vermillion border will become hypertrophic.

Treatment depends on the cause physiological

causes can b treated with habit modification counseling and therapies such as Cognitive Behavioral Therapy, Habit Reversal Training, Dialectical Behavior Therapy while physical cause requires clinical treatment such as correction of the underlying cause. Medications prescribed are antidepressant and anti obsessive medicine such as clomipramine or selective serotonin reuptake inhibitors.[17,18]

Conclusion

Habits are increasing day by day due to stress and poor attention from parents. Child needs proper care for good behavior development. Habits once developed are hard to break because repeated action becomes imprints in our neural pathway. Abnormal oral habit can cause great destruction to both dental and facial structure; it also affects the general health. Hence, Dentist plays an important role in habit modification. Dentists not only repairs tooth and dentofacial structure but also identify unnoticed habits (due to parents unawareness) and helps in the prevention and treatment of the underlying cause. To replace bad habits with a good habit integrated approach is required between parents and patients, behavior modification technique, physical exercise, habit breaking appliance and orthodontic treatment are required. But most importantly parents should be educated about harmful oral habits their etiology and side effects to stop habit in early age for healthy dentition and good health.

Recent Advances in Non-pharmacological Behavior Management Technique in Children

Tirtharaj Brahma

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

A conventional communication along with a caring attitude develops an affinity with a pediatric patient. Non-pharmacological behavior modification approach allows pediatric dentists the ability to effectively alleviate behavioral issues by balancing their preference of treatment with that of the child's type of mutual practice. Whereas Activity informed adult patients with dental phobias is the product of an offensive approach employed in childhood. Hence to overcome these disadvantages newer non-pharmacological techniques were handled by Pediatric Dentists which provided long term reinforcement in younger children. This review will focus on reckoning the recent advances in non-pharmacological behavior management techniques in children.

Keywords: *Audiovisual distractions, videos games, virtual reality.*

Introduction

Wright (1975) defined behavior management as tohow the dental health team effectively and efficiently performs treatment for a child patient and at the same time instills a positive dental attitude. The strategies of governance include correspondence and schooling. The partnership with the infant, the families of the infant and the dental staff is a complex operation. It will begin before the patient arrives at the operation and may include written material as well as speech, voice sound, facial expression, body language and contact. Successful child patient care depends on the willingness of the dentist to meet immediate dental needs, which emphasize enhancing communication and patterning with children and parents to encourage a positive attitude and good oral health.[1] Child management in the dental office relates to the approach of gaining child care consent in the dental chair based on adequate child/parent interaction through empathy counseling and hearing the idea behind the action of a child is to handle them instead of simply running the tooth alone. No one approach would work in all cases, but the correct intervention techniques will be selected based on the particular requirements of the infant.[2]

The wide used non-pharmacological behavior modification method include Tell-Show-Do, Non-Verbal communication, enhancing control, voice Training, modeling, Distraction, Positive Reinforcement, Hand Over mouth movement and defensive stabilization, while these traditional strategies include successful in directing children,the invasiveness inherent with these method reduces the acceptability that leads to them in turn.[3]

Material and Method

This review article aims to expand on current advances in current advances in non-pharmacological behavioral treatment approaches in adolescents. A search was performed on the Pubmed online database using the following terms: behavior and children, child behavior, behavior management and pediatric dentistry, child behavior and Dental anxiety, behavioral therapy in dentistry, non-pharmacological clinical treatment

and pediatric dentistry, infant and adolescent dentistry, clinical intervention and babies, augmented reality and dentistry, children's audiovisual entertainment, computer games and education, mobile gaming and virtual reality.[4]

Background: The aims are to create contact, to minimize apprehension and anxiety, to provide quality dental treatment, to develop a trusted relationship between dentist/staff and child/parent, and to foster a positive attitude of the child towards oral health care. (AAPD Reference Manual, 2011). The result of these strategies may preserve good coordination or bring an end to aggressive actions related to dental care. Behavior guidance should never be punished for misbehavior, power assertion, or use of any strategy that hurts, shames, or belittles a patient. Recently, innovations have been paired with therapeutic strategies to strengthen coordination and promote healthy dental behavior in a stress-free manner.[5]

Recent Behavior Management Technique:

A. Audiovisual Distraction: Audio-visual stimulation incorporates the idea of visualization and relaxation provided by audio-visual aids, thereby removing the emphasis on dental operations, preventing anxiety-provoking sensations and offering calming interaction during the procedure. The aims of audiovisual diversion are creativity (helps to divert children from the current situation), commitment (allows children to concentrate on one thing) and inspiration (helps children to seek care for dental disorders in the future).

I. Management of dental anxiety: Amal Al Khotani performed a study to assess the efficacy of watching videotaped cartoons through an eyeglass device as an audiovisual (AV) distraction technique for aggression and distress in children undergoing dental restorative care and found out that AV stimulation tends to be an efficient way to minimize apprehension and distress in children during dental care and also more favorable responses to injection of local anesthesia. Kaur R et al 2015 compared audio and audiovisual diversion to mitigate anxiety in children during their first dental appointment and found audiovisual relaxation decreases anxiety in nervous dental patients.[6]

II. Management of pain: Attar RH 2015 did a study on Comparative effects of active and passive diversion during vital pulp therapy of children using iPad vs audiovisual eyeglass and found out that its Effective on minimizing pain and behavior with an iPad displayed greater results than passive interference utilizing AV glasses. Oliveira NCAC et al 2016 found that audiovisual diversion could minimize pain severity during painful puncture procedures. Nuvvula S et al 2015 used three-dimensional audiovisual stimulation to relieve anxiety during local anesthesia administration.

B. Video game distraction: While a wide variety of behavioral intervention strategies are available to treat extremely distressed infants, it was difficult to redirect the child's attention during pain experience in intrusive procedures. The use of videogame as a coping device is based on the concepts of cognitive-behavioral therapy and neurofeedback strategies for children with anxiety disorders. Videogames are exciting and widely accessible resources that can help to promote diversion in children by active child involvement in dental procedures.

Used in the Following:

(a) Ko JS et al 2016 used Ipads to minimize anxiety in children during their orthopedic appointments. Sil et al 2013 and Wohlheiter KA et al 2013 used videogames to minimize pain tolerance during cold-pressure tests. Videogames may be an important distractor and improve oral health-related outcomes, but comprehensive trials are required in the field of pediatric dentistry.

(b) Aljafari A et al 2017 Used Oral health awareness-based video games to encourage safe eating and good oral hygiene for children at high risk of caries.[7]

C. Virtual reality-based distraction: In 1968, Ivan Sutherland and Bob Sproull invented augmented reality using a head-mounted system attached to a monitor. Earlier in 1998, Heim described virtual reality as an immersive computer-based platform that can be used to immerse children in a simulated world that fully obstructs the actual situation. The VR equipment includes a head-mounted monitor and a tracking device. The head-mounted unit includes a projection screen that shows the virtual reality world in a 3600 view. The tracking device tracks the rotation of the eyes. Equipment includes a keyboard, joystick or computer gloves accessory for playing sports.

Uses of Virtual Reality:

I. **Clinical Procedures**: Researchers used the virtual reality experience for children undergoing surgical operations involving anesthesia and found that there was an increase in the perception of perceived discomfort to drugs, fear and decreased levels of tension in children and parents. In 2020 Custodio NB did a study on the usage of virtual reality glass which is an important method for enhancing actions and the experience of pain during dental care of children. Children who used VR eyeglasses performed differently during caries removal and had a lower sense of pain during reconstruction. In 2011, Hoffman et al found that virtual reality decreased pain sensitivity in children by decreasing pain-related brain activity, however further research on VR as a method to train patients for dental care is needed due to the shortage of studies in this field.[8]

II. **For Distraction:** The augmented reality experience provides the potential to remove the child's mind from the emotions associated with therapy and to provide immersive entertainment in a simulated world. Factors that affect stimulation when utilizing a virtual reality system are the degree of curiosity displayed when the child and the extent of the child's absorption in the virtual environment.[9]

Contra indications for Virtual reality:

(a) Medically impaired children, particularly children with epilepsy, migraine and vestibular disturbances

(b) Children with a prior history of nausea or dizziness following use of VR.

D. Tell-show-do and Mobile dental app: In 2019, Elicheria SR performed a comparative appraisal review on the effectiveness of the mobile app and Tell-Show-Do methodology utilizing heart rate scales and the RMS scale and found that educating a child before a dental operation utilizing a smartphone application would dramatically minimize anticipatory distress and involve children in dental care during their first visit.[10]

Conclusion

Recent technology such as audiovisual aids, video games, smartphone devices and augmented reality can be used as an alternative to traditional method due to its immersive, exciting and creative capacity to handle children with behavioral difficulties and to enable dentists to administer successful care in a stress-free atmosphere.

Pit and Fissure Sealant: A Review

Pratyusha Mohanty

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In recent times, carious infection of the tooth is considered as a major worldwide concern, significantly impacting the health, safety and quality of life of the patients affected by it. The required routine oral hygiene procedure along with fluoride use ensures prevention against dental caries. Apart from these, another important prophylactic measure can be followed against the caries by sealing the pit and fissures of a tooth that is more prone to caries occurrence. The main purpose of this article is to present a general overview of the sealing of pits and fissures, materials typically used to seal the occlusal surfaces along with the implications and side effects. This article also presents a detailed review of safe, effective use and cost-effectiveness of pit and fissure sealants as a preventive measure for caries. The finding drawn from this is that primary, as well as permanent teeth, sealed pit and fissures are an efficient and appropriate approach for preventing and arresting dental caries. But conducting a proper regular dental check-up is necessary to ensure that there is no advanced tooth decay caused due to any leakage in the sealing.

Keywords: *Dental caries; Pit and Fissure sealants; Prophylactic therapy; Regular checkups.*

Introduction

A change in the composition of the bacterial biofilm causes dental caries which is a multifactorial infection. This change leads to an imbalance between the demineralization and remineralization process which gradually becomes the cause for the formation of a carious lesion in primary and permanent dentition. The instances of dental caries expanded the most in the nineteenth and twentieth century because of more and simple accessibility of sugar for the populace.[1] The availability and use of sugar became popular among the population of developed countries mainly. There has been a long and creative part of the dental battle against pit and fissure caries which includes innovations in the preventive measured like early physical blocking of pit and fissures with the help of zinc phosphate cement, eradication of fissures mechanically and chemically treated with silver nitrate. These preventive measures continued with the testing of new materials, methodology and technologies each year. Soon the technique of acid etch bonding to the surface of enamel came to limelight and a major step in its use was to prevent pit and fissure decays. Therefore the prevention for dental caries then focused on pit and fissure caries because tooth with pit and fissures is more prone and vulnerable to caries occurrence. These sights are most convenient for the early occurrence of dental caries. In a recent study, the cariesin the smooth surface showed a very notable decrease in the occurrence which might be an outcome due to the expanded utilization of fluoride.[2]

Fluoride is not as effective in the pit and fissures as on a smooth surface because the fluoride must follow up on the nearby level which isn't mechanically convenient with pit and fissure of the tooth. After all, the dental plague develops without any disturbance in the pit and fissure of a tooth due to which the enamel gets dissolved by the repeated acid attacks.[3] In children, the natural cleansing mechanism of oral cavity by lips, cheeks, and majorly by the tongue during biting of food and gulping is missing for which the occlusal surfaces of developing tooth is mainly affected due to absence of cleaning. In result to that, the bacteria and residual food products gather up in the pit and fissure that forms a plaque and then gradually results in demineralization and caries ultimately. Therefore a recent study showed that the use of sealants can be utilized in the pits along with fissures as a method of preventive intervention for dental caries in children during tooth eruption.[4]

Pit and Fissure Sealant Material: The terminology of pit and fissure sealants are mainly used to depict a material that forms a micromechanical bond, protective layer against the caries-producing bacteria when brought into the occlusal pit as well as fissures of caries prone tooth. Pit and fissure sealants are divided into 3 sealant material.[5]

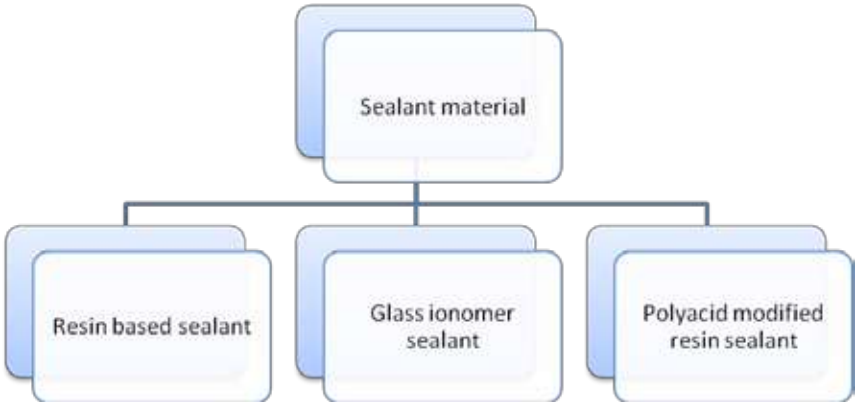

Figure 1. Classification of sealant material

The three major types of sealants are described as below:

1. Resin-based sealants (RBSs)

Determined by the method of polymerization, Resin-based sealants are classified into

- **1st gen:** The initiators in the materials that initiate polymerization are polymerized by the activity of UV rays. This sort is not, at this point being used.An example of 1st gen Resin-based sealants is Nuva-seal which was first introduced sealant to the market.
- **2nd gen:** They are known as the auto polymerizing resin-based sealants. Also sometimes called as chemically cured sealants. However this autopolymerizing resin-based sealants have now been supplanted by the 3rd era of RBSs.
- **3rd gen:** This sort involves visible light polymerizing resin-based sealants. Here, the visible light activates the photoinitiator which is available in the material of the sealant. This is very responsive to visible light in the frequency of about 470nm (blue area).[6]

Resin-based sealants can likewise be grouped by their consistency as (1) filled (2) unfilled. The addition of filler particle on sealants has fewer changes in clinical results. The filled type of sealant usually has high wear resistance but their capacity to enter into the pits and fissures is less. Whereas, unfilled type of sealant has low viscosity but provide proper penetration into pits and fissures resulting in better retention. Based on translucency, sealant materials can also be divided as opaque and transparent. Opaque are white or tooth-colored sealants whereas transparent sealants are seen as clear, pink or amber. White opaque pit and fissure sealants have better visibility during application and to recognize clinically during routine checkups and follow up as compared to clear sealants.[7]

2. GI sealant material: Traditional glass ionomer materials are utilized as pit and fissure sealants. Through an acid-base responsein between an aqueous-based polyacrylic acid solution and fluoroalluminosillicate glass powder, it forms a chemical bonding to enamel and dentin. This type of sealant is further grouped as (1) low viscosity type (2) high viscosity type. There is also a variety called resin-modified glass ionomer (RMGIC) which has been utilized as pit and fissure sealants. It is formed when the resin is mixed with glass ionomer cement. Continuous fluoride release is the main asset of GI cement-based sealant. Its preventive impact may also last after the noticeable loss of the material of the sealant. This material has an easy application method and is moisture friendly. Glass ionomer based sealants are mainly indicated in deep fissure primary molar which is hard to isolate because of the uncontrollable behavior of a child.[8]

Polyacid modified resin-based sealant: Otherwise called compomer, polyacid modified resin-based sealants is used as a material for sealing pit and fissures which joins the profitable properties of the visible light polymerized resin-based sealant which includes better adhesion property to enamel and dentin with the fluoride discharging property of the glass ionomer based sealants.[9]

Clinical Technique of Sealant Placement:

1. **Cleaning and preparation of tooth:** There have been many studies discussing various techniques of enamel surface preparation preceding the acid etching and sealant use. The early application method for pit and fissure sealant includes cleaning of the tooth surface that is treated with pumice and water slurry with a rotating brush which can be pointed or flat ended. Before carrying out the procedure it is mandatory to remove plaque and debris from the enamel and the pits and fissures. Interference with etching technique and sealant penetration into the pits and fissures will occur if the debris is not removed properly from the enamel surface. The polishing of the tooth surface can be done by using the prophylaxis cup and pumice.
2. **Isolation and drying of the tooth surface:** Prevention of salivary contamination during sealant application is considered to be the most significant and critical step in sealant application. The surface enamel that is etched can be contaminated if it is exposed to salivary proteins even for a split second. Hence a proper isolation of the tooth is necessary. The utilization of a barrier that is a rubber dam is considered to be the best method to accomplish isolation.[10]
3. **Acid etching:** Acid etching is the procedure in which the monomer penetrates the micropores which are formed by etching. It also removes organic materials and debris from the surface. The degree of etching depends on mainly the concentration of acid and duration of exposure. Orthophosphoric acid is normally used in liquid form using a hairbrush for about 30-60 seconds.
4. **Rinsing, drying, and isolating the tooth:** 30 seconds of rinsing along with 15 seconds for drying the tooth is convenient to remove all the acid etchants which help in achieving the result of characteristics chalky white frosty appearance. Isolation is mandatory in this stage because salivary contamination at the stage is the major common cause of failure of sealant application.
5. **Application of material:** After following the above steps and drying the tooth thoroughly, the particular sealant material is then placed on the tooth and is polymerized. Proper care should be taken for the prevention of air bubbles in the material while applying it to the tooth.
6. **Sealant evaluation:** After polymerizing and before the removal of the rubber dam, the sealant should be examined properly by the operator for any deformity like voids, bubbles, or deficiencies in the material. The retention of the sealant ought to likewise be evaluated by the help of an explorer in a trial to dislodge it. Excess of sealant should be removed over the distal margin that may result in the formation of the ledge. Occlusal high points are also checked and if present is corrected.[11]
7. **Periodic maintenance:** Re-evaluation of the sealants is mandatory at recall visits. If any loss in the sealant material seen, a new fresh material can be applied over the old sealant.

Sealing of Primary Tooth: The primary teeth are more prone to carious activity to anatomy and lack of natural cleansing factor. Therefore primary teeth benefit the most from sealant application. If the tooth has deep fissures along with signs of decalcification, pit and fissure sealants are indicated. In the case of caries or restoration of adjacent teeth, sealants are also indicated. Children with medical, physical, and psychological impairments are advised to go for sealant application. For simplification of the clinical procedure to make it progressively worthy to small kids, the etching time is shortened to lessen the opportunity of moisture contact. The procedure time can also be shortened by using a self-etching bonding agent as an option in contrast to the regular acid etching method.[12]

Follow Up: There is a chance of loss of sealant from the molar tooth. Therefore regular maintenance of sealant is necessary to boost the efficiency, maintenance of peripheral integrity, and to provide the necessary protection. By visual method, tactile method and radiographically, the retention and durability of the sealants can be checked.[13-15]

Cost-Effectiveness of Dental Sealants: The most effective intervention which is also cost-effective is sealant application. Application of sealants on primary

or permanent tooth especially the molars lessens the much higher expense by the prevention of increasingly costly treatment. The sealants are mainly indicated and seem to be more cost-effective when utilized in children with a higher risk of caries on teeth that are more prone to bacterial invasion. Therefore it is highly prescribed that sealants ought to be applied specifically relying upon the caries risk of a youngster along with anatomy of the fissure. The cost-effectiveness of the sealants can be more enhanced by using trained dental professionals for sealant application, use of sealant material in which the rate of retention is higher and application of a sealant on the tooth specifically which are more prone to caries.[16]

New Developments: From this review, it is proven that sealants are safe and effective preventive material for caries. However, certain improvements can be made to the material and technique of application. Mechanical preparation of the fissure surface can be beneficial for better retention and microleakage. Shorter etching time is found to be equally effective for longer times. Similarly, the use of a sodium bicarbonate air polishing system in the cleaning method helps in higher retention of sealant.[17,18]

Conclusion

A powerful way to prevent pit as well as fissure caries in primary and permanent tooth is the use of pit and fissure sealants. Therefore, in patients with higher risk of caries, dental professionals ought to be urged to usepit and fissure sealants alongside other prophylactic measures. The tooth with early non cavitated carious lesion additionally gets benefit from utilization of sealant which prevents any progression of caries. The sealant application is a technique sensitive method which requires a moisture-controlled environment. The material for the sealant is selected based on the age of the patient, behavior of the child, and the tooth eruption time. Lastly, maintenance is essential to boost the adequacy of the treatment.

Swellings of the Palate: A Review

Srishti Chatterjee

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India,751003

Abstract

The palate which forms the roof of the mouth can be divided anatomically into hard and soft palates. These areas are actively involved with feeding and speech. The posterior part of the hard palate consisting of the minor salivary glands is a common site for palatal swellings. However, these are quite challenging for the clinician to diagnose and because of the importance of the oral cavity in terms of both function and cosmetics, management of such swellings requires a thorough understanding of the lesion and its progression. This article reviews the various palatal swellings in terms of their etiologies, clinical features, diagnosis, and management.

Keywords: *Mouth, Soft Palate, Hard Palate, Minor Salivary Glands, Speech.*

Introduction

The palatal anatomy comprising of the hard and soft palate is actively involved with feeding and speech. The hard palate consisting of the minor salivary glands is a common site for palatal swellings.[1]

The palatal swellings may originate from various structures within or beyond the palate and have different etiologies. They are painful when infected or painless when benign. The congenital swellings are associated with unerupted teeth and torus palatinus. The acquired conditions would include – salivary gland neoplasms, dental abscesses, epithelial and connective tissue neoplasms, and fibro-osseous lesions. These swellings are examined clinically by inspection and palpation. Further radiographic aids using panoramic radiographs and histological examination with a biopsy helps to arrive at a specific diagnosis.[2]

A review of the various palatal swellings has been discussed here based on the classification of palatal swellings as given in the table below:

Palatal torus (Plural–Palatal Tori): It is an overgrowth of bone that is seen on the palatal midline on the cruciform suture that joins palatal and maxillary bones.

Etiology: Idiopathic and multifactorial with the involvement of both genetic and environmental factors such as masticatory hyperactivity and parafunction.

Clinical features: Palatal Tori is asymptomatic, unless secondarily infected and is generally discovered during routine clinical examination. It is more common than the mandibular tori with a predilection for females than males in the age group of 10 – 30 years. The shapes may vary between flat, nodular, fusiform, or lobular with a size range of 2–6 mm. The most common, however, is flat shaped one with a smooth and symmetrical distribution. The overlying mucosa is thin and less vascularized.[2]

Radiographic features: For radiographic identification, CT is the preferred choice. Radiographically, it appears denser with limited narrow space & less osteoblastic activity. Cloudyradiopacities can also be seen superimposed on teeth contour.

Treatment: Palatal tori is a benign maxillary bone tumor which is slow-growing & painless. Thus, it can be left as it is. In case of problems such as ulceration during mastication, inadequate maintenance of oral hygiene due to food accumulation, psychological fear of malignant transformation, and difficulty in speech, surgery can be opted followed by prosthesis.

Table 1: Classification of palatal swellings

Etiology	Associated swelling
1. Developmental	Palatal Torus
2. Inflammatory/Reactionary	1. Palatal abscess 2. Inflammatory papillary hyperplasia 3. Fibroepithelial polyp 4. Pyogenic Granuloma 5. Adenomatous Hyperplasia 6. Atypical lymphoproliferative disorder/Follicular lymphoid hyperplasia
3. Cyst	1. Radicular Cyst (Periapical cyst) 2. Dentigerous cyst 3. Median anterior maxillary cyst (Nasopalatine cyst) 4. Median palatal cyst 5. Incisive canal cyst 6. OKC
4. Neoplasms	**a. Salivary gland** 1. Pleomorphic Adenoma 2. Adenoid Cystic Carcinoma 3. Mucoepidermoid carcinoma 4. Polymorphous Low-Grade Adenocarcinoma 5. Carcinoma ex-pleomorphic adenoma 6. Necrotizing sialometaplasia **b. Odontogenic** 1. Ameloblastoma 2. Adenomatoid odontogenic tumour 3. Odontogenic myxoma **c. Others** 1. Fibrous Histiocytoma 2. Schwannoma 3. Neurofibroma 4. Lymphoma 5. Osteosarcoma 6. Chondrosarcoma 7. Fibrosarcoma

Palatal Abscess: These abscesses generally involve the palatal roots of the posterior teeth, being bounded by the cortical plates of hard palate inferiorly, periosteum of bone superiorly and alveolar process of maxilla and teeth laterally. They may occur because of periodontal abscesses in the palatal pockets or apical abscess in the palatal roots of posterior teeth.

Clinical Features: It appears as a well-circumscribed fluctuant or tense palatal swelling associated with pain, fever and poor oral hygiene. It is located in premolar – molar region, mostly laterally and rarely towards the midline of the palate which then becomes difficult to diagnose.

Treatment: Treatment involves incision and drainage through the mucosa of the bone. Hopeless teeth may require extraction followed by antibiotic therapy.

Inflammatory papillary hyperplasia (also Palatal epithelial hyperplasia, papillary hyperplasia of the palate, palatine papillomatosis)

It may occur due to – poor denture hygiene, frictional irritation due to ill-fitting dentures, suction chamber in palatal seating, amalgam filling material, and *Candida albicans*.

Clinical features: It does not have any predilection for age or sex, appearing exclusively on palatal mucosa under dentures with a warty appearance. They are small, painless, papular, or polyploid masses which can be red and soft (inflammatory stage) or firm and pale pink (fibroid), thus giving an 'overripe berry appearance' or 'cobblestone appearance'.

Treatment: This involves – removal of dentures at night to rest tissues or use of tissue liners; and surgical removal by curettage, electro/cryosurgery and microabrasion in fibrosed cases.

Pyogenic granuloma[6,7,8]: (Also granuloma pyogenium)

It is the most common benign growth, first described by Huliken in 1844. It is considered to be a clinical entity that resembles a tumor originating due to the response of tissues to minor trauma or any specific infection in which there is a proliferation of fibrovascular connective tissue. It is mostly caused by the microorganisms – Streptococci and Staphylococci during trauma to gingiva. Other causes include local irritants like calculus and hormonal changes.

Clinical Features: It usually occurs between the 2nd and 4th decade with a predilection for females. The most common site is gingiva, followed by the tongue, lips, buccal mucosa, and interdental papilla. The symptom includes nodular growth with a smooth, lobulated, or warty surface. The color varies from red to reddish-purple depending upon the vascularity of the lesion. It has a moderately soft consistency which bleeds readily. The Surface is mostly ulcerated with a discharge of pus sometimes.

Diagnosis: Clinical manifestation of a Reddish-purple lesion which is soft inconsistency. The laboratory diagnosis by biopsy would show the presence of localized granulation tissue with the overlying epithelium being thin, atrophic & hyperplastic.

Treatment: The adjacent tooth should be scaled properly to remove calculus as irritation might lead to recurrence.

Radicular cyst (Also special periodontal cyst, Dental root end cyst, Periapical cyst)

Radicular cyst is the most common inflammatory cyst of odontogenic origin which is a common sequela of bacterial invasion and death of the pulp. It can be defined as "Slowly growing epithelial sac at the apex of a tooth lining a pathologic cavity in alveolar bone whose lumen is filled with a low concentration of proteinaceous fluid".[9]

Clinical Features: It occurs during the 3rd – 4th decade of life with a predilection for males. It is more common in the maxillary anterior teeth due to the occurrence of caries and trauma. The patient reports with a non-vital tooth which is non-tender on percussion and has no response to electrical/thermal stimuli. There is a previous history of pain. The signs include – non-tender expansion of cortical bone in curved/circular shape with the presence of intra-oral & extra-oral swelling where consistency is bony hard with crepitations. The adjacent tooth might be displaced due to pressure from the cyst and become mobile.

Radiographic Features: Appearance of a unilocular rounded/pear-shaped radiolucency at the apex of the affected tooth on the mesial/distal root surface at the opening of an accessory canal about 1.5 – 3 cm in diameter with smooth well-defined borders.

Treatment: Root canal treatmentis the treatment of choice to establish drainage which subsides the inflammation and fibroblast starts producing collagen again which decreases the blood supply to epithelial cells, ultimately getting degenerated and removed by macrophages. Other options include – Extraction of hopeless tooth or enucleation and marsupialization of large lesions.

Dentigerous cyst (Also known as Follicular cyst, pericoronal cyst)

It is the most common type of odontogenic cyst enclosing the crown of the unerupted teeth. Discovered by intra-oral radiograph because of a missing tooth or tilted tooth or tooth out of alignment. Its origin can be traced to fluid accumulation in the Reduced Enamel Epithelium. This causes the proliferation & cystic transformation of epithelial islands in the connective

tissue wall of the dental follicle.

Clinical Features: It is most common in children and adolescents in the 2nd and 3rd decade with a predilection for males. The most commonly involved sites are mandibular 3rd molar & maxillary canines. It is usually asymptomatic unless secondarily infected. The cyst may expand to compress sensory nerves resulting in referred pain which may be perceived as headache. There is progressive painless enlargement of jaws with facial asymmetry. Displacement of teeth and pathologic fracture might occur.[11]

Radiographic Features: A mostly unilocular well-defined radiolucency around the unerupted tooth with hyperostotic well-defined borders unless infected.

Treatment:

i. Surgical treatment:
   a. If small, it should be removed.
   b. If large, surgical drainage should be done followed by marsupialization.
ii. Orthodontic treatment should be done to keep the tooth in place.

Odontogenic Keratocyst (OKC): OKC can be defined as "a cyst derived from the remnants of the dental lamina with a biologic behavior similar to a benign neoplasm with a distinctive lining of 6 – 10 cells in thickness that exhibits a basal cell layer of palisaded cells & a surface of corrugated parakeratin". It was first described by Mikulicz in 1876.

Clinical Features: This is more common in males between 10 – 20 years of age with a predilection for blacks and mandible with its ramus and body amongst sites. The common symptoms are pain, swelling in antero-posterior detection, soft tissue drainage, and at times paresthesia of lower lip. There may be chances of downward displacement of the alveolar canal along with teeth being deflected into ascending ramus or orbital floor.[12]

Radiological Findings: Radiolucency is mostly unilocular with a scalloped border. Multilocular radiolucency representing a central cavity with satellite cysts can also be present.

Management:

i. Enucleation – followed by vigorous curettage of the cystic cavity is the most satisfying method of removal of cysts without damaging any adjacent structure.
ii. Marsupialization – indicated in the case of large cysts.
iii. Peripheral osteotomy – is done to reduce recurrence.
iv. Chemical cauterization – with Carnoy's solution.
v. Decompression with the help of polyethylene drainage tube kept in the bony cavity.

OKC has a high recurrence rate because of – the presence of satellite cysts, difficulty in the enucleation of thin and friable lining, intrinsic growth potential, and basal cell proliferation.

Median anterior maxillary cyst (Also nasopalatine duct cyst, nasopalatine canal cyst, and vestigial cyst)

Its etiology can be – developmental, due to trauma, bacterial infection, mucous retention, or genetic factors. The nasopalatine duct degenerates progressively during development and the presence of epithelial remnants give rise to nasopalatine duct cyst.

Clinical Features: It is among the most common developmental, non-odontogenic cysts with a 3:1 male predominance and affecting people between 40 – 60 years of age. It is located specifically in the midline of the anterior maxilla and appears as a swelling associated with pain, discharge, and salty taste in the mouth. It may perforate the palatal bony plate and cause tooth displacement. It is often associated with burning sensation and numbness as the nasopalatine nerve is affected.

Radiographic Features: A heart-shaped radiolucency can be observed superimposed over apices of the central incisors along with erosion of bone posterior to the canal.

Treatment: Enucleation through a palatal or buccal approach is advised unless there are clinical symptoms.

Median palatal cyst: It can be described as a posterior extension of the incisive canal cyst which arises due to entrapment of epithelium along the line of fusion of the palatal process of the maxilla.

Clinical Features: Its incidence is rare and without any sexual predilection, mostly occurring in adults. It is situated along the midline of the palate to produce an

asymptomatic but definite clinically visible swelling which on aspiration gives an amber-colored fluid.

Radiographic features: It shows a well-circumscribed radiolucent area opposite to bicuspid, molar region, and bordered by sclerotic bony layer.

Treatment: Treatment involves surgical removal of the cyst followed by curettage.

Pleomorphic adenoma (Also Iceberg tumor, Endothelioma, Branchioma, Endochondroma)

It is benign and the most common salivary gland tumor. It was named pleomorphic because of the unusual mixed histologic feature of the lesion. The genetic etiology is a putative pleomorphic adenoma gene (PLAG1) on chromosomes 12.

Clinical Features: It occurs between 30 – 50 years of age with a 3:2 predilection for females. The lower side of the superficial lobe of the parotid gland is the most common site. The palate is involved if minor salivary glands are affected.

The tumor starts as a round/oval painless nodule which slowly increases in size. When the lesion grows medially between ascending ramus and stylomandibular ligament, it acquires a dumb-bell shape. A palatal tumor is generally dome-shaped with a smooth surface found on the lateral aspect of the palate. Sialography provides a ball in hand appearance.[13]

Management: Surgical excision of the tumor along with the involved salivary gland or the overlying mucosa in case of palatal involvement with a 5 – 30% recurrence.[14]

Necrotizing Sialometaplasia: (Also called salivary gland infarction)

First reported by Abrams in 1973, it is a benign, inflammatory, self-healing reaction of salivary gland tissues which manifests itself as a swelling with or without ulceration which both clinically and histologically mimics a salivary gland malignancy. Trauma leading to vascular ischemia, ill-fitting dentures, tobacco intake or spontaneous are some of the etiologies for the disease.

Clinical features: The disease is more prevalent in the 4th and 5th decade of life with a predilection for males. The most common sites are palate, lip, retromolar pad, buccal mucosa and labial mucosa. It begins as a mild swelling which is painless, causing numbness or an area of looseness in palate from where pieces of tissues might fall. It commonly occurs unilaterally, but may also occur bilaterally or in the midline with clean, sharp and indurated margins. The lesion is covered by inflammatory exudate and necrotic debris.

Treatment: It is a self-limiting disease that does not require any treatment with periodic evaluation of the affected site.

Ameloblastoma (also Ademantinoma epithelium, adamantinoblastoma, epithelial odontoma, multilocular cyst)

Robinson defined ameloblastoma as "Benign tumor that is usually unicentric non – functional, intermitted in growth, anatomically benign and clinically persistent". It is the 2nd most common odontogenic neoplasm. It originates from – cells of the enamel organ, cell rests of Malassez, Hertwig's epithelial rest sheath, and epithelium of odontogenic cysts. The etiologies include – irritation, infection, trauma, dietary deficiencies and virus.

Clinical features: It accounts for 11% of all odontogenic tumors, occurring between 20 – 50 years of age with a predilection for males.

Maxillary ameloblastoma spreads more rapidly due to porous bone. Patients report with gross facial asymmetry, pain, paraesthesia and tooth mobility. Eggshell cracking of surrounding thin bone occurs on palpation.[15,16]

Radiologic Features: It appears as a multilocular bony septa described as 'Honeycomb appearance/Soap bubble appearance'.

Treatment: Radicular and conservative surgical excision in combination with Radiotherapy is usually recommended. Chemical or electrocautery can also be preferred.

Lymphoma: It is a neoplastic proliferation within the reticuloendothelial system occurring as a primary tumor of lymph nodes, but not as common as a metastatic tumor. It can be – Hodgkin's lymphoma and Non-Hodgkin's lymphoma.

Clinical Features: Non-Hodgkin's lymphoma is more common, occurring in children and young adults. It appears as firm, elastic swelling with or without

ulceration in gingiva and palate. It may be present unilaterally or bilaterally as a rubbery mass with painful and tender lymph nodes, mostly occurring in the palate. The risk is higher in patients with HIV.

Treatment: Radiotherapy or chemotherapy are the treatments of choice.

Conclusion

Various palatal swellings may have similar clinical features. Thus, the clinician needs to have a thorough knowledge of each of them and alongside make use of other diagnostic aids judiciously to zero in on a specific diagnosis and render appropriate treatment for each of them.

Glucocorticoids: A Boon or Bane in Dentistry

Subhashree Sahoo

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The people who had undergone or are undergoing glucocorticoid therapy present distinctive issues for dental surgeons. The people receiving the steroid therapy have their responses altered to infection and injury assuage. More importantly, the patients who are taking or have taken glucocorticoids have a possibility of suffering from acute-adrenal insufficiency when they are introduced to a stressful situation. When a patient with a history of glucocorticoid therapy is under treatment, actual details on the medical history must be obtained. The dentist must regulate the requirement for the ensuing preventive measures: a) Systemic antibiotic therapy, b) anxiety control, c) increased administration of glucocorticoids.

Keywords: *glucocorticoid therapy, acute-adrenal insufficiency, prophylactic measures, administration of glucocorticoids.*

Introduction

Glucocorticoids are powerful medicines that work with our immune system and fight against the inflammation to treat the various health problems. Although corticosteroids were used in the field of medicine since 1944, it was not until 1951 that the field of dentistry began to use them. Corticosteroid is one of the anti-inflammatory drugs that has been listed in Dental' Practitioners' Formulary.[1] These have been used for managing the inflammatory diseases for the last 50 years. Glucocorticoids or steroids are the substances that are naturally synthesized in our body. The se are one of the most widely prescribed drugs in both the dental and medical fields. Dental patients with a history of corticosteroid therapy may require special consideration and brief medical information before receiving any treatment. The current misuse of the steroids is that it is overly prescribed, even before minor dental procedures. Glucocorticoids or corticosteroids have revolutionized the treatment of several disabling conditions, but its use in terms of the dosage is not appropriate.[2]

Glucocorticoids-A Brief Idea: Glucocorticoids are derived from "glucose+ cortex+ steroid" which reflects their i) role in the regulation of glucose metabolism ii) adrenal cortex origin iii) steroidal structure. Glucocorticoids area class of corticosteroids, which are a class of steroid hormones. The se are a kind of corticosteroid hormone that shows their effects in the reduction of the inflammation and annihilation of the immune system. Due to inflammation, our immune system acknowledges intruding substances and trauma and hence is an important part of our alleviating process. They include corticosteroid hormones that are synthesized naturally in the adrenal cortex and are comparable to those produced in laboratories.[3] These have been used broadly and are successful in treating many oral diseases, due to outstanding anti-inflammation and immune-modulation effects. However, if the habitual control systems that are in charge of switching off the action of the inflammation do not work, then the tissues are in danger of being destroyed. The continuation of the inflammation is seen to be in association with several chronic conditions which include obesity, diabetes, depression, cancer and lastly heart diseases. Hence, they are sometimes termed as "double-edged sword" due to their potential side-effects. Glucocorticoids include an applicable diagnosis, a crystal view of the desirable

management, and the understanding of whether the treatment is pointed at a chronic illness or a heightened resolution of a small-term issue. The positive effects must be considered concerning the probable risks. [4]

All the glucocorticoids have a similar structure but differ in their doses (potency). 5 mg of prednisolone is considered to be equivalent to 4 mg of triamcinolone and 0.75 mg of betamethaone. High doses of prednisolone most likely cause salt and water confinement and an increase in the elimination of potassium. Its adverse effect is more than that seen in the intake of increased doses of triamcinolone, dexamethasone or betamethasone. The standard prescriptions and doses of prednisone, triamcinolone, and methylprednisolone last from 12-36 hours in the body while dexamethasone and while betamethasone lasts from 32-72 hours.Prednisone is considered one of the most popular glucocorticoids due to its inexpensiveness. It is transformed into prednisolone in the liver and it is available only through oral route.[5,6]

Use of glucocorticoids in dentistry: Among the various specialties of dentistry, oral and maxillofacial surgery, oral medicine, and endodontics are the most avid users of glucocorticoids. Most of the glucocorticoids used in dentistry are mostly prescribed for topical application for a short term use.[7]

Endodontics: The effects are seen in the reduction of the inflammation of the pulp as well as root resorption. Zinc oxide eugenol along with steroids helps as an effective root canal sealer. It is also used to reduce postoperative thermal sensitivity.[8]

Pain following root canal treatment: One of the main reasons that people avoid going to the dental offices is anxiety and fear of getting the root canal treatment done. Hence, managing pain during the treatment and after it, is very important. The pain following the root canal treatment is undesirable, for the patient as well as the dental practitioner. It has been investigated that there are several reasons for the occurrence of pain after root canal treatment. It is a multi-factorial phenomenon, including mechanical, chemical, host and microbiological factors. Besides, the pain before treatment could be due to demographic factors such as age and gender. The post-operative pulp status and the type of teeth also influence the pain. Investigations have shown glucocorticoids can be used for pain management following root canal treatment.[9,10]

Orthodontics: Patients need to be reviewed and asked for their previous history of steroids use since it has appearedthat upon the treatment with hydrocortisone, teeth show a lower amount of tooth movement.

Oral Surgery: It is used to limit the postoperative inflammation after oral surgical procedures. It is also reported that steroids help to prevent ulceration and excoriation, which occurs during retraction during surgery over the lips and corners of the mouth.

Oral Medicine: Topical glucocorticoids have proven to be very effective in the treatment of a variety of oral mucosal lesions which includes oral ulcerations and manifestations of the auto-immune diseases of the body. In oral medicine, corticosteroid injections are an integral part of the management of tempero-mandibular joint degeneration. Glucocorticoids are an important part in the treatment of various diseases as summarized below:-

OSMF: Topical application over the painful or ulcerative mucosa shows a direct healing action on the mucosal patch due to its anti-inflammatory property.[11]

Oral Lichen Planus: Clobetasol propionate with nystatin in orabase -0.05% 3-4 times per day appears to be effective in controlling lichen planus.

Erythema Multiforme: Prednisolone is the drug of choice for erythema multiforme.

Pemphigus: Prednisolone or topical and systemic steroid combination-betamethasone is the drug of choice for pemphigus.

Desquamative Gingivitis: The drug of choice is triamcinolone and fluocinonide.

Oral Submucous Fibrosis: A dose-dependent enhancement of fibroblast collagen phagocytosis is caused by corticosteroids. Hydrocortisone, betamethasone are the drugs of choice.

Melkersson Rosenthal Syndrome: Due to the anti-inflammatory action of steroids, it is used to reduce persistent edema and swelling. Prednisolone is the drug of choice.

Bell's Palsy: The drug of choice here is prednisolone 60-80 mg daily during the first few days.

Central Giant Cell Granuloma: For non-surgical treatment, intracellular corticosteroid injections are given and topically, triamcinolone acetonide can be given as it

works by suppressing an angiogenic component of the lesion.

These are some of the conditions and their management using glucocorticoids. There are innumerable diseases and conditions, for which steroids are very beneficial.[12]

Guidelines for dental use: Evidence shows that maximum people suffering from adrenal insufficiency can go for non-surgical regular dental treatment without the requirement for any glucocorticoid. The dental treatments do not encourage cortisol secretion as much as those of oral surgical procedures, and the local anesthesia blocks neural stress pathways that are needed for the production of adrenocorticotropic hormone secretion. For patients who undergo general anesthesia for minor surgery, then hydrocortisone of 100 mg should be administered intramuscularly and the usual glucocorticoid doses should be maintained. For any major surgery, 100 mg of hydrocortisone must be delivered as a tablet preoperatively, which is then followed by 50 mg 8-hourly for 48 hours.[13]

Adverseeffects: When the glucocorticoids are prescribed in an approved dosage for a small period, then the drugs are safe. Regular or large doses of the drug can cause some severe adverse effects. Many of the complications start with the dose and the duration of the therapy. Several of the complications occur in patients who are already under extensive therapy. So in patients like these the administration of steroids must be monitored.

If glucocorticoids are given regularly or daily then the adrenal cortex stops producing it and the tissues of the adrenal gland get atrophied. It becomes a concern when the drug therapy is suddenly stopped, because adrenal glands cannot immediately produce it again. This is known as acute adrenal insufficiency. The manifestations include nausea, irritation; join problems, vertigo, and low blood pressure. So to avert this from happening, the corticosteroid drugs have to be removed unhurriedly, over some time, like in weeks or months, to allow the adrenal cortex to restart its complete functional competency.[14]

For patients under long-term therapy, an additional amount of glucocorticoids must be given amid stressful times such as surgery or serious infection, similar to the cortisol rush usually produced in the system. Since these hormones subdue the immune system, the danger of infection increases. Certain viral infections like measles and chickenpox may be more serious in patients on steroid therapy.

An increased use of glucocorticoids can result in causing Cushing's syndrome whose manifestations include a protuberance between the shoulders, a round face, irregular menstrual cycles, and an increase in weight, depression, and weariness. Other effects include- Discomposure and irritation, Cataracts(or glaucoma), Vertigo, Blurred vision, Rise in facial hair in women, Difficulty in concentration, Retention in fluid, Headache, Irregular heartbeat, Increase in blood pressure, blood sugar levels, cholesterol, or triglycerides levels, Rise in the level of gastric ulcers or gastritis, Osteoporosis caused due to the body's inability to absorb calcium, Osteonecrosis, Reactivation of latent tuberculosis, Sleeplessness, Weight gain, breathlessness.

Minimizing the effects of steroid therapy: When under steroid therapy, probiotics play a very crucial role in minimizing the effects of candidiasis. The action of probiotics is in three ways. Firstly, it helps in inhibiting pathogenic enteric bacteria. Secondly, it improves the function of the epithelial and mucosal barrier by enhancing the mucus production, and hence enhancing the barrier integrity and the production of short-chain fatty acids Thirdly, it helps in altering the immune regulation by stimulating the secretor immunoglobulin production, hence decreasing the tumor necrosis factor expression, by the introduction of interleukin-10.[15]

Conclusion

The risks that are associated with glucocorticoids are parallel to the benefits of their therapeutic power. The benefits are many but the side effects are well known. Hence they are known as a double-edged sword. Their potential to cause many adverse effects presents the dental practitioner with the difficulty of the management of the patients undergoing steroid therapy. The drugs should not be used for trivial reasons and it should be carefully considered before each individual is administered these drugs. However if the dental practitioner maintains the proper guidelines of administration and care then the patients on glucocorticoid therapy have the highest benefits and the lowest possible risks. Hence, glucocorticoids are a boon in our profession and relief to our patients but when administered carefully.

Microbes and Immunity: The Periodontal Battle Zone

Priyanka Jena[1], Gatha Mohanty[2]

[1]Intern, [2]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, Odisha, India

Abstract

Periodontal disease is known around the world as a significant health concern and a common cause of adult tooth loss. Periodontal diseases are common inflamed disorders such as gingivitis and periodontitis caused by the pathogens present in the biofilm which is seen subgingivally such as *Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis*, *Treponema denticola* and *Tannerella forsythia* that activate inflammatory, innate and adaptive responses of the immune system. The immune system plays a vital role in preservation from pathogens with the maintenance of commensal microbiota at the mucosal surface. This article is focused on discussing the role of microbes and the basis and concept of immunology in periodontal disease in brief.

Keywords: *Periodontitis, Pathogenesis, Immunology.*

Introduction

A chronic inflammatory disease of the periodontium known as periodontitis is characterized by loss of periodontal ligament and destruction of surrounding alveolar bone.[1] There is ample evidence that the presence of microorganisms and persistent inflammation in periodontium give rise to the development and/or initiation of many systemic inflammatory diseases like diabetes, obesity, metabolic disease, rheumatoid arthritis, chronic kidney disease, etc.

Many of the key pathways leading to systemic inflammation are the direct or indirect effects on certain body sites of circulatory bacteria, mediators of inflammation and/or immune systems from infected/inflamed tissues of the periodontium.

Bacteremia may be caused by oral bacteria entering the bloodstream via mechanical processes involving periodontal debridement, flossing, and brushing techniques. Products from bacteria especially LPS from gram-negative bacteria can also contribute to systemic inflammation. The response of inflammation by bacteria of the periodontium in the inflamedtissue of periodontium is an origin of recurrent persistent systemic inflammation. P.*gingivalis* is considered to be the only bacteria capable of inducing enzymatic peptide citrullination with subsequent production of autoantibodies of the anti-citrullinated peptide.

During periodontitis, pro-inflammatory mediators and biomarkers are found to be substantially higher in serum and gingival crevicular fluid as compared to the periodontally well individuals. When defending against infections, the immune system plays an essential function when preserving commensal microbiota on the mucosal surface. Innate immunity provides a first line of protection against infection that creates a homeostatic network capable of detecting infectious microorganisms that cause immune reactions to remove them. Along with innate immunity, adaptive immunity cells and characteristic cytokines play a vital role in the pathogenesis periodontal disease involving $CD4^+$ T-cells (T-helper cells.[2]

Factors in causation of periodontal disease: Diseases of periodontium are usually inflaming disorders such as gingivitis and periodontitis occurs due to pathogens present in the biofilm which is seen subgingivally.

Such bacteria cause the gingival epithelium to develop cytokines and chemokines, resulting in molecular adhesion, elevate permeability in capillaries of the gingiva, and chemotaxis of polymorphonuclear neutrophils via junctional epithelium to the gingival sulcus.[3] Further continuation of this process results in inflammation that extends into the tissues and results in loss of alveolar bone and reinforcing connective tissue and also causes initiation of periodontal pocket. The inflammatory mediators and cytokines are capable of stimulating the demolition of the periodontium andthe destruction of collagen via matrix metalloproteinases extracted from tissues.

Various and distinctive ecosystems that are present in the human body provide a unique environment for the colonization of microorganisms. Typically the periodontal disease involving *Aggregatibacter actinomycetemcomitans, Porphyromonas gingivalis*, and *Tannerella forsythia*are associated with a scanty bacterial typespresent in the biofilm which is seen subgingivally.

According to a study report,in most patients and active sites, the red complex types *P.gingivalis* and *T.forsythia* were found to be elevated in populations of persistent inflammatory disorder of periodontium in Chile, Spain and Colombia.[4] *P.gingivalis* were more often observed in patients of Chile (83.8%) and less commonly in Colombians (65.9%). *T.forsythia* were found to be lower in Spain (36.1%) than in Chile (16.2%) and Colombia (39%). This study also reports that the active sites of chronic periodontitis in Chileans have higher mean percentages of total anaerobic*P. gingivalis* and no major variations for *T.forsythia* have been reported.

Research on Latin American populations show a high prevalence of T.forsythia and P.gingivalis in Chileans with chronic periodontitis. A high incidence of T.forsythia and P.gingivalis were recorded in Brazilians (45% and 68% respectively) and Mexicans (97.4% and 100% respectively) using DNA-based method. **Botero** etal,in Colombian patients with chronic periodontitis using microbiological culture, reported high-frequency T. forsythia and P. gingivalis (50% and 75.4% respectively).[5]

Actinomycetemcomitans in chronic periodontitis use microbiological culture and DNA samples to detect this pathogen in a lower ratio than *T.forsythia* and *P.gingivalis* in the Chilean population. Some populations with aggressive periodontitis have been found to have a higher rate of P.gingivalis as oppose to those of chronic disease of periodontium by using microbiological culture of periodontal pathogens.

For example- Chilean patients with chronic periodontitis have 76.4% frequency isolation of *P.gingivalis* compared to 86-100% in aggressive periodontitis.[6]

Besides, fimbriae is another clinical virulence factor that is the filamentous component on the surface of the cell, and its subunit protein fimbrillin (fimA) significantly performs on bacterial contact with tissues of the hosts by mediating adhesion of bacteria and target site colonization.[5] Several experiments have been conducted in the subjects of various disorders of periodontium at distinct geographical locations to evaluate the pervasiveness and dispersal of the fimA genotypes. Based on this finding, itcan be concluded that the type fimA genotypes are most common in patients of periodontitis whereas the second most prevalent genotypes were seen to type A, type B, or type Cdepending on the studied ethnic group. The subjects type A and type B fimA are more common in non-periodontitis cases.[7]

Moreover, a large molecule consisting of a lipid component (lipidA) and a polysaccharide component known as lipopolysaccharides which is a major component of the outer membrane of P.gingivalis and compares with most gram-ve bacteria.[6] Heterogeneous molecules from *P.gingivalis* lipid A induce an agonistic and antagonistic response of the innate immune system by one week. It is proposed that these mechanisms are critical for disrupting oral homeostasis and oral health.

Innate immunity in periodontal diseases: The response of the innate immunity system is a mechanism of homeostasis that provides the primary line of protection, and is alsocapable of recognizing invasion of pathogens as non-self, activating immune reactions to remove them. The responses of the innate immunity system are organized by a wide variety of chemokines, cytokines and receptors on the surface of the cell, and an inflammatory state created by innate immunity

stimulation. Adaptive immune strengthens the effector mechanisms of innate immune, providing a methodical loop for clearance of microbes, where activating actual innate systems guarantees a successful adaptive immune response that potentiates the action of these innate factors against periodontal bacteria.[8]

Polymorphonuclear neutrophils: Polymorphonuclear neutrophils after chemoattractants such as interleukin-8, connective fibroblasts, and immune cells are one of the first respondents of inflaming cells to move towards the site of inflammation of the periodontium.[7] Polymorphonuclear neutrophils are a characteristic of acute inflammation. Changes in their functions causeacute, serious, andgeneralized periodontitis in humans. Such modifications may include varying roles such as adhesion potential, reaction to chemotaxis and phagocytosisand thereby implication, the particular timing of the immune responses depends on polymorphonuclear neutrophils.

The cytoplasmic granules of polymorphonuclear neutrophils contain many enzymes that degenerate the structure of the cells of the tissues and the extracellular matrix when released. These are the brief-lived cells thatdemise in larger numbers at acute inflaming sites of periodontium due to interaction with pathogens and their toxins. The aggregation and huge death of polymorphonuclear neutrophils are the main causes of deterioration of tissue in developing disease of periodontium.[9]

Role of T-cell subsets and cytokines: In periodontal disease pathogenesis,the production of adaptive immunity mediated by T-cellis influenced by innate immune-associate cellspresenting antigen which, after antigen attack pass through a procedure of maturation and emigrate to the lymph nodes, where they generate different cytokine forms which cause successive polarization and activation of specific T $CD4^+$ lymphocytes.[7]

The $CD4^+$ T-cells are two subsets based on their cytokine development pattern, mainly T-helper 1 and T-helper 2. T-helper 1 cytokines are related to infectious inflammatory degradation of the bone, whereas T-helper 2 cytokines have been expressed to reduce loss of bone. The other regulatory subsets of T-cells are Tr1 and T-helper 3 which are identified respectively by the common development of transforming growth factor-b or interleukin-10. And additional subsets of T-helper just as T-helper 22 and T-helper 9 cells have played a vital role in the transition of inflammatory immune responses. T-helper 17 and T-regulatory cells together play a vital role in the organization ofresponses of the adaptive immunity and also have a significant impact on inflammatory and autoimmune diseases outcome.[9]

T- helper 1: T-helper 1 cells are produced under the interleukin-12/interleukin-1 signaling effect, which results in the incitation of the T-bet transcription factor. T-helper 1 cells primarily participate in the immunity mediated by the cells. Production of inflammatory cytokines, chemokines and activation phagocyte is correlated with interferon-$\gamma\gamma$, the T-helper 1 type response signature cytokine.According to a review by the **Gamonal and Garlet**, the interferon- $\gamma\ \gamma$ is highly present associated with progressive lesions or severe forms of periodontal diseases in humans and experimental periodontal lesions. Human and experimental evidencesuggest that theinterferon- $\gamma\ \gamma$ can give rise to the development of inflammation of periodontium by distinct mechanisms.[10]

T- helper 2: The activity of T-helper 2 cells depends primarily on interleukin- 4, the T-helper2 and the transcription factor GATA3. Interleukin- 4 has distinct suppressive and anti-inflammatory properties that are intervened by its ability to interrupt the transcription of pro-inflammatory cytokines and interferon- then suppress the polarization of T-helper 1 cells.[8] Interleukin-4 can hamper the development of factors causing tissue degradation including matrix metalloproteinases and the main osteoclastogenic factor RANKL. Interleukin- 4 can also induce regulation of its respective TIMPs and osteoprotegerin inhibitors in distinct tissues through their anabolic properties. In gingival crevicular fluid (GCF) the congregation of interleukin- 4 found to reduce from periodontal health to disease, indicating that this cytokine may intervene in the revocation of lesions of the periodontium.

T- Regulatory cells: In particular, regulatory T cells control the renewing, augmentation thereby regulating the outcome of many settings of immune systems varying from infective diseases to pathology of immune system and autoimmunity. The T- regulatory cells were initially identified as $CD4^+$,$CD25^+$ T cells. T regulatory cells serve the transcription factor forkhead box p3 (FOXp3), CD103, the glucocorticoid- inducible tumor necrosis factor receptor (GITR), inhibitory molecule cytotoxic

T-lymphocyte- related molecule 4(CTLA-4) and cell surface transforming growth factor-β1, in the middle of additional surface molecules. In some non-inflamed peripheral tissues, the T-regulatory cells are known to be in a relaxed state with minimum suppressor activity, but these cells are activated in inflammatory conditions and go through quick reprogramming to obtain helper/ effector functions.

According to a study paper, **Gamonal** et al demonstrated that T-regulatory cells- associated levels of cytokines have a negative association with RANKL levels, supporting their defensive role in active periodontal lesions against tissue destruction. In line with such theory, Garlet group was the first to recognize a reaction in an experimental model of periodontitis, in the association between the intensity of periodontitis via the ablation role of T-regulatory cells.

Role of prostaglandins: The transformation of arachidonic acid to prostaglandin catalyzed by the enzymes COX-1 and COX-2 cyclooxygenase. Prostaglandins in particular are the most significant inflammatory mediators especially, prostaglandin E_2 (PGE_2) which contributes to vasodilation and production of cytokines by different cell types. PGE_2 released remarkably in the periodontium by macrophages, fibroblasts from different cell types. PGE_2 is involved in the activation of MMPs and resorption of osteoclast and has an important role in tissue damage characterizing periodontitis.

COX-1 is a constituent enzyme involved in the initiation of physiologically active prostaglandins while COX-2 is an inductive enzyme mainly caused due to pro-inflammatory cytokines and results in the initiation of prostaglandin. Over the last years, the role of prostaglandin has been under investigation in the pathogenesis of periodontitis. PGE_2 and leukotriene B4 were present in GCF of localized aggressive inflammation of the periodontium, indicating a character for these molecules in the disease of periodontium. The use of a COX-2 inhibitor as an alternative to the periodontal therapy was investigated in several clinical trials. Such inhibitors increased the clinical results following periodontal therapy.[9] Thesestudies indicate that bone resorption induced by periodontitis may involve prostaglandin especially PGE_2.

Role of Osteoimmunology: The transformation of monocyte-macrophage precursor cells into osteoclasts induced by an increased level of RANKL mRNA and protein in periodontal tissue and alveolar bone loss caused by osteoclast maturation and survival has now been evident for days.[9]

RANK, RANKL, and OPG are TNF-α family cytokines. RANK is a receptor present on the surface of osteoclast precursor. A variety of other forms of cells produce RANKL primarily T-helper 17 and lymphocytes. Attachingto RANK without inducing any distinction, OPG competes with RANKL. The proportion of the expressions RANKL and OPG is essential in inflammation-induced resorption of bone including periodontitis. In order to determine the RANKL/OPG ratio, various clinical trials studied the congregations of RANKL and OPG in gingival tissues or GCF derived from individuals with periodontitis. This study shows that there is a rise in soluble RANKL in chronic periodontitis with or without a decrease in OPG compared with healthy individuals. The finding was typically that in people with periodontitis the RANKL/ OPG ratio was higher than in healthy individuals.[9]

Matrix metalloproteinases: Matrix metalloproteinases are the main proteases in destructive periodontal diseases. The relationship between inflammation of periodontium and chronic infection of bacteria controls the neutral proteinases manner and function. Especially the MMP family,which causes a continuous breakdown of the supporting tissues of the periodontium.[9]

Matrix metalloproteinase is a family ofhuman zinc-dependent endo-peptidases associated with a wide rangeof physiological and pathological processes includingthe growth of skeletal system and remodeling, healing of the wound, cancer andinflaming disease. MMPs are made up of an auto-inhibitory prodomain which is often involved in the identification and placing of MMP substrates for enzymatic latency, the catalytic domain, and the c-terminal hemopexin like domain.[10] MMP activity is closely regulated by gene expression, pro-enzyme activation, enzyme inhibition, and endogenous inhibitors. They are grouped particularly in collagenases, gelatinases, stromelysins, matrilysins, and membrane-type MMPs according to their substrate. MMPs are the master regulators of inflammation-related with a large variety of inflaming disorders. [10]

Conclusion

According to some evidence the disease

of periodontium has complex aggravation and revocationstates that can be defined as cycles of development and reversion of disease. Widespread forms of vital events of disease of periodontium can be related to dissimilarity in the population of supracrestal inflaming cells,where there are a substantially greater number of monocytes/macrophages and plasma cells inactive sites in comparison to inactive sites.

Treatment of Chronic Periodontal Disorders: A General Practitioners Perspective

Ayesh Das[1], Gatha Mohanty[2]

[1]Intern, [2]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, Odisha, India

Abstract

A greater number of patients will experience gums-associated disorders at one or the other point in their lifetime and also a section of the community is suspected to suffer from advanced gum associated disorders. Sound treatment is essential in dental practice (i.e. dental practitioner's perspective). A comprehensive layout of treatment which includes gum assessment, treatment, revisit of long-standing periodontitis cases in regular dental care, and treatment is discussed in this review.

Keywords: *Primary essential periodontal examination (PEPE), Chronic Periodontitis, Pocket, Gingivitis, Periodontitis, Oral health conditions.*

Introduction

Unidentified unattended periodontal disorder is a rapidly increasing concern in dentistry and there are restricted guidelines that describe the accessibility to its treatment.[1] Dental care burden is rising by 85%.Elderly people over 65 years of age exhibit long-standing gum diseases which represents significant negligence in dental care. This article aims to provide information about various dental treatments of long-standing gum disorder in dental care and practice. The information focuses on the risk factors and oral hygiene (OH) method. Long standing gum disorders is associated with anaerobic bacteria. Management of chronic periodontal conditions can only be possible by patient cooperation and this/her desire to continue with good dental hygiene. Hence information is mainly based on OH maintenance, since it is well recognized and easy to follow.

e-mail: gathamohanty@soa.ac.in.

Primary Essential Periodontal Examination:

Various codes are used to determine the criteria for basic periodontal examination.[2]

Code 0: Bleeding is not seen after gentle probing, plaque retentive factor is absent, and pocket is not seen over 3.5mm.

Code 1: Bleeding is seen after gentle probing, plaque retentive factor is not found, no pocket seen over 3.5mm.

Code 2: There is no pocket exceeding 3.5mm. Retentive plaque factor is seen.

Code 3: Probing depth is from 3.5 –5.5 mm

Code 4: Probing is greater than 5.5mm on one or more sites. Furcation involvement is seen.

Different Periodontal Disorders:

1. **Chronic Gingivitis:** In Chronic Gingivitis gingival inflammation is present due to plaque-induced inflammation. Abnormal redness of skin resulting from dilation of blood vessels, swelling of gums is seen. During brushing, probing gingival bleeding is seen. Detachment of the gingiva from the teeth is seen occasionally.[3,4]

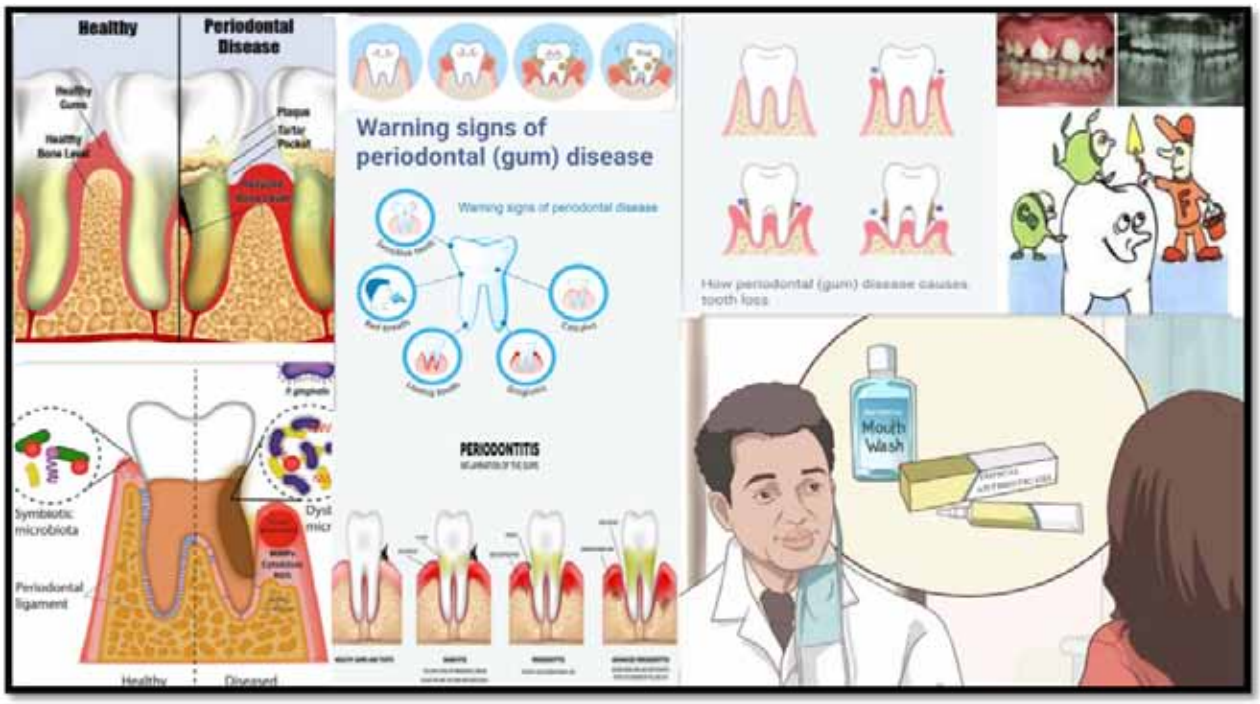
2. **Acute Ulcerative Gingivitis:** Usually seen in patients who smoke or who present with poor oral hygiene. In the tip of the interdentally papillae painful ulcerations are present, grey necrotizing sloughing tissue is seen on the area of the ulcers. Loss of interdental papillae may be seen. Loss of blood is spontaneous in gingiva. Halitosis is present with tender or palpable sub-mandibular lymph nodes. Fever and malaise may be also present.

3. **Gingival Hyperplasia:** Caused by medication of calcium channel blockers, cyclosporine, phenytoin. It is also caused by irritation from calculus and repeated friction and trauma.[5,6]

4. **Chronic Periodontitis:** Age, Smoking, diabetes, and family history are the most responsible factors for chronic periodontitis. Subgingival calculus is mostly seen, with prevalence in adults, the progression rate is from slow to moderate with related amount of dental plaques.[7]

5. **Aggressive Periodontitis:** About 1in 1000 patients experience more quick auxiliary loss, alveolar bone destruction, and rapid attachment loss. Patients under 35 years of age are susceptible.[3]

6. **Acute Necrotizing Periodontitis**: Presence of attachment loss, associated mandibular lymph node may be tender and palpable, spontaneous gingival bleeding and there may be loss of interdental papillae, halitosis, fever and malaise.[6]



7. **Periodontal Abscess:** It is an acute infection in the gum pocket. The periapical and periodontal abscess should be differentiated if present together, since it's difficult to distinguish. Abscesses can be acute or chronic and asymptomatic if freely draining. The tooth will be vital if there is no endodontic component.

8. **Periodontitis associated with endodontic lesions:** Vitality of the tooth may not be present. Lesions may be independent or coalescing and may originate either from the gingiva or apex.

Probable prospect for gum disorders: Amount of destruction gives rise to dental changes and can be associated with a rise in bacterial plate in dens; moreover many internal and whole system structure risk factors can aggravate susceptibility and severity of the issue. Patient personal history and clinical examination will help in highlighting these local and systematic risk factors for gum disorders. Systemic risk factors include medical conditions like diabetes, leukemia and many more. Patients who are under medication like phenytoin, cyclosporine and calcium channel blockers show inflammation. Stress, smoking and any family history of periodontal disorders can aggravate the condition.[5] By examination, we can also know about the overhanging restorations, calculus deposition, root caries, enameloma and adamantoma etc.

Guidelines for long-standing gum disorders: The British Society of Periodontology offers various guidelines explaining the basic periodontal examination which can help us in providing basic treatment.[10, 11] Deep cleaning is the elimination of bacterial plate bio-factor and calculus deposition from the unseen portion of tooth and pockets. Making use of power-driven scaler or machine-driven scaler which are more useful for patients and clinicians over hoes, chisel, and files for root surface debridement due to their effectiveness.[12,13] Root surface debridement could be ended for periodontal pockets 4mm or more. Presentation of minimal dental cleanliness habits is an inseparable principle to be observed with any protocol of mechanical debridement. Oral hygiene education (OHE) must always be considered the treatment Hence an integral portion of the guidance utilizes OH to assist different and suitable treatment that can bring maximum welfare to dental health – which may be predominantly Oral hygiene education, Root surface debridement or either of them. The intensity or extent of the disorder can also be related to other portable parts of guidelines that include evaluating and labeling these. By categorizing OH as good, moderate, poor determining the level of dental hygiene of patients treatment planning may be done.[14]

Radiographs: X-ray helped to identify the horizontal bone level, any vertical bone defects, and furcation involvement. Criterion for bitewing radiographs: displays sufficient bone level in posterior sextants. Vertical bitewing can be useful where bone loss has so far taken place. Long cone periapical were advised for localized views. Further radiographs are only required for clinical explanation.

Analyzeand emphasize patient complain: Patients' authority and management of dental hygiene is foremost important if they want to extract maximum profit from the treatment. Dental hygiene instructions and education are an integral part of treatment that contain tailored instructions on maintaining dental hygiene habits and interdental habits. Medium to develop dental hygiene behavior contains: Aim determination, monitoring dental habits, identifying the cause and significance of treatment, and proper revisit to confirm, visually motivate and utilize the dental cleanliness practices.[15] Instructing the patient by advising and talking with them on planning their treatment and supporting and motivating them to follow the proper instruction to maintain their dental hygiene is important.[15]

Individuals having gum bleeding can also be motivated to use home care method which are budget-friendly and can be used by all classes of society. After some time survey can be done to check the improvement.[16]

Bacterial plate and different indicators should be used together with a proper diagnosis which can be helpful for the patients to know there bacterial plate level and accordingly manage it.

"O'Leary indicator" helps to determine the existence or lack of bacterial plate at 4 times on various dental surfaces. Suitable indicating agents like plaque search indicator or similarly any other medication or chemical is applied in every area of dental surface. Assessment can be done after rinsing the mouth once and any of the disclosed amounts of plaque visible can be recorded and the record can be worked out as a percentage.

Bacteria plate monitoring index should be utilized for uplifting compliance and provide a regulation when a patient is treated with (RSD) Root Surface Debridement to get the best outcome.[17] A bacteria plate results for better gum health response and it should be no more than 25%, minimal bacteria plate result, and must not be less than 10%respectively. It is considered that 15% is advised as a maximum. This is done to get a good result after root surface debridement.

Conclusion

Dental practitioners should discuss and share their treatments with their group for better treatment. Educate or train nurses about dental hygiene education and plaque scoring. Note writing or detailed forms should be maintained to defend themselves in case of an allegation made against the practitioner. Following the Treatment guidelines recommended help in clinical and in non-medical treatment of long-standing gum disorders in daily dental practice.

Effect of Fluoride Varnish in Dental Caries: A Review

Rupsita Sahu[1], Ramesh Nagarajappa[2], Debashruti Naik[3]

Intern, Professor and Head, Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dental caries remains amongst the most common oral health problem affecting people in the developing countries. The use of fluoride ions in the form of gels, foams, and varnishes are effective in preventing caries. The varnishes have been routinely used in the western European and Scandinavian countries in the last 30 years because of its ability to provide an increased contact time between enamel surface and fluoride, thus inhibiting demineralization of enamel. The technique of fluoride application, along with its advantages, disadvantages, indications, contraindications, and side effects have been discussed in this review.

Keywords: *Dental caries, Fluoride ions, Fluoride varnishes, Enamel, Oral health.*

Introduction

Oral health is a necessary and integral part of general health. Dental caries is by far the most important oral health problem affecting people of every age group and community.[1,2] The resultant pain and discomfort along with a heavy burden on finances impairs the quality of life of an individual.[3] According to Sturdevant, dental caries is defined as a multifactorial, microbial infectious disease characterized by demineralization of the inorganic and destruction of the organic substance of the tooth. Fluorine, derived from the Latin term fluore meaning to flow, is the most electro negative and reactive element of the halogen family. It combines chemically to exist as fluorides and represents about 0.06% to 0.09% of the earths crust, mostly in the form of minerals such as Fluorspar, Fluorapatite and Cryolite.[4,5]

Advances in technology and research have enabled dentistry to shift from reparable art to preventive-oriented science. The emergence of fluorides has convincingly demonstrated a decline in caries prevalence.[6]

Mechanism of action of fluorides[7]: Simultaneous working of several mechanisms enable the fluorides to act against caries which have been briefly enumerated: Figure 1.

1. **Increased enamel resistance and reduction in solubility of enamel:** The fluoride acts on enamel and forms fluorapatite crystals which are less soluble and hence prevents dissolution of enamel in the following ways:
   - Reduces bacterial acid production and acidurance
   - Reduces equilibrium solubility of apatite
2. **Increased post-eruptive maturation rate of hypo mineralized areas:** The hypo mineralized areas of newly erupted teeth are prone to caries. Fluoride enhances the rate of post-eruptive maturation of these areas with the deposition of organic material from saliva.
3. **Remineralization of incipient lesions:** The deposition of minerals in a dynamic process over the previously damaged areas of the enamel reduces its solubility. This leads to a growth in the

crystals and becomes more resistant to caries. The remineralization occurs when fluorides combine with calcium and phosphate ions in the saliva. However, when too much fluoride combines with calcium phosphate, the formation of calcium fluoride takes place, which in turn prevents the growth of hydroxyapatite crystals.

4. **Interference with microorganisms:** At higher concentrations fluoride is bactericidal, whereas at lower concentrations fluoride is bacteriostatic. In an acidic environment, fluoride diffuses into the cells as hydrofluoric acid. This continues until the concentration in the external and internal compartment are equal.

5. **Modification in tooth morphology:** Ingestion of fluoride during tooth development results in a more caries resistant tooth with smaller diameters and cusp depths, thus enabling self-cleansing.

Fluoride delivery method

There are two method of delivery-topical and systemic.

1. **Topical fluorides:** These can be placed directly on the teeth with some preparations providing a low concentration of sustained fluoride release while others providing a higher concentration over a shorter span.[8]

The topical fluorides can further be divided into:

- Professionally applied products: These are dispensed by dental professionals in the dental office and uses a concentration between 5000 - 19000 ppm. These are available as gels, foams, and varnishes.
- Self-applied products: These are dispensed by the patient on the recommendation of a dental professional with the concentration range being 200 - 1000 ppm.

2. **Systemic fluorides:** These are allowed to circulate in the bloodstream and are given at a low concentration over a longer time span.[9]

Fluoride Varnishes: Fluoride is usually more effective when applied topically by professionals in the form of gels, foams, and varnishes. While using gels and foams, a high amount of fluoride is leached away in the first 24 hours and almost two-thirds are lost within days.[10-12] Thus, an increase in the contact time between enamel surface and topical fluoride agents became necessary to increase its efficacy.[13,14] This led to the incorporation of fluorides into a varnish-like coating by Schmidt in 1964. Varnishes were found to be a safe vehicle for exposing the enamel to fluoride for longer periods with deeper penetration into the enamel surface. Arends and Schutof using microradiography and micro-hardness tests have shown that a 24-hour exposure of enamel to fluoride varnishes can inhibit demineralization completely.[15] The prolonged retention of fluoride in the form of varnishes is because of a coating of pellicle proteins and secondary phosphates. During caries attack, a low pH results in the loss of pellicle coating, releasing calcium fluoride. The fluoride ions are absorbed onto the enamel surface to increase the rate of remineralization.[16-19] The various types of fluoride varnishes available today includes the following[20]:

i. **Duraphat:** Duraphat is a yellowish viscous material consisting of 22600 ppm sodium fluoride in a neutral colophonium base. The amount of caries reduction was found to be between 7% - 44% in deciduous and between 30 - 40% in the permanent dentition.

ii. **Fluorprotector:** Fluorprotector is a clear polyurethane-based product containing 7000 ppm fluoride in the organic compound Difluorosilane. It is dispensed in the form of 1 ml ampules, each containing 6.21 mg of fluoride. Its clinical efficiency has been established between 1% - 17%.

iii. **Carex:** The fluoride content of Carex is 1.8% with an efficacy similar to that of Duraphat as a caries-preventing agent.

The mean fluoride release from various fluoride varnishes have been demonstrated in **Figure 2**.

Technique of varnish application: When the varnish is freshly squeezed out of the tube, occasionally dark streaks may appear representing a separation of the ingredients inside and containing only a fraction of the required fluoride content. Thus, the freshly squeezed out varnish should be discarded. Alternatively, a rotary tube shaker can be used to obtain a uniform mix of the varnish.[12] While applying the varnish, teeth are dried post prophylaxis. Around 0.3- 0.5 ml of varnish is dispensed amounting to 6.9-11.5 mg of fluoride for full coverage of the dentition. The varnish is applied starting with the proximal surfaces, sequentially on the lower arch followed by the upper arch using a single tufted small brush. The patient is then asked to wait for 4 minutes with his mouth open before spitting to allow

the fluoride to set over the teeth. Finally, the patient is instructed not to rinse or drink anything till the first hour and not to eat anything solid till the next morning to prolong the interaction time between the fluoride and enamel.[21] **Figure 3.**

Some of the brands of fluoride varnish in regular use includes:

i. Colgate PreviDent varnish

ii. Embrace varnish

iii. Enamel Pro varnish

iv. Varnish 3M

Advantages, disadvantages, indications and contraindications and side-effects of fluoride varnishes[22-25]

Advantages:

- Easy to apply
- Have different flavours
- It has a sticky consistency which helps to stay in contact with tooth for several hours
- Dry rapidly
- Reduce the number of cariogenic bacteria s. mutans by over ten-fold
- It has a higher concentration than the foam and gel

Disadvantages:

i. They may cause a temporary change in the surface of teeth due to the color and adherence

ii. Varnish may damage by eating and brushing so the yellowish color fades

iii. Cost is more than gel

iv. Some patients can cause nausea due to the taste of varnish especially when consuming food within 24 hours post-treatment

Indications:

i. Fluoridated cavity varnish

ii. For high caries

iii. Remineralization of lesion in root dentin

iv. For orthodontic bands and brackets

v. On advanced enamel carious lesion

Contra-indications:

i. May cause discoloration in the area

ii. For open cavities area

iii. Low-risk caries

Side effects: The use of too much fluoride can cause fluorosis which gives white patches on teeth.

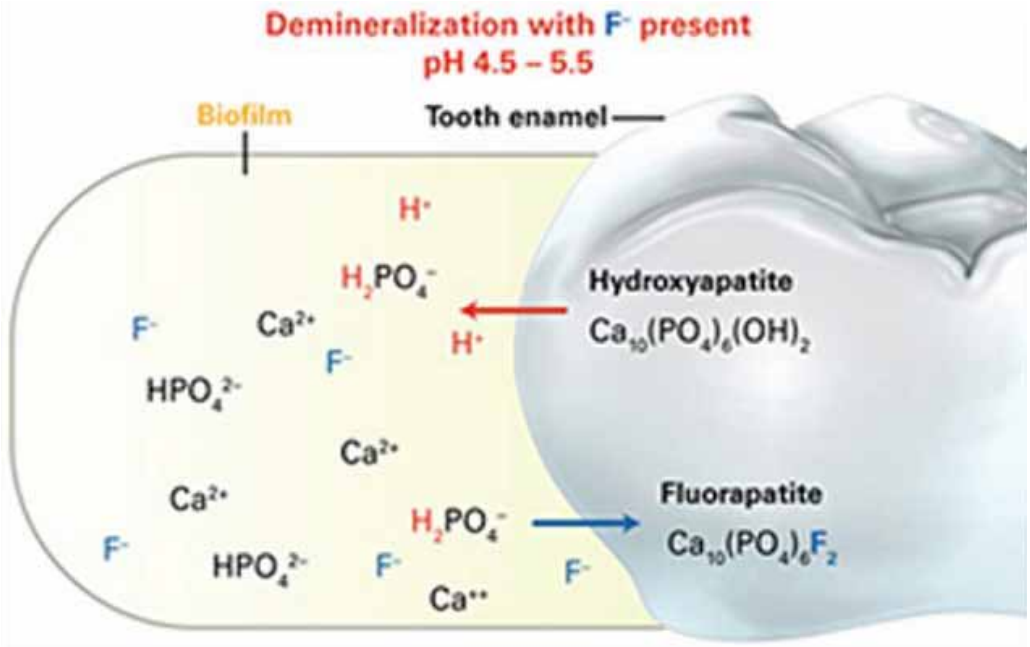

Figure 1: Mechanism of action of fluorides

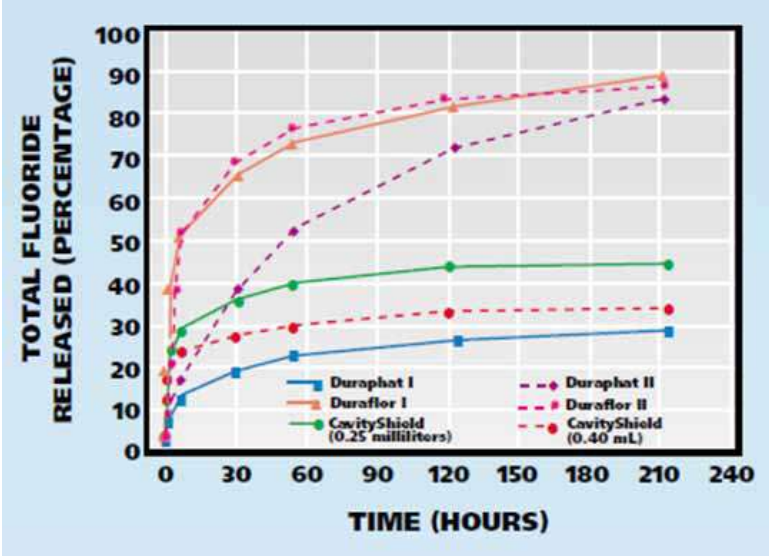

Figure 2: Graph showing mean fluoride release from various types of varnishes

Figure 3: Application of fluoride varnish helps remineralization and prevents caries

Conclusion

The fluoride varnishes have been routinely used as a standardized form of fluoride for professional applications in the Western European and Scandinavian countries for the last 30 years because of their well-documented effectiveness and safety. The shorter chairside time, easier application, better taste with increased acceptability, and cost-effectiveness make it more appropriate for using it in public health settings among children with high caries risk.

Mineral Trioxide Aggregate v/s Calcium Hydroxide: A Review Article

Gayatri Padhee[1] Susant Mohanty[2]

[1]Intern, [2]Professor & Head, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The main purpose of this article is to compare the mineral trioxide aggregate and calcium hydroxide in pediatric dentistry. Both of the endodontic cement are frequently used in different cases of pedodontics. This article aims to present the various characteristics of mineral trioxide aggregate and calcium hydroxide in a review article.

Keywords: *Mineral Trioxide Aggregate Calcium Hydroxide, Dental cement.*

Introduction

Over several years, different kinds of dental types of cement have been developed to avail of various purposes and to be applied to numerous events in dentistry. MTA is a distinctive endodontic cement & was developed by Torabinejad & members at the Loma Linda University, California, USA. Firstly, it was used as a root-end filling material in endodontic treatment. Over the years, MTA has been expanding its applications which includes root-end filings, direct pulp capping, perforation repairs in roots or furcation. U.S Food & Drug Administration has approved for the endodontic use of MTA in 1998. However, calcium hydroxide is also one of the most important medicaments used in the treatment of pulp disorders and apical periodontitis. Calcium hydroxide is a dental cement has been used in dentistry over the decades.[1]

Mineral Trioxide Aggregate (MTA): MTA is considered as one of the most multifunctional material in dentistry. MTA was identified as root-end filling material as it is a hydraulic cement that settles down in the existence of moisture. Through the internal bleaching of endodontically treated tooth, MTA act as a barrier. It can be utilized as capping material within mechanically exposed pulp & root-end induction. MTA favours the regeneration of tissue along with easy manipulation, possess good sealing stability & acquire long term prognosis.[2]

Composition: MTA gets settled easily in moisture as it is made up of hydrophilic particles. It is mainly constituted of fine hydrophilic particles of tricalcium silicate, tricalcium aluminate, tricalcium oxide, silicate oxide & bismuth oxide. MTA resembles Portland cement in composition expect bismuth oxide which is added to MTA for radiopacity. On comparison to Portland cement, particles of MTA are little and identical in size.[3]

MTA is available in 2 types: White MTA (WMTA); Grey MTA (GMTA). These two types mainly differ in lesser amounts of Iron, Aluminium & Magnesium oxides on WMTA than GMTA. GMTA has longer setting time, less radiopacity, solubility & pH value than WMTA whereas WMTA has more compressive strength than GMTA.

Mechanism of action: As soon as MTA is placed in direct influence with human tissues, the dental cement. The dental cement undergoes cell attachment & proliferation when comes in contact with human tissues. It resembles calcium ions which form calcium hydroxide. Due to alkaline pH, it gives antibacterial environment. Modulates the production of cytokine. Undergo hard tissue differentiation which stimulates the migration of cells. Biological seal by the formation of hydroxyapatite (carbonated apatite) on the MTA surface.[4]

Method of preparation: MTA powder should be stored in tight containers and dry condition. Before its use, MTA mixture should be prepared instantly. The

mix should prepare on a glass slab or paper slab with the use of plastic/metal spatulas. The powder water ratio should be 3:1 to obtain putty-like consistency. The mix should be carried with the help of plastic/metal carrier to the place of application. If the location is very wet, dry piece of gauze/foam is used to remove extra moisture whereas water can add up to mixture, if it is very dry. After mixing, MTA has a pH of 10.2 and it increases to 12.5% after a set time of 3 hours. Mixing time is of great importance, dry mix is seen if the mixing time is being lengthened. Mixing time should be below 4 minutes. Islam et al claimed it 2 hours 55 minutes for GMTA & 2 hours 20 minutes for WMTA.[5]

Calcium chloride and sodium hypochlorite lessen the setting time while saline and 2% lidocaine raises the setting time.

Properties: As the MTA material sets, its compressive strength shows identical to IRM and Super EBA. GMTA has more compressive strength than WMTA. MTA radiodensity is same as Zinc Oxide Eugenol. It can be seen radiographically.[6]

The set MTA is insoluble whereas solubility may increase if more water is added while mixing. When the set MTA exposes to water, it releases $Ca(OH)_2$ which may be responsible for cementogenesis induced property. The setting of MTA doesn't hamper in an acidic environment.

MTA has excellent sealing ability perhaps as expansion during setting. Residual calcium hydroxide may inhibit the adaptation of MTA to dentin which reduces the sealing ability. This is of great importance as when $Ca(OH)_2$ is placed in between the appointments before the positioning of MTA. As it provides good seal & prevents microleakage, it indicated as an antibacterial agent. MTA doesn't respond or inhibit with any restorative material. They are biocompatible. MTA can activate cementoblasts and produces cementum. It allows bone healing & regeneration of periodontal ligament. MTA induces thicker Dentinal bridge formation with less inflammation, necrosis and frequent odontoblastic layer formation as compared to $Ca(OH)_2$.[7]

Advantages: Antimicrobial, Microleakage, Cement conductive, Nontoxic, Cell Adherence & Growth. Periodontal Attachment To Cementum Growth, Dentinal Bridge Formation

Disadvantages: High cost, Difficult to manipulate, Longer setting time, Prolonged maturation phase

Uses: Direct pulp capping, Apical plug, root-end filling, Perforation repair, Furcation involvement, Resorptive defects, Apexogenesis/Apexification.

Commercially Available: Pro Root MTA, White ProRoot MTA, Ortho MTA, MTA Fillapex.

Calcium Hydroxide: Calcium hydroxide was introduced to the field of dentistry in 1921. Herman demonstrated the formation of the dentinal bridge in an exposed pulp & now it is considered as the 'gold standard for pulp capping agents.'

Composition: It is composed of calcium hydroxide powder, a vehicle & a radiopacifier.

Vehicle: Mainly there are 3 types of vehicles:

First is water-soluble substances. Some examples are water, saline, methylcellulose, anaesthetic solutions, carboxymethylcellulose & Ringers solution. Second is viscous vehicles. Some examples are glycerine, polyethyleneglycol (PEG), propylene glycol. The third is oil-based vehicles. Some examples are olive oil, silicone oil, camphor, eugenol, some fatty acids.[8]

Radiopacifier: Vehicle is not radiographically seen easily as it does not possess radiopacity. An ideal radiopacifier such as Barium sulfate & bismuth, a compound containing Iodine & Bromine have an atomic weight higher than calcium for radiopacity.[8]

Mechanism of Action: Vehicles in periapical tissues & in the root canal, calcium hydroxide will be solubilized & resorbed/absorbed at different rates as it decides the ionic dissociation kinetics. Calcium hydroxide activates in the presence of moisture and pH increases to 12 and above with minutes when $Ca(OH)_2$ is used as Intracanal medicament. Average time for the treatment is 1-4 weeks.

$$Ca(OH)_2 + H_2O \text{ -----> } Ca^{2+} + OH^-$$

Due to the huge concentration of hydroxyl ions from calcium hydroxide, cytoplasmic membrane damages its protein acts on the organic component & transport the nutrient (OR)

By saponification reaction, during the peroxidation process, the phospholipids/unsaturated fatty acids of the cytoplasmic membrane are being demolished.[9]

Calcium hydroxide has been provided in different modes. As varnish, it is supplied as a liquid which composed $Ca(OH)_2$ suspend in a solvent or even provided as a paste in that calcium hydroxide is suspended in methylcellulose. As a catalyst, $Ca(OH)_2$ present in the oral environment, it responds quicker & structures a tough amorphous compound in a minute. Calcium hydroxide as paste, when it exposes to brightening from a handheld blue light, calcium hydroxide hardens, as it contains polymer resin.[7]

Method of preparation: Up to the desired consistency is attained, mix both calcium hydroxide powder and water. It is the easiest method to prepare $Ca(OH)_2$ paste. Leonardo *et al* expressed in 1982 that a paste doesn't possess good physicochemical properties since it isn't radiopaque and penetrable to tissue fluids when the paste is made with water or more hydrosoluble non-viscous vehicle. It is dissolvable & resorbed in the periapical region and inside the root canal. Insertion of different substances to the calcium hydroxide paste is purposed by him.[6,7]

Uses: Intracanal medicament, Endodontic sealer, Pulp capping agent, Apexification, Pulpotomy, Weeping canals

Advantages: They are bactericidal and act as a mild irritant which stimulates hard tissue formation. They are inexpensive and easy to use and they stop internal resorption

Disadvantages: Formation of tunnel defects, bacterial reinfection, long term usage of $ca(oh)_2$ in apexogenesis may weaken the root, susceptible to fracture, less effective against *Enterococcus faecalis* & *Candida albicans*, chronic pulpal inflammation & internal resorption in a primary tooth, poor coronal seal & strength

However, calcium hydroxide is not generally used in pulp therapy for primary teeth. A mixture of calcium hydroxide & iodoform is found to be easy to apply & resorbs at a slightly faster rate. It has no toxic effect on succedaneous teeth & is radiopaque. Reasons outlined mixture of calcium hydroxide & iodoform can be considered to be a nearly ideal primary tooth root canal filling material.[7,8]

Recent advances: Recent advances of medicaments in Paediatric Endodontics includes dentine, BioRootTm RCS, Smartseal

Biodentine: It is a calcium silicate-based product specifically design as "dentine replacement" material. It has become commercially available in 2009. It was introduced to overpower all the drawbacks of $Ca(OH)_2$ and MTA. It has greater potential to favour the repair of perforations of the pulpal floor, open immature tooth, retrograde filling, apexification, pulp therapy.

Bio Root Tm RCS: It is a mineral-based root canal filling material with Active Biosilicate Technology for permanent obturation. This material helps to stop bacterial growth & alleviates the risk of intracanal reinfection due to high pH. It is biocompatible, resin-free, has good flow and hydrophilic due to which it set even in the presence of moisture.

Smartseal: It is recently introduced material based on polymer technology. Its principle is based on the hydrophilic nature of the obturating points.[10]

Conclusion

In comparison, the characteristics of both the dental materials it is clear that MTA is more effective than calcium hydroxide in various cases. However, calcium hydroxide cannot be used on the primary tooth as it will lead to internal resorption while MTA has major drawbacks which include high cost, discolouration potential. Nowadays, the emergence of calcium silicate-based material such as Biodentine has overcome MTA's limitations.

Microbiological Aids in Periodontics

Soumya Ranjan Panda

Intern, Institute Of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

New approaches to periodontal diagnosis, including advanced microbiologic, biochemical, and genetic tests, have been shown to provide the clinician with the information not available by traditional means. The purpose of a diagnostic test is to confirm, exclude, classify, or monitor disease to guide treatment. Their clinical value depends on whether the information they provide leads to improved patient outcomes. This can be assessed by randomized trials, which compare patient outcomes from the new diagnostic test versus the old test strategy. So, the current paper aims to focus on the practical utility of this rapidly emerging plethora of periodontal microbiological diagnostic tools, emphasizing the critical issues surrounding the clinical application of microbiologic investigations, employed for periodontal diagnosis.

Keywords: *Microbiologic investigations; Periodontal diagnosis; Clinical application.*

Introduction

A clinical diagnosis of periodontal disease does not indicate the prognosis, causative agents, progress and prognosis of the disease. For several decades, the microbiology of periodontal disease has been the focus of intense investigation. This focus is justifiable since bacteria (*A.actinomycetemcomitans, P. gingivalis, P. intermedia*, etc) are the etiological agents of periodontal diseases. Microbiological tests are used not only to identify the putative pathogens and indicators of disease initiation and progression but also utilized to observethe treatment of periodontal disease directed at the suppression or elimination of periodontal pathogenic microorganisms.[1]

Microbiological Aids:

1. **Direct Microscopy:** Dark-field or phase- contrast microscopy is the oldest method of microscopy and it is used to identify spirochetes and other motile organisms in plaque sample.[1] However, most of the putative periodontal pathogens like *Aa*, *Pg, Tf;* which are nonmotile and therefore this method cannot identify these species. Therefore this technique is not ideal for the diagnosis of periodontal diseases. This method can use to educate and motivate the patient.[2]
2. **Bacterial Culturing:** Bacterial culturing is still considered as a reference method (gold standard) against the newer techniques which are compared to establish their efficacy.[2] Generally samples are cultivated under anaerobic conditions; due to the majority of periodontal pathogens are anaerobes in nature.[3] Several systems perhaps used to create an anaerobiotic atmosphere are;

- Bio Bags
- Pre Reduced Anaerobically Sterilized Media (PRAS)
- Anaerobic chambers and anaerobic jars

Among the above, anaerobic jars and anaerobic chambers are most frequently used. These are used with a coalesce of basal and selective media for isolation of periodontal pathogens.[3]

e-mail: soumyaranjanpanda97@gmail.com

3. **Immunodiagnostic Method:** Immunologic assays recognize bacterial antigens to detect target micro-organisms. This reaction can be revealed by various procedures like; Immunofluorescent assays (IFA), Enzyme-linked immunosorbent assays (ELISA), Flow cytometry, Latex agglutination, Membrane assays.[2]

Immunofluorescent Assay: It is of two types; Direct immunofluorescent assay and Indirect immunofluorescent assay. Indirect immunofluorescent assay,the antigen is reacted directly with a fluorescein-conjugated antibody. In indirect immunofluorescent assay, the secondary fluorescein-conjugated antibody reacted with primary antigen-antibody complex.[4]

Flow Cytometry: It is also known as Cytofluorography. It allows detection of single or multiple microbes in plaque samples, based on their atypical cytometric parameters. The bacterial cell labeled with a second fluorescein-conjugated antibody and also with species-specific and after that these are undergoing for separation of bacterial cells into a single cell suspension by using flow cytometer. The implementation of flow cytometry in clinical microbiology is not yet widespread due to lack of approach or due to lack of knowledge.[5,2]

Enzyme-linked immunosorbent assay (ELISA): ELISA is the widely accepted, simple but sensitive method.[6] In this method, for labeling purposes, an enzymatically derived color reaction is used. The strength of color is directly proportional to the concentration of antigen. This method is previously used to identify the serum antibodies to periodontal pathogens but now a dayby the help of specific monoclonal antibodies, it has been also used for subgingival samples, to express the amount of specific pathogens present in this sample.[2]

4. **Enzymatic Method:**

BANA Test: The“red complex” bacteria like Porphyromonasgingivalis, Treponema denticola, Tannerella forsythia are colonizing the surfaces at or below gingival and leads to the destruction of periodontal ligament and alveolar bone. This destruction of PDL and alveolar bone causes loss of attachment to the tooth.[7] The above-mentioned species have trypsin-like enzymes and also share a common enzymatic profile.[2] N-benzoyl-DL-arginine-2-naphthylamide (BANA enzymatic test)is a rapid and reliable chair-side diagnostic test, which can give information about the bacteria by hydrolyzing the trypsin-like enzyme.[7]

During hydrolysis, it releases chromophore naphthylamide. A drop of garnet is added to the solution and the solution turns into orange-red. Positive BANA findings indicate Td, Pg, or both are present at sampled sites.[2] In this test, there is always a lack of quantitative data and they cannot identify the pathogens which do not produce trypsin-like enzyme.[6]

5. **Diagnostic Assays Based on Molecular Biology Techniques:**

DNA Probes: These DNA Probes are single-stranded pieces of nucleic acid. Under suitable conditions (pH, temperature and ionic strength), an enzyme which is labeled on DNA probesis help in hybridization with complementary single-stranded DNA or RNA and then detect micro-organisms. The principle of working of DNA probes is sequencing the DNA base.[8] Commercially available DNA probes are DMDx, Omnigene.[2]

Checkerboard DNA-DNA Hybridization Technology: In the year 1994, according to Socransky et al, DNA checkerboard is a method that gives a synchronous and significant analysis of up to 28 plaque samples against 40 microbial species.[9] The assays use DNA probes, which are labeled by digoxigenin and are whole genomic. In this technology, for identification of cells of each microbial species, the DNA probes are used and these are usually modified to allow identification of cells of each species.[2] This technique is used for ecologic studies and also for epidemiological research, because they do not need bacterial viability.[6] It does not provide an estimate of the total bacterial mass in the specific site and also this technology needs sophisticated lab equipment, which are demerits of this technique.[6]

Polymerase chain reaction (PCR): In the year 1983, PCR was introduced by Mullis and he won Nobel Prize for this discovery. The development of polymerase chain reaction is beneficial in genetic analysis for the diagnosis of genetic diseases. It has appeared as a very powerful tool, which allows development, knowledge about transcription of RNA and genes. The PCR test was able to identify periodontal pathogens (Porphyromonasgingivalis) more often than cultivation. Various category of PCR are: Nested polymerase chain reaction, Quantitative polymerase chain reaction,multiplex polymerase chain reaction Real-time polymerase chain reaction, Allele-specific polymerase chain reaction, and Colony polymerase chain reaction.[10]

Conclusion

There are many potential markers for periodontal disease activity and progression. Reinforcement of the identification of periodontal disease can be done by microbiological aids. It also can be utilized to guide the treatment of periodontal disease, so that the suppression and eradication of causative organisms can be done. In all microbiological tests, ranging from interacting bacteria thatare capable of causing periodontal diseases is difficult and the combination may differ between individuals. After all these years of intensive research, we still lack a proven diagnostic test that demonstrates a high anticipating value forthe advancement of the disease, has a proven effect on disease prevalence and incidence, and safe, simple and also cost-effective.

Ectodermal Dysplasia: An Overview

Sruti Prava Panda

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Ectodermal dysplasia is a rare hereditary disorder with a characteristic physiognomy. It is a genetic disorder mainly striking the growth or purpose of the teeth,hair, nails and sweat glands. Ectodermal dysplasia can also affect the skin, the lens or retina of the eye, partsof the inner ear, the growth of fingers and toes, the nerves and other parts of the body providing to thes pecific syndrome. All the syndrome generallyinvolves a different combination of symptoms, which can range from mild to severe. The antiquity andlessons learned from hypohidrotic ectodermaldysplasia (HED) can serve as an example for investigating the root and pathogenesis of other ectodermal dysplasia syndromes by denoting that phenotypically identical syndromes can be caused by mutations in different genes, mutations in the same gene can lead to different phenotypes and that mutations in the genes further ensue in the same indicating pathway may alter the phenotype quite profoundly. This paper aims to describe and discuss the etiology, genetic review, clinical manifestations and treatment options of this hereditary disorder.

Keywords: *Ectodermal dysplasia; Symptoms; Genetic disorder; Therapeutics.*

Introduction

The term Ectodermal Dysplasia (ED) used to a geneticchange in the ectoderm, which is characterized by faulty growth during embryogenesis in one or moretissues. The syndrome is regarded as a change of sex-linked recessive trait, while some forms of abnormality can betransmitted as autosomaldominant or recessive. According to some authors,there are two types of ED: Anhidrotic or hypohidrosis,called Christ-Siemens-Touraine Syndrome, and hidrotic, called Cloustonsyndrome. The anhidrotic was first described by Thurnam in 1848 and later by Darwin which is generally transmitted by a recessive gene linked to chromosome X. Women is the carrier of this gene and the disorder is generally seen in men,denoted by the deprivation of some dental elements, dental abnormalities like conical teeth, lack of body hair, nailmalformation and decreased sweating, and specific facialfeatures[1]. Hypohidrosis is the mostobvious feature of this type of ED consideringhidrotic ED is a rare autosomal dominant disorder characterized by dystrophic, alopecia nails, and palmhyperkeratosis. The teeth and face abnormalities rarely present, and sweating, although Coskun and Bayraktaroglustated the presence of sweat glands disorders. Ocular abnormalities include strabismus, premature cataracts, and conjunctivitis. Otherabnormalities seenare hearing reduction, polydactyly, and syndactyly. Mental development is delayed. It isevaluated that the frequency of the male population is 7:10,000 births. By compromising these individuals self esteem the social life can be changed,especially if it is a child. Loss of vertical dimension and the lip,resulting from improper development of the alveolar process lump which is caused by the absence of some dental elements is some other consequences of thisanomaly.[2] Dental changes related to ED manifest early,can be easily detected in childhood. Since patients with these conditions are

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: srutiprava9@gmail.com

usually withdrawn, shy and complexso the detection should be done as soon aspossible so that the treatment can lead to physicalemotional and social development. Treatment of patients with the syndrome is complex and must have essential action and monitoring while the development of the child to the adult stage, to raise self-esteem and restore maximum functional and aesthetic. Dental defects represent a core clinical feature of many EDs: anodontia, polydontia, dysplasticteeth, retained primary teeth, deficient enamel development (amelogenesisimperfecta), dentine deficiency (dentinogenesisimperfecta), and underdevelopment of the alveolar ridge. In some EDs, the number of erupted teeth is reduced, the spacing of the teeth disrupted, and the periodontium is affected. There are a defect of the central nervous system (CNS), the adrenal medulla the oral, nasal and rectal mucosa and their associated glands. The pharyngeal and laryngeal mucosa may be so, atrophic that it results in dysphonia and hoarseness of voice.[3]

Etiology and Frequency: Hypohidrotic ectodermal dysplasia (HED) is usually passed on as an X-linked recessive trait where the female is the carrier and is manifested in males. In X-linked form carrier mothers show minimum expression in the form of hypodontia and/or conical teeth and decreased sweating. As a carrier, the female who is not affected has a 50% chance of transferring this condition to her male child. Likewise each female offspring has a 50% chance of inheriting the diseased gene. Rapid mutation of genes is possible and can be seen in any family without any history of this condition. The prevalence in the population has been assessed as between 1:10,000 and 1:100,000 male live births. A variety of ectodermal dysplasia is caused by the mutation or deletion of particular genes that are being located in different chromosomes. As ectodermal dysplasia is caused by genetic/hereditary defects, it can be passed down to the family line. It is not necessary to have a history everytime, this can be also seen in person without any past/genetic history of ectodermal dysplasia. In this condition *de novo* mutation has taken place. Genes responsible for ectodermal dysplasia are **EDA, EDAR, EDARADD**. Mutation in *EDA, EDAR, EDARADD* gene cause hypohidroticectodermal dysplasia. In x linked hypohidrotic ectodermal dysplasia EDA is only responsible. Both *EDA, EDARADD* are associated with both autosomal and recessive forms of hypohidrotic ectodermal dysplasia.[4,5]

Genetic Pathogenesis: During embryogenic development, *EDA, EDAR, EDARADD* gene provides instructions for making proteins. These proteins (Ectodysplasin A) form a part of an indicating pathway that is censorious for the interconnection between two cell layers, the ectoderm and the mesoderm. During embryogenesis; the initial stage of the embryo, the basis for many of the body organs and tissue are formed by these cell layers. The formation of various structures that emerge from the ectoderm which involve the skin, hair, nails, teeth, and sweat glands are because of ectoderm and mesoderm interactions. When mutation occurs in *EDA, EDAR, EDARADD* gene result in faulty ectodysplasin A formation which thereby intercept normal interconnection between the ectoderm and the mesoderm and teeth. The improper formation of this ectodermal structure leads to the characteristic feature of hypohidrotic ectodermal dysplasia.[4,5]

Classification: According to Freire-Maia"s classification, EDs aredivided into two groups: ***Group A***which consists of all the entities withdefects in two or more of the standard structures, and ***Group B*** comprises of those with disturbances inonly one of these structures plus another ectodermaldefect.11 subgroups have been included in Group A depending on the involved structures: 1-2-3-4 (hairteeth-nailssweat glands); 1-2-3 (hair-teeth-nails); 1-2-4 (hair-teethsweat glands); 1-3-4(hair-nails-sweat glands); 2-3-4(teeth-nails-sweat glands); 1-2 (hair-teeth); 1-3 (hairnails); 1-4 (hair-sweat glands); 2-3 (teeth nails); 2-4 (teeth-sweat glands); 3-4 (nails-sweat glands). Similarly,Group B is classified into four subgroups with number 5 added at the end, depicting that another ectodermal anomaly is present: 1-5, 2-5, 3-5, and 4-5. Other ectodermal derived structures like mammary glands,thyroid gland, thymus, anterior pituitary, adrenal medulla, central nervous system, external ear, melanocytes, cornea, conjunctiva, lacrimal gland and lacrimal duct that may also be involved in EDs.[4-6]

Hypohidrotic Ectodermal Dysplasia: Alteration in the gene **ectodysplasin** causes Christ-Siemens-Touraine syndrome which is the most common form of ectodermal dysplasia. Ectodysplasin is located at Xq12-13, which encodes for a transmembrane protein called ectodysplasin composed of 391 amino acids. X-LHED is caused by mutation in the ectodysplasin gene. EDAR is mapped to 2q11-q13, has been implicated in an autosomal dominant and recessive form similar to X-LHED. EDAR acts as a receptor for ectodysplasin.[7]

Hidrotic Ectodermal Dysplasia: Hidrotic ectodermal dysplasia is also known as cluster syndrome. Mutation in connection gene, GJB6 causes this condition. Both males and females are equally affected. Hair loss, nail dystrophy & palmoplantar keratoderma are the characteristic features of this syndrome. Hair growth becomes very less resulting in atrichia or hypotrichosis.[8]

Clinical Manifestations: During the 1st trimester of pregnancy ectodermal dysplasia is usually seen. In severe form; it is seen before the 6th week of embryonic life where the dentition gets affected. Ectodermal structures get affected after the 8th week. Hypohidrosis is the exceptional feature of hereditary ectodermal dysplasia. HED is a clinically homogeneous condition along with major involvement of ectodermal structures in perturbed formation and maturation of teeth, hair, nails and sweat glands. Genetic studies have identified 4 subtypes of HED, by splitting the autosomal dominant and recessive form into 2 distinct entries caused by mutations in either EDAR, EDARADD Gene's. Children with hypohidroticectodermal dysplasia will have fine, scanty, light coloured hair that thickens and darkens as the patient grows up.Oligodontia of primary and permanent teeth is the most distinctive feature. Tooth are usually of conical shape. Teeth are missing both in maxilla and mandible but with a higher incidence rate in mandible. Maxillary retrusion is seen in children due to sagittally under developed maxilla.[9]

Therapeutic Aspects: A person with ectodermal dysplasia usually suffers from poor psychological and physiological development which is a result of unacceptable aesthetic and abnormal function of orofacial structures. Early treatment is suggested. Ideal treatment requires integrated efforts from pediatric doctors, psychiatrists, ENT specialists, and speech therapist. To improve appearance, mastication and speech dentist is solely responsible. Dental treatment depends on the severity of the condition. According to age, growth, and development of stomatognathicsystems of the patient the treatment varies. The goal of a pedodontist is to provide the child with an oral appliance that will provide the ideal aesthetic and function to allow the patient to develop physically, emotionally, and socially. [1-5]

For the child's growth and development consistent dental treatment is required. The ideal pattern of treatment consists of fabrication of dentures, and as the child grows the denture will be modified or replaced. During the mix dentition period, the prosthesis will require modifications to accommodate the loss of exfoliated primary teeth and the appearance of newly erupted permanent teeth. During permanent dentition, the removable prosthesis maybe replaced by fixed depending on the number and position of the teeth. Another treatment option is the use of implants. In adult use of implant has been seen but there are no clinical reports of use of the implant in growing children. [3-6]

Conclusion

Diagnosis of ectodermal dysplasia is solely based on lack or type of hair, absence of teeth and tooth buds and tooth morphology. Eczema, asthma and frequent respiratory infections may provoke the disease. Ectodermal dysplasia is a diverse group of inherited disorders that have many overlapping features. It is difficult to classify them. The clinical manifestations of ectodermal dysplasia cause significant social problems in affected individuals. Both oral and body functions are affected. A prompt diagnosis and rehabilitation by the multidisciplinary approach is the key to successfully manage ectodermal dysplasia.

Unusual facial features exacerbate the social challenges of meeting new people. Lowered self-esteem, speech defects, decreased academic performance and social isolation may result from merely looking different from one's peers. Therefore, cosmetic and prosthodontic measures should be introduced as early as possible to have the child resemble his peers. It is also important to inculcate awareness among parents regarding early management. To ensure adequate care, a child with ectodermal dysplasia should be managed by a team which includes pediatrician, pediatric dentist, prosthodontist, dermatologist, otolaryngologist, speech therapist, and psychologist. However, an appropriate change has to made in the denture so that the appearance is always appropriate for the age. Relining or change of dentures should be done every 1 or 2 years due to preadolescent growth in jaw dimensions, wear of the acrylic teeth, under the extension of the dentures and posterior open bite.

Plaque Control with Newer Dimension in Children

Harshita Singh

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Plaque management is the routine removal of dental plaque, oral biofilm and also the avoidance of its accumulation on the teeth surface and other adjacent parts of the oral cavity. Occurrence of the common gingival and the periodontal diseases in the oral cavity is due to the presence of dental plaque which is the utmost primary etiological factor related to this. Dental caries along with periodontal disease are the major diseases that start very early during childhood and which should be stopped before the gradual onset of the disease. Dental plaque management using distinct approaches and agents benefit track the onset of periodontal diseases. An aggregation of multiple oral hygiene edification and mechanical skilled teeth brushing at regular time intervals will avoid the progression of dental caries and periodontal diseases almost entirely. Hereby, this article provides an overview of mechanical plaque control approaches with certain changes to include children and adolescents for successful dental plaque management.

Keywords: *Plaque control; Dental plaque; toothbrush; oral biofilm; Dental floss, Periodontal diseases*

Introduction

One of the most important changes in dentistry has been the advent of modern theory and dental care focused on prevention and not any substitution. Despite these significant health changes,dental disorder appears to be a persistent health issue.[1] The two dominant dental illnesses begin in childhood, namely dental caries and periodontal disease, and have long sequelae. Before the insidious onset of these conditions, primary preventive dental care should start early in life. The key etiological factor for the development of periodontal diseases is the dental plaque, which is a common but highly variable structural entity resulting from colonization and growth of micro-organisms consisting of different species and strains embedded in an extracellular matrix. Biofilm formation inhibition and mechanical removal tend to be the leading procedures for dental caries and periodontal disease prevention and treatment.[2] Specific routine oral hygiene is essential for oral health by brushing and using other aids in accordance with professional plaque inspection. This article focuses on efficient plaque management procedures with significant advances in oral disease prevention and good oral hygiene maintenance.[3]

Dental plaque: Dental plaque, also referred to as "Oral Biofilm, " maybe characterized just as the smooth tenacious substance adhering the tooth surfaces which is not easy to get rid of by just rinsing with water, although seeing more precisely, it is a variably specific structural entity resulting from the salivary glycoproteins and extracellular microbial products in the form of a biofilm-forming on the hard, non-shedding surfaces in the mouth. Dental plaque is mainly composed of both organic (polysaccharides, protein, glycoproteins from saliva, lipid) and inorganic (Ca, Na, P, K, F and GCF). It is mainly classified as two types the supragingival and subgingival dental plaque.[4-7]

Importance of plaque control: Dental plaque is directly linked with dental diseases. There is a clear correlation between plaque and gingivitis and it would be prudent to consider temporal factors because it is determined that the best way to avoid periodontal disease

e-mail: harshitasinghb14@gmail.com

is by introducing adequate plaque control steps. Plaque management decreases the risk of periodontal diseases. Thus, the personalized use of mechanical and chemical agents to prevent the onset of diseases is necessary.[8]

Mechanical plaque control aids: The most commonly used oral hygiene aid by William Addis first invented in 1780 is by far the most widely known and accepted method of teeth cleaning. Toothbrushes plays an exceptional role in the prevention of periodontal diseases and their progression is very significant.

The various mechanical aids are:

Toothbrush, Depending on function: Manual & Powered

Depending on the diameter of bristles: Soft, Medium, Hard, Interdental Aids, Dental floss, Interdental brushes, Wooden tips, Tongue Scrapers

Table 1. ADA Specification of toothbrush

Length	1-1.25 inches
Width	5/16 to 3/8 inches
Rows	2-4 rows/bristles
Tufts	5-12/row
Bristles	80-86/tuft

NEWER TOOTHBRUSHES MODIFICATIONS

Powered toothbrush: The first electric toothbrush came much later and was first used in the 1960s as an alternative to manual toothbrushing process. Brush head present in the powered toothbrush act as a power source which provides different motions. Earlier, it was introduced with movement back and forth. Powered toothbrushes display different modes of movement, such as oscillating/rotating, side-to-side (sonic), and counter-oscillating, circular motion, which makes them useful. Later on, numerous studies have confirmed that powered toothbrushes when compared with manual are more effective.[9-12]

Ultrasonic toothbrush: The ultrasonic toothbrush is a manual toothbrush, in which the brush head is mounted in a Piezoelectric ultrasonic emitter which is operated by a power supply in the handle at 1.6 MHz. The ultrasound force killing plaque and the smooth, gentle healing wave action of sonic vibration reach the gumline to a depth of 5 mm. Emmi-dent is the first ultrasonic toothbrush to have its non-abrasive nano-bubbles toothpaste produced. The se brushes can be used immediately after undergoing oral surgery, like that of implants. It is mild enough to prevent damage to the teeth and gums. It is very painless for the use in areas with sensitivity along the teeth and gingival areas.[13]

Ionic toothbrush: Ionic toothbrush operates on the polarity principle, that each element in nature has a positive or negative charge. Plaque removal is improved by ionic interaction, along with the natural mechanical action of the bristles on the tooth surface.[14]

Chewable toothbrush: It is a minuscule pliable tooth-brush that are feasible for value without water. There stand availability of various flavors in the market like mint, bubblegum. Bristles are attached with smaller sized toothpaste stick which are breakable and made of plastic. The best about a chewable toothbrush is it can even be used in the absence of water, proving it useful for small children.

Tooth towelettes: If tooth brushing is not possible it is an effective plaque removal process. Finger brushes are mounted on the index finger of the brushing hand, and the agility and sensitivity of the finger are used to clean the teeth.

Foam brushes: Foam brushes imitate a plastic fluffy sponge soaked on a stick with chlorhexidine. They are used particularly in medically compromised and immunocompromised patients to reduce the risk of oral and systemic infection.[15]

Interproximal Brushes: The above-mentioned brush mainly the cone-shaped that are manufactured along with the presence of bristle that is arranged above the handle of the brush and can be exceptionally used for scrubbing the broad, irregularly placed, or else the round tooth surfaces present adjoining the immense interdental space and widely purchasable in various size.

End-Tufted Brushes: They are a category of toothbrush that is used to clean along the gingival sulcus present bordering the teeth surface. Bristles are designed in a sharp arrow decoration which enables nearer gum adaptation which is suitable for cleaning along the areas between crowns, bridges, misalignment teeth, and fixed orthodontic appliances.[16-18]

Interdental Cleaning Aids:

Dental Floss: Dental floss is a very common interdental cleaning process. Supragingival and

subgingival dental plaque is successfully removed by flossing but requires manual effectiveness.

Powered flossing devices: One of the latest advances in mechanical plaque control is the powered flossing device. These consist of nylon tips that move quickly between the teeth and are very sensitive to the gums. The se are equally effective as the manual ones.

Wooden Tips: These are smooth, triangular-shaped tips that could be positioned in the gingiva and slip in interdental space through contact to the surface of the proximal tooth. Along with soft debris removal also decreases the gingival inflammation.[19,20]

Oral irrigation: A dental water jet or else the water flosser in other words well-known as the oral irrigator (OI) act as an electrical system that conveys a pulsating fluid stream (including chlorhexidine, stannous fluoride, iodine solution, antibiotics such as 5% tetracycline hydrochloride) utilizing controlled pressure aimed at removing interdental furthermore subgingival plaque biofilm covering tooth surfaces to lower inflammation as a result of inflammation. It is a power directed or else non-power directed device which provides a marked function of a pulsed or substantial water stream for debris removal.It is an additional aid in oral hygiene. This method is healthy and provides the general public with benefit for gingival safety,but does not routinely clean the interproximal spaces. One such device is Waterpik is an oral irrigation system which consists of a reservoir and a handle with replaceable tips,which varies according to use.[21]

Dentifrices: Toothpastes consist of sodium fluoride and monofluorophosphate are found to be communally available as Cheerio gel and Colgate (fluoridated along with anti-carious properties)to remineralize carious lesion. Brushing twice a day after 3 years with the use of fluoride-containing toothpaste and brushing in-between the teeth day to day with floss or with any other interdental cleaner is endorse. The se are effectual in the degradation of plaque as well as gingivitis.[22-25]

Conclusion

With recent advancements and changing lifestyles, it's very important to look after ones personal hygiene approach which includes the most important one the oral hygiene. Good oral hygiene reduces the risk of periodontal problems and dental caries. Dental plaque is one of the most important factors causing dental problems must be effectively reduced and prevented. The most effective way to get rid of the frequent dental plaque accumulation is through mechanical plaque monitoring. The se recent advancements should be started in daily practice,which will reduce plaque accumulation and are less time-consuming. Further developments are on the way which may reduce and control plaque easily, and effectively within seconds.

Complications of Local Anesthesia

Stutishree Tripathy

Intern, Institute of Dental Science, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003,Odisha, India

Abstract

This chapter is presenting the local and systemic complications associated with the local anesthetics used in oral and maxillofacial surgery. The prevention of complications and management method are also given importance. Dental procedures are frequently performed under local anesthesia; thus, drug-related complications often come across. It is mandatory to have a preoperative evaluation of the patient and choosing the proper local anesthetic agents.

Keywords: *Local anesthesia, complication, systemic complication, local complication, treatment*

Introduction

Local anesthesia is defined as a loss of sensation in a circumscribed area of the body caused by depression of excitation in nerve endings. Local anesthetic agents have been used in clinical dentistry to eradicate pain associated with invasive operations. It is also used in oral and maxillofacial surgery. [1]

Composition:

- Local anesthetic agent: lignocaine hydrochloride (2%)
- Reducing agent: sodium meta-bisulfite
- Preventive agent: methylparaben
- Diluting agent: distilled water
- Fungicide: thymol
- Isotonic solution or ringer's solution: sodium chloride
- Vasoconstrictor agent: adrenaline

Complications: Various complications of local anesthetics can be evaluated systemically and locally. Common systemic reactions due to local anesthesia are reported as psychogenic reactions, systemic toxicity, allergy, and methemoglobinemia. Common local complications associated with local anesthesia are given as pain at injection, needle fracture, prolongation of anesthesia and various sensory disorders, lack of effects, trismus, infection, edema, hematoma, gingival lesions, soft tissue injury, and ophthalmologic complications.[2]

Local Complications:

Trismus: Also called lockjaw, is reduced opening of the jaw. May be caused by spasm of the muscles of the mastication. Several factors cause trismus such as multiple injections in a short period in the same area, intramuscular injections inside the muscle which cause hematoma formation and fibrosis, needle fracture in the muscles inserting to styloid process, inaccurate positioning of the needle when giving the inferior nerve block and other masticatory muscles, a low-grade infection. Excessive volumes of local anesthetic solution deposited into a bounded region which causes expansion of tissues.

Cause:

Intraarticular: Ankylosis, Arthritis synovitis

Extra-articular: Infection (Odontogenic & Non-Odontogenic)

Odontogenic: Pulpal, Periodontal, Pericoronal

Non-odontogenic: Tonsillitis, Tetanus, Meningitis, Brain abscess, Parotid abscess

Trauma: Fractured mandible, Fractured zygomatic arch

Infection: Infection may extend to tissues by penetration of the needle through a contaminated tissue, because of the needle being contaminated before an operation. A latent viral infection may be reactivated due to the trauma of the procedure which may be responsible for neural sheath inflammation. Antiseptic mouthwash solutions such as chlorhexidine gluconate should be taken for all regional techniques. The local anesthesia should not be injected through the infected area.[3]

Edema: Swelling of tissues can be due to trauma during injection, infection, allergy, hemorrhage, and injection of irritating solutions. The management of edema is dependent on the cause. Allergy-induced edema treatment consists of intramuscular epinephrine injection as mentioned above and, additionally, antihistamine and corticosteroid administration and consultation with an allergist to determine the precise cause of the edema. Trauma-induced edema should be managed as a hematoma. For the treatment of edema produced by infection, antibiotics should be prescribed.[3-6]

Hematoma: Hematoma formation as a complication of local anesthesia. It is an abnormal collection of blood outside of a blood vessel. It occurs because the wall of a blood vessel, artery, vein, or capillary has been damaged. And blood has leaked into tissues where it does not belong.

Symptoms: Pain, Swelling, Redness

Gingival lesions: Gingival lesions consist of recurrent aphthous stomatitis. Isolated lesions of gingival arise in succession to the hyperinflammatory reaction. No management is necessary until there is severe pain. To relieve pain, topical anesthetic solutions (e.g., viscouslidocaine) may be used on affected areas. Triamcinolone acetonide without corticosteroid can remedy pain.

Soft tissue injury: Soft tissues which include the tongue, lips, gums, and lips are injured when they are accidentally be bitten while eating or in an accident, or when hot food is kept inside the mouth. Chewing on hard objects also damage soft tissues. And the main symptoms are persistent, throbbing pain.[3-6]

Treatment of gum trauma:

- Rinsing the mouth out with salt water, helps to keep the woundsclean.
- If the bleeding in the mouth is particularly heavy some gauze is applied to stem the flow of blood.
- An ice pack or cold compress is also used to reduce swelling in the mouth.

Wounds in the oral cavity heal faster still being less cared than the wounds in the other parts of the body. Saliva creates a humid environment which improves the survival and functioning of inflammatory cells that are crucial for wound healing. Saltwater has a disinfectant quality which in turn helps in healing the wounds at a faster rate.

Pain on injection: Pain on injection can be due to specific circumstances such a temperate of the solution, velocity of injection, dull needles, damaging soft tissues, blood vessels, nerves, or the periosteum and causing more pain and other complications. It can be very distressing to the patient. The rate of injection and the acidity of the solution are the main factors on which burning depends. Lidocaine causes an intense burning sensation when injected locally. When the needle penetrates a nerve, the patient may also feel a sudden “electric” shock, suddenly moving the head, with the risk of self-inflicted damage. Local anesthetic administration with intradermal or subcutaneous lignocaine infiltration is associated with discomfort.[4]

Factors contributing to the pain during local anesthesia:

- Number of injections
- Size of the needle
- Amount and type of anesthetic
- Level of anxiety of the patient

Sodium bicarbonate was added to the local anesthetic solution which reduces the stinging sensation caused by adrenalin. Bupivacaine was used local anesthesia is used for a longer time. Topical anesthetic is applied to prevent the discomfort of the patient during injection. Switching to a fresh needle is the utmost important work when injection is applied multiple times to the same lesion.[5]

Needle fracture: Needle breakage in the oral cavity after local anesthesia is a rare complication, since the use of non-reusable, stainless steel dental local anesthetic

needles. In most cases, needle fracture happened with 30-gauge needles and during inferior alveolar nerve block, as a result of either wrong injection technique, improper choice of hypodermic needle magnitude, or unexpected motion of the patient or assistants. The needle may damage the intraneural blood supply, resulting in a hematoma or the needle may traumatize the medial pterygoid muscle which results in trismus. When seen in a case of a broken needle, the foremost duty is to remove the broken needle with a hemostat. In case, it is not accessible, a CT scan can be the method for accessing the broken needle by operating the patient under general anesthesia. If a nerve is damaged due to dental local anesthesia, the first treatment should be managing the pain. Only the use of high concentration agents' infiltrations is the source to decrease nerve injury caused due to local anesthesia and to avoid inferior alveolar nerve blocks which in turn prevents frequentative injections.[6]

Systemic Complications:

Systemic Toxicity: Systemic toxicity means toxicity at a cellular level that causes failure of organ leading to the possible death of the organism.

It can be of three types: Acute, Subacute, Subchronic

Local anesthetic systemic toxicity develops when a toxic concentration of anesthetic drugs in the blood level reaches to the central nervous system and cardiovascular systems. Initial symptoms are characterized by central nervous system signs such as excitation, convulsions, followed by loss of consciousness and respiratory arrest. These symptoms are often accompanied by cardiovascular signs such as hypertension, tachycardia, and premature ventricular contractions. Predisposing factors are associated with age, weight, other drugs, gender, the presence of disease, genetics, vasoactivity, concentration, dose, route of administration, the rate of injection, vascularity of the injection site, and the presence of vasoconstrictors.[7]

To prevent systemic toxicity, these should be followed:

- The patient should be evaluated.
- The volume of local anesthesia should be decreased,
- Accurate and slow injection technique,
- Adjustment of dosage divided administration
- Aspirating technique, using agents with low toxicity such as ropivacaine and levobupivacaine.

Allergy: Allergy is also known as hypersensitive reactions. Two types of reactions are involved in allergic reactions to local anesthetics: Immunoglobulin E mediated type I & Tcell-mediated type IV reactions. Allergic reactions may include mild symptoms, such as urticarial, erythema, and intense itching, as well as severe reactions in the form of angioedema and/ or respiratory distress. Before the LA is injected in a person's body, first a skin prick test is done to observe if any kind of reaction is taking place in the person's body. If the test result is seen negative intradermal testing is performed. Intradermal tests are performed by beginning with a lower concentration of the potential allergen and gradually increasing its concentration. Although rare, adverse effects from local anesthetic may be encountered at any time in clinical settings. In these cases, it is important to determine whether the patient is having an allergy. And if a local anesthetic that does not cause adverse effects can be identified, then that drug should be used for local anesthesia in performing dental treatments. If no such drug is available, then the use of general anesthesia might be unavoidable.[8]

Anaphylaxis is an acute potentially life-threatening hypersensitivity reaction. The clinical symptoms of anaphylaxis are depending on the organ systems involved. Uncontrolled co-existing asthma, mast cell disorders, and patients with specific allergens such as peanut and tree nut allergy are the risk factors for anaphylaxis.

Methemoglobinemia: It is a blood disorder in which an abnormal amount of methemoglobin is produced. Hemoglobin is the protein in the red blood cell that carries and distributes oxygen to the body. When methemoglobinemia, the hemoglobin can carry oxygen, but it is not able to release it effectively to body tissues. Methemoglobinemia is a unique dose-dependent reaction where the iron in hemoglobin is stabilized in the ferric (Fe3+) form, unable to attach oxygen.[9]

Causes: Congenital & Acquired

There are two forms of inherited MetHb:

- **Type I:** erythrocyte reductase deficiency, occurs when RBCs lack the enzyme
- **Type II:** generalized reductase deficiency, occurs when the enzyme does not work in the body.

Symptoms of cyanosis will be observed in nail beds and mucous membranes. In more severe cases, headache, dizziness, fatigue, dyspnea, and tachycardia are seen. Management of methemoglobinemia begins with supplemental oxygen (100%) immediately. As a guideline, methylene blue, which is a heterocyclic aromatic chemical compound increasing the rate of conversion of methemoglobin to hemoglobin.

Psychogenic reactions: The patient's body counterbalance to an anxiety-inducing situation or adrenaline secreted by the vasoconstrictor agent are the main factors associated with the psychogenic reactions. Due to psychogenic reactions mood change, respiratory rate, heart rate, blood pressure is also affected. Relaxation of the patient before administering local anesthetic injections is important for the prevention of psychogenic reactions. Using oral sedatives is an effective method to manage dental fears. Patient's physic such as health, age, weight and duration of operation are the main factors for the initial dosage of local anesthesia.[10]

Conclusion

Complications from local anesthesia are often due to overdosage. Predisposing factors, such as the patient's age, weight, state of health, and other medications that the patient may be taking may cause increased free local anesthetic blood levels due to a lack of plasma proteins available for binding. During administration, both the rate of injection and the route of administration can also have an impact on the dosage effect, as rapid injection can lead to increased plasma levels of local anesthetic. Drug factors may also be related to overdosage. While administrating anesthesia, the painless injection should be performed, avoiding intravascular or intramuscular or direct trauma to the nerve. The best way to avoid nearly complications relating to the administration of local anesthetics is to use the right technique and to have a good knowledge of the anatomy of the trigeminal nerve and the adjacent anatomical structure. Concluding the article by the statement that "**New developments should be followed by the practitioners to reduce possible complications associated with the local anesthesia".**

Role of Interleukin (IL-1β) In Periodontal Disease Progression: A Literature Review

Lipsa Behera[1], Abhaya Chandra Das[2], Sourav Panda[2], Rashmita Nayak[3], Rinkee Mohanty[3], Gatha Mohanty[4]

[1]Intern, Institute of Dental Sciences, [2]Reader, [3]Professor, [4]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan, (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Interleukin (IL)-1B, a proinflammatory cytokine, was uplifted and engaged in periodontal disease progression. And also the linkage in the middle of IL-1B and periodontal disease progression was manifested by clinical documentation; similarly, the expanded IL-1B activates a succession of erythrogenic responses and encourages the bone resorption. At present, IL-1B blockage has been a medicinal plan of action for autoimmune disorder and autoinflammatory diseases such as rheumatoid arthritis, cryopyrin-associated periodic syndromes, gout, and type 2 diabetes. It is theorized that IL-1B be an inherent remedial target for periodontal disease. The review emphasizes the manufacturing, implementation, available treatments, and future potential plan of action for IL-1B in periodontal disease.

Keywords: *Bone resorption, interleukin IL, proinflammatory cytokine, periodontal disease.*

Introduction

Tooth supporting tissues get hold of contamination due to periodontal disease which is an erythrogenic disorder and tooth losing persuade in due course.[1] Microbiological variance of the host and oral microbial flora are disintegrated below the cytology of periodontal disease.[2] The stability of chronic inflammation gets hold by a miscellaneous moderator. The provocative cytokines embrace of IL-1B, tumor necrosis factor (TNF)-α, IL-6 & IL-17, which lead the way to periodontal infection and tissue trauma. One more category incorporates regulative cytokines such as IL-10. IL-β is a strapping stimulator of periodontal tissue demolition.[3] The properties of IL-1B incorporate further bone resorption and as well as the production of tissue demeaning proteinases. Except for periodontal disease, pro-inflammatory lymphokines such as TNF-α, IL-1B, and IL- 6 regulate intrinsic diseases. Consequently, cytokine-grounded plan of action have the prospective to enhance both periodontal disease and systemic health.[4] This review anchors on new cytokines based strategies associated with IL-1B in periodontal disease progression.

As unhealthy cytokines, IL- 1B engage in infection, unsusceptible proclamation, and bone reabsorption in periodontal disease.[5] The clinical discovery furnishes strong documentation about its consequences. The biological reverberations of IL-1B turn on its tissue engrossment, which is upraised in periodontal disease. Strengthen the extent of IL-1B is repeatedly recognized in the saliva and gingival crevicular fluid (GCF) of a patient with periodontal disease differentiated with healthy guidance.[6] Patients with profound pocket depths and more relentless bleeding on probing (BOP) have enlarged the intensity of GCF IL-1B. Besides, serum IL-1B in patients with persistent periodontal disease also holds to a high-rise in magnitude, counting an

e-mail: drabhaya2011@gmail.com

intrinsic reverberations. This discovery exhibit that IL-1B is a practicable uninhibited linkage in the middle of periodontal disease and intrinsic diseases such as cardiovascular diseases. The bob-like receptor proteins-3 (NLRP3) apoptosome indicating passageway, which is accorded to the invigoration of IL-1B, is convoluted in the periodontal pathologic process. The mRNA proclamation of the NLRP3 apoptosome compound was strengthened both gingival inflammations as well as in periodontal disease progression.[7]

Production of IL-1B in Periodontal Disease Progression: Phagocyte and antigen-presenting cells are predominantly indicated by IL-1B. Although, gingival fibroblasts, periodontal ligament cells, and osteoblast cells can also exude IL-1B.[8] The excretion of IL-1B is distinctive. The lymphokines are initially assembled as a proprotein, which is successively proteolyzed towards its agile conformation through caspase-1.[9] The indolent progenitor, pro-IL-1B, is processed in retaliation to microorganism- correlated molecular design. PAMPs and DAMPs concern via design identification of anatomical structure, for example; toll-like receptors, to trigger the signalize adaptor myeloid progenitors demarcation principal retaliation 88(MyD88). MyD88 exhilarating reaction in humiliation of IL 1B as a consideration for the rescue of NF-Kb subdued and in consequence which stimulate to pro-IL-1B dissemination.[10]

Pro-IL-1B is assembled as a biologically immobile configuration that must be proteinase split to obtain ascetic recreation. Caspase-1, to begin with, acknowledgment as an IL-1-transforming enzyme, is up to split pro-IL-1B, directing to the terminating emission.[9] Caspase-1 come in for invigoration by a multimolecular assemblage also called as the apoptosome. Apoptosomeis unflustered of the sensor (PRRs including NLRP1, NLRC4, Pyrin, and AIM2), the adaptor ASC (apoptosis-associated spec-like protein containing a CARD), and caspase-1. As yet, almost all considerations have engrossed on the NLRP3 apoptosome is triggered in retaliation to a variation of PAMPs and DAMPs as shown in figure 1. In macrophages, NLRP3 apoptosome invigoration is suggested to be a two-signal route.[7] The primary gesture is prepared, which is persuaded by microorganisms or else internal stimulants that encourage NLRP3 and pro-IL-1B utterance throughout the invigoration of NF-Kb. The subsequent gesture is prepared, which is activated by estranged ATP, pore-forming contamination, and gritty proceeding detectors, which operate the NLRP3 apoptosome and caspase-1 and cleave pro-IL-1B under its full-grown configuration.[10] The protein gasdermin is an additional substance of active caspase-1. Active caspase-1 cleaves gasdermin at the N terminus and C terminus. The N terminus of gasdermin line orifice on cytomembrane and successively instigate programmed cell death (pyroptosis).[11]

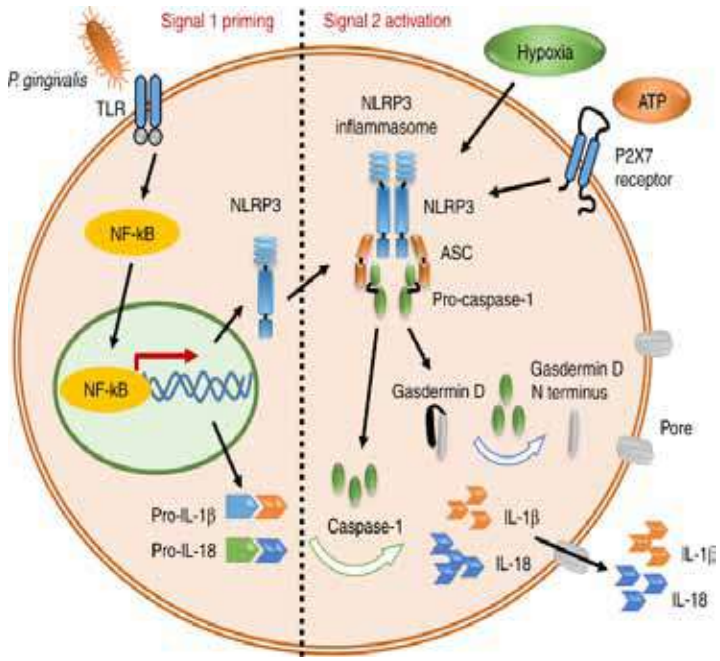

Figure 1. The Two Signaling Pathway For the activation of the NLRP3 apoptosome in periodontal disease progression.

Role of IL-1B In Periodontal Disease progression: In the wake of production, the assembled IL-1B set off a succession of erythrogenic response and engages in the morphology of periodontal disease. Predominantly, IL-1B in the erythrogenic exposition for lengthening internal blood circulation, erythrocyte stipulation, and leukocyte percolation. Besides, IL-1B reacts as a strong impetus of bone constriction, producing a recommended cytokine in periodontal disease. The considerable working is manifested in figure 1.[10]

IL-1B intensifies the proclamation of collagen breaking enzymes, matrix metalloproteinase (MMPs), that cough up to extravascular matrix humiliation, and sequentially guide to bone constriction and tissue demolition. MMP-9 is a principal guideline of the extremity and continuance of periodontal disease. IL-1B deregulation MMP-9 declaration in varied cell types intricate in periodontal disease, as well as bone-forming cell (osteoblast), resorption of bone tissue, and leucocytes, and cementoblast cell as shown in figure 2.[12]

The bodily structure catalyst of inherent feature Kappa-B ligand (RANKL) and osteoprotegerin (OPG) arrangement to synchronize osteochondrosis. Expanded RANKL and accordingly affects osteochondrosis.

RANKL is an anatomy of the integument- correlated TNF substance suborder and is perceived on osteoblasts, bone marrow connective tissue, triggered T cells, periodontal ligament melanocyte, cementoblasts, and endothelium-dependent cells.[12]

RANKL holds together its anatomical structure, receptor catalyst of NF-kB(RANK), indicated on the bone cell predecessor cells, evolving in the invigoration of the bone cell. The conclusive of RANKL to RANK eventually triggers the evidence of NFATc1, c-Fos, and NF-Kb-associated with genetic code, which are extended in periodontal disease and moderate the multiplication, distinction, and invigoration of bone cell. IL-1B too modulates the manufacturing of OPG, and which is a dissolvable cellular structure for RANKL that intercepts it from unalterable to RANK. The OPG administration is transformed by IL-1B and has been correlated with bone transfiguration.[12]

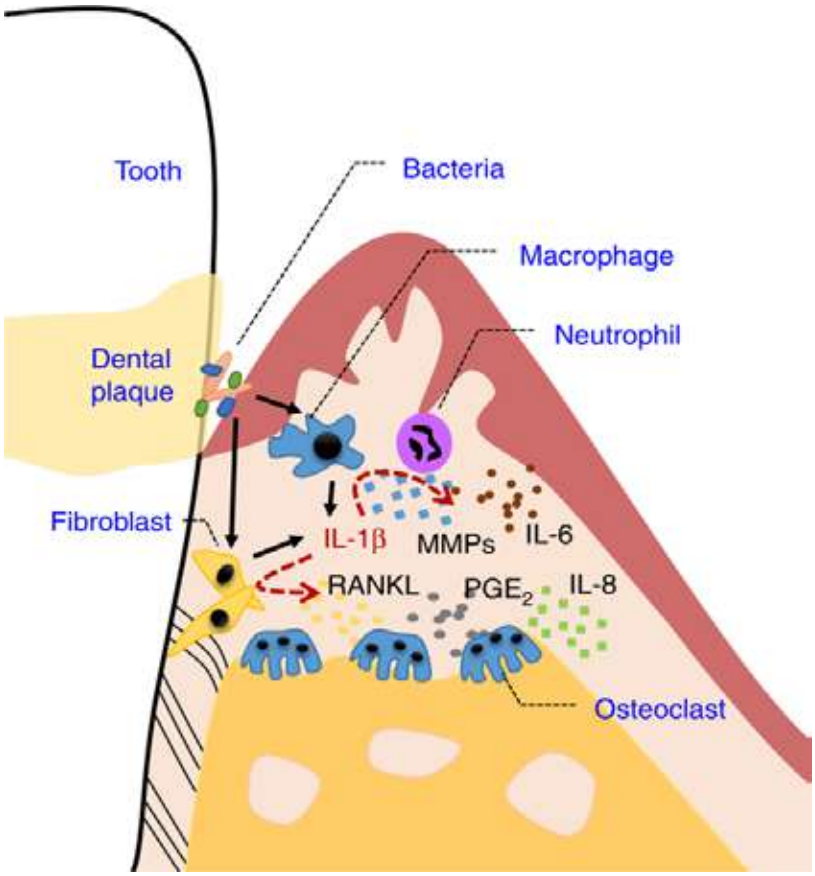

Figure 2: Role of IL-1B In Periodontal disease

Influence of Current Therapies on IL-1B: The following periodontal therapy is done for the treatment of periodontal disease, which may influence IL-1B.

Scaling and Root planing (SRP) and surgery: The minimum interfering and medical procedure therapy to put a stop to and domination to periodontal disease are SRP which is worthwhile too.[2] Although, the involuntary therapy may potentially be insufficient in abolishing the pathological microbes. The extent of unhealthy interferons may be uninterrupted towering after therapy. Precursory wok establishes that SRP did not crucially beneath the IL-1measure. Various contemporary studies also manifest that the IL-1B volume is reduced in the wake of SRP therapy.[13] SRP effects in a reduction in the volume of IL-1B in GCF or saliva. Although, the aggregate is stock-still elevated than in the fit grouping. Also, an evident expansion in the IL-1B volume is encountered featureless in the wake of papillose flap surgical procedure, which propounds that injury and sore relieve effect in lengthening construction Of IL-1B.[13]

Because of the substantial access by SRP, the requisitioning of plaque and transferable cells can be declining in a few areas. Admitting SRP therapies are efficacious in diminishing clinical limitation, it is inadequate in the pro incendiary therapy for enlarged conciliator. Consequently, few helpful treatments have been looked over for this reason.

Antibiotics: The district and organized management of sulfa drugs are subordinate therapy for periodontal disease. Medication as an example (antiprotozoal) metronidazole, roxithromycin (Z), Vibramycin, and augmentin are consistently taken. Objective work has manifested that sulfa drugs assist clinical limitation. Although, its outcome depend on IL-1B is restricted.[14]

The local management of minocycline microcapsules in alveolar resorption during periodontal preservation remarkably diminishes IL-1B in GCF at 5 months. Although, there are no differences on top of 22 months. The integral management of augmentin and antiprotozoal drug is an ancillary therapy for antagonistic periodontal infection.[14] This therapy decreases the IL-1B volume in GCF at 2 months, though it has no outcome at the 5 months check out. Roxithromycin (z) remedy is put in cyclosporine-A- persuades gingival growth. Though, there is no result on the volume of IL-1B.Although, sulfa drugs at or under minimum diffidence applications expand IL-1B production in phagocytes by convincing themto get rid of LPS by *P. gingivalis*.[1]

Laser Therapy: Lasers conceivably applied in a single agent, as an addition to SRP, or in a treatment for opening. Laser treatment on condition that nominal opening of soft tissue and biostimulation results on tissue reconstruction.[15]

Laser treatment remarkably improves clinical limitation, as well as the plaque guide, gingival guide, probing depth, and clinical attachment level as well as BOP.[16] The pathogen limitation IL-1B and TNF-α were turned down as well. Laser treatment lessens IL-1B in aggressive periodontal infection as well as chronic periodontal infection. Though, SRP added to the ancillary utilize of diode laser treatment did not decrease GCF IL-1B volume differentiated to SRP singly, neither it diminish the disease in areas with greater than 5mm PD.

Various categories of lasers are furthermore efficacious in a few specified clinical sites. As Suggested, the laser conceivably applied to cut out gingival tissue and was the at most laser for attainable periodontal reconstruction.[16] The attending corroboration manifests that the laser was even productive in diminishing IL-1B. Although, large indication regarding the varieties of lasers, the difference in wavelength is the most vulnerable criteria required to appraise laser treatment.

Antimicrobial Photodynamic therapy: It is a disinfectant therapy. The treatment is oxygen restricted photochemical reaction that takes place on high light set off invigoration of a definite photo activation combination.[17] The response eventually guides to the fabrication of toxic cells susceptible to oxygen order, for the most part singlet state oxygen, which makes away with pathogens as well as viruses, microbes, and fungi. Due to its disinfected outcome, Antimicrobial Photodynamic therapy beside with SRP is commanding and efficacious in the therapy of periodontal disease.[17] Antimicrobial photodynamic therapy plus SRP developed in a remarkable depletion in probing depth and a repression of IL-1B and MMP-8 in GCF when differentiated with SRP singly Antimicrobial Photodynamic therapy as well as a ratio in GCF when differentiated along with SRP singly. Differentiated along with systemic application of antiprotozoal medication, Antimicrobial photodynamic therapy remarkably let down the pathogen burden and IL-1B volume of the gingival sulcus of rats with periodontal disease. These effects recommend that Antimicrobial Photodynamic therapy has a disinfecting outcome on IL-1B.[17]Generally, typical therapy, together with SRP,

surgery and sulfa drugs, has restricted consequence on IL-1B.[17] Few more auxiliary therapies, along with laser treatment and antimicrobial photodynamic therapy, are analogously highly systematic than normal therapies. Few probable auxiliary therapies might be a newer plan of action to object IL-1B.

Conclusion

IL-1B is a major provocative cytokine take part in periodontal disease progression. As a strapping encouragement for bone constriction, uninterrupted bone deprivation may be persuading by IL-1B. Standard treatment, sulfa drugs, surgery, and SRP have restricted consequences on IL-1B. IL-1B obstruction by blockage, receptor competitors, plant acquired material, agglutinogen, and anti-inflammatory drug factors are advantageous for diminishing IL-1B obstruction to be applied in periodontal disease cure or as an auxiliary therapy in the subsequent.

Recent Advances in Surface Characteristics of Dental Implants: A Mini Review

Pooja Mohanty[1], Manoj Kumar[2], Saurav Panda[2], Rinkee Mohanty[3], Rashmita Nayak[4], Anurag Satpathy[4]

[1]Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, India, [2]Associate Professor, [3]Professor and Head, [4]Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

Implants have become an integral part of dentistry today and are widely being used for the replacement of missing teeth. A considerable amount of advancements has come in Implant dentistry including the quality of material, surface coatings and processes, and the surgical techniques as well. This review will deal with the implant surface design and its characteristics which have been done till now to enhance the implant-bone contact resulting in better osseointegration and subsequent long-term success of dental implants.

Keywords: *Dental Implants, Osseointegration, Surface coatings.*

Introduction

The idea of permanently being able to replace the teeth has been a desire of civilization since the days of the Egyptians.[1] Periodontitis is the common cause for missing teeth but except that, other causative factors are dental caries, trauma, and genetic disorders.[2] For replacement of the missing teeth, there is various types of materials have been used into the jaw in ancient ages,but the demerits of these materials are, never able to achieve a stable state with surrounding tissues.[2] But luckily our modern dentistry introduces many dental implantation method that are much more successful & painless than previous method of implantation. In the 1950s, Dr. Per-Ingvar Branemark in Sweden discovered an implant with titanium which has sufficient strength to cope with load transferer and named this phenomenon as "Osseointegration".[1] Modification in generally the surface of implants results in exceptional osseointegration.

Surface Design of Implant:

Before the current implant systems, which are used today; there were various implant systems with geometric designs have been developed.[3] Some common designs of implants are listed below:

1. **Endosseous Implants:** These implants are created to utilize a vertical column of bone, similar to the root of the natural tooth.
   - Bladelike
   - Pins
   - Cylindrical
   - Disk like
   - Tapered type
   - Screw type
   - Both tapered and screw type
2. **Subperiosteal frame like implants:** These are used in the treatment of atrophic mandibles.[3]
3. **Transmandibular implant:** These are developed to retain dentures in the edentulous lower jaw.[3]

The implant microstructure is represented as threaded or nonthreaded. Threaded type is most commonly used now a day. 3 threaded shapes are most commonly used: V-shaped; Square shaped; Reverse buttressed. Threaded implants also classified as self-tapping or pre-tapping.

Surface Characteristics of Implant: It has been shown thatthe healing process improves positively by the surface characteristics which are also called as microtopography of implant.[3] Surface roughness is an important componentinthe osseointegration of the surface of the implant. Roughness in surface of implant shows reinforcement of osteoblastic action at 1 to 100 μm in comparison of smooth surface.[2]

Modifications in Surface Characteristics of Implant: Over the past 15 to 20 years, improvement of implant surface characteristics has been a major area of research interest and development.[3] Modifications of the surface of implant has been investigated and implemented to progress biologic surface properties favouring osseointegration.[2] Modified implant surfaces shows an increase in adsorption of cytokines, mineral ions and proteins; which results in cellular migration and attachment at the molecular level.[3] To improve the quality of bone formation, modification of surface characteristics (microscale or macro scale) is important and it is only possible by treating the implant by various technology, which is already done by today's technology.[3]

Additive Process: The name itself denotes that it is the process in which material should be added. By this process, chemicals are added to the existing surface which results in an improvement in microstructure and macrostructure of the implant surface. Inorganic mineral coating like calcium phosphate, bisphosphonate, hydroxyapatite, etc; plasma spraying, biocoating with growth factors (platelet-derived growth factor, bone morphogenic protein, fibroblast growth factor, transforming growth factor-beta, vascular endothelial growth factor); peptide and extracellular matrix components (hyaluronic acid, chondroitin sulphate, collagen) are different method used as additive materials and/or chemicals to the implant surface. In addition to hydroxyapatite to the surface of the implant, it has been shown that there is both improvement and acceleration in the primary bone cells proliferation or adaptation.[2]

Hydroxyapatite crystals: The key inorganic element of natural bone is the hydroxyapatite crystal. The layering of this key element (hydroxyapatite crystal) permits an influenced and also a quick osseointegration by connecting living bone and the surface of the implant; which was manifested by many investigations.[4] With hydroxyapatite coating the survival rate or continuity rate at 4-8 years, the effect was upto 93.2-98.5% and at 10 years, the effect was upto 82.0%.

Titanium plasma-sprayed: In this method, the survival rate or continuity rate at 20 years, the effect was upto 89.5%.[2]

Plasma spray coating: A combination of HA coating on titanium alloys substrate has good biocompatibility and mechanical properties, which received much attention. The process of layering of hydroxyapatite, incorporates spattering of thermally liquefied materials on the implant substrates.[5]

Subtractive Process: The name itself denotes; it is the process in which there is elimination of materials takes place. In this process, to improve or enhance or to modify the microstructure and chemical nature of the surface of the implant, elimination or alteration of the existing surface is done. It can be done by various ides or method like machining, blasting, acid etching, or a combination of these processes. These method improve the quantity or speed of osseointegration. Among all these the first-generation design of the surface of the implant is the machined surface of implant which is with a rotating surface implant. Surface of implant treated by a process known as grit blasting, in which dispersion of particles can be done by silica or ceramic material. Roughening off the surface of titanium implant by using strong acid like nitric acid, sulphuric acid, or combination of these acids, hydrofluoric (HF) acid is done by acid etching. Sandblasted and acid-etched is the type of acid etching after sandblasting with 250-500μm large grit particles. [2]

Sandblasted and acid-etched (SLA) process: In sandblasted and acid-etched (SLA) process, the continuity rate at 10 years effect was upto 98.8% to 99.7%.[2] Inductions of surface erosins by applying a strong acid onto the blasted surface is done by this SLA process. The combination of large grit sand particles and acid etching is used in this process to obtain macro roughness and micropits. [5]

Grit blasting: It is a frequently implemented physical method, which is used for surface treatments. Grit blasting is followed by an acid etching to remove

the residuals. This process is done by projections of pressurized particles or projections of silica onto the implant surface.[5] Many frameworks, as for examples: size, type, pressure and temperature of the particles may get an influence on the final consequences.[6]

Discrete crystalline deposition: By the process of sol-gel, Calcium phosphate particles of size 20-100nm are coated on a double acid-etched surface named discrete crystalline deposition. Exertion of an intense adhesive force of surface of the implant and making up of surface upto 50% can be done by these particles.[7]

Anodic oxidation: In this method, the implant is exposed to an electric circuit in which it is serving as anode.[7] It is said that when there is surface roughness is 0.44-8.68µm by modification of any surface then it provides a good surface for osseointegration.[2] Mostly good roughness of implant surface can be achieved by doing acid etching and coating.

BIOACTIVE GLASS

The use of bioactive glass to improve the surface characteristics has shown positive results. By the addition of bioactive glass, the bio-inert nature of the titanium dental implants may benefit.[8] Bioactive material helps in the formation of a hydroxyapatite layer with a bond forming between the tissue and a higher dissolution rate and thus faster apatite formation.[8] Bioactive glass has proved to reduce biofilm mass invitro conditions.[8] Bioactive glass actively bonded to the bone and provide antimicrobial protection and it also helps in the reduction of treatment time.[8] 45S5 bioglass, 58S(sol-gel derived) bioglass, S53P4 bioglass are mostly used bioglass materials.45S5 bioglass contains 46.1mol% SiO_2, 24.4mol% Na_2O, 26.9mol% CaO, 2.6mol% P_2O_5. 58S (sol-gel derived) bioglass contains 60mol% SiO_2, 36mol% CaO, 4mol% P_2O_2.S53P4bio glass contains 53mol% SiO_2, 23mol% Na_2O, 20mol% CaO, 4mol% P_2O_5.[9]

CONCLUSION

Dental implants are now the state of art for dental restorative therapy. In order to achieve an abundance integration of hard and soft tissue, adhesion and proliferation of osteogenic as well as fibroblastic cells and minimization of attachment of bacterial during upgrading the recruitment should be the focus of attention of implant development. Several preclinical scrutinizations have shown the superiority of certainsurface modifications concerningto histomorphic properties and biomechanical characteristics. Clinicians should consider the fact that even if several new surface treatments have been proposed, only long term results and rigorous studies can eventually prove its efficacy. To assure an everlasting success in clinically demanding circumstances, the evolution of versatile surface modifications and coatings is essential and recent findings about surface modifications have improved the success rate of implants.

Isolation of Teeth in Children: A Review

Prajna Nibedita Behuria

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Isolation is done for proper control of moisture, good accessibility and visibility, to provide adequate space for instrumentation and operation. Most of the children are non-cooperative during treatment. So, isolation is mandatorily necessary for pediatric patients. Studies have shown that there are successful retention rates of adhesive restoration when a rubber dam is used rather than any other isolation technique. The judicious use of rubber dam ensures greater patient comfort and delivery of high-quality dental care to pediatric patients.

Keywords: *Access, Rubber Dam, Cotton Rolls, Isolation.*

Introduction

Any operative procedure needs adequate space over the operating field. There must be proper control of moisture, good accessibility and visibility as well as spacious for instrumentation around the working area. For easy manipulation this kind of environment is necessary. Isolation of the working area includes isolation from saliva, blood, gingival crevicular fluid and soft tissues like lips,cheeks,gingiva and tongue.

Goals of Isolation:

Retraction & Access: Without proper retraction and access the details of any kind of operative procedure can not be managed. Maximal exposure of the operating site is provided by retraction access.[1]

Moisture Control: If the moisture in the mouth is not controlled,operative dentistry can not be executed properly. Elimination of gingival sulcular fluid,saliva and bleeding from the working area is referred to as moisture control. It also prevents the spray from hand-piece and debris of restorative material from being swallowed or aspirated.

Corresponding Author:
Prajna Nibedita Behuria
Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Harm Prevention 2: Isolation of the operating field is done to prevent the patient from being harmed during the ongoing procedure. A patient may accidentally aspirate small instruments,restorative debris. Accidentally soft tissue may get damaged. Use of isolation is used bothfor harm prevention and patient comfort and operator efficiency.[1,2]

Types of Isolation in Pediatric Patients[3]

A. Fluid absorbent B. Saliva ejector C. Rubber dam D. Use of Drugs

Fluid Absorbents: By absorption of salivary secretions,the isolation can beachieved. The se are used for short periods when absolute dryness is not required. e.g. examining oral cavity,polishing fluoride application. Various materials that can be used for this purpose are- 1.Cotton rolls 2.Gauze or throat shields 3. Absorbent paper

Cotton Rolls: These are available in different sizes,cut to variant lengths with plain or woven surfaces. The se are placed sublingually,over or lateral to salivary gland orifices. Cotton rolls slightly retracting the cheek provides visibility and access.[1, 2]

Gauze or Throat Shields: It is used in pieces of 2''X2'' or larger. For large areas than cotton rolls, these are better suited. Gauze has less adherence to dry tissues and better tolerated by delicate tissues as compared to cotton.

Absorbent Paper: These are of different shapes to fit various locations in the mouth. The y are more absorbent.

Saliva Ejectors & High Volume Evacuating Equipment: Saliva ejectors are used to prevent pooling of saliva at the floor of the mouth. High volume evacuating equipment removes solid debris along with water.[1, 2]

1. **Metallic**-have rubber dip to avoid irritating the delicate tissues on the floor of the mouth and these are autoclavable.
2. **Plastic-**are inexpensive and disposable.

Requirements: To face backward the tip should always be molded with a slight upward curvature. To prevent injury to soft tissue the floor of the mouth under the tip should be covered with gauze. The lip or cheek mucosa should not get traumatized. Instrumentation should not have interfered. It should be used with other adjuncts e.g. cotton rolls,gauze.[1-3]

Advantages:

(1) Adequate dry field along with the advantage of washed field. (2) No dehydration of oral tissues.

Precautions: Care should be taken to avoid cross-contamination. After each use, the saliva ejector should be disinfected. Disposable tips are preferred. The child should not close his mouth to hold the tip since it may cause backflow of contaminated solution into his mouth as a result of pressure changes.

C. **Rubber Dam:** This is usually latex rubber and one of the most effective means of isolating teeth. It was developed by BARNUM (1864).

Rationale: (1) The clean and visible field is maintained .(2) Aspiration of foreign bodies is prevented. (3) Clinician protection. (4) The risk of cross-infection to the root canal system is reduced. (5) Soft tissues are retracted and protected. (6) By minimizing patient conversation and the need for frequent rinsing efficacy is increased. (7) Medicaments are applied without the fear of dilution.(8) Properties of restorative materials are improved.[3]

The patient gets a psychological benefit.

Contraindication 3:

(1) A child with Upper respiratory tract disorder,Congestion of nasal passage or nasal obstruction. (2) If there is any fixed orthodontic appliance. (3) Any recently erupted tooth that can not hold a clamp. (4) Allergy to latex.

Disadvantages 7: (1) Trauma to tissue. (2) Patient acceptance. (3) Latex allergy. (4) Trauma to tissues. (5) Pressure marks on face due to frame. (6) The build-up of saliva. (7) Psychological intolerance

Benefits to the Child: As glasses are used to protect the eyes,thus rubber dam is used to protect the airways and the esophagus. By doing this a good analgesia has been obtained,the child can feel distanced from the operation. Sometimes it is useful to show the child his isolated tooth in the mirror.[4]

Benefits to the Dentist: This reduces the effort required by the operator to protect the soft tissues of the mouth and the airways. Correctly placed rubber dam allows the operator a better view of the area to be treated by gently pulling the cheeks and tongue away from the operative area. Rubber dam gently pulls the gingival tissues away from the cervical margin;makes it easier to see the extent of any caries close to the margin.

Precautions: (1) The patient should not breathe through the mouth. (2) To retrieve the clamp if ingested or aspirated, clamps must be tied to a floss thread and tightly secured in place. (3) The dam should not cover nostrils. (4) To prevent drying of lips,these should be lubricated properly. (5) The clamp should neither impinge on the gingival tissue nor traumatize the nearby teeth. (6) Latex-free rubber dam should be used on patients with allergy to latex. Rubber dam napkin is used to prevent the latex rubber dam from contacting the patient's tissues.[5]

Armamentarium: I. Rubber dam sheet II. Rubber dam frame III. Rubber dam punch IV. Rubber dam forceps V. Waxed dental floss VI. Scissors VII. Rubber dam napkin VIII. Lubricants IX. Clamp

Euphenisms Used for the Armamentariums: Rubber dam sheet–Raincoat, Frame–Hanger, Clamp–Clip

Rubber Dam Sheet: Rubber dam is available in different thicknesses.

Thin -0.15mm

Medium – 0.20mm

Heavy – 0.25mm

Extra-heavy – 0.30mm

Special heavy – 0.35mm

It is available in prefabricated sizes,i.e. 5"X5" or 6"X6",while non-latex rubber dam is of only 6"X6" size. This has two surfaces which are shiny and dull. As it is less reflective,the dull surface is kept facing occlusally.

Rubber Dam Frame: There are two types of frames i.e. metal frame and plastic frame. The young frame is a metal frame whereas Star visiframe, Nygard-Ostby, Quick dam or Handidam frames are plastic frames. Starlite visiframe, a U-shaped frame,exerts less force on the dam and is easier to use. Nygard Ost by frame does not require any absorbent napkin and stands away from the face. A quick dam comes with a flexible attached frame, which is effective for the control of saliva in the anterior part of the mouth than the posterior part. Handidam has a built-in frame with a rod for insertion to keep the dam open and it comes in one size. Drydam does not require a frame.[6]

Rubber Dam Punch: It is used to punch holes corresponding to teeth size on the rubber dam sheet.

Lubricants: For easier placement of the dam, lubricants are applied in the area of punched holes,which should be water-soluble e.g. shaving cream and soap slurry.

Clamps: These are made up of stainless steel, consisting of a bow and two jaws. The se are used to aid anchoring the dam to the tooth and soft tissue retraction.

Rubber Dam Clamps Used in Pediatric Use: Partially erupted permanent molar- 154A,8A Ivory, Fully erupted permanent molar-14,8 Ivory, Primary second molar-26,27,SS White,3 Ivory,Primary first molar, bicuspid, permanent canine-2,2 A Ivory, Primary incisors and canine-0 Ivory.[7]

Procedure of Rubber Dam Placement: As with any other dental procedure, the preparation of the child for rubber dam application should be done. In a situation where the clamp might impinge on the gingival,local anesthesia should be obtained. The clamp should be secured with floss for easier in quick retrieval;if the clamp is dislodged accidentally. Clamp should be placed using rubber dam forceps on the tooth. Using the rubber dam punch and template punching of an appropriate hole on the sheet should be done. The sheet is stretched with the hole over the clamp lingually, distally and buccally below the jaws of the clamp. The sheet is passed through a rubber dam napkin so that the latex sheet does not come in direct contact with the skin. To prevent bunching of the sheet,stretching and securing the sheet over the rubber dam frame should be done. Where necessary,there ligation of teeth with dental floss and placement of wedges for additional retention should be done. The dam around the tooth should be inverted using a blunt instrument or compressed air from the air syringe. The n, the planned dental procedure can be carried out. Removal of the rubber dam is done by cutting ligature,removing used wedges,cutting interdental material with scissors and removing the rubber dam frame,dam sheet, and clamp.[8]

It is not appropriate to include more teeth in the rubber dam than necessary to get adequate working space. If the first or second permanent molar is the single tooth in the quadrant which is carious in an occlusal area it is often referred to as punch only one hole in the dam.

For single tooth class I or V restorations,only one the carious tooth must be isolated. To restore proximal lesions, at least one tooth before and one tooth after to the tooth being restored should be isolated. It helps in better access, gives more convenient ways to place a matrix and proper field of visualization of where can be done appropriate carving of the restoration along the side of marginal ridges.. This procedure requires only seconds and can save many times.[9]

Recent Advances Inrubber Dam Isolation: Hatdam is a clear plastic form shaped like a hat without a top which is trimmed and fitted around the crown that can not be clamped,to hold the rubber dam in place. Cushioning metal clamp jaw is made up of Ferrite-N which can be pressed in the embrasure area. The material is light-cured,over which the clamp is seated. Cushees are soft thermoplastic cashew-shape nodules which are slipped over tooth attachment blade of the clamp before clamp application. Fiber optic clamps are used in the endo illuminator system. Liquid dam is a resinous material applied to the gingival aspect of the tooth surface used to blockout undercuts before take impression.

Drugs: Antisialagogues can be used to decrease excess salivation e.g. Atropine. Local anesthesia,in addition to the vasoconstrictor in it, brings about a reduction in pain and salivation.

Children's Reaction Towards Isolation: Several studies have been investigated the physiological and psychological responses of children during the dental procedure and their behavior may vary with the type of dental procedure,the number of visits and during the procedure of visit itself. From a previous traumatic experience, originated anxiety and fear or due to general health problems, it might exhibit an emotional upset for most of the children[11]. Children's anxiety and fear of dentistry should be reduced as much as possible before dental treatment[12]. Compared to cotton rolls isolation, rubber dam causes less anxiety in children and adolescents. Most of the children overrule cotton rolls as they think that it may not be as effective as saliva ejector in isolation. In a rubber dam, isolation children feel that the treatment is taking place outside of their mouth. Sometimes, most of the children prefer saliva ejector,as saliva ejector takes away all the saliva,making the operative field clear along with the feeling of control over situation. This happens due to the use of inductive logic i.e. making broad generalization from specific observations by the children of this age group.[10]

Conclusion

From all of the above isolating techniques, rubber dam is the most convenient one. Studies have shown that there are successful retention rates of adhesive restoration when a rubber dam is used rather than any other isolation technique. The judicious use of rubber dam ensures greater patient comfort and delivery of high-quality dental care to pediatric patients. Recently, pre-framed rubber dam sheets have been introduced in which, individual rubber dam sheets are attached to modified frames. The y are easy to use as the rubber dam and holder are applied as a single unit. The se are comfortable for the patient and is easily accepted by patients. These are easily removable. This takes less time to operate.

Immunity and Periodontal Disease

Prangya Elina Singh[1], Manoj Kumar[2], Rinkee Mohanty[3], Rashmita Nayak[4], Anurag Satpathy[4], Gatha Mohanty[5]

[1]Intern, Institute of Dental Sciences, [2]Associate Professor, [3]Professor & Head, [4]Professor, [5]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha "O" Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

Periodontal diseases are the inflammatory disorders mostly include gingivitis and Periodontitis, which further leads to tooth loss. Now-a-days periodontal disorders become the most common disease worldwide. Though it is of microbial origin, the destruction mostly depends upon the host response. This article concentrates on the essentials and importance of immunology in periodontal diseases. Significant aspects like immunity, cell of the immune system, Major histocompatibility complex system and Human leukocyte antigen system, participation of the inflammatory cells in the development of the disease, release of chemokines, cytokines, molecular biology etc.

Keywords: *gingivitis, periodontitis, immunity, cells of immune system, host response.*

Introduction

Periodontal disease is a persistent bacterial infection which mostly attack the gingiva and the nearby tissues that support the tooth to hold in the proper position and in the alveolar bone.[1,2] This inflammatory disease results from the bacterial response in dental plaque or biofilm. The bacteria like P. Gingivalis, A. Actinomycetemocomitans and T. Forsythia involve in this disease and remain confine to the gingival tissue with minimal destruction.[1,2,3] But some genetic, environmental and host response can lead to this alteration in tissue to the level of epithelial attachment loss and tooth loss.[2,3] Only the presence of pathogenic bacteria can't be the cause of periodontitis. The defense mechanism of the host plays an important role by including the release of anti-inflammatory cytokines, providing the more numbers of Neutrophils and building the protective antibodies.[1,2] But,this disease progress rapidly due to other factors which may include high levels of inflammatory mediators like cytokines, matrix metalloproteinase (MMPs), low level of interleukin-10 (IL-10), Transferring growth factor and inhibitors of MMPs in the body as the outcome of the disruption or disturbances in the host defense mechanism to the pathogens.[2,3] These mediators stimulate the resorption of the alveolar bone and extracellular matrix destruction in the gingiva.[2,3] This review article further describe the immune system briefly and the impact of this in periodontal disease.

Immunity: Immunity is the reluctance to accept any foreign antigen by the host and towards the injury caused by microorganisms and their products.[4] Immunity is of two types, one is innate or native and another adaptive or acquired. Innate immunity categorized into species immunity, Racial immunity, Individual immunity. And Acquired immunity classified into Active and Passive. Both active and passive immunity further divided into Natural and Artificial type.[4,5]

Innate Immunity: Gives the first line of defense against any kind of infection and microorganisms.[5,6,7] It constitutes of four types of barriers:

Anatomic: Include skin which has thinner outer epidermis and thicker inner dermis. And mucosal member which also consists of an outer epithelial and inner connective tissue.[6]

Physiologic barrier: include temperature, ph. and chemical mediators.[6,7]

Phagocytic barriers: contains Neutrophil, macrophages and Nkcells.[6,7]

Inflammatory Barriers

Acquired Immunity: Develop in the body by the host after the contact with suitable antigen or after transfer of antibodies or lymphocyte from an immune donor.[5,6,7] The acquired immunity has four characteristics features named as; Antigenic specificity-The capability of recognizing even minute difference between antigens.[6,7] Diversity-entitle immense diversity through antibodies as the immune system has perceived and reacted accordingly.[6,7] Immunological memory-remains through out the life of the individual and a second exposure will be responded.[6,7] Self, non-self-discrimination of molecules.[6,7]

Cells of immune system: Lymphoid and myeloid arm of the Hematopoietic system give rise to the principal cells of the immune system. Cells like erythrocyte, phagocytes (Neutrophils and monocyte), eosinophils, platelets, basophils, peripheral dendritic cells, mast cell precursors are derived from myeloid arm in the bone marrow. Peripheral DCs, monocytes and mast cell precursors again get transformed in the tissue.[7,8] Monocyte may change to become a macrophage. Similarly, Natural killer (NK) cells, pre-T cells and B cells are derived from the lymphoid arm in the bone marrow. T cells are found in the thymus; as they are the differentiated form of the Pre-T cells in the thymus. DCs, B cells and antigen presenting cells convert the antigens to T cells in the lymph node and the spleen, which are considered as the secondary lymphoid organs. Final differentiation of T cells and B cells happens in the lymph node and spleen.[7,8]

Mast cells are mostly responsible for the immediate hypersensitivity reaction. They remain very close to the blood vessels and consists of cytoplasmic granules filled up with mediator molecules or effect. Tissue and mucosal mast cells are the two form of mast cells. They vary from each other by their activities, anatomical placements.[7]

Basophils release their cytoplasmic granules which have pharmacologically active components and oppose against the foreign pathogens or microorganisms. They are also associated with allergic response.[3,5,7] Eosinophils have anti-parasitic and bactericidal activities. DCs are found in the basal and supra basal layer of oral mucosa as the cell component of innate immune system. The mechanisms that are lie behind the periodontal diseases by these cells are; conversion or transition of adaptive response, direct relation to the pathogenic signals and ability to impact the other cells of immune response.[3,7]

Macrophages are the quick protective mechanism. Whereas the MHC molecules contain various glycoprotein which recognize the T cells by binding the antigen over it. So, it is also known as "antigen presentation". Neutrophils act as phagocytic cells and they are in large number.[3,5]

Lymphocytes: There are 3 types of lymphocytes like T cells, Bcells and NK cells based on their functions and surface markers. Interleukin-7(IL-7), the triggering factor for forming these lymphocytes from the bone marrow stem cells. Tcells are the important part of acquired immunity. Some different subsets of T cells are present in periodontal tissue. They directly attack and breakdown the infected cells with the help of active macrophages. B cells manifest the humoral immunity.[5,7] The number of B cells is more than the Tcells. NK cells are the particular type of lymphocyte which don't have class 1 MHC molecules and kill the infected cells.

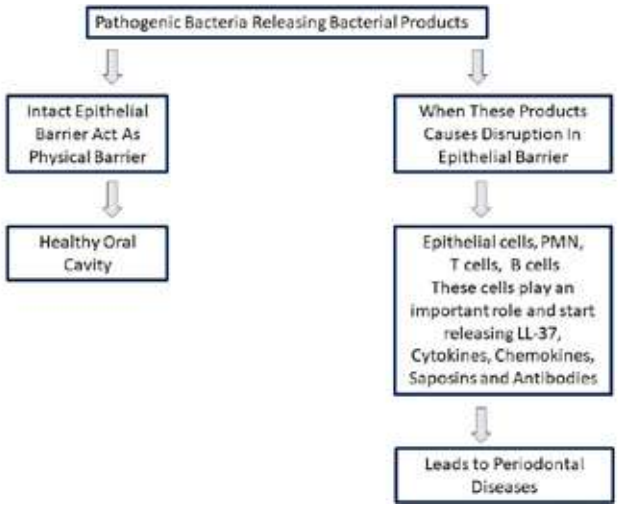

Fig. 1. Mechanism involved in the development of periodontal disease.

Response of innate immunity in periodontal disease: Polymorphonuclear leukocyte plays the main role in continuing the healthy status of periodontium.[1,3] Patients with cyclic neutropenia and leukocyte adhesion deficiency disorders are more vulnerable to the gingival infection or early and sever form of the periodontitis.[3] Defects in PMN in molecular basis can result in development of periodontitis. The protective response of PMN against the periodontal pathogens is degrade when they failure to transmigrate into the endothelium, this ultimately increases the inflammatory response. [5,7,9]

Periodontal epithelium acts as a physical barrier towards the infection. The physical barrier is formed by the epithelial cells, as they remain in constant contact with bacterial products.[9] Incase of disease formation of deep periodontal pocket, inflammation of connective tissue and bacterial invasion is formed due to the migration of epithelial cell.[10] Epithelial cells counter the pathogens by changing the cell differentiation, by proliferation, by changing their cell signaling events.[10,11] Langerhans cells and dendritic cells have the connection with acquired immunity. Epithelial cells create different types of antimicrobial peptides which have been found throughout the body in human.[12,13] These are also related to saliva or remain in the dentogingival junction.[14,15] When the microbial pathogens attack cell-cell junction, the integrity of the epithelial barrier breakdown.[1,11,12,15] These proteins or peptides have an action against gram+ve, gram-ve, yeast and some viruses. They linked to the anionic microbial surface, then assemblage to form pores or damage the microbial membranes, new evidence shows some has cytoplasmic targets.[15,16,17,18] These peptides complement histatins, lysozyme and salivary immunoglobulins, the antimicrobial factors of saliva having a role in innate host defense responding to an infection.[14,15,17] Some peptides like alpha- defensins and cathelicidin LL37 activate the classical complement pathway and increase the IL-8 production by epithelial cells, which enrich the neutrophil count to the site of infection.[11,17,18] Innate immunity has an ability to admit bacteria as non - self agents because the microorganisms have PAMPs in bacterial wall, which are cognized by pattern recognition receptors on immune cells.[17,18,19]

Adaptive immune response in periodontal disease: The adaptive immune response come into role when the epithelial barrier and its component of innate systems, are ruptured.[12,18,19] The balance between Th1 and Th2, Cytokines regulate the immune response against the infection.[16,19] According to some studies a decrease in Th1 response and increase Th2 response may develop periodontitis, some also shows the superiority of Th1 response over the Th2 response. Boyel et al advocated that the integrity of tissues in bone depends on the equilibrium between osteoclasts and osteoblasts.[20] During synthesis, osteoblast express some chemokines receptors. Besides, some important chemokines which are take part in recruitment of PMN and different lymphocyte, can be produced by an osteoclast.[18,20]

Chemo attrition of inflammatory cells in bone environment due to the production of chemokine may lead to bone disruption and tissue destruction.[21] Periodontal disease tissue contain both Tand B cells.[3] The phagocytic activity of macrophages and neutrophils would increase or intensity when INF-alpha is produced by T cells. B cells are activated by IL-4 production which cause the antibody production.[10,20,22] These antibody acts against specific bacterial antigens like LPS of A. Actinomycetemocomitans LPS of P. Gingivalis. This antibody response is mostly facilitating the bacterial clearance and stop the progressive nature of disease and provide protection against bacteria.[9,10]Regulatory T cells are the definite subgroup of CD4+ T cells which give response to any kind of infection depending on the cytokine pattern induced.[8,22] According to Cardoso et al, more no of T regulatory cells in gingival tissues with chronic periodontal disease patient provides the idea of involvement of type of cell in periodontal disease. Anyhow, the action of Tcells in developing periodontal diseases remain unrevealed. [6,7]

Conclusion

This review details about the periodontal disease, contribution of pathogenic bacteria with other factors in development of inflammatory reaction. It also emphasizes the immune system of human body and implication of innate and acquired immunity in initiation and progression of various periodontal disease. Further, there is less evidence about the immune system control the disease as more studies are going on over this.

Hypochondriac Disorder in OSMF Patient

Baba Sankar Sahu[1], Abhishek Ranjan Pati[2]

[1]Intern, Institute of Dental Science, [2]Associate Professor, Department of Oral Medicine & Radiology, Institute of Dental Science, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

The main purpose of this article is to present a review on oral submucous fibrosis patients, those who are suffering from hypochondriasis disorder and identifying its interrelationship with their family how they are also suffering due to this problem. The article also focuses on the sign and symptoms of this disorder. Also, it highlights the treatment planning of this disorder.

Keywords: *Hypochondriasis, Oral submucous fibrosis, Sign and Symptoms, Management.*

Introduction

Hypochondriac disorder means 'health anxiety', this is one kind of obsessive disorder that means obsession about a particular condition that may be medically diagnosed or undiagnosed. This usually occurs during adulthood. Oral Submucous fibrosis is a premalignant disorder of the oral cavity. It is a progressive and chronic disorder. The malignant alteration rate of oral submucous fibrosis (OSMF) into squamous cell carcinoma (SCC) is high. OSMF is a multifactorial origin. The most important etiological factor is the habit of chewing tobacco, areca nut product like pan masala, etc. smoking also an important etiological factor for OSMF. Also, alkaloid arecoline identifies as a principal etiological factor for OSMF.[1] The sign and symptoms of OSMFare blanching present in the oral mucosa which leads to rigidity of the oral mucosa and gradually restrict the mouth opening. It occurs at any age but mainly occurs in the 2nd to 4th decade of life(25 to 35 years old). It commonly occurs in southeast Asia and the Indian subcontinent. OSMF divides into different stages of grades, according to their clinical and functional criteria.[2]

Corresponding Author:

Hypochondriac Disorder: Hypochondriac disorder means anxiety, where an individual is extremely concerned about having a severe disease in his/her body or oral cavity. So we are discussing hypochondriac disorder on OSMF patients. So etiological factor for oral submucous fibrosis is tobacco and nicotine products. So those are having a habit of chewing tobacco and other nicotine product, they are prone to OSMF. When the patient sees the initial sign and symptoms of this disease, they have started panic to see these signs and symptoms. And then repeatedly think about that and after a few days gradually he/she become depressed, so this is called hypochondriasis and a person with hypochondriasis is called a hypochondriac disorder.[3]

Hypochondriasis:

Other names: health anxiety (HA), hypochondria, illness anxiety, Disease, somatic symptom disease

Symptom: fear, anxiety, depression, mentally disturbance

Differential diagnosis: obsessive-compulsive disorder,panic disorder, (OCD), generalized anxiety disorder

Treatment: However, hypochondriasis continues even after a dentist has examined an individual and reassured them about the disease and their symptoms, if the condition is severe then take an appropriate step for this disease. Many hypochondriac patients center of attention on a particular symptom as the catalyst of their

Complications[13]:

A hypochondriac disorder associated with:

1. Relation or family problemsdue to excessive worrying about the disease.
2. Excessive absences at work cause poor performance and other work-related problems.
3. Financial problems due to constant medical visits and their bills.
4. Problem function in day to day life.
5. Having also other psychological disorder such as somatic symptom disorder, depression, anxiety disorder, and personality disorder

upsetting such as palpitation, muscle fatigue, gastro-intestinal problem, and also it affects the relationship with their family. To be eligible for the diagnosis of hypochondria disorder, the signs and symptoms must have been experienced for at least 6 months.[4]

Hypochondria disorder is characterized by the fear that minor bodily or mental symptoms may indicate a serious illness, continuously self-examination for example 'a person see white patches or white blanching in the mucosa of the oral cavity, then after the patient continuouslysee their oral cavity in the mirror or the phone's front camera' and then self-diagnosis by searching on the internet and this self-diagnosis enhances the patients' fear.[5]

Many persons with hypochondriasis express disbelief and doubt in the dentists' diagnosis, due to this doubtless and disbelief most patients judge the dentists and think this dentist doesn't know anything and then the patient goes for another dentist and then another. And gradually the patient becomes depressed. Many hypochondriac patients experience increased stress, blood pressure, anxiety in the occurrence of doctor/dentist, or nurse a condition known as "white coat syndrome". Most hypochondriac patientsneedcontinuous reassurance about their disease from the dentist or family or their friend. Some hypochondriac patients try to avoid any kindof reminder of an illness. Some patients constantly visit the dentist and frequently ask questions about their illness until their satisfaction. Some sufferers may never speak about it or don't express it in front of anybody anywhere.[6]

Signs and symptoms: Hypochondria disorder is a somatic amplification disease, this is a disorder of cognition and perception, it's a tendency to respondto the initial perception in a harmful manner and further debilitate. This manifests in many ways. Many people have severalinvasive thoughts and physical sensations that force them to check with family, friends, and dentist, for example, a person having severe headache may think that they have brain cancer. Most people are so afraid of any reminder of illness and some avoid thinking as a minor problem. Some also think that the disease is the penalty for past misdeeds.[7]

Hypochondria disorder is quite similar to the other kind of psychological disorder as like bipolar disorder, obsessive-compulsive disorder (OCD), clinical depression, somatization disorder, phobias, and also generalized anxiety disorder. Most hypochondriac patients experience a cycle of invasive thought followed by a compulsive examination which is related to the signs and symptoms of obsessive-compulsive disorder. Some hypochondriac patients are worried about having illness and obsessive-compulsive disorder patients anxious about gettingsick or of transmitting sickness to others. These kind patients are over-possessive and overprotective for themselves and also for others.[8]

Hypochondriac patients are more depressed and anxious to think about their symptoms but they don't aware that depression and anxiety cause the other mental and physical disorders or disease. For example hypochondriac patients experience change in appetite, weight fluctuation, fatigue, decrease the motivation of life, decrease interest to do something like extracurricular activity, or any kind of entertainment. And the most important thing is that this disorder not only affects the patient but also severely affect their family member due to the behavioral change of the patient. Because of this reason family members cannot tolerate the patient's behavior. Intense anxiety causes sweating, increased heartbeat, stomach discomfort, muscle tension, shortness of breath, dizziness, tingling, numbness in a certain part of the body like hand, forehead, etc.[9]

Effects on their life and their family: Above, we discussed oral submucous fibrosis, hypochondriac disorder and its sign and symptoms but now we are going to discuss the most important and the most sensitive topic that is how this disorder impact the patient's life and his/her family members. As we know the medication is the only way to treat this disorder but along with medication, we should assure them that don't think very much about this disease and strictly aware them about to stop bad habits like chewing nicotine products and don't see their oral cavity repeatedly in the mirror.[10]

Those patients don't follow the dentist's advice, they are suffering the most. As before when they repeatedly see their lesion present in their oral cavity, they don't control their habit, as a result, they become mentally unstable. Due to mentally unstable they could not focus on their day to day life and don't eat properly, etc. So in this time family member's support is the most important role. They should stand with them rather than leave them alone.[11,12]

Management of Epileptic Patient in Pediatric and Preventive Dentistry

Prangya Elina Singh

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Children are the representative of our future society and their proper growth and development must be the chief concern of all. The condition of the oral cavity in special children like a child having Down syndrome, Epilepsy, Cerebral palsy, Autism is mostly connected to their affliction. Due to a load of medical treatment, normally the parents of these special children do not pursue dental treatment. But in the current situation, the complete care for the oral cavity of these children has been provided by the dental professionals. Epilepsy in children is the most common and damaging neurological disorder nowadays. This review shows the management of the diseases related to the oral cavity of an epileptic patient in various method and approaches.

Keywords: *Epilepsy; Pediatric dentistry; Preventive dentistry; Management.*

Introduction

The human brain is full of numerous neurons, tissues in between them, and their extensions. The cells of the brain produce the electrical currents and transfer it to the other cells. The transmission of these electrical signals helps in brain functioning.[1] Seizures are the episodic neurological dysfunction that occurs due to sudden electrical discharge;may be uncontrolled or insufficient. Epilepsy, a condition of chronic, recurrent, unprovoked seizures with abnormal electrical activities within the brain.[3] When the disease gets started in childhood, it may have an impact on the social, physical, and psychological life of that person.[2]

Epilepsy has the incidence of 0.05%and prevalence of 0.5-0.8%.prognosis for the epileptic pediatric patient is good but 10-20%have sedulous seizures which are due to drugs and those cases have management challenges.

The epidemiological study of Karolyhazy et al showed that; epileptic patients have remarkably worse oral status; than the healthy and sound person. The index of dental diseases is high in these patients due to the lack of maintenance of oral hygiene, oral cavity injury, and socioeconomic background. It's about 50million people in the world have been affected by epilepsy and out of them, 90% belong to the developing countries. It is a group of many types of seizures which alter in their seriousness, aspect, origin, sequel, and management.[3]

The individuals often face the temporary loss of their consciousness with a risk of any harm to the body parts due to this epileptic seizure. Young children and people more than 65 years of age are the most vulnerable age group for this neurological disorder. There is no time specification for the Occurrence of the seizure attack.[3] Epilepsy is a syndrome, not a single disease with greatly conflicting symptoms.[10] Some epilepsy is restricted to specific phases or periods of childhood. Anticonvulsant medications are the primary treatment of epilepsy. Somehow these drug helps in reducing the frequency of the seizures, but some patients don't show any improvement, in these difficult cases surgery may be the choice of treatment.[10,11] Longterm use of these medications shows different types of adverse effects which is also a major problem for these patients.[4]

About 125,000 new epilepsy cases appear in each year, 30% of them are younger than age 18.[5] At the minimum of 8% of the population have one seizure attack but don't have epilepsy. From the latest studies; it shows that 55lacks persons have been affected in India. History of Epilepsy- The word derived from a Greek word called, Epilum-banein meaning to attack. Hippocrates, the first person who wrote a book on epilepsy in 400Bc. According to him, epilepsy is a curse or a sign from God. During the middle-aged people in Europe, epilepsy is called "falling sickness". [5]

Etiology for most of the cases is unknown. Epilepsy may be due to symptomatic or idiopathic reasons.[2-5] Most of idiopathic epilepsy has a genetic origin. About 30-40% of epileptic patients have a genetic origin.[2] When genes are correlated to mutation,it results in different abnormal functioning. Some of epilepsy display the Autosomal transmission. Juvenile childhood absence epilepsy, photosensitive epilepsy, and Generalized epilepsy with febrile seizures plus (GEST) are some of the hereditary epilepsy. In the case of symptomatic epilepsy, pathology of brain-like brain malformation,injury, or some diseases are associated. Brushing the teeth for a prolonged time may be the reason for reflex epileptic seizures according to some of the case report.[5] Metabolic disorder like electrolyte imbalance, hyperglycemia, hypoxia, hypoglycemia, acidosis, CNS infections, trauma, congenital CNS abnormalities, and hypoxic-ischemic encephalopathy are the various important common case in early infants and neonates.[2] Trauma after birth and infectious diseases may be the most common reason for the febrile seizure in early childhood and late infancy stage.[2] Some syndromes such as West syndrome, childhood absence epilepsy, Lennox Gastaut Syndrome, in childhood are related to epileptic or seizure attacks.[6]

Pathophysiology: Seizures are manifested due to the paroxysmal discharge in the cortical neuron. An unexpected variance in the excitatory and inhibitory forces within the cortical neurons leads to a seizure attack. The grey matter of the cortical or subcortical area is the originating place of the seizure. Then abnormal firing of the fewer amount of neurons occurs. Breakdown of normal membrane conductance and inhibitory synaptic currents extent locally to manifest a local seizure or widely to produce a generalized seizure. This onset involves nearby areas by physiologic pathways.

Abnormality of potassium conductance defect in voltage-sensitive ion channels, deficiency in membrane ATPase leads to neuron membrane instability which can cause seizure attacks. In another aspect deficiency of inhibitory neurotransmitters, and a rise in excitatory neurotransmitters evoke abnormal neuronal activity which also results in a seizure attack. Some types of epilepsy may be associated with the mutation of genes. Generalized epilepsy and infantile seizure syndromes have a relationship with the genes that code for protein subunits of voltage-sensitive and ligand-activated ion channels.[7]

Opening of the defective sodium channels for a longer period conducts neurons hyperexcitable which develop the release of glutamate, an excitatory neurotransmitter in huge amount. Then this glutamate binds with the close by glutamatergic neurons; this activated the release of calcium in excessive amounts in the postsynaptic cells and this acts as neurotoxins to the other cells. This mechanism in the mutated genes that code for the sodium channel proteins; is related to the specific form of inherited epilepsy.[8]

Classification:

According to International League Against Epilepsy 2017, Epilepsy is

Focal Onset-Divided into aware/impaired awareness, motor onset, non-motor onset.

Generalized Onset-Is of motor and tonic-clonic type

Unknown Onset-Motor, tonic-clonic, Non-motor

Generalized Type-Each hemisphere of the brain is affected at the same time in this type of epilepsy. The patient is remaining unconscious during the attack; and there is no previous indication of it.[2] The generalized type is divided into; generalized tonic-clonic seizures (grandma), absence seizures (petit mal), and atonic seizures.[2,5,12]

Partial Type-In this type only a particular area of the cerebral cortex is affected. We can diagnose this type of epilepsy by seeing the electroencephalogram results and clinical symptoms. This type also classified into three groups Simple partial seizures; Complex partial seizures; Secondarily generalized seizures.[9]

Status Epilepticus-This term refers to any continuous seizure .most frequently arises after a tonic-clonicseizure. It can be fatal when it remains untreated.[9]

Injuries such as laceration of soft tissue like tongue or buccal mucosa, fracture of facial structure, traumatic injuries like avulsion, Luxation, and fracture of the tooth, TMJ subluxation are induced due to seizure attack.[19] Including that injury like gingival hyperplasia, development of recurrent aphthous ulcers, developmental anomalies like microdontia, delayed eruption, due to neglect in oral hygiene practice there may be the development of secondary infection of the fibrous growth which results in hemorrhagic tissues and enlargement of the lymph node in the cervical region are caused by taking the therapeutic drugs.[9]

Things to be taken into account while delivering the treatment to the patient: Some detailed information must be taken from the patient or the parents before starting the treatment; this must include, the seizure attack frequency, date of the previous seizure attack, patient's consciousness and respiratory state during seizure attack, patient's physical condition after the attack, the appearance of any aura before the attack, presence of any aura weather always leads to seizure attack or not, factors evoking the epileptic attack.[9]

Management of Epileptic Patient in Dental Office:

Preventive Measures: First of all we have to take a detailed and complete medical history about the patient's experience of the seizure attack and also the type,frequency of episodes before the treatment. The most important task to make the patient stress free or reduce the stress by the psycho behavioural preparations, sedation,etc. Diazepam as an anticonvulsant is the drug of choice. The appointment of the patient should be early in the morning hours. The session must be kept short; avoid the use of dental chair light and loud noise. Also avoid the drugs that evoke the seizure attack like phenothiazine, local anesthesia. Proper drug therapy should be given to the patient. Before doing any surgical removal of gingival hyperplasia,the dentist should take the consult of the patient's physician.[10]

Management During The Seizure Attack: When the seizure attack occurs in the dental chair, stop the treatment procedure immediately, and remove all the instruments and dental prostheses, if any there. The supine position is accurate and mostly needed chair position during that time.[9] To prevent the injuries due to attack, the use of tongue blade, mouth prop of rubber,or plastic must be there. If the patient is wearing any tight clothing, it should be loosened. The patient should be moved to another place where she/he cannot injure themselves. During the attack, preventing injury must be the main goal of a dentist. If the patient is unconscious during the attack, then try to maintain the airway patent and regular monitoring of the vitals is necessary.[7] Avoid the aspiration of secretions by using suction, if not possible then turn the head to the side. When the seizure lasts more than 3 minutes,the drug-like diazepam 1mg/kg iv slowly up to 10mg must be given. If the seizure lasts after the drug administration, then shift the patient to the hospital. If the patient becomes conscious; then send him/her to the home to take some rest and postpone the treatment.[11]

Conclusion

Dental issues like tooth loss, caries, and periodontal diseases are found more frequently in an epileptic patient due to poor oral hygiene, adverse effect of the medicine, and trauma during the attacks. Thatswhy they require more attention than other patients. Accordingly, after a detailed informative history and examination, an epileptic patient can get better dental management.

Intracanal Medicaments in Paediatric Endodontics

Praspita Parlin Patro

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The basic motive of Paediatric Endodontic Therapy is to remove microorganisms such as bacteria from the root canal system in which the remaining bacteria cannot survive. Intracanal Medicaments is an imperative step in killing the bacteria in root canals. Moreover, in Paediatric Endodontic, cleaning & shaping is important than intracanal medicaments. The objective of Intracanal Dressing is for a blockade coronal discharge from the space between filling materials and cavity walls. For intracanal medicaments, calcium hydroxide mixed with slim paste is more convenient as it is stable, harmless to the body and bactericidal. If multiple visits to endodontic are chosen, it is strongly recommended. Therefore, the purpose is to examine the need for an intracanal medicament.

Keywords: *Paediatric Endodontic; Medicaments, Formocresol, Glutaraldehyde, Calcium hydroxide.*

Introduction

Intracanal Medicament is a cardinal step in killing the bacteria in root canals and is considered to be an integral part of the success of Root Canal Therapy. In Endodontic Therapy of deciduous teeth because of the convoluted structure of the root canal and the change in the biomechanical preparation is restricted to the only debridement of Root Canals. There is no need of Intracanal Medicament in the vital pulp. When the Root canal space is left unfilled microbial recolonisation takes place and provide shelter to the microorganisms and they are by-products within the pulpal tissue for which it becomes an important part for placing the medicaments within the pulp chamber by their antimicrobial effect.[1] Out of which 2% glutaraldehyde, potassium iodine is reported to have better effect. Dical is also available in two forms which are base (titanium dioxide in glycol salicylate with pigments) and catalyst paste (Calcium Hydroxide and Zinc Oxide in Ethyl Toludine Sulphonamide).[2]

e-mail: praspitapatro1997@gmail.com

History: In 1045 AD Serebonium, initialised oils and wine in the mouth of the patient which was a drastic attempt to achieve a topical anaesthetic effect on the tooth. In 1800, various Medicaments were used for Paediatric Endodontic treatment; Phenol was added to preserve and sterilize the canal contents and to pacify pain.[3]

Table 1. Classification of Intracanal Medicaments by Grossman

Essential Oils	**Eugenol**
Phenolic Compounds	Phenol, Parachlorophenol, Cetylpyridinium Chloride (CPC), Formocresol, Metacresylacetate (Crestatin), Cresol, Creosote (Beechwood), Thymol
Aldehydes	Formocresol, Glutaraldehyde
Halides	Sodium Hypochlorite, Iodine, Potassium Iodide, Steroids, Calcium Hydroxide, Antibiotics

Composition of Medicaments:

For Primary Tooth: It includes medicaments such as Formocresol, Glutaraldehyde, Calcium Hydroxide and Ferric Sulphate.

For Permanent Teeth: It includes medicaments such as Calcium Hydroxide, Electrosurgery, Laser Pulpotomy, Bone Morphogenic Proteins (BMP), Osteogenic Proteins I, II, Mineral Trioxide Aggregate (MTA)

Ideal Requirements: It should be stable in solution which is an effective antimicrobial agent. It should have low surface tension and does not stain tooth structure. It should be non-irritating to the periradicular tissue. It should be active in the presence of blood serum and protein derivatives of tissues. It should have a tedious antimicrobial effect with a non-induced cell-mediated immune response.[4]

Properties:

Duration: Activity can inhibit the regrowth of bacteria because of calcium hydroxide. Phenolics dissipate their activity within 24hrs while Tetracycline activity lasts up to 12hrs but the clinical effectiveness of MTAD decreases the duration to 4weeks.

Toxicity: To become a foreign substance, medicaments act as chapters which elicit an immune response. Phenolics and Aldehydes are generally potent cell killers. Due to strong alkalinity of Calcium Hydroxide, it may destroy the Carboxylate and Phosphate groups which results in the collapse in the dentine structure.[5]

Antibiotics: In primary teeth, Ciprofloxacin, Metronidazole & minocycline are used for sterilization of infected root dentine to prevent the resistance development against microorganisms. These drugs penetrate deep into the root dentine which eradicates bacteria. Root canal dressings are found to be effective in a combination of antibiotics. Thus, it can be widely used as an Intracanal Medicaments in Paediatric patients.

Indications: For persistently wet or weeping canals. For neutralizing tissue debris with rendering root canal contents. For eliminating excess microbes which act as a barrier against leakage and for dressing in symptomatic cases.[6]

Recent Advancement of Intracanal Medicaments Used in Paediatric Dentistry:

Bioactive Glass: Invented in 1969, by Dr French, it allows the hard and soft tissues so that the surface gets directly bonded with the materials. Due to their antimicrobial effect pH level is raised which is not effective for bacterial and host cells. Because of complex particles, the dentin powder solution act as a recipient and in aqueous suspension the glass act as a catalyst. As mineralisation of dentin is induced and it possesses a negative effect when used as an intracanal dressing which harms the teeth. It is more effective than Calcium Hydroxide and less effective than 2% CHX.[7]

Ozonised Oil: It can be used as Intracanal Medicaments in various possible ways by dissolving the ozone with oil for lubrication and disinfection purpose. After its use on behalf of Intracanal Medication, the success rate for periradicular lesions and their antibacterial activity is also very high. So it can be used because of its greater efficacy and productivity.

Propolis: It serves as a better Intracanal Medicament because of its anti-inflammatory and good antimicrobial agent but when compared with saline and NaCl, propolis activity is equal to that of NaCl. In the case of pulp and periapical pathologies, it can be used as short term medications.[7]

Octenidine: Due to the prolonged bacterial anti-adhesive activity, it is more effective than chlorhexidine. Hence, complete elimination of root canal is ensured due to its anti-bacterial action which may harm the paediatric patients. Microorganisms may be guarded against the Intracanal Medicaments within the dentinal tubules by the inhibiting effects of dentin and progressive resistance after direct contact with them to Intracanal Medicaments.[7]

Other commonly used intracanal medicaments

Calcium Hydroxide:

Introduced by Hermann, in 1920, as a Calcium Hydroxide paste which is prepared by diluting with sterile or saline water. Lentiluspiral is used for placing the paste inside the canal to full working length. They are used for root inflammatory resorption is inhibited and microbial control is obtained. It serves as temporary obturating material. It stimulates hard tissue formation. It heals the inflammation of the periapical region.[8]

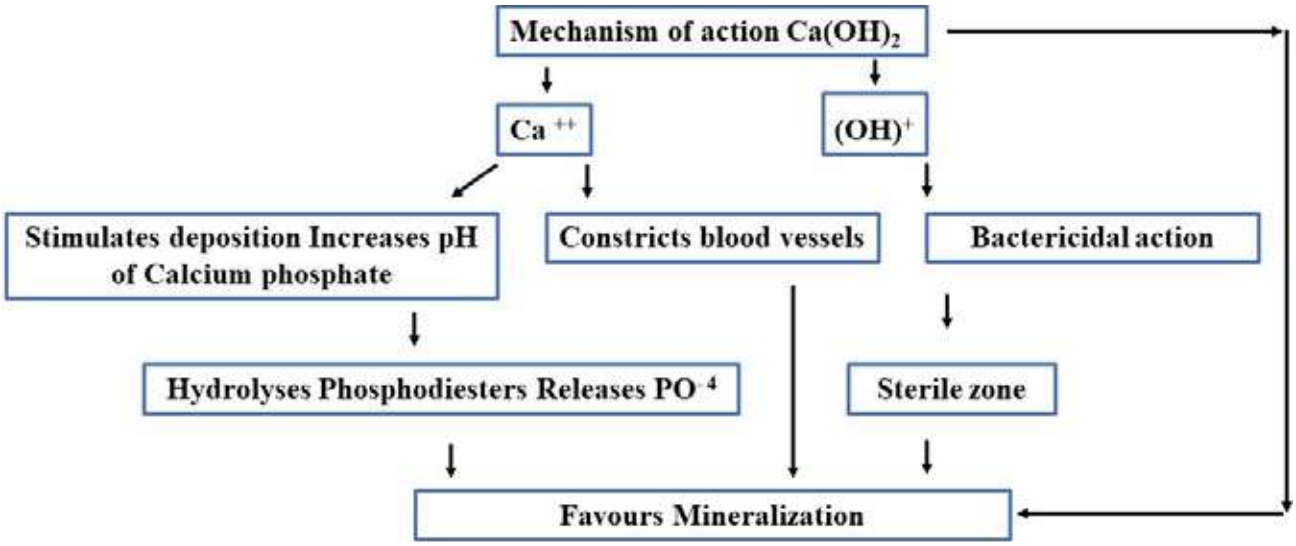

Figure 1. Mechanism of action of $Ca(OH)_2$

Formocresol: It was coined by Buckley, in 1906. It is composed of 35% Cresol, 46% water and glycerine and lastly 1% formaldehyde. It has a proportional ratio of 1:2. It is prepared with a particular mixture which is 3 parts of glycerine diluted with 1 part of distilled sterile water to dilute 4 part in which 30ml formocresol is added to obtain 150ml of diluted Formocresol.[8]

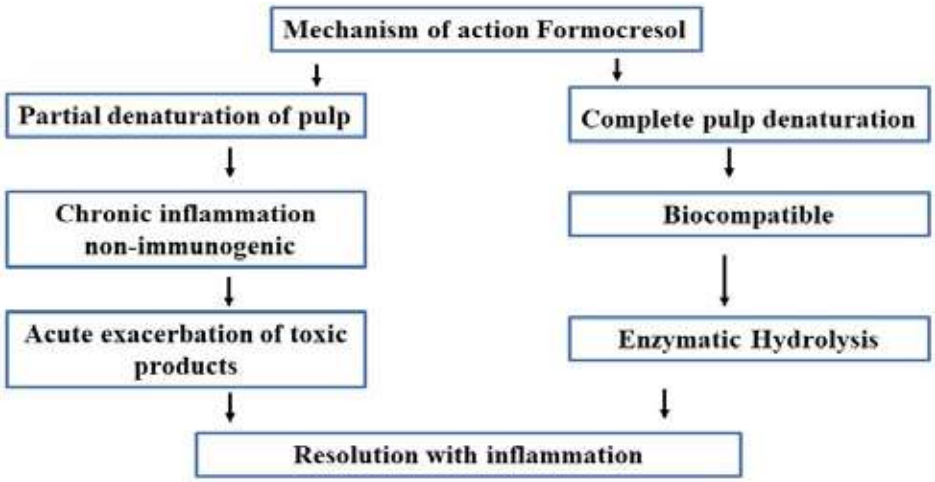

Figure 2. Mechanism of action of Formocresol

Gluteraldehyde: Properties: It is available as 2% Glutaraldehyde. It acts as an excellent bactericidal agent which leads to less necrosis of pulp tissue. It has across Linkage formation with limited depth of penetration. The irreversible changes occur on binding with protein as a result there is no response to the immune system.[9]

Advantages of Glutaraldehyde Over Formocresol: Glutaraldehyde at high concentration act better fixating agent leading to less necrosis of granulation tissue formation on exposition to loner periods than Formocresol. In Primary Tooth, 2% Glutaraldehyde solution placed over root stumps and a drop into ZOE paste, the solutions give better outcome (2% solution) than the drop. Because of smaller molecular size, it cannot reach the apical foramen creating a minimal disturbance in the systematic circulation.[9]

Chlorhexidine Digluconate: It is available in various forms such as MOUTHWASH- (0.12% & 0.2%)–decrease in content of Streptococcus Mutans after 24 hours, GEL- 1% Medicament, VARNISHES- (1%, 10%, 20%, 35%). It is least toxic and effective against *Enterococcus faecalis* which is found in root canal filling with a common pathogen. In Intracanal medicaments, it is used in the form of 2% CHX gel and a mixture of CHX and Calcium Hydroxide which is active against aerobic and anaerobic bacteria.[9]

Rationale and Application of Medicaments: There are signs of canal infection while treating teeth as maintaining asepsis is the means of preserving the antibacterial canal. If there is a violation in asepsis chain the antiseptics measures are necessary to prevent infection in vital pulp extirpation. To prevent infection from the root canal, the rationale behind the intracanal antiseptic medication is to eliminate bacteria. Chemo mechanical preparation cannot eliminate all the bacteria from the root present in dentinal tubules as it has an important cleaning effect. For several days or weeks, it is recommended that root canal should be filled between an appointment with an antibacterial diffusion through the tubules which another aspect in using intracanal medicaments.[10]

Complications and Side Effects: The pulp has ready accessibility to the periapical tissues of systematic circulation. The drug has side effects because of the physiochemical and galenic formation properties which increase the risk of vascular complications. At the site of injection with obliteration of vascular flow, acidic substances cause tissue necrosis. Surgical removal of necrotic substances and extruded materials is the sole motto of the treatment protocol.[10]

Conclusion

In human primary teeth, complete eliminating of aerobic and facultative anaerobic microorganisms was effective as usually not used intracanal medicaments that are Calcium Hydroxide, 1% CHX gel, 1%Metronidazole gel. The intracanal medicaments commonly used is Calcium Hydroxide because of its versatile action, open root apex and weeping canal. For a long time, the root canal compared to other intracanal medicaments retains its effectiveness. In root canal therapy the only important thing is root canal medicament. Efficacy of poly antibiotic paste consisting of Ciprofloxacin, Metronidazole and Minocycline is used in primary teeth referred to as "Lesions Sterilization and Tissue Repair". The increase in the success rate and prognosis of Endodontic Treatment is because of the use of Intracanal Medicament along with efficient biomechanical preparation with copious irrigation. In the initial phase of Endodontic Therapy followed by Calcium Hydroxide dressing, antibiotic is associated with Corticosteroids which is helpful for root resorption and periodontal healing. From the article's perspective, Intracanal Medicaments plays an influential role in Paediatric Endodontics.

TMJ Ankylosis: A Reveiw

Ethena Priyadarsani

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Temporomandibular joint (TMJ) ankylosis is a pathologic condition where the mandiblar fusion takes place to the fossa by bony or fibrous tissues. It interferes with normal day to day activities such as mastication, speech, oral hygiene, etc. Trauma to the chin is the most common factor of TMJ ankylosis followed by infections. This article highlights the eitiology, clinical features, various classifications radiographic features, histopathological features and surgical management of TMJ ankylosis.

Keywords: *TMJ Ankylosis, Unilateral Ankylosis, Bilateral Ankylosis, Gap Arthroplasty, Condylectomy, Interpositional Arthroplasty.*

Introduction

TMJ ankylosis is defined as the merging between the condyle of mandible, fossa, maxilla, zygoma, or bottom of the skull. The fusion may be fibrous or bony. It occurs due to several factors such as trauma(13-100%) most common factor, local or systemic infections (10-49%), or systemic diseases (100%) such as rheumatoid arthritis, ankylosing spondylitis, otitis media, mastoiditis, osteomyelitis of mandible, Reiter's syndrome, hemarthrosis and psoriasis. Trauma to the chin is the most important factor causing TMJ ankylosis. Other etiological factors include secondary rheumatoid arthritis or it may be congenital. It can also occur due to TMJ surgery.[1]

In TMJ ankylosis the chin has deviated towards the affected side resulting in deformity of the face. It leads to various difficulties such as abnormal facial growth, problems in chewing, swallowing, digestion, speech, appearance, and lack of good oral hygiene with multiple dental caries and impacted teeth. Physical and psychological disability may occur due to compromised airway as a result of disturbed facial and mandibular growth. It affects all age groups but more common in children below 10 years of age. It equally affects males as well as females. It is usually seen in the Asian subcontinent.[2]

Kazanjian (1938) classified TMJ ankylosis is of two types: True (intraarticular)- The spinous surfaces of the TMJ are fused. The fusion may be either by bone or fibrous tissues. False (extracurricular)-It takes place outside the joint due to some pathologic condition that results in very less mandibular movements.

Sawhney (1986) graded TMJ ankylosis into four types: Type 1: flattening or condylar deformity with little joint space as seen on radiograph. There are extensive fusions of fibrotic tissues around the joint. Type 2: bony fusion of outer edges of articular surfaces with no fusion in deeper areas of the joint, Type 3: a bony bridge is seen between the ramus of the mandible and the zygomatic arch, Type 4: the whole of the joint is replaced by a bony mass.

Topazian (1966) classified TMJ ankylosis as: Stage 1: Bony ankylosis extending to the condylar process, Stage 2: Here the bony ankylosis has reached the sigmoid notch, Stage 3: Bony ankylosis has extended to the coronoid process. Generally, the classification of TMJ

ankylosis can be done by the area involved (internal or external), variety of tissue involved (fibrotic or bony), facial symmetry(unilateral or bilateral), and extent of ankylosis (partial or total).[3]

Unilateral TMJ Ankylosis: In unilateral ankylosis due to facial asymmetry chin is deviated towards the affected side. Here the mouth opening is very less. Asymmetry of the face is seen along with fullness in the affected side and relative flattening of the unaffected side of the face.

Bilateral TMJ Ankylosis: In bilateral TMJ ankylosis both sides of the face are affected. Here bird face appearance (micrognathia) is seen. There is no gliding movement neither protrusive nor lateral movement. The presence of a scar on the chin is seen (mostly due to trauma). Class 2 malocclusion occurs along with protrusive incisors and anterior open bite. In a long term case there may be atrophy or fibrosis of muscle. In a congenital bilateral ankylosis there is the difficulty of introducing the nipples into the mouth of newly born infants.[4]

Radiographic Features: In radiographs TMJ ankylosis is detected by various findings such as reduced height of mandibular ramus, joint space is either partially or completely obliterated with sclerotic bone, condyle may be replaced by shapeless bony mass, a prominent antegonial notch is seen in the affected side of the mandible. There is elongation of the coronoid process of the mandible. Sometimes a transverse or oblique dark line is seen crossing the mass of dense bone showing fibrous.

Radiographic investigations of TMJ ankylosis includes lateral oblique view, O.P.G view, cephalometric radiograph, submentovertex view, posteroanterior view, CT Scan.[5]

Histopathological Features: In Type 1 ankylosis irregular fibrous tissue is filled in the joint space. On both sides the cartilage cell layer is thickened and the mid of the joint space is loaded with non-uniformly distributed fibrous tissues. In Type 2 ankylosis the joint space is mostly filled with fibrous tissues and some cartilaginous tissues. In Type 3 ankylosis, joint space is principally packed with the cartilage resembling likehyaline cartilage. Here the chondrocytes were seen enlarged, calcified and expanded towards the bony cavities and joint space showing the bone was active. In Type 4 the joint space disappears, so it is not considered in the histological examination.[6]

Management of TMJ Ankylosis: TMJ ankylosis can be treated both surgically and non-surgically. Non-surgical treatment includes physiotherapy- it includes continuous passive movements, use of tongue blades, etc. Orthodontic treatment includes use of functional appliances.

Surgical management of TMJ ankylosis: Surgical management aims to create a gap between the fragments adequately, to make the joint mobile for improvement of patient's oral health, speech,chewing,etc. It aims to preserve the vertical height of mandibular ramus. It decreases the recurrence rate and preserves normal facial growth pattern. Various complications may occur during surgical treatment such as haemorrhage due to injury to the superior temporal vessels, facial artery, etc. Injury to the external acousticmeatus, auriculotemporal nerve, malar and temporal branch of facial nerve and teeth. Infections and open bite may also occur.Various procedures for surgical treatment of TMJ ankylosis includes condylectomy, gap arthroplasty, interpositional arthroplasty, extraction of the specific dentition.[7]

Condylectomy: It is usually done in fibrotic ankylosis. In this procedure first preauricular incision should be given then a cut is given at the mandibular condyle neck. The top portion of the condyle should be detached from the upper attachment thoroughly. Then suturing should be done in layers. Most common defect of this process is divertion towards the ankylotic side. Anterior open bite may also occur.

Gap arthroplasty: Gap arthroplasty is mostly done in case of bony ankylosis. Here gap is created between the glenoid fossa and ramus of the mandible by removing the bony wedges. Gap helps in mandibular movements. The gap should be atleast 1 cm in order to avoid re-ankylosis.

Interpositional arthroplasty: Interpositional arthroplasty is modified form of gap arthroplasty. Here the gap is filled with certain materials to prevent recurrence of ankylosis. In this procedure gap is created as in gap arthroplasty but here materials are inserted in the gap between the two surfaces in order to maintain adequate vertical height of mandibular ramus and to prevent recurrence of ankylosis. Materials used in interpositional arthroplasty may be autogenous, heterogeneous or alloplastic. Autogenous materials such as temporalis muscles, temporal fascia, fascia

lata, cartilaginous grafts such as (CCGs, metatarsal, sternoclavicular graft,auricular graft), dermis of skin, etc are used. Heterogeneous materials such as chromatised submucosa of pig's bladder, lyophilized bovine cartilage are used. Alloplastic materials includes metallic and non-metallic materials. Metallic includes tantaliumsheets, stainless steel, titanium, gold, etc. Non-metallic includes silastic, teflon, acrylic, nylon, ceramic, etc.[8]

Another treatment for management of TMJ ankylosis include **Kaban's protocol (1990)** It includes **seven** steps: Aggressive resection, ipsilateral coronoidectomy, contralateral intraoral coronoidectomy, creating lining of joint, mandibular ramus is again reconstructed withthe costochondral graft, rigid fixation, early mobilization and aggressive physiotherapy.

Kaban's protocol new (2009) includes the following steps:

Excision of the ankylosed mass: A preauricular incision is given to approach the TMJ along with a hemicoronal incision in order tounveil thetemporalfascia and muscle, zygoma, ankylotic part and the sigmoid notch. A horizontal incision is given to the periosteum above the arch and thenit is then repeatedover the fibro-osseous or bony partand is then continued to the visible portion of ramus of the mandible which is not affected. Then invasive excision of fibrotic or bony part is done. If any TMJ defect is detected thenseggregation of ramus of mandible from base of the skull is done by extension of major osteotomy into the joint. If ulnar notch is identified then minor osteotomy is done by posterior extension 1.5 to 2 cm below the ankylosed mass margin. Then a bur is used for reshaping the base of the skull into a glenoid cavity.

Ipsilateral coronoidectomy (contralateral if necessary): At first a pit is made below the coronoid process and then a wire is placed for the pull. From the depth of the ulnar notchthe osteotomy extends to the intersection of the parallel and perpendicular portion of ramus of the mandible. After completion of the osteotomy the coronoid is placed on the traction with the wire. The whole of the coronoid is removed by cutting the left over temporalis muscle and tendons. If the coronoid tip removal is inadequate, reformation of coronoid occurs and it attaches to the temporalis tendon.

Glenoid fossa lining: During resection of the ankylosed mass if an unaffected part is detected then it should be separated, and replaced on the top of the new glenoid cavity. In some instances the temporomandibular joint is lined with temporalis muscle and temporal fascia flap based inferiorly which is turned and placed into the joint. The flap is inferiorly supported over the deep temporal artery. In order to construct a barrier the deep temporalis fascia and the superficial muscle layer are shifted in order to aid in normal functioning of the ramus which has been constructedor condylar part and to support the blood supply of the flap. Then suturing of the flap done on the front and back side of the soft tissue with 4-0 monocryl suture.[9]

Reconstruction of mandibular ramus and condyle unit: An infra-mammary incision is given to obtain a CCG for the construction of the condylar unit. The cartilage then contoured to have rounded edges. Thickness of the cartilage should be 1 to 2 mm. Trimming and contouring of the rib is done to obtain a good bony interface. Submandibular incision is given. Then the graft with cartilaginous articulating surface is placed against the temporalis flap. This is secured with 2.0 mm titanium bone. Then suturing is done in layers. Reshaping of remaining part of the mandible done in order to obtain a disc shaped tip. Corticotomy is performed, leaving sufficient bone to act as transportation medium. After securing decompression device corticotomydone and movement of the segment is checked by starting off the half buried single directional decompression device. After around 4 days of the treatment active distraction starts at the rate of 1 mm and rhythm of 2 to 4 activations daily. The distraction is ended after the contact of transport disc with the base of the skull. As a result pressure will not be created. Benefits of this are physiotherapy can be started after the surgery on that day donor site and morbidity are not required.[10]

Early mobilization and aggressive physiotherapy: It includes sidewise movement of the mandible in repeated mannerand pulling the digits in front of the mirror. The exercises should be repeated 3 to 4 times per day for 3 to 5 minutes. After completion of 6 weeks of surgery solid food items can be given and the 'Thera-Bite Rehabilitation System should be done 4 to 5 timesper day for 3 to 5 minutes. The physiotherapy procedures also involvesheat treatment,rubbing and kneading and mastication. If the sufferer is unable to achieve the maximal interincisal opening during the surgical treatment orelse if there is no signs for improvement of the maximal initerincisal opening after 6 to 8 weeks then stretching of the mandible should be done under general anaesthesia. Utililizing the Thera Bitesystem 4

to 5 times daily, chewing of gums and manual finger stretching exercises should be done and patients should follow this routine regularly for 1 year.

Recurrence of TMJ Ankylosis After Surgical Treatment: TMJ ankylosis may reoccur after surgical treatment due to following reasons such as lack of sufficient gap between the fragments, if costochondral graft is fractured, if the surface of glenoid fossa is not covered properly, if postoperative physiotherapy is not done adequately and if there is increased osteogenic potential and periosteal osteogenic power which is more common in children.

3 most important factors to prevent re-ankylosis includes adequate gap should be maintained between the fragments of width (1.5 to 2 cm), interpositional barrier should be carefully placed and stabilized that should completely cover the surfaces of the sectioned bone. Adequate jaw exercises should be done regularly for a long term. Amongst the three factors most important one is the use of exercise regularly.[8-10]

Conclusion

From the above discussion it is clear that TMJ ankylosis mainly occurs due to trauma and certain infections and usually takes place in children of younger age. Most of the time due to lack of understanding of clinical features and radiographic features of TMJ ankylosis by the dental surgeon may lead to poor diagnosis of TMJ ankylosis. Patients usually faces difficulty in mastication, speech, facial growth pattern, etc. Patients suffering from this have limited mouth opening. Psychological disorders may also occur. Thus it causes functional as well as aesthetic problems. When it occurs in early age it interferes with the development of mandible. But can be treated by both surgical and non-surgical ltreatment. In surgical management the recurrence rate is very high if not operated carefully. It can be managed by proper exercise of the jaw regularly for several years. Thus if proper diagnosis and proper surgical treatment is done on time with sufficient exercises then good results can be obtained.

Management of Cleft Lip and Palate in Pediatric Dentistry: A Review

Subhangi Chandan

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha-751003, India

Abstract

Birth of a child is considered the happiest moment of a parent's life and magical experience where God entitles a mothering power of creation. When a child born with a cleft, it represents a disaster for parents. Surgical restoration of soft tissue continuity of the lip and palate consequences in an approximation of the maxillary segments irrespective of surgical technique. The degree of maxillary width reduction depends on several factors, including surgical technique, the surgeon's skill, scar formation, degree of tissue deficiency, and timing procedures.

Keywords: *Cleft Lip and Palate; Management; Pediatric Dentistry.*

Introduction

Cleft palate is also known as harelip. Orofacial clefts are among the foremost common congenital anomalies. Such anomalies can have several consequences like impaired suckling, defective speech,difficulty in hearing, upper protrusion,gross facial impairment, severe mental disorder. Cleft of the lip and palate is one such condition that happens at such a strategic place within the orofacial region and at such an important time that it becomes a posh congenital deformity. Clefts are complicated conditions,which affect the look, and the activity of the child will concern many other consultants.[1-3]

Incidence: The frequency and geological distribution of clefts vary largely around the world due to discrepancies in birth prevalence as well as failure in the recording of childbirth and congenital malformation. In males,cleft lip is more, not unusual and in the case of women, cleft palate is more commonplace. There are two varieties of clefts that are unilateral clefts and bilateral clefts. About 80% of prevalence seen in one-sided clefts and about 20% of incidence seen in both sided clefts. In the case of one-sided clefts, the left side is mostly affected which is around 70%.Least prevalence noticed among Negroids(0.4/1000) and the highest incidence visible in mongoloid and afghans(4.9/1000).[4-6]

Embryological Background: By fusion of several embryonic processes, the face is formed around the primordial oral cavity. Five branchial arches developed at the position of the future neck around the fourth week of intrauterine life. The first arch, called the mandibular arch performs an important role in the improvement of the naso-maxillary complex. The developing forebrain which is covered by mesoderm proliferates and protrude the stomodeum.

On either side of the mandibular arch,the dorsal end gives rise to bud called the maxillary process.[7]

The frontonasal process gets divided into a medial nasal process and two lateral nasal processes with the formation of the nasal pits. By the fusion of the maxillary process,the upper lip and primary palate are formed with the one medial and two lateral nasal processes. By the 6th week of gestation,the upper lip and the primary palate frequently start merging.[8]

Corresponding Author:

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha-751003, India

Development of Palate: The palate is formed utilizinga maxillary manner, frontonasal method, and palatal cabinets have given off using the maxillary procedure. The frontonasal manner gives rise to premaxillary vicinity and palatal cabinets from the rest of the palate. In the 8th week, the fusion of palatal cabinets begins and continues until the 12-seventeenth week. Palatal cabinets covered through an epithelial lining. If palatal shelves be a part of, epithelial cells degenerate. Connective tissue present in palatal shelves be a part of every other and resulting in their fusion.[8]

Development of Lip: The lower lip is formed by the fusion of mandibular sides and the upper lip is formed by the medial nasal and maxillary processes. By the fifth week's gestation, the medial nasal and the maxillary process should be failed by merging one or both sides in the cleft lip.[9]

Table 1. Etiology, predisposing factors & clinical features and syndromes[10-12]

Etiology	1. Infection; 2. Heredity; 3. Environment; 4. Lack of inherent development; 5. Effect of alcohol and certain drugs during the formation
Predisposing factors	1. Toxemia; 2. Diabetes; 3. High maternal age; 4. Reduced blood supply; 5. Folic acid deficiency; 6. Radiation; 7. Racial mongoloids
Clinical features:	1. Inability to suck the mother's milk; 2. Facial deformity; 3. Nasal intonation for the cleft palate; 4. Nasal regurgitation; 5. Tooth defects like supernumerary teeth peg lateral, germination, etc.
Syndromes associated with cleft lip and palate	**Autosomal Dominant:** a: Vander Woude syndrome; b: EEC (Ectrodactyl, ectodermal dysplasia, Cleft).
	Autosomal recessive: a. meckel syndrome; b. Roberts syndrome **X-linked:** a. orofacial digital syndrome type-1; b. Isolated cleft palate with ankyloglossia **Chromosomal:** a. Trisomy 13; b. Trisomy 18 **Non-Mendelian:** a. Pierre Robin syndrome; b. clefting with congenital heart disease **Autosomal recessive:** a. meckel syndrome; b. Roberts syndrome **X-linked:** a. orofacial digital syndrome type-1; b. Isolated cleft palate with ankyloglossia **Chromosomal:** a. Trisomy 13; b. Trisomy 18 **Non-Mendelian:** a. Pierre Robin syndrome; b. clefting with congenital heart disease

Classification of cleft lip and palate:

The following are some of the widely used classifications of cleft lip and palate.

1. Davis classification (1942):According to Davis,clefts are divided into(A) Group-1:Pre-alveolar clefts; (B)Group-2:Post-alveolar clefts; (C) Group3:Alveolar clefts.

2. Kaushal classification (1987):L:Lip; A:Alveolus;H:Hard palate; S:Soft palate; H:Hard palate; A:Alveolus; L:Lip[13]

Problems associated with cleft lip and palate:

1. Ear problem: Conductive hearing loss and chronic suppurative otitis media occur.

2. Speech difficulties:A:velopharyngeal insufficiency; B::Abnormal air

3. Dental problem:a.Local problemFused teeth, enamel hypoplasia, gemination, presence of natal and neonatal teeth,congenitally missing teeth,ectopically erupting teeth,anomalies of tooth morphology,aberrations in a crown shape.b.orthodontic problemAnterior and posterior crossbite, Spacing and crowding,deep bite

4. Feeding difficulties: Cleft lip: for an infant more difficult to suck on a nipple, Cleft palate: breast milk to be taken up into the oral cavity, Upper respiratory tract infection, and regurgitations should be frequent.

5. Nasal deformity and esthetic problem:A:poor nasal shape;B:poor lip function;C:poor dental alignment and smile[14]

Management:

To control cleft lip as well as cleft palate,many experts are associated with it. The crew members are:

1. Maxillofacial surgeons: Maxillofacial surgeons pick out who diagnose and deal with the abnormalities associated with the skeletal pattern of the skull, facial bones, and gentle tissues in coordination with specialists.

2. Pediatrician: The boom of the kid have to be monitored by using the prediction.

3. Pedodontist and Orthodontist: Pedodontist and orthodontist are those who evaluate the position and alignment of the jaws and enamel and coordinate a remedy plan.

4. Speech specialist: Speech expert During developmental stages, the kid is closely monitored and evaluated to assess the communicative abilities incomplete speech

5. Otolaryngologist: Ear contamination and listening to loss is managed

6. Audiologist:To help the evaluation and control of listening to difficulties

7. Genetic counselor: Medical and family history is reviewed to observe the kid's help in analysis.

8. Nurse team co-ordinates Specialized pediatric nursing with the care of the child.

9. Social Worker: The baby and their own family are guided and counseled to address social and emotional aspects.

10. Prosthodontist:

11. Patient care-coordinator[15]

Role of Pedodontist in the management of cleft lip and cleft palate:

A. Feeding and nutritional device: A cleft baby faces difficulty to suckle and encounters problems of nasal regurgitation and malnourishment. Advise proper feeding method 1: Breastfeeding; 2:Bottle feeding

a. Breastfeeding: Ensure if toddler requires prosthetic feeding equipment and in fabricated appropriately a: Require long feeding time; b: Lot of air is suckled thru cleft and consequences in aerophagia which calls for common burping after every 1/2 OZ of feed; c: Mothers have to be advised to take a look at the infant for chocking, cyanosis and stomach disinfection for the duration of feeding; d: Infants must be held at 30-forty five position

b. Bottle feeding: Advise the mother to preserve the toddler at 30-45 angulation or in an upright position. Use of suitable clean teats with good enough slit. Various kinds of teats: 1:Mead Johnson cleft palate nurser; 2: Habermanfeeder. Other normally used teats are: 1: Pigeon cleft teat; 2: Nucknipple; 3: Chu-chu clean feed teat; 4: Chu -chu pass reduce feed teat

B. Dental Management: A thorough examination,

research, and diagnosis of dental anomalies and sickness are necessary. A: Advice Safe diet; B: Prophylactic measures should be needed; C: Obtain proper impressions to fabricate an obturator; D: Educate both patients to keep clean gum pads; E: fluoride application; F: Sealant therapy; G: Early intervention of carious tooth; H: Reinforce the affected person to manage up and ward off mental stress; I: Monitor modifications in speech/heavily capabilities of the kid.[16]

Orthodontic Management: The orthodontic management of cleft lip and palate are:

A: Stage one: treatment done from birth to 18 months of age; B: Stage two (primary dentition stage): from 18 months to the fifth year of life; C: Stage three (mixed dentition stage): from sixth to eleven years of life; D: Stage four (during permanent dentition): From 12-18 yrs of age.

Stage one treatment: 1: Fabrication of passive obturator; 2: Presurgical orthopedics; 3: Surgical management of cleft lip; 4: Surgical management of cleft palate.

a. Passive maxillary obturator: It is a type of intraoral prosthetic device that reduces the incidence and feeding difficulties.

b. Presurgical orthopedics. Reduces the size of clefts and improved speech;

c. Surgical lip closure-Surgery should be performed within 45 days of birth. A rule often should be applied here. According to Millard,surgery should not perform less than 10 weeks of age, body weight is not less than 10 pounds and Hb not less than 10 grams%;

d. Surgical palate closure:(12-24 month of age)- It improves hearing,normal speech and improves swelling.[16]

Stage two treatment: 1: Intra-oral obturation adjustment;2:Check on eruption pattern; 3:Oral hygiene instructions;4:Restoration of decayed teeth

Stage three treatment: Mixed dentition stage, Secondary alveolar bone grafting

Stage four treatment: Regular oral hygiene and dietary counseling is required.

Complication and Disadvantages: 1: Skin irritation; 2: Ulceration of intramural tissue; 3: Irritation of oral mucosa tissue; 4: Parent compliance required.

Diagnosis: 1: Prenatal counselling; 2: Prenatal ultrasound-2D or 3D; 3: Color Doppler ultrasonography; 4:73%-feral cleft lip;5:1.4%-isolated cleft palate.[17-19]

Conclusion

Treatment of cleft lip along with cleft palate should be done at the correct time. If behind schedule in remedy there may be the possibility of advanced abnormalities. So to prevent troubles like speech problems, facial asymmetry, feeding trouble, infection to the nasal cavity, and unaesthetic appearance the remedy is necessary. Oral clefts are the second most commonplace congenital anomaly. It frequently affects speech, hearing, cosmetics, and may at times lead to airway obstructions. The oral and maxillofacial health care professional is a key member of the cleft lip and cleft palate team, to perceive and manage many of the troubles.

Topical Fluoride for Prevention of Dental Caries: A Review

Padmaja Nayak

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha-751003, India

Abstract

Topical Fluoride has been the primary human action of dental caries hindrance for many decades. There are various mechanisms that kind it advantageous including inhibiting pathology, enhancing remineralization, and inhibiting microorganism maturation. This paper represents the development, mechanism of action, and manner of use of various fluoride products. The comparative study between the different forms of fluoride preparation is over viewed here. Fluoride toothpaste, mouth rinses, varnishes are some of the products usually utilized for caries prevention. The practician must ascertain sort of topical preparation suitable for different types of patients who are at different risk levels.

Keyword: *Professionally applied topical fluoride; Self-applied topical fluoride; Acidulated Phosphate Fluoride, Monofluorophosphate; Caries prevention.*

Introduction

The water fluoridation system is one of the effective and economical measures for caries prevention, but it is available for a small group of people, therefore other method are required for the application of fluoride. The topical fluoride method is one such method in which high amounts of fluoride are ingested topically or locally. When the tooth erupts, the application of fluoride topically should be done, so that the injection of fluoride occurs and the enamel becomes more caries resistant.[1]

Table 1. Type of topical fluorides[3]

Professionally applied topical fluorides	A. 2 percent Sodium Fluoride. B. 8 percent Stannous Fluoride. C. 1.23 percent Acidulated Phosphate Fluoride. D. Fluoride Varnishes a. Duraphat (Sodium Fluoride b. Fluorprotector (Silane Fluoride) c. Carex. E. Fluoride Foam. F. Fluoride Prophylactic pastes. G. Fluoride containing restorative products.
Self-applied topical fluorides	A. Fluoride Dentifrices. B. Fluoride Mouthrinses. C. Fluoride Gels.

Topical fluorides are of two types:

1. Professionally applied topical fluorides: In the year 1942, Bibby discovered that the use of sodium or potassium fluoride caries can be reduced in the case of children. Mainly 5000-19000ppm i.e, 5-19mgF/ml concentration of fluoride is used.[2]
2. Self-applied topical fluorides: 200-1000ppm i.e, 0.-1mgF/ml fluoride concentration is used.[2]

Indications:

1. Patients with a carious tooth.
2. Children just after tooth eruption period.
3. Patients who are under medication to reduce salivary flow or have undergone head and neck radiation.
4. Mentally or physically challenged persons.
5. Patients who have undergone periodontal surgery when the roots have been exposed.
6. Patients having a dental prosthesis.
7. Eating disorder patients.
8. Patients who have undergone any restorative procedures.

Professionally Applied Topical Fluorides:

A. 2 percent Sodium Fluoride: This technique was given by Knutson. Powder and liquid forms are available. It is made by adding 0.2gm of powder in 10ml. of distilled water. 4 weekly applications of 2%NaF at 3,7,11 and 13 ages.[3]

Method of application: Teeth should be cleaned and polished, Isolate and dry by using cotton rolls, Apply quadrants, Apply for 3 minutes with a cotton applicator, Repeat in remaining quadrants, and Instruct the patient to avoid eating or drinking or rinsing for half an hour.[4]

Mechanism: Sodium Fluoride reacts with hydroxyapatite crystal to form a product i.e, Calcium Fluoride. Then there will be choking off i.e, reduction in the rate. Further Calcium Fluoride reacts with hydroxyapatite to form Fluoridated hydroxyapatite. It leads to an increase in fluoride concentration by converting the tooth surface into the stable in nature and caries resistant.

Advantages: Stable, Acceptable taste, Non-irritating, and No discoloration.[5-7]

Disadvantages: The patient has to make four visits in a few days.

B. 8 percent Stannous Fluoride: It was given by Muhler. This technique involves the use of Stannous Fluoride in powder form. It is made by dissolving 0.8gms of powder in 10ml. Distilled water. The resultant solution is acidic.[5-7]

Method of Application: Teeth should be cleaned and polished, Isolate and dry with cotton rolls, Apply the solution using the cotton applicator on all teeth surfaces, Repeated loading is done and swabbing is done for 4 minutes, Patient is allowed to expectorate after removal, and A six-monthly interval should be advised for next appointment.[5-7]

Mechanism of action: Stannous Fluoride reacts with Hydroxyapatite to form Stannous Tri-fluorophosphate. The product formed is very much useful for the reduction of caries. The stability of the product is also great. Tin hydroxy phosphate is also formed. It is the reason behind the metallic taste which is one of the disadvantages.

Advantages: The frequency of appointments is less.

Disadvantages: Metallic taste, Gingival irritation, Brown pigmentation, and Each time fresh solution has to be prepared. [5-7]

C. 1.23 percent Acidulated Phosphate Fluoride: The solution is known as Brudevold's Solution. Available as a solution or gel. The solution is made by adding 20 gms of NaF in 1lit. of 0.1M Phosphoric acid and adding 50% Hydrofluoric acid. For the preparation of gel, Methylcellulose gelling agent is added to the solution. Other gelling agents like hydroxyethyl cellulose may be used. Frequency-Twice a year. [5-7]

Method of Application: Solution: Oral prophylaxis should be done. Isolate and dry with cotton rolls. Then the solution is applied for four minutes. The patient is instructed to keep his/her mouth close and not to eat or drink anything for a half-hour. Gel: Mouth trays are used. The patient should be in an upright position. If we use Suction it can be easier to do the procedure or else it might be difficult and clumsy. The tooth should be dried. Enough gel should be used but not more than 2-2.5gms per tray. Should be applied for four minutes.

Mechanism of action: Initially, dehydration occurs. Shrinkage of hydroxyapatite crystals occurs. Then hydrolysis and Dicalcium Phosphate dehydrate (DCPD). The penetration of fluoride ions occurs and forms fluorapatite.

Advantages: Stable, No staining, and Self applicable.

Disadvantages: Acidic taste and Glass can't be used as a container.[6-8]

D. Fluoride Varnishes: It is a temporary material that allows the fluoride to adhere to the tooth surface for a longer duration.

Advantages: Well accepted and safe. Requires minimal training.

Duraphat (NaF): First fluoride varnish which was tested. Consists of 2.26 percent Sodium Fluoride or 22.6mgF/ml. In the presence of saliva, it becomes a hard yellowish-brown coating. The effectiveness of Duraphat is between 30 to 45%.

Floor protector (Silane Fluoride): Discovered in 1970. Consists of 70000ppm Fluoride. The main ingredient in this product is Silane Fluoride.

Carex: Tested in Norway. Consists of 1.8% Fluoride. Its efficacy is equivalent to Duraphat.

Method of application: At first oral prophylaxis should be done. Dry and isolated with cotton rolls. First mandibular arch then maxillary arch. Small amounts (0.3-0.5ml or 2drops) of varnish should be dispensed, by using single tufted brush starting proximal surfaces. After that patient is advised to sit opening the mouth for 4minutes. Instruct the patient to avoid rinsing or drinking and also eating any solid food. Advised for taking liquid or semisolid for 18 hours.[6-8]

E. Fluoride Foam: 0.92% F (9200ppm) at pH 4.5.and Commercially available.

Advantages: Less in density and better flow, Lighter than conventional gel, so an only small amount is needed and Doesn't require suctioning so offers home use.

Disadvantages: Retention is less.

F. Fluoride Prophylactic pastes: Prophylactic pastes containing Sodium Fluoride was developed in 1946. In 1960 Stannous Fluoride containing paste was discovered. Nowadays various new products are available like pastes containing Zirconium silicate and Acidulated Phosphate Fluoride silicone dioxide paste etc.

Functions: These pastes contain abrasive materials which remove the deposits present over the teeth. Polishing the tooth surface as well as the restoration. In the case of periodontal or cosmetic reasons, these pastes are recommended. Various studies demonstrate that alone these pastes can't be the effective cariostatic method.[6-8]

Table 2. Comparison between the effectiveness of Professionally applied topical fluoride agents

Agents	2% Sodium Fluoride	1.23% APF	8% Stannous Fluoride	Fluoride Varnish
The concentration of fluoride (ppm)	9200	12300	19500	22600
Effectiveness in caries reduction (in %)	29	22	32	38

Self-Applied Topical Fluorides:

A. Fluoride Dentifrices: Fluoride dentifrices play a big role in the reduction of caries in view that it requires lively participation utilizing the patient to have any effect. It has been demonstrated that the patient who brushes twice a day or greater with 1000ppm or 1500ppm or 2500ppm fluoride dentifrices have substantially reduced caries prevalence. Some of the fluoride products which have been examined for use as dentifrices are Sodium Fluoride (0.2%), Stannous Fluoride (0.4%), Sodium monofluorophosphate (0.76%), Acidulated phosphate fluoride, and Amine Fluoride[6-8]

Mechanism of action: There are two mechanisms of action. One of them is, MFP ions are integrated into the hydroxyapatite crystal. Then there will be the release of fluoride ion, which is further replaced by hydroxyl corporations to form the product called fluorapatite. The second mechanism is, MFP ions itself is integrated into the crystals having alternative products like one or many phosphate groups. As caries activity becomes more in the tooth surfaces, there will be a decrease in the pH level, but by using the fluoride toothpaste, the enamel which has become demineralized can be made back to the original condition, so it is one of the easy and successful method of dental caries prevention.[6-8]

How to use the dentifrices: To prevent further caries, people of almost every age group should use the fluoride toothpaste. The kids under the 6 years age group should also be advised to use but under the supervision of an adult otherwise immoderate ingestion of fluoride can occur. In kids, only a very small amount (less than 5mm) approximating the 'pea-size' have to be placed on the brush.

B. Fluoride Mouth rinses: Over the preceding years, fluoride mouth rinsing has flip out to be an effective and important method of prevention of caries. Various fluoride products used as mouthwashes are Sodium Fluoride, Stannous Fluoride, Amine Fluoride, etc. Among all of these, Sodium Fluoride is mainly used. For the school-based programs, 2gm Sodium Fluoride is added in 1-liter water. By its regular use, caries reduction occurs by 20-30 percent. For personal use, tablets are there i.e,

200mg Sodium Fluoride tablets in 5 teaspoons of water. It is best for mouthrinse for a family who uses it regularly. [6-8]

Recent Advances in Topical Fluoride: At present, there is a drop in the caries prevalence across countries. More and more children are turning caries-free nowadays. Many types of research are also going on in the production and utilization of newer fluoride products. Various fresh and new fluoride products are launched day by day, i.e, fluoride mouth rinses, fluoride whitening agents, toothpaste, fluoride varnishes, etc. Stannous Fluoride Sodium Hexametaphosphate (SFSH), a new fluoride product was presented against the caries problem of various patients. It was used in the mid-2005-2006 year as a composition of the dentifrice. Researches revealed that Silver Diamine also used as an effective material currently. Also, more and more fluoride-containing restorative products are used nowadays rather than usual restorative products. Fluoride varnishes have a higher rate of effectiveness than that of Sodium and Stannous Fluoride.[9,10]

Conclusion

From the various researches and clinical investigations, it was concluded that topical fluoride is one of the easy to use and effective method of caries prevention. It is cariostatic for all age groups. One of its advantages is fluorosis generally doesn't occur due to topical fluoride application. On the other hand, these products might have some side effects like nausea it is high in cost than water fluoridation. Nowadays newer products are discovered and examined for a better purpose which will be more and more useful for the reduction of caries prevalence.

A Traumatic Restorative Technique: A Review Article

Anwesha Subuddhi

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

The art procedure is minimally invasive. It is mainly based on minimum discomfort & preservation of maximum healthy tooth tissue. Using hand instruments reduces pain & vibration, unlike rotary instruments. This procedure is getting more popular,acceptable in children & those individuals who fear & have anxiety about the dental procedure insocioeconomically weaker areas are becoming more popular. Art is suggested to utilize around the world, not only in developed countries but also in industrialized nations. This article gives a short review of art and its uses in the current situation.

Keywords: *A traumatic restorativetreatment (art); Glassionomercement (gic).*

Introduction

Art is a part of the primary oral health program in Tanzania(support of who).Art was needed to be available in less developed countries like the socioeconomically weaker section. Art is the excavation of soft carious dentin with hand instruments only & then restoration is done by using modern restorative material. To minimize the onset of secondary caries presently fluoride leaching gic were used. High viscositygic; simplifies the process of restoration & enables dentine pulp complex to respond against the carious process.[1]

Table 1. History a traumatic restorative technique[2]

Mid 1980	Pioneered in Tanzania done by university of diaries salaam
1986	At the scientific meeting of Tanzania dental association, the results of the piolet study were presented & later officially art born.
1991	Comparison between art & the mobile conventional equipment approach was done by community field trial in rural Thailand.
1992	In the Thailand study, it was clear that children more happily participated who had been treated by the art approach rather than those treated with traditional rotary hand piece approach.
7th April 1994	Art was officially adopted by who on "world health day
1996	In 25 countries, art was used.
2002	Art was declared as minimally invasive dentistry by FDI in Vienna

Definition: Art is defined as a minimally invasive care approach in preventing dental caries and stopping its further progression.

Principles: Evaluating the carious part utilizing hand instruments. With the help of glass ionomer cement. i.e. A restoration material restores the carious lesion which adheres to the tooth.

Goals: To preserve tooth structure, reduce infection, and to avoid discomfort.

Armamentarium: The accomplishment of any treatment relies upon the administration knowing the capacity of different instruments and utilizing them effectively.[3]

Essential instruments:

a) Mouth mirror: to reflect light onto the field of operation to see the hole by implication and to withdraw the cheek or tongue.

b) Explorer: to recognize where delicate caries dentine is present. Do not stick the point into very small caries sore. This may decimate the tooth surface and caries arrestment process. Also do not test into profound pits where yo may harm or presentation the mash.

c) Pair of tweezers: to convey cotton wool rolls and wedges.

d) Dental hatchet: the instrument is utilized for enlarging the passageway to the cavity, for cutting ceaselessly the unsupported and carious polish left.

e) Small, medium-sized spoon excavator: the instrument is utilized to expel soft caries dentine. The little excavator has a distance across of 1mm. This instrument is for use in little holes and for cleaning the veneer/dentin intersection. The width of this medium spoon is 1.5mm. It is utilized for expelling delicate caries from enormous pits adjusted surface is utilized to drivethe material into small pits.

f) Glass slab:this is provided with the cement.

g) Carver: the instrument with double end has two functions. The blunt end is utilized for embedding glass ionomer cement into the cavity and sharp end is utilized to expel the overabundance material and shape the reclamation.

h) Spatula: the spatula is might be metal or plastic.[4]

Material

a) Gloves: for cleanliness reason.

b) Cotton rolls: to assimilate the spit.

c) Glass: ionomer restorative material (powder, liquid)

d) Wedges: these are utilized to hold the plastic strips near the state of the proximal surface of atooth with the goal that remedial material is constrained between the tooth and gums.

e) Petroleum jelly: to forestall glass ionomer cement adhering to the gloves for conclusive protection.

f) Plastic strips & water: utilized for forming the proximal surface in different surface reclamation.

Pre-treatment precautions:

What steps we should do before the start of the procedure:

a) Before doing the art of a carious sore you must know how to set up a good working place.

b) Select and utilize the right instrument.

c) Cross disease

d) Utilize material i.e. Glass ionomer cement.

Why we use hand instrument:

a) Less injury to the tooth conservative/moderate arrangements.

b) Minimal effort of hand instrument

c) Improved contamination control.

d) No use of anesthesia, which decreases physiological injury to children.

e) Makes helpful construction accessible for all population gatherings.

Why we use glass ionomer cement material:

a) Chemical adhesive- limits cutting.

b) Fluoride discharge- caries prevention.

c) Does not cause pulp aggravation consequently atraumatic restorative technique gives preventive and remedial treatment in on the strategy.

Procedure: This method comprises essentially in the removal of carious lesions by hand instruments and filling the subsequent cavity with glass ionomer cement. In any case,it is important to feature that the therapeutic systems are only a piece of the treatment that incorporates oral cleanliness guidance, preventive, and remedial activity.[5]

Light source:

a) The light source can be the sun (normal) or counterfeit.

b) Counterfeit light is more dependable and consistent than regular light.

c) To improve permeability, an uncommon light source fixed to a couple of display outline that is controlled by a battery-powered battery source (voroscope) is utilized.

d) This unit likewise allows amplifying glasses to be connected.

Work stand and positions:

a) The operator ought to sit immovably on the dental chair,having back straight,thighs corresponding to the floor and two feet level on the floor.

b) The stool's height ought to be balanced so that operator can see the patient's teeth.

Patient's position:

a) Patients should be lying on a level surface.

patient head position:

a) For proper accessibility to upper teeth, jawline should be lifted backwardly.

b) For proper accessibility to lower teeth, jawline should be dropped forwardly.

Techniques:

a) Cotton rolls are used to isolate the tooth.

b) Wet cotton pellets are used to clean the tooth surface to be treated

c) A hand instrument is used for widening the entrance of the lesion to remove unsupported enamel rods.

d) Small & medium-sized spoon-shaped excavators are used to remove dental caries.

e) If necessary, calcium hydroxide paste is used for pulpal protection.

f) Clean the cavity surface along with the occlusal margin.

g) According to the manufacturer's instruction mix the glass ionomer cement.

h) The cavity is slightly overfilled by the mixed glass ionomer.

i) Petroleum jelly is coated over the gloved finger & pressed over the entire occlusal surface & slight pressure is applied.

j) Check the bite.

k) Sharp carver used to remove excess material.

l) All high points are removed by rechecking the bite.

m) Once again petroleum jelly is applied on the filling or sealant.

n) Instruct the patient to not bite for at least half an hour.

Indication: Based on evidence & strength of the approach for a certain situation, indication divided into 2 levels.[6]

At the patient level:

a) The art approach is acceptable by patients majorly.

b) Art rarely requires local anesthesia, unlike traditional restorative treatment.

c) The approach should be minimally invasive by nature i.e. Removal of necrotic tissue only.

At the tooth level:

a) Art; single surface restoration using high viscosity gic.in both primary & permanent teeth have a high survival rate.[7]

b) asart restoration are minimally invasive & caries protective unlike traditional restoration method it is considered as a treatment of choice for single surface caries lesion.

c) Art is suggestable for multiple surface restoration but its survival rate is lower as compared to single surface restoration.[8]

Contra Indications:

a) There is the nearness of growth or fistula.

b) The pulp of the tooth is uncovered.

c) Tooth has been agonizing for quite a while (chronic pulpitis).

d) There is a conspicuous carious cavity, however, the opening is unavailable to hand instrument.

e) There is an away form of the cavity, for example in a proximal surface, but the cavity cannot be entered from the proximal or the occlusal bearing.

Advantages:

a) The use of a hand instrument eliminates the noise & vibration of dental handpieces.

b) The need for acid etching, water coolant is eliminated along with accompanying high-velocity suction.

c) The need for local anesthesia is also eliminated because of the use of hand instruments for caries removal.

d) Fluoride-releasing restorative material helps prevent further decay.

Limitation:

a) Long term survival rate of art restoration is unknown.

b) Because of lower wear resistance & strength of the material; used only in small & medium sized one surface lesion.

c) Due to the hand mixing technique, an unstandardized glass ionomer mix is produced.

Failure of the process: Restoration may not be worthy or inadmissible any longer for a few reasons. It is missing, an enormous part of it has broken, cracked restoration, the restoration has eroded or caries has created at the rebuilding edge or somewhere else on the tooth surface.[9]

Restoration is completely missing due to: During restoration procedure contaminated by saliva or blood. The blend of the material was excessively wet or excessively dry. Not all soft caries had been expelled. This sabotaged finish had been abandoned and this later severed.

Part of the restoration has broken: It is plausible that the restoration was excessively high or air bubbles were caught in the material during the arrangement of the restoration whatever the explanation clean the tooth surface and/or staying therapeutic material with a wayfarer or little excavator and wet cotton wool pellets first, before molding the whole surface and materials, fill the hole with another blend of glass ionomer cement and guarantee that the reclamation is not excessively high.[8,9]

The restoration has fractured: this most regularly occurs in a different surface restoration which was too high. The approach to fix it relies upon the area of the crack line and the portability of the brokenpart. if the crack part is free and can be evacuated, fix the hole as portray as above. However, if the broke part cannot be expelled fix through workmanship is an absurd and conventional treatment utilizing a drill is required.[8,9]

The restoration has worn away: Potential reasons, the patient eats hard nourishment as often as possible, the patient grips his/her teeth much of the time or the blend had been excessively wet or excessively dry. The restoration ought to be reconstructed, guarantee that all the outside of the tooth and the rest of the rebuilding are spotless and liberated from soft tissue apply dentin conditioner over the glass ionomer and the depression dividers. Spot another layer of glass ionomer cement on the bygone one, finish the rebuilding as depicted before.[8,9]

Caries has developed:

maybe in nearby fissure or pit. Expel all the delicate rot. Clean and reestablish the new cavity adhere to the restoration as per the standard technique.[10]

Conclusion:

Art is a perfect approach for both alternative & biological treatment in developing countries & social groups in the industrialized world. The outcome results from art restoration in class 1 cavities are much effective than the class 2 cavities. The procedure is very cost-effective so as it is a friendly procedure. It should be considered as an interventional procedure for class 2 cavities, art in both industrialized countries & developing countries are needed to validate its effectiveness & acceptability.

Stainless Steel Crown: A Review Article

Harsha Agrawal

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The upkeep of the primary dentition is a non-pathological and sound condition which is important for the general wellbeing of the kid. Stainless steel crown was presented in 1947 by the Rocky mountain company and advanced by Humphrey in 1950. Pre-assembled stainless-steel crown can be adjusted to singular primary teeth then being cemented to give a complete restoration. It provides full coverage restoration, cost-effective, generally modest, and is durable. It is used as a restorative material in both deciduous and permanent teeth where intracoronal restoration comes up short.

Keywords: *Primary tooth, stainless steel crown, pediatric dentistry.*

Introduction

In 1950, a stainless steel crown was introduced by Humphrey to pediatric dentistry. Since then it is used for the treatment of primary teeth that are badly broken as invaluable restorative material. Superior & longer clinical life span than multi-surface amalgam restoration. Durable, relatively inexpensive, quickly & easily placed with minimal technique sensitivity. The main disadvantage is the silver metallic appearance. One of the most widely recognized issues seen in pediatric dentistry in the early childhood caries of primary dentition that influence babies and little youngsters. This early childhood caries results in basic demolition of the teeth along with the nutritional problem. The most widely recognized approach to fix and keep up the rest of the tissue of seriously harmed teeth is utilizing stainless steel crown and covering the harmed crowns of the teeth.[1]

Table 1. History of Stainless-steel crown[2]

1950	Recommended by Humphrey & Engel.
1968	Encouraged familiar treatment molality by mink & Bennett.
1960	Significantly improved crown.

Stainless Steel Crown: Stainless steel crown is a semi-permanent restoration used in a primary and young permanent molar. This crown in primary dentition is the most proficient and reliable technique for restoration. Its resistance as well as retention form offers the advantages of this restoration.[3]

Types Stainless Steel Crown:

1. **Pretrimmed crown:** These crowns have straight, noncontoured sides, however, are decorated to follow a line corresponding to gingival crest. They still require shaping & some cutting.
2. **Precontoured crown:** These crowns are decorated & are likewise pre-contoured. Some cutting and molding might be vital however for the most pre-contoured part are negligible. On the off chance that cutting off these crowns becomes necessary, the pre-contoured will be lost and the crown will fit more freely than before cutting.
3. **Preveneered crown:** These are the treated steel crowns that have gum-based composite clung to the occlusal & buccal surface to make a more aesthetic posterior crown. They are more costly than normal tempered steel crown, require more tooth reduction & take into account just negligible pleating for crown adjustment.[4]

Table 2. Composition of different metal crowns

Stainless steel crown (Rocky Mountain)	a. 17-19% chromium b. 67%iron c. 10-13%nickel d. 4% minor elements

Nickel base crown (In Conell 600 alloy)	a. 72% nickel b. 6-10% iron c. 14%chromium d. 0.04% carbon e. 0.35% manganese f. 0.2% silicon

Table 3. Factors considered for pre-operation evaluation and armamentarium used before the use of mellitic crowns

Factors considered for pre-operation evaluation:	a. The patient's dental age b. The patient's cooperation c. Medically compromised patient d. Motivation of patient
Armamentarium:	1. Burs 2. Instrument 3. Pliers 4. Polishing & isolation 5. Cementing medium

Procedure: Administration of effective local anesthesia so that it will protect from some inevitable trauma of gingival as procedure extend sub-gingivally. Placement of rubber dam provides better visibility, protect tissues around the tooth, improve efficiency. The chosen crown should re-establish the contact area and occlusal arrangement of the readied tooth. The crown determination can be done by estimating the mesiodistal width of the tooth space with the help of a divider. It also measures the components of the contralateral tooth. Tooth preparation removes caries completely and provides sufficient space for a stainless steel crown. Re-establish the tooth using a glass ionomer cement or compomer before the stainless-steel crown preparation. Decrease the occlusal surface by about 1.5 mm with no. 247 flame-shaped bur. The occlusal reduction should be done with the preservation of tooth structure, pulp exposure chance should be less with proper crown retention potential. With the help of tapered diamonds but, cut interproximal cuts mesially & distally. Little buccolingual decrease is required which should be done as less required because these surfaces are significant for retention. Contact with adjacent teeth must be broken gingivally and buccolingually.[5] A suitable size of the pre-contoured crown is picked by estimating the mesiodistal width. For multiple crown placement in the same quadrant, the adjacent proximal tooth surface should be reduced more than usual. Try it should be done before the procedure of cementation. Crown ought to sit close to 1mm sub-gingivally. Crown should be cemented with glass ionomer cement or polycarboxylate cement. Remove the excess cement from the margins. The absence of release of excess amounts of cement reveals inadequate cement. The interproximal surface is cleaned, the region beneath the contact area is cleaned with dental floss. At last, the crown is checked for occlusion. The patient ought to be prompted that there might be some transitory gingival uneasiness when the local anesthesia's wear off.[6]

Hall Technique: Introduction of Hall techniques causes a drastic change in the use of stainless steel crown over the last 10 years. In Scotland, the hall technique was reported and during the audit of dental care, it was identified. Hall's technique is a novel method, for managing carious deciduous molars by cementing preformed metal crown over them. This technique is performed without local anesthesia, caries removal and tooth preparation are not required. To improve consistency in children and decrease nervousness related to dental treatment, apply techniques of behavioral management, stainless steel used should be increased by clinicians. Circumvent expenses of relish treatment and avoid negative child health impact. Reduce tooth extraction and broad treatment.[7]

Procedure:

1. The child should be upright.
2. Choose the smallest size crown to place.
3. All the cusp should be covered with a spring-back effect.
4. During try in the attempt of seating crown should not be done.

Advantages:

1. Clinically acceptable by dentists and patients.
2. Because of its resistance, retention, replacement, and life span stainless-steel crown is preferred over amalgam restoration.
3. Inexpensive and are durable.
4. They adjust to the tooth appropriately and do not bring about any spillage.
5. They offer full inclusion for the tooth, ensuring that it remains secure.
6. They can be set effectively on the tooth.
7. The best treatment of choice for children who need general anesthesia.

8. When contrasted with different materials utilized for restoration, a stainless steel crown has a 6% rate of success.
9. A tooth can be restored even if there is a significant loss in crown structure.

Disadvantages:

1. Unaesthetic because of metal exposure.
2. In partially erupted tooth it cannot be used.

Post-treatment instructions:

1. Precautions should be taken that child does not bite their tongue, cheek, or lip due to the effect of the anesthesia.
2. A mild pain killer can be given to the child by the dentist as to when the numbness has worn off, some discomfort may be experienced.
3. Stay away from sticky food for 3-4 days after crown insertion so that cement under it gets time to get harden.
4. Brushing and flushing should be done.

Alternatives: Silver amalgam, Composite

Stainless steel crown modifications:

Undersized tooth or the oversized crown: This normally occurs when long-standing interproximal caries cause space loss. To decrease the crown perimeter a cut is made on the buccal surface to the occlusal surface. The slice edges are re approximates to cover each other creation the crown periphery smaller. The crown is taken a stab at the tooth and the measure of disregarding fundamental is set apart on the crown. The covered edges are then spot welded. The crown is polished with a rubber wheel and fine abrasive.[8]

Oversized tooth or undersized crown: Isolate the edges varying and weld a bit of 0.004-inch orthopedic band material over the cut surface. After forming apply the bind to fill any infinitesimal insufficiency in the seal. Polish the soldered crown.

Deep subgingival caries: One methodology is to finish the indicated pulp treatment and afterward reestablish the pit planning with silver amalgam is considered as the substitute for the tooth structure. The proximal territory is cut as in standard crown preparation. The stainless steel crown is adjusted with the amalgam substitute for tooth structure at the interproximal finish line. If subgingival caries happens interproximal the unfestooned rocky mountain crown will be sufficiently profound to cover the arrangement.

Complications:

Crown tilt: Due to caries or inadequate use of instruments there may be the destruction of the lingual or buccal wall which may bring about completed crown tilting toward the inadequate side. Before crowning, restoration should be placed which offers to prevent tilting of the crown.

Interproximal ledge: If bur's angulation is not given correctly, then a ledge will be delivered rather than a shoulder free interproximal cut. Failure to expel this ledge brings about trouble in seating the crown.[9]

Inhalation or ingestion of crown: Till cementation proper isolation i.e. rubber dam should be placed because of cough reflex present in a child there will be more chances of crown ingestion. If this happens, the child should be held upside down as quickly. This results in the removal of the crown. If this is ineffective, clinical referral ought to be accomplished for a quick chest radiograph. If the crown remains in lung or bronchi, then it can be expelled by bronchoscopy.

Poor margin: Marginal integrity is decreased if the crown is ineffectively adjusted. Results in recurrent caries. An increase in gingivitis and plaque retention may occur. Stainless steel crown can be used as a restoring material where more than two surfaces are affected in a primary molar. Used in a child who is less than 6 years. In pulp therapy procedures. In the case of fractured primary molars. Excessive loss of tooth surface .eg Abrasion, erosion, bruxism. Children having high caries susceptibility. Used as an abutment. In the case of crossbite. Used in case of repetitive caries around the existing restoration. In the case where restoration is expected to last more prominent than 2 years.[10]

Contraindications: If a primary molar is about to exfoliate where the radiograph shows more than half the primary tooth resorbed.

1. Uncooperative patient.
2. Patient allergic to nickel.
3. In the case of grade 3 mobility.

Conclusion

A conclusion has arrived from clinical investigations that stainless steel crown may last longer than fillings for carious essential teeth, stainless steel crown outperform plastic reclamations when used to re-establish multisurface carious sores in deciduous molar teeth. Besides, it is the most cost-effective, extremely durable, and has minimum technique sensitivity material. All accessible evidence recommends that stainless steel crown should be used as a restorative material in deciduous primary molar tooth.

Assessment of Restorative Skills for Amalgam Restoration

Jagruti Nanda[1], Lora Mishra[2]

[1]Intern, [2]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Dental treatment procedures are mostly governed by factors such as biocompatibility of restorative materials, patients demand for esthetics and conservative approach for the minimal loss of tooth structure. GV Black followed 'EXTENTION FOR PREVENTION' for restorative treatment which follows classical cavity forms and principles which almost remained unchanged and unchallenged for 50years using amalgam. Though it required uniform depth, ease of manipulation and excessive tooth structure damage for proper retention of it. The support from clinical observation of success and failures of different restorations has presented with the concept of new designs. This article reviews the literature on assessing and evaluation of amalgam restoration. Information on the characteristic material, its rate of progress with time and its nature of the association. Mainly focusing on the relationship between the deterioration of amalgam restoration and risk of secondary caries.

Keywords: *Caries, Creep, Silver Amalgam, Tarnish, Restoration.*

Introduction

The restorative dentistry is provided with a wide range of material to store any derangements of a lesion in hard tooth substance. The success and failure of restoration depend on the degree of involvement, the skill of operator and properties and limitations of materials and technique. The purpose is to determine the quality of amalgam fillings and its longevity. The ability of the amalgam restoration to withstand the masticatory forces mainly depends on the distribution of internal stresses and the design of the cavity.[1] The most straight forward method would be restoring a tooth with amalgam material and subjecting the same tooth with forces of similar nature and magnitude to that present during mastication. It can be anticipated that the precision of this technique would be affected by morphologic differences between the duplication of cavity design and variation of the strength of condensed amalgam. The average lifespan of an amalgam restoration is 10-15 years of correct manipulation. Amalgam has been ubiquitously believed to be restorative material of choice for small and large cavities. Despite the use of composite resins with advanced esthetics, amalgam is considered as the restoration of choice for elaborate posterior tooth preparation due to its longevity and ease of use and low cost.[2] According to Healey and Philip, mainly the failure of amalgam restoration occurs due to 56% inadequate cavity preparation and 42% due to faulty manipulation. Many investigators have reported the need for frequent and possible premature replacement of amalgam restoration. Despite continuous preventive programs and the development of better materials, the replacement rate has remained unchanged. The physical properties are generally appraised as adequate for a dental restorative material.[11] The assessment methodology used for cavity preparation must be valid, reliable, and reproducible. The performance of amalgam may be influenced by several factors including its composition, manipulation, presence of moisture, use of varnish and cavity designs.[3]

Table 1. Criteria for A Successful & Method of Assessing a Restoration Clinically

Criteria for A Successful Restoration Assessment	1. Stop of original insult and its further recurrence 2. Restoration of function/mastication 3. Restoration of esthetics 4. Absence of recurrent caries 5. Marginal accuracy and adaptation 6. Patient comfort and satisfaction
Method of Assessing a Restoration Clinically	1. Marginal Ditching 2. Isthmus fracture 3. Tooth fracture 4. Excessive Discoloration 5. Post Restoration Hypersensitivity 6. Gingival & Periodontal Affections 7. Improper Anatomical Contour 8. Improper Proximal Contact 9. Improper Occlusal Contact 10. Overhangs

Marginal Degradation (Ditching): The breaking of a thin edge of a restoration creating an irregular V-shaped creviceis known as Marginal degradation, ditching or crevicing. This is the most common mode of clinical observation. They are also called as Dyscrasia. Most commonly seen on cavosurface margins. Buccal end of proximal marginal ridge more prone to ditching.

Diagnosis: Either visual/tactile, Amalgam-Enamel interface if evaluated with an explorer or probe, Margins into which the probe penetrates are referred to as open or defects.[4]

Causes: Depletion of support at margin, Voids, Excess Mercury.[4]

Depletion of support at the margin: Amalgam with its property of low tensile strength and low shear strength makes it a brittle material. So, there should be enough of the tooth structure to support it. It may be dueto lack of support or insufficient bulk of the material at margins due to beveling of the occlusal outline.[4]

Voids: The presence of voids in the amalgam cause decreased density and strength of it. They are usually localized. Voids may be due to: Corrosion, Dry mix, Inadequate condensation, Moisture contamination of amalgam

Excess Mercury: Excess Mercury in amalgam decreases its strength. It occurs due to improper proportioning of alloy/mercury ratio, under trituration, inadequate condensation force.[4]

Isthmus Fracture: The occlusal and auxiliary portion of a cavity has the narrowest junction called as the Isthmus. There should be a state of balance between the external and the intrinsic tensile stresses at the isthmus area.

Clinically: Starts as a crack line. Then it propagates and widens upon masticatory forces, and fracture occurs. Hypersensitivity is a common occurrence with food impaction. Factors attributing to isthmus fracture, increase tensile stresses, inadequate resistance and retention form, irregular surface with discontinuities and excessive occlusal force.

Inadequate resistance and retention form: The restorations that are not adequately and not independently retained are easily and quickly broken down by the masticatory forces. So, restorations should have proper resistance and retention form. This is achieved by, flat pulpal floor, gingival floor perpendicular to the direction of the force, walls parallel to the direction of masticatory forces, cavo surface angle 90 degrees, proximal axial grooves, use of the effective adhesive system, use of threaded pins or amalgam pins.[5]

Irregular surface with discontinuities:

a. Poor polishing leaving the surface rough and full of pits

b. Over carving into deep grooves weakens the restoration by decreasing its bulk

c. Presence of internal voids

Excessive occlusal forces:

a. Biting on the restoration before the setting time

b. Under carving of the marginal ridge leading to premature contact

Decrease tensile strength:

a. Insufficient bulk of amalgam

b. Inherent weakness

c. Excess Mercury

d. Structural discontinuity

Insufficient Bulk of Amalgam: Amalgam being a brittle material have a low tensile strength and shear strength. The bulk of amalgam should be at least 1.5-2mm to have sufficient tensile strength. Insufficiency may be due to over carving or decreased cavity depth.[5]

Excess Mercury: This flaw of amalgam decreases the amount of gamma phase resulting in low strength of it, providing the maximum strength to the amalgam by increasing the gamma 2 phase, which is considered to be the weakest.

Structural Discontinuity: This occurs due to corrosion products, moisture contamination, dry mix and lack of condensation force.[5]

Tooth Fracture: Tooth fracture is the fracture of a cusp or ridge under functional forces due to lack of tensile strength to support the remaining tooth structure and much less able to reinforce weak cusp. The careful visual and tactile examination is done to locate the fracture line. This leads to the worst outcome if the restoration is extensive enough, leading to less support of the remaining structure.

It can be prevented by eliminating all undermined enamel as well as weak cusps and ridges.[7]

Excessive Discoloration: These are discolorated areas often seen through the enamel in teeth that have amalgam restorations. It occurs as a result of leaching of corrosive products of amalgam into dentinal tubules.

Clinically:

a. Tarnish- loss of surface lustre

b. Corrosion- the rough, pitted amalgam surface

c. Amalgam Blues- dark bluish discolouration

Tarnish: Formation of a surface film of discolouring oxides and sulfides leading to loss of amalgam lustre. Excess Mercury and moisture contamination enhance this.

Corrosion: It is the actual disintegration of the bulk of amalgam.

It is of two types:

Chemical Corrosion- due to ack of polishing and food stagnation leading to halogenation and sulfurization.

Electric Corrosion- due to two dissimilar or similar metallic restorations (old/new)[10]

Amalgam Tattoos/Blues: Amalgam hues appear through the enamel surfaces. Corrosive products which get entrapped within gingival tissue known individually as amalgam tattoo.

Causes:

a. Thin or undermined enamel

b. Penetration of metallic ions and corrosive product into dentinal tubules.

Post Restoration Hypersensitivity: Hypersensitivity is an amalgam restored tooth maybe because of stimulation of freshly exposed dentine by

a. Galvanic stimuli generated on immediate contact with opposing dissimilar metals.

b. Thermal stresses

c. Pressure or premature contact

d. Stimuli by fluids penetrating through leakage

Clinically appears as:

a. Severe pain after insertion of restoration indicating pulp involvement

b. Pain on hot/cold application

c. Pain on biting indicating premature contact or fractured restoration

d. Dull aching pain after restoration due to delayed expansion of it

Gingival & Periodontal Health: The interplay between the periodontics and restorative dentistry include margins of the restoration, crown contours, and the response of gingival tissue to restorative materials and preparations.

Clinically: Bleeding on probing, Discomfort, Food stagnation, Tooth mobility[7]

Factors: Gingival overhangs, thick subgingival margin, ragged cavity margins, sharp margin restoration, open contact.

Improper Anatomical Contour: Amalgam restoration should duplicate the normal anatomical contour of the teeth. Restoration impinging on the soft tissue has poor embrasure form and proximal contact preventing use of dental floss and are defective restoration. It should be correctly recontoured or replaced to maintain proper periodontal health. Over contoured proximal and facial and lingual surfaces impinge on the soft tissue and act as plaque trap.[9]

Improper Proximal Contact: The importance of proper contacts and contours of restoration is to enhance correct occlusion with sound periodontal

health while preventing gingival overhang. Matrixing is a vital step during placement of different restorations proximal contact are of an amalgam restoration against the adjacent tooth should be evaluated with a string of dental floss.[7] If the contact is open and is associated with poor interproximal tissue health and food impaction, the restoration is defective and should be replaced while tight contact between teeth results in the recorded degree of mobility of both restored and neighboring teeth.[9]

Improper Occlusal Contact: Improper occlusal contact induces destructive effect on the restoration and the tooth due to excessive forces. Occlusal interferences or high points indicate defective restorative skill. It called a high filling when too much of restorative material projects out from the tooth cavity. Clinically tooth with the high dental filling will be sensitive to hot and cold changes and masticatory forces. Premature occlusal contacts appear as shiny spots on the surface or detected using occlusal markings/articulating papers. Correction of occlusal contact in centric and eccentric occlusion should be done. The restoration should be either replaced or adjusted.[9]

Overhangs: Amalgam overhangs are defined as an extension of the amalgam restoration beyond the confines of cavity preparation. Overhangs mainly the proximal ones, possess an obstacle for improper oral hygiene and food impaction, causing severe inflammation of adjacent soft tissues. They also decrease access to proximal cleansing devices. It is challenging to examine the overhanging restorations for a posterior tooth. Therefore, a bitewing radiograph is usually helpful. Overhanging restorations are one of the primary causes for the failure of the amalgam restoration. They are mostly iatrogenic caused by poor operator skill. It is advisable to replace the whole of faulty restoration rather than removing the overhang only.

Clinically:

a. Buccal, Lingual and occlusal overhangs seen visually

b. An explorer can be used for buccal, lingual, occlusal or proximal overhangs by tactile sensation.

c. Dental floss with threading which is passed proximally or proximal overhangs.

Recurrent Caries: Caries developed in a previously restored tooth is termed as recurrent caries. The term Secondary Caries is also given to it. It occurs on the marginal area of the restoration and is detected mainly by the radiographic method. Therefore, also called as marginal caries. The occlusal view is considered as the best view to visualize it.[1] A significantly higher proportion of Streptococcus mutants is found at the cavity margins. Once the restored tooth is diagnosed with recurrent caries, it should be replaced.[10]

Table 2. Causes of recurrent caries

Incomplete elimination of original lesion	a. Improper excavation of caries b. Improper evaluation of lesion
Improper outline form:	a. Leaving defective and retentive pits and fissure b. Leaving undermined enamel
Incorrect restoration	a. Lack of adaptation due to marginal leakage and moisture contamination b. Failure to restore proper anatomy, contact and contour c. Improper finishing of the restoration
Retention of bacteria plaque	a. Retentive pits and fissures b. Marginal overhangs c. Open interproximal contact d. Marginal ditching

Clinically: Carious lesion at the margin of the restoration or extending deeper underneath the restoration.

Conclusion

The article systematically analyzed the performance and clinical success of amalgam restorations. The assessment of the restorative material can be summarized

on the basis of the deterioration of the same. Many factors are leading to the deterioration, including the material, type of tooth, operator and manipulative forces. The deterioration continues with the time but at a decreasing it. Amalgam restorations reduce the need for mechanical retention, conservation of tooth structure, and reducing the effects of microleakage. Despite this, it can be considered the material of choice for more extensive restorations. However, there have been controversies and debate on the use of amalgam in dentistry due to potential release of Mercury and its adverse effect on health. This has led practitioners to explore other alternative restorative materials.

Benefits of Early Orthodontics Intervention in Children: A Review

Debashreeta Nanda

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

When it comes to your children orthodontic treatment then a diamond seems less precious than time. There is an optimal time span to begin your child's early intervention treatment. Mixed dentition is a period of development following the eruption of permanent 1st molar and incisors. During this period, phase-1 treatment is done earlier and often a mixed dentition treatment is meant to concentrate on modification of skeletal system rather than dental system. At little smile's our goal is to provide both timely detection of problems and greater opportunity for more effective treatment to benefit your child/children. The dentist must understand the growth and development patterns before planning a treatment, as jaw growth is the primary factor in orthodontic treatment. Though comprehensive treatment may be required at a later date, the need for early intervention cannot be denied.

Keywords: *Mixed dentition, Children, Early orthodontic correction, Interceptive orthodontics, Preventive orthodontics.*

Introduction

The aim of early orthodontic treatment is to interrupt the growing problem, removing the source, guide the facial development, and jaw bones and allow adequate place for coming permanent teeth.[1]

Purpose:

- Correct obvious problems.
- Intercept developing problems.
- Prevent obvious problems from becoming worse.

The problem can be prevented or complexity can be reduced to an extent, so that further treatment is simplified. From early treatment, almost all types of malocclusion could be benefited. Effectiveness of the intervention depends on malocclusion. The term was given by Lyman Wagers as pre-orthodontic guidance and correction to replace prevention and interruption respectively. The treatment aims to Correct aesthetics of the dentition and facial aesthetics of the patient, improving chewing function and restore proper occlusion. To achieve this goal a repeated multi-speciality dental care is necessary. There are 3 outcomes of early orthodontic treatment. Firstly, no treatment is expected to be necessary. Treatment may be needed in future, while the face and jaws continue to grow, so the child will be followed periodically. If there is a problem, that leads itself to early treatment.[2]

Mechanism affecting occlusal development:

- Occlusal development and craniofacial growth interaction.
- Genetics and environmental factors.
- Locked occlusion.
- Form and function.

Table 1. First Dental Visit Guide[3]

Early signs of your child which may indicate the need for treatment	• Early or late loss of deciduous teeth • Misaligned bite • Crowding teeth • Large gap between teeth • Front teeth do not meet • Grinding and clenching of the teeth • Thumb sucking, tongue thrusting and other habits • Improper relationship of the upper and lower jaw • Unbalanced facial appearance • Asymmetrical smile • Speech disorder • Difficulty in breathing and chewing or biting • Injury to the mouth or teeth • Extra or missing teeth • Cleft lip and Cleft palate

These above problems and any other orthodontic conditions can be corrected to avoid potential problems for future adult teeth. Many of the orthodontic conditions are inherited while others can arise from dental injuries, accident or anomalous swallowing. These issues could be easier to modify if they are detected and treated early.

Table 2. Timing of Eruption

Mandibular	Maxillary	Range (in Years)
1st Molar	1st Molar	6-7
Central Incisor	-	6-7
Lateral Incisor	Central Incisor	7-8
-	Lateral Incisor	8-9
Cuspid	-	9-10
1st premolar	1st premolar	10-12
2nd premolar	2nd premolar	10-12
-	Cuspid	11-12

Intra-arch Features: In mixed dentition, crowding of the incisors is typical, as the combined thickness of the permanent incisors is 7mm and 5mm greater than primary incisors in the maxilla and mandible respectively.

Early Orthodontic Treatment:

Timing for treatment: Treatment of early orthodontic aims to modify existing or growing skeletal, dentoalveolar and muscular variance to enhance the occlusion and aesthetics of the patient before eruption of the permanent teeth. Many children require the guidance of dental and facial development as the phase-1 of orthodontic treatment.[4,5]

Interceptive Orthodontics (Phase One Treatment): It can help identify along with treat early before they develop into more serious oral problems. It begins when child has most of the primary teeth and the jaw is still growing around age 7.At this age such over-crowding and cross bites may be easier to correct. This concept is used in minor problems during development of dentition. It may increase complexity if untreated. Its main function is to give direction to the growth of the jaw bones which supports the teeth. When the children grow and develops, they initiate early signs of jaw problems. Maxilla which grows too much or too narrow can be seen at a young age.[6] When children above 7 years of age are found to have this discrepancy of the jaw, they should be going for initial orthodontic correction. And also, when children above 8 years of age have malaligned front tooth, initial correction can avert the need to remove permanent teeth. An effective Phase -1 treatment would create space for permanent teeth to an eruption path, or else they will be impacted or shifted. [7]

Pre-orthodontic guidance: Children who have malocclusion in the period of mixed and primary dentition, but don't need banding for therapeutic correction. Early mixed dentition is the ideal time to start phase–one correction.

Goals:

- For growth of the jaw in a way, to achieve the growth of the jaw that will hold all the permanent teeth.
- Improving the way of maxilla and mandible so that they can occlude together.

Advantages:

- Future orthodontic procedure might be more costly, complex and time consuming.
- Greater ability to modify skeletal growth.
- It improves your overall health by reducing or eliminating malocclusions, which are caused by tooth or jaw misalignment.[8]

Benefits if early diagnosis and treatment: Interceptive orthodontics prevents or reduces progression of malocclusion later in life.

1) Achieving better results.
2) Determine a better prognosis for how the permanent teeth will develop.
3) Creates more space for crowded teeth to erupt.
4) Habits are corrected such as thumb sucking and tongue thrusting.
5) Bite problems are corrected such as open bite, cross bite and deep bite.
6) The growth of the jaw is guided to accommodate emerging teeth.
7) Damage to any protruding teeth risk is lower.
8) Functional arrangement of teeth, lip and face are recreated.
9) Improving child's appearance, aesthetics and satisfaction of parents.
10) Improve facial symmetry.
11) Greater ability to modify growth.
12) Reduces time for phase-2 treatment with better and more stable results.
13) Undesirable oral habits can be prevented.
14) Later corrective orthodontic treatment can be prevented.

If untreated, this problems lead to unhealthy environment for the growth and development of teeth, gums & jaws and face.

Table 3: Major Benefits[6-10]

Earlier is better	Some conditions are easier to correct, while identified earlier in life
Developing Mouth	In mixed dentition period ample space is present. If it is determined earlier that dental arch is small to fit all permanent teeth, then it may be possible to expand the arch. This can guide the teeth into better position in the mouth and makes more space in the mouth and reduces the need to extract teeth.
Early Prevention	It can help a child to avoid braces in future, which will save the child's stress from oral hygiene maintenance as well as parent's money
Out with the Old, In with the New	It can help detect and correct harmful habits like thumb sucking and tongue thrusting habits. As these problems start earlier in life.
Enhance Confidence	Every child needs a better occlusion for an attractive face. Early intervention can help to improve facial aesthetics.

Contra Indications:

1. Impracticable treatment due to social immaturity of the child.
2. Due to social and parental pressure, patient is unable to treat the misaligned teeth.
3. Unco-operative patient to continue the treatment.

Monitoring Progression of teeth:

- After the completion of Phase – 1 Treatment, teeth are not in their final place.
- It will be decided and achieved in the Phase – 2 correction.
- Removal of certain primary teeth may be enhanced eruption during this phase of rest.

- Accordingly, for monitoring periodic recall appointments and mandatory on a 6 – months basis.

Phase-2 treatment: This treatment will be required in many patients. It begins when the child has most of the permanent teeth in their final position. Teeth and jaw alignment are completed with upper and lower braces. It moves all the permanent teeth and gives proper position to the teeth, jaws and a beautiful smile with an attitude face and profile. Certain type of appliances was established in the diagnosis and treatment scheme was used to modify and realign the teeth and jaw, at the beginning of phase – 1 Treatment. Phase – 2 Treatment begins after all the permanent teeth have exploded and typically includes braces for an average of 2 years on all the teeth. Retainers are worn following correction in Phase – 2 Treatment is over to ensure your child retains his or her beautiful and healthy smile.[9-11]

Purpose: Extending transparency to achieve the optimal balanced functional and aesthetic outcome that will remain stable throughout your child's life.

Goals: To ensure that each tooth has an exact position in the oral cavity and compatibility with the tongue, lips, cheeks and other teeth. Once this balance is established the teeth should work properly together.[9-11]

Conclusion

Orthodontic modification in the period of mixed dentition opens the door to apply his acuity and experience to an orthodontist and a pedodontics. Malocclusion is not necessarily predictable and also not necessarily avoidable. However, with regular dental check-up and early orthodontic evaluation and treatment, your child may be able to avoid it in the future. Absence of proper scheme can give rise to a big disadvantage. It should be noted that there is commonly more risk in, "Too much too soon, rather than in too little too late".During developing and growing phase of teeth and bone, growth modification is required. If they are identified earlier in life, then some orthodontic conditions are easier to correct. Most acceptable results can be achieved by thorough diagnosis and treatment scheme. Early orthodontic intervention plays a major role in children.

Bell's Palsy: A Review

Sumanta Sourav

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Bell's palsy is a facial nerve defect of unknown etiology. The aim of this article is to put forth a review on Bell's palsy and identifying its clinical presentation, differentiate it from other similar conditions, having a brief idea of various existing treatment modalities. Treatment usually focuses on restoring the function of facial muscles and recovery.

Keywords: *Bell's palsy, clinical features, differential diagnosis, various treatment modalities.*

Introduction

The term **facial palsy** generally refers to the "weakness of the facial muscles, mainly resulting from temporary or permanent damage to the facial nerve"[1]. If the etiology of facial palsy is not known then it is considered to be Bell's palsy. It is a unilateral acute peripheral neuritis originating due to disruption in the lower motor neuron of the facial nerve. Immunological, infectious diseases and ischemia may lead to Bell's palsy still its etiology are questionable. If we talk about the history of discovery of Bell's palsy, much research has been done for it, the disorder is named after the scientist Sir Charles Bell while his research in the royal society of London. When we talk about the clinical feature of Bell's palsy, we find that it happens suddenly, usually affecting one side, facial palsy of lower motor neurons accompanied with pain in the posterior part of the ear, alteration of taste sensation, subjective alteration in facial sensation and hyperacusis.[2,3] Treatment usually focuses on restoring the function of facial muscles and recovery.

Discussion

Bell's palsy is diagnosed more often in young females. Cases are usually reported in the age group of 21-40. The right side of the face is commonly affected. [4] As many times recurrence is reported in the first two years from the onset so follow up of patients should be carried out for 2-3years, mainly child patients.[5] The incidence rate varies from 11.5 to 40.2 out of every 100 00010 people with an annual incidence rate in the United Kingdom 20.2 out of every 100 000 population, in Japan 30 out of every 100 000 and in the United States 25–30 out of 100 000.[3,6]When Virus infection is the cause of Bell's palsy, it progresses by the inflammation and facial nerve gets demyelinated. As for maintenance of myelin sheath vitamin B plays a major role, so demyelination can prolong the time required for the normal function of the facial nerve.[7] When evaluating a patient, the following note should be kept in mind, in case of a patient of Bell's palsy occurs suddenly (within 3 days), the diagnosis should eliminate all the reasons for facial muscle fatigue, mostly unilateral, usually self limits itself.[8] Certain risk groups are more prone to Bell's palsy, those are pregnant lady, obese persons, hypertensive patients diabetic cases, upper respiratory tract infections.[1] There are still some factors may lead to Bell' palsy: change in atmospheric pressure, cold exposure, facial nerve compression near stylomastoid foramen, bacterial, fungal, viral infections (herpes zoster, EB virus, hepatitis B virus, HIV, etc), Melkerson–Rosenthal syndrome, Multiple Sclerosis, pregnancy.[3]

Table 1. Conditions & Disting

Condition	Distinguishing Factors
Guillain-Barre	Paralysis starting from feet going up to trunk and hand
Melkersson-Rosenthal syndrome	Edema in face and lip region and presence of fissure or folds on the dorsal surface of the tongue
Multiple sclerosis	Atypical neurological symptoms
Ramsay Hunt syndrome	Vesicular eruption in-ear canal or pharynx
Sarcoidosis	Bilateral
Stroke	Extremities on the affected side are often involved
Lyme disease	History of tick exposure, rash
Otitis media	Earache, pyrexia, deafness
HSV	Fever, malaise
Encephalitis	Headache, stiff neck, CSF abnormalities

To diagnose whether there is Bell's palsy or not, look for asymmetry of the face during the interview; observe closely than the blinking pattern, the commissure of lips, and the nasolabial folds. Under general examination; otoscopy, checking for growth near the head and neck region by palpating that area, and skin examination is done. Assessment of motor function, done by checking whether the patient can normally move eyebrow upward-downward, forceful closure of eyes, Smiling,blowing the cheeks, pursing the lips, grimacing if clinically indicated, then go for assessment of special sensation like the sensation of ear and the face, gustatory sensation of anterior two-thirds of the tongue. Orbicularis muscle reflex is checked taping the glabella and observing whether there is an asymmetry in the opening-closing pattern of the eye or not. Bell phenomenon: observe the upward movement of eyes during forced eye-closure. [12] In Inverse Bell's phenomenon, there is a downward movement of eyeball rather than upward, which can be seen in patients with Bell's palsy, after conjunctival scarring, even in the normal population.[13] Clinical features of Bells palsy include ipsilateral paralysis or weakness of the lower and upper muscles of the face, drooping of eyelids of the same side, incomplete closure of eye that causes drying of eye, epiphora,drooping of the corner of the mouth, altered gustatory sensation on the same side, dysphagia due to muscle weakness leading to accumulation of food on ipsilaterally, saliva rolled down from corner of mouth, ipsilateral loss or alteration of sensations of the face pain or due to involvement of stapedius muscle hyperacusis (sensitivity to sound increases.)[14]

Treatment: "Kabat rehabilitation consists of the facilitation of the voluntary response of an impaired muscle through the global pattern of an entire muscular section that undergoes resistance."In this rehabilitation protocol, three regional fulcra were taken into consideration: upper, intermediate, and lower fulcrum whose activation is done by various facial exercises. Kabat rehabilitation when accompanies with standard steroid treatment of severe Bells palsy, in maximum cases there is better and faster recovery than only medication is given.[15,16] If a patient is suspected for acute Bell's palsy then asses eye closure, whether it is adequate or inadequate. If adequate then no eye protective measures needed, and if it is inadequate then eye-protective eye measure will strongly be recommended. Then next assess the severity of paresis, if it is mild to moderate then corticosteroids will be strongly recommended and if severe to complete paresis is there then along with corticosteroids antivirals will also be recommended. If there is complete recovery during follow up and assessment then good or else if there is a failure to recover or progressive weakness then go for exercise and physiotherapy[17], consult specialist, imaging is used to exclude out any neoplasm.[18–20] The treatment approach of Bell's palsy targets the reduction of inflammation and viral infection. For inflammation, steroids are given like prednisolone, betamethasone, hydrocortisone, methylprednisolone, dexamethasone, and cortisone and for viral infection acyclovir, famciclovir, and valacyclovir is usually used.[21–23] (The use of steroids plus antivirals and the use of steroids plus mecobalamin are 2 good choices.)[24] MIRE therapy in which infrared light of wavelength 890nm, is used on

the area anterior and posterior to the ear, the temporal and lower jaw area of the affected side for the half-an-hour cycle.[25,26] When a case of facial palsy comes to a dentist,the following can be followed: thorough history taking and physical examination to exclude all possible causes for facial palsy, routine laboratory testing, and diagnostic imaging should be avoided if it is a new case of Bell's palsy, oral steroids (prednisolone) can be given within 72 hours of the appearance of symptoms,(For adults who come within 72 hours of onset treatment recommendations are " Corticosteroids: Prednisone 50 mg orally daily for 5 days, followed by 10 mg less each day for 5 days, Prednisolone 50 mg OD for 10 days, Antivirals: Valacyclovir 1 g TID for 7 days, Acyclovir 400 mg OD five times daily for 7 days)."[12] The basic treatment is neuromuscular re-education training. Exercises include (wrinkling of the forehead, smiling,snarling, and puckering of the lip) with speed and amplitude variation; exercises are done on one side of the face to have controlled movement, relaxing lower jaw doing exercises for eye and mouth simultaneously inhibiting synkinesis (small slower movements)[27,28]

Table 2

Possible complications	Treatment
Incapable of the closure of eye of affected side (causing corneal irritation and ulceration)	Artificial tears
Impaired muscle eyelid	Tarssoraphy or gold weights implantation in the eyelid of the upper eye
For asymmetrical face or Muscular rigidity	Cosmetic surgery or BOTOX injections

Conclusion

Bell's palsy with higher neutrophil to lymphocyte (NLR) ratio usually linked with prolonged time for recovery. Therefore NLR can be used for the prognosis of time taken for recovery of Bell's palsy patients. However, the patient may complain like symptoms such as facial spasm, synkinesis, and paresis.

Ossifying Fibroma of the Anterior Maxilla: A Case Report

Satya Ranjan Misra[1], Shivani Sahu[2]

[1]Professor & Head, [2]Intern, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (deemed to be University), Bhubaneswar-751003, India

Abstract

'Ossifying fibroma'can be described as a rare benign neoplasm classified under fibro-osseous lesions. Arising from the periodontal ligament's mesenchymal blast cells, it forms bone, cementum as well as osteo-cementum like hard tissue. Though a benign osseous tumour, it exhibits an aggressive behaviour on recurrence. Clinical features vary from swelling, facial asymmetry, mild displacement of teeth, pain or paraesthesia when there is entrapment of nerves. As in other osseous neoplasms, this also has radiologic changes ranging from a mixed radiopaque-radiolucent to a totally radiopaque appearance, but there is no pathognomonic manifestation. Maxillary lesions have to be differentiated from fibrous dysplasia. A case report of ossifying fibroma in the anterior maxilla is reported here.

Keywords: *Benign aggressive tumour, fibro-osseous lesion, mixed radiolucent-radiopaque appearance.*

Introduction

Ossifying fibroma is currently defined by WHO as a benign neoplasm, often presents well-demarcated borders and is composed histologically of fibro-cellular stroma and variable amounts of mineralised materials showing different morphological appearance. Initially WHO had classified Ossifying Fibroma (OF) as a fibro-osseous neoplasm. In 1972, WHO had first classified it into 'ossifying fibroma' and 'cemento-ossifying fibroma'. In 1992, WHO brought it under 'cemento-ossifying fibroma'. In 2005, it was replaced by WHO as 'ossifying fibroma'[(1)].

OF, a benign neoplasm mostly occurs in the tooth bearing areas of the jaws[(2)], commonly seen in mandibular molar and premolar regions[(3)], and do not arise in the long bones. This lesion is predominant in 2nd to 4th decade of life and more common in females, although the central variant is rare among females[(1)]. This lesion is believed to arise from the multipotent periodontal ligament cells which form cementum, alveolar bone and fibrous tissues. Treatment is done conservatively if the lesion is small, otherwise surgical resection. Recurrence rates of OF is low, but follow-up should be done.

Case Report: A female patient of age 27 years, reported to the hospital, complaining of swelling on the left upper front teeth region of the face for the past 3 months. History revealed that the swelling was a slow growing one and was not associated with pain or any discharge. On clinical examination extra orally a single localized, bony hard swelling was visible on the right side of the upper part of anterior maxilla. The swelling was not mobile but the skin over the swelling was freely movable without any secondary changes. Intra orally the bony swelling in the anterior part of the maxilla involved the alveolus of central, lateral and canine region and extended both labially and palatally without any secondary changes. There was displacement of 21 and 22, extrusion of 21 and spacing between 21 and 22.

Since the history revealed that the swelling was a fresh one, slow growing and bony hard in consistency and the swelling was well localized it is a bony swelling.

As the swelling extends both labially and palatally, it is a benign bony neoplasm. Fine needle aspiration cytology (FNAC) was performed and no aspirate was obtained suggestive of the solid nature of the lesion.

Patient was subjected to radiologic investigations. Periapical radiograph of maxillary left anterior region shows well defined unilocular radiolucency which is ovoid in shape and is present between 21 and 22. Maxillary cross-sectional occlusal radiograph shows unilocular radiolucency ovoid in shape in between 21 and 22 regions with slight displacement of 21 and 22. Panoramic radiograph revealed a well circumscribed unilocular radiolucency involving 21-22 region displacing 21 and 22. Radiolucency was ovoid in shape with a radiopaque border.

Computed tomography scan of the swelling in axial, coronal and sagittal sections shows a space occupying lesion in the left maxillary alveolar segment. The lesion gives areas of both hypodense and hyperdense. The Hounsefield value was 750 suggestive of a benign bony neoplasm. 3DCT shows extension of the lesion till the floor of the nasal cavity on the left side without breach in the nasal floor.

Under local anaesthesia, incisional biopsy was done in 21-22 region and specimen stored in formalin and sent for histopathological examination. Histology revealed cellular fibrous tissue containing mineralized material. Connective tissue stroma with cementum like areas within the connective tissue; with spindle and stellate shaped cells. Histopathologic features suggestive of ossifying fibroma. The patient underwent complete surgical excision of the lesion for treatment.

Discussion

'Ossifying Fibroma' term has been used since 1927, and grouped together as 'cementum containing tumours' since 1968[4]. According to Eversole et al, Central Ossifying Fibroma (COF) can be described as:a well-demarcated benign fibrous neoplasm which is aptly designated as an 'fibro-osseous lesion'. Menzel described cemento-ossifying fibroma in 1872, while Montgomery coined it in 1927. Until 1948, COF and Fibrous Dysplasia were considered as variants of same entity, but OF has been considered a distinct lesion after Sherman and Sternberg described it in detail[5].

This lesion shows female preponderance, initially ratio being 3:1, while currently it has been recorded as 1.8:1[6]. In a report done in 2017 by Tapas et al suggests of female predominance in the range of 2:17 to 5:111[2]. Odontogenic fibroma (OF) is a 'benign odontogenic tumourwhich is characterized by various amounts of odontogenic epithelium in a mature fibrous stroma. Two types of the lesion are: an intraosseous or central OF (COF) and an extraosseous or peripheral. The intraosseous variant is an extremely rare tumour with clinical, radiographic, and histopathologic variable findings. A thorough review of the English literature revealed 78 cases of COF so far. Thus, we report an additional case of COF occurring in the maxilla of a 27-year-old woman. In addition, we performed a brief description and discussion of the cases reported in the maxilla and mandible. Matos et al has noted that this lesion was exclusive to mandible, however epidemiologic profile has changed with an equal distribution between anterior maxilla [54.4%] and posterior mandible [45.6%][6]. Eversole has reported in his studies that most frequent lesion occurred in mandibular molar [52%], then premolar [25%] as the second most common site in mandible, then incisor [12%]as third and lastly cuspid [11%] regions, the least commonly affected site of mandible[3]. OF has been reported to be prevalent in 2nd to 4th decades of life. In cases of maxilla, it is commonly seen in canine fossa and zygomatic arch area. OF clinically appears as a slow-growing expansile asymptomatic infra-bony mass presenting with facial asymmetry. Displacement of teeth may be an early clinical feature, while it may be present for some years. Pain and paraesthesia may be uncommon, yet still reports of presence have been recorded.

The cause of origin of OF is mostly considered to be the pluripotent mesenchymal cells of Periodontal Ligament. Pathogenesis of tumour can be induced by trauma to PDL from extraction, chronic inflammation due to pericoronitis, fibrosis due to periapical infection, or injury, etc. Brademann et al presented a hypothesis claiming mesenchymal cells present in bones other than maxilla and mandible can differentiate into PDL and a trauma may induce the lesion. Recently it has been discovered that a gene mutation of HRPT2, a tumour suppressor gene, can cause this lesion[1].

Fibro-osseous lesions are considered as there placement of bony constituent by fibrous tissue that later mineralize into woven or lamellar bone or cementum, presenting with various clinical features and microscopic appearances[3]. Radiographically the lesion appears variably due to difference in degree of mineralisation.

Amount of calcification differentiates a unilocular or multilocular radio-opaque image, or a radiolucent image with mixed density of opacified material. Root resorption and mobility can be appreciated in few cases[7]. Rind sign is a characteristic radiographical feature which is seen as a radiolucent line around the lesion's periphery, suggesting a capsule like nature[5]. MacDonald-Jankowski claims that OF is well demarcated and round or ovoid in shape as compared to Fibrous Dysplasia (FD), whereas OF presents an irregular shape, especially if occurs rapidly. If it grows along the body of the jaw, showcases an aggressive local growth. As compared to OF, fibrous dysplasia has the classical ground glass appearance radiographically. Radiotherapy is contra-indicated as a definitive measure of management.

Histological image suggests of ossified islands of bone and cementum within the hypercellular fibrous stroma. The trabeculae are variable in sizes, from lamella to woven patterns[8]. The characteristic sign of OF is interspersion of bony trabeculae and cementum like materials in a connective fibrous tissue stroma, along with presence of osteoblastic rimming[5]. CT and CBCT aid in radiographical differential diagnosis of OF[1].

Table 1 the comparison between OF and FD needed for their differential diagnosis, as they present similarities in their features.

Table 1: Differences between COF and FD

	Central Ossifying Fibroma	**Fibrous Dysplasia**
1. Category	Benign neoplasm	Bone disease
2. Clinical features	Painless hard swelling, facial asymmetry, tooth dislocation	Painless hard swelling, facial asymmetry, compression (paraesthesia, deafness)
3. Age prevalence	2^{nd}-4^{th} decade	1^{st}-2^{nd} decade
4. Sex predilection	Female	Both genders are equally affected
5. Variants	Juvenile and Normal	Mono-ostotic and Polyostotic
6. Etiology	PDL (induced by trauma), HRPT2 gene mutation	Gene mutation of GNAS1 gene
7. Hormone involvement	Not hormone related	Hormone related
8. Invasive	Continuous growth	Self-limited
9. Radiographically	Well demarcated bony margins, 'rind' appearance	Ill-defined margins, ground glass appearance, radiolucent lytic lesion
10. Histopathology	Fibrous capsule, osteoblastic rimming, deposits of osteoid	Chinese letter pattern, woven bone, loosely arranged fibrous stroma
11. Treatment	Surgical enucleation	Surgical recontouring
12. Radiotherapy	Contra-indicated	
13. Prognosis	Good, though there are chances of recurrence for larger lesions	Good

Taking into consideration the size, location and aggressiveness of the lesion, there are varied ways for management of the tumour, e.g. conservative observation, curettage, resection. In smaller size lesions, management is approached conservatively. In such cases long term follow-up is maintained. Recurrences in those conditions are treated by resection. Although resection of a massive portion of the jaw even though the lesion is benign in nature, is discouraged by many dentists. Some authors contradict radiotherapy for the management of this neoplasm, although roentgen therapy can be advocated to inhibit further growth of remnants left after operation. Aggressive lesion can be managed by en bloc resection as a definitive therapy[5].

Figure 1a: A single localized, bony hard swelling was visible on the right side of the upper part of anterior maxilla; 1b: A well circumscribed swelling in the left anterior maxillary lateral incisor region with bicortical expansion. 1c: A well circumscribed swelling in the left maxillary lateral incisor and canine, with displacement of 21, obliterating the labial sulcus; 1d: Diffuse swelling in the left anterior hard palate in relation to maxillary lateral incisor and canine.

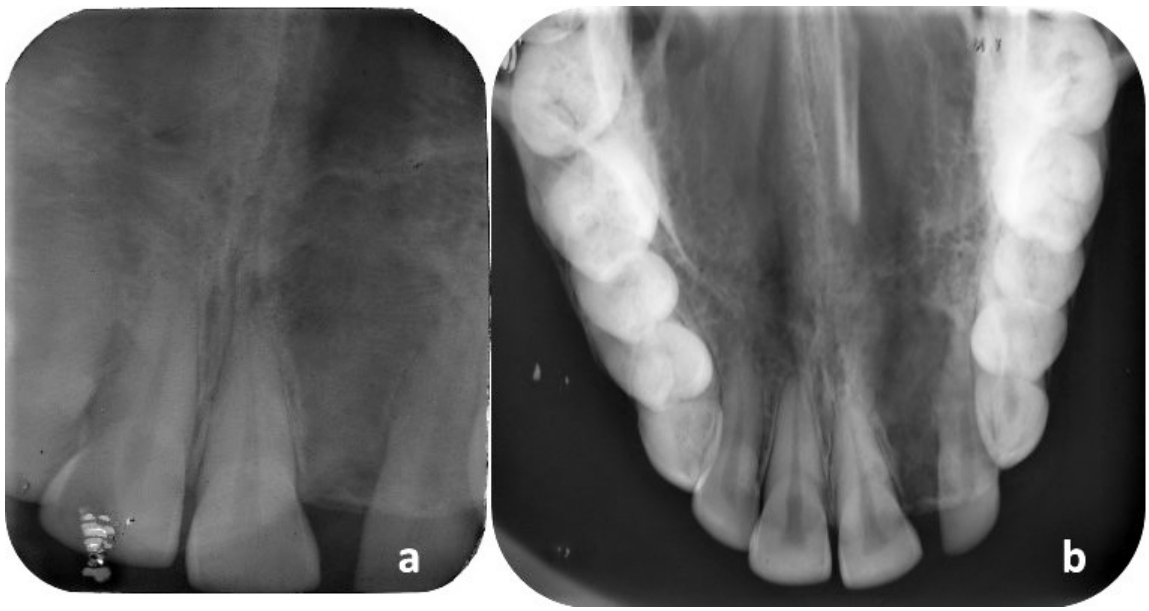

Figure 2a: Intra-oral periapical radiograph showing well defined unilocular radiolucency which is ovoid in shape and is present between 21 and 22. 2b: Maxillary cross-sectional occlusal radiograph shows unilocular radiolucency ovoid in shape in between 21 and 22 regions with slight displacement of 21 and 22.

Figure 3: Panoramic radiograph revealed a well circumscribed unilocular radiolucency involving 21-22 region displacing 21 and 22. Radiolucency was ovoid in shape with a radiopaque border.

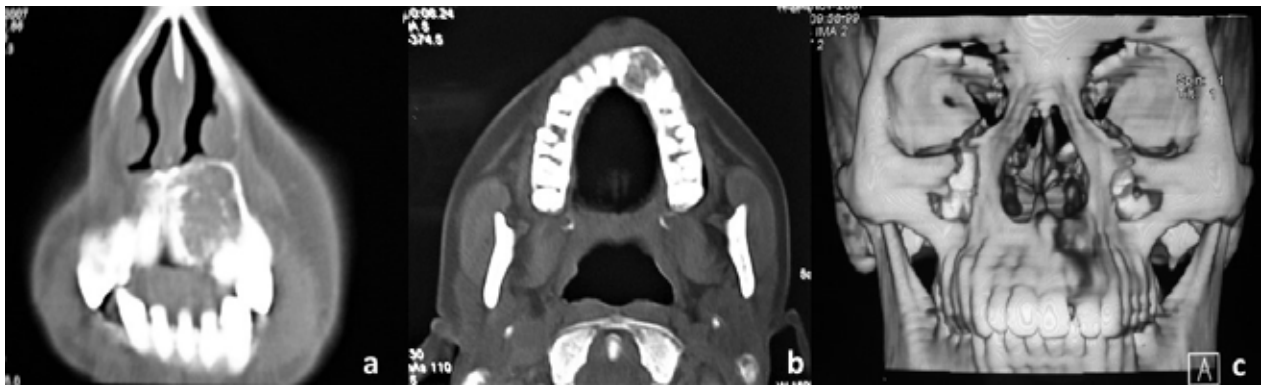

Figure 4a: Computed tomography scan of the swelling in coronal sections shows a space occupying lesion in the left maxillary alveolar segment with heterodense internal structure; 4b: Computed tomography scan of the swelling in axial sections shows a space occupying lesion in the left maxillary alveolar segment with areas of both hypodense and hyperdense. 4c: Three-dimensional reconstructed Computed Tomography scan shows extension of the lesion till the floor of the nasal cavity on the left side without breach in the nasal floor.

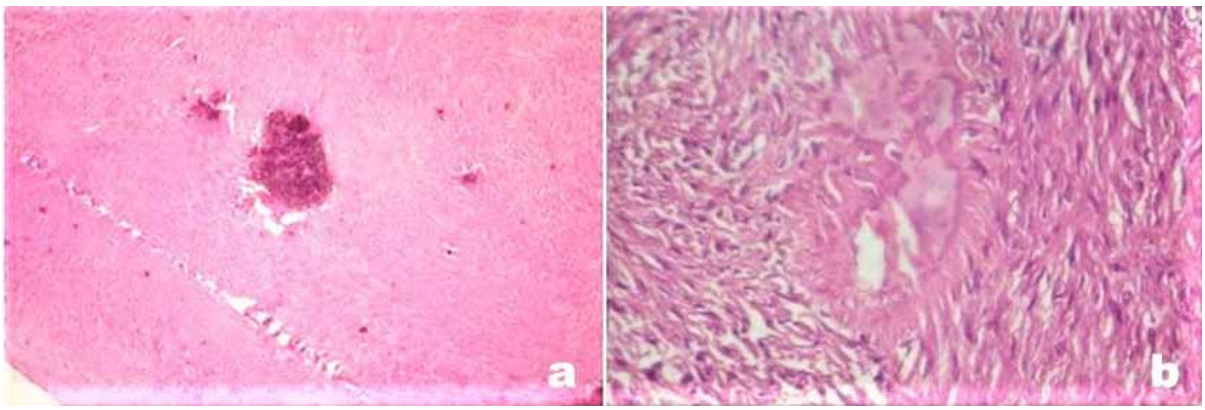

Figure 5a: Histopathologic examination (original magnification 10X) revealed cellular fibrous tissue containing mineralized material. Connective tissue stroma with cementum like areas within the connective tissue; with spindle and stellate shaped cells, suggestive of ossifying fibroma; 5b: Histopathologic examination (original magnification 40X) revealed cellular fibrous tissue containing mineralized material. Connective tissue stroma with cementum like areas within the connective tissue; with spindle and stellate shaped cells, suggestive of ossifying fibroma.

Conclusion

Amongst the many bony swellings encountered in the oro-facial region, odontogenic tumours and cysts are amongst the most common lesions. However, fibro-osseous neoplasms like the ossifying fibroma should be considered in the differential diagnosis and maxillary lesions especially have to be differentiated from fibrous dysplasia because of the aggressive nature of this benign neoplasm, the treatment has to be quite radical.

Inhalational Inducing Agents

Manisha Mohapatra

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Inhalational Inducing Agents include gas like Nitrous Oxide and volatile liquids like Ether, Halogenated halothane, Enflurane, Sevoflurane, Isoflurane, Desflurane and Methoxyflurane. They have exterminated pain and anxiety control in Dentistry as well as in General Medicine for over a century. The following article outlines the detailed history, correspondence, distinction, and the clinical implementations of the few most prevailing inhalational agents used in Dentistry.

Keywords: *Inhalational anesthesia, Nitrous oxide, Isoflurane, Sevoflurane, Desflurane, Minimum alveolar concentration, solubility, cardiac output.*

Introduction

Inhalational Anesthetic agents are a chemical compound acquiring properties of a general anesthetic that are administered via Inhalation. They are delivered through a face mask, laryngeal mask airway or tracheal tube attached to an anesthetic vapouriser and an anesthetic delivery system. Dental and oral or Maxillofacial procedures have tended to perform office-based inhalation anesthesia along with the emergence of a more compact and transportable anesthesia apparatus. Inhalational Induction is comparatively slower. It depends on the inspired anesthetic agent, it's concentration in the blood, alveolar ventilation, the blood-gas partition coefficient, and cardiac output. if the blood-gas coefficient is less, then the anesthetic agent is more effective and the onset of anesthesia is faster. Anesthetic agents have to have a pleasant smell and a carrier gas like oxygen or oxygen with air is required for its use.[1]

Inhalational Anesthesia is being considered equivalent to General Anesthesia. Even though there exist many drugs that can also be employed, whether through inhalation or intravenous to induce general anesthesia, Inhalational Inducing Agents are mostly used today in many of the hospitals and ambulatories. With continued progress of newer surgical approaches and easier obtainability of current short-acting drugs such as the addition of the intravenous agent Propofol, there is a sharp rise in the ambulatory services in the last Twenty Years. It also plays a significant role in children and needle-phobic patients[2].

Inhalational Anesthetic Agents must have these following characteristics: It must be possible to obtain a pure compound; It should be stable and not broken down by light or alkali; It should have low gas/blood coefficient; It should be a nonflammable and nonexplosive agent; It should not undergo metabolism and should be free of organ toxicity; It should have a pleasant smell; It should be readily reversible; There should be no adverse side effects if breathed in low concentration for a longer period; It should have minimal effect on the cardiovascular system; It should be practically potent, to allow use of an elevated concentration of oxygen; There should be no carcinogenic or teratogenic effect on the patient; It should own both analgesic and hypnotic property.[1,2]

History: All around History usefulness of herb

extracts to tonics and concoctions to sponges immersed with narcotics have been recorded to be used in surgical procedures. Explorations in the Eighteenth century made way for modern anesthesia. Diethyl ether, an inhalational anesthetic was the first publicly presented Anesthetic of the modern era. These agents have played an important role in Anesthesia history. Valerius Cordus was the one to synthesize Diethyl ether in 1540 and thus was seen to reduce pain. In the year 1772, Joseph Priestly synthesized Nitrous oxide and then sir Humphrey davy acclaimed its capability to reduce pain. The years 1920 to 1940 presented the introduction of Ethylene, Divinyl Ether, and Cyclopropane. But these drugs except for Nitrous Oxide were established to be nephrotoxic and combustible, making them unsuitable to be used in a clinical setup. Nitrous Oxide is known to be the most ancient anesthetic drug in clinical practice preceding Diethyl ether. Anesthesia was born on the 16th of October in the year 1846 known as Ether Day when there was a public Demonstration by Morton of Ether Anesthesia. Ether and Nitrous Oxide added with oxygen rendered anesthesia for a Century with fair competition in the 1930s to 1950s from Cyclopropane, Divinyl Ether, and Trichloroethylene.[3]

Modern Inhaled Anesthetics were introduced from the 1950s with agents that were partially or completely Halogenated which made them more stable and less noxious. Fluroxene was first synthesized with Halothane in the year 1951. The later one was then approved for clinical use in 1956. Similarly, Enflurane was popularised in 1972 and Isoflurane in the year 1980 and they did not pose threat for liver and kidney, unlike Methoxyflurane. Sevoflurane and Desflurane were manufactured in the year 1960s and 1970s but they were not economically accessible for clinical practice in the United States up until 1994. Xenon is a rare noble gas that was discovered by British Chemist sir William Ramsay in the year1898 and was first used as an anesthetic agent in 1951. Speedy Introduction with controlled nausea and vomiting facilitates for the drive of discoveries yet the 'modern' Agents continue to reform and rise upon those in the past. The most intriguing contrast over time is the potential to rapidly introduce new agents into the practice.[3]

Pharmacology: The Pharmacological characteristics of the recently used drugs sevoflurane, Isoflurane, and Desflurane are nearly equivalent to each other. They are noncombustible and remain as clear liquids at the normal room temperature. Their actions are as follows; They result in depression of the CNS and a decrease in the frequencies of the electroencephalogram and amplitude; they cause a surge in the cerebral blood flow which results in a rise in intracranial pressure; They also suppress the autoregulatory response to the cerebral blood flow; They produce a decline in Blood Pressure which is dose-dependent by reducing SVR except for sevoflurane; There is a prompt compensatory increase in the heart rate to maintain cardiac output despite peripheral vasodilatation and a decrease in peripheral vascular resistance.[3,4]

As compared to Sevoflurane and Desflurane, Isoflurane is the most potent vasodilator which was once known to give rise to coronary artery steal syndrome. studies and clinical trials have shown that Nitrous Oxide may cause a lenient increase in cardiac output followed by a sympathomimetic response with a higher concentration of the drug. The three volatile drugs namely sevoflurane, Isoflurane, and Desflurane create a surge in the respiratory rate which is dose-dependent and with a simultaneous decline in the Tidal Volume and a rise of arterial CO2. The breathing pattern in the case of volatile agents is swift but shallow. The reason behind the respiratory depression seen in cases of Inhalational Anesthesia is caused due to medullary depression of the ventilator drive of the central nervous system and also because of a cutback in the contraction of the muscles that are concerned in respiration. [3,4]

Overton and Meyer noticed a clear relationship among anesthetic efficacy and their solvability in olive oil, concluding that anesthetic drugs work unspecifically on the hydrophobic and lipid components of the cells. It has also been established in the last few decades that inhaled anesthetic agents depend on the action of protein receptors like ligand-gated ion channels. Inhalational Anesthetics decrease the supraspinal stimulation by declining the transposal of noxious afferent information that ascends from the spinal cord to the cortex of the cerebrum through the hypothalamus. It also reduces pain due to movement response by suppressing the spinal efferent neural activity. These agents affect the ion channels of neural tissue which can cause either presynaptic release of neurotransmitters and modify the post-synaptic response threshold to neurotransmitters or the two. They also have an inhibitory effect on the post-synaptic neuronal excitability by expanding the GABAa receptor facilitated inhibitory CL- current. [3,4]

Pharmacokinetics of Inhalational Anesthetic Agents: The Inhalation agents are titrable and their

pharmacology is unique; their uptake and release completely relies on the alveolar concentration of the anesthetic drug and its absorption by the pulmonary circulation through the alveoli. Their concentration relies mainly on 3 factors namely: Inspired concentration of the drug: the larger the inspired concentration, the more rapid is the rise in alveolar concentration to the inspired concentration and the fast induction of anesthesia. The second factor being the alveolar ventilation: alveolar ventilation is directly proportional to alveolar partial pressure as it steadily replaces the inhalational agent that is taken up by the pulmonary blood circulation. The last factor is functional residual capacity: A large functional residual capacity results in dilution of the inspired concentration of gas leading to an initial low alveolar partial pressure and slow advance of anesthesia. [4, 5]

The drug uptake from the lungs depends on the four factors namely:

Solubility: It is the blood-gas partition coefficient that illustrates the parallel affiliation of an anesthetic agent for two phases and how it distributes itself amongst both the phases when an equilibrium has been attained. It is the estimation of the solvability of an anesthetic agent amid the alveolar gas and pulmonary venous blood at equilibrium. An increase in the blood-gas partition coefficient results in higher uptake by the pulmonary circulation but a gradual and slower surge in alveolar partial pressure of the drug leading to a more late recovery from anesthesia. The values for brain: blood, fat: blood, and muscle: blood have an important influence and mainly for anesthetic procedures of longer duration for the drug is reallocated to the body compartments. The brain has a high perfusion rate and will achieve equilibrium quicker than fat or muscle. As the coefficient for blood: tissue is comparatively higher leading to most of the anesthetic being transported to the fat which perfuses it. The effect of anesthesia is increased for the fatty tissues having a higher affinity for them. The blood-gas partition coefficient for isoflurane, Sevoflurane and desflurane is 1.4,0.68 and 0.4 respectively at normal body temperature.[4,5]

Pulmonary alveolar blood flow: Pulmonary blood flow equals to cardiac output in case of a lack of a shunt. An increase in cardiac output leads to a higher intake of anesthetic agents from the lungs and further speedy distribution to the tissues along with the central nervous system. Thus low cardiac output results in decreased and a high alveolar pressure thus leading to faster induction of anesthesia. Increased delivery fastens the equilibrium of anesthetic partial pressure of tissues with that of arterial blood and leads to a decrease in the induction process.[4,5]

Difference between Alveolar to venous partial pressure and their tissue uptake: The contrast between the two is because of their uptake of inhalational agents by the tissue. Tissue consumption is reliant on the blood flow within tissues, the contrast between blood-partial pressure of tissue and blood-tissue solubility coefficient. An equal amount of anesthetic would be there both in the venous blood returning to the lungs as well as when it left the lungs in the absence of any uptake by the tissue. As the brain is highly perfused with blood, it equilibrates quickly unlike in the muscle tissue.[4,5]

Blood-gas solubility and how it presents in obese patients: Overweight patients contain a larger compartment for fat leading to prolonged time for equalization after induction and a sustained emergence time because of an increase in absorption and a slow release of anesthetic agents from the fat tissues. [4, 5]

Minimum Alveolar Concentration (MAC): It is defined as a measure of the efficacy of Inhaled anesthetics and is delineated as the minimum alveolar concentration at a constant state of an inhaled anesthetic at 1 atm of pressure that restricts deliberate movements in reaction to a surgical stimulus in fifty percent of the test population. It measures the somatic responses and can reflect the activity of an inhalational anesthetic drug on the spinal cord. The concentration required to repress the feedback to vocal and tactile stimulation and prevent consciousness is estimated by MAC-awake; where memory is being lost and MAC-BAR is the concentration required to hinder adrenergic reaction to surgical stimulation. Experiments have drawn an inference that MAC-awake is approximately 1/3rd of MAC for desflurane, isoflurane, and sevoflurane.[6]

Clinical Considerations of Nitrous Oxide, Isoflurane, Sevoflurane And Desflurane:

Nitrous Oxide: It is also known as 'laughing gas' and is a sweet-smelling, non-irritating, colorless gas, nonflammable, tasteless, inorganic gas that is not metabolized in the body and is the least hepatotoxic and teratogenic. Among all the prevailing inhalation inducing agents that are used in dentistry, Nitrous oxide is notably the commonly used drug in maximum dental procedures and surgeries and most commonly in

pediatric patients. It has to be often coadministered with oxygen or other volatile anesthetics because it cannot be utilized alone due to its high MAC value of 104%. The gas is stored as a liquid in the cylinders at a pressure of 760psi. It is known to be a powerful anesthetic but has a weak analgesic property; it does not produce adequate muscle relaxation. It does not depress the respiration and there is rapid elimination mostly through the lungs, and in small amounts through the skin, sweat glands, urine and intestinal gas. It can concentrate the halogenated anesthetics in the alveoli when they are simultaneously administered because of its fast uptake from the alveolar gas known as the 'second gas effect'.[7]

It does not affect the cardiovascular system and the cerebral blood flow. Nitrous oxide can have a very deadly effect on gas-filled spaces, it can diffuse up to 20 times quicker into closed spaces than it can be removed leading to the expansion of pneumothorax, bowel gas, or air embolism. Functions of nitrous oxide sedation are they reduce fear, anxiety, and fatigue. They increase pain reaction threshold, tolerance for longer appointments, and aid in the treatment of special patients. They also control non-compliant or uncontrolled behavior and pain by replacing local anesthesia. The drawbacks of using this agent are they need supplementation to be administered, they can cause hypoxia and inhibit vit B12 metabolism and methionine synthetase which is necessary for myelin formation and DNA synthesis. Prolonged exposure to this drug can cause bone marrow depression leading to megaloblastic anemia.[7]

Isoflurane: It is an isomer of enflurane and a halogenated ether derivative which is a colorless, volatile liquid, has a pungent odor, and is stable. The induction dose is 1.5-3% and the maintenance dose is 1-2%, by special vaporizer. Effects of this drug are; It causes dose-dependent depression of ventilation; It is a muscle relaxant and also causes relaxation of uterine muscles; It is a myocardial depressant and also causes coronary vasodilatation; the administration of this drug causes an increase in cerebral blood flow and a reduction in the cerebral metabolism.[7]

The advantages of this drug are there its fast induction and recovery with minimal risk of hepatic or renal toxicity. There is less nausea and vomiting. It does not induce cardiac arrhythmias, there is reduced myocardial depression and no myocardial sensitization to adrenaline. It is a very stable molecule and undergoes little metabolism. The disadvantages are they have a pungent odor, irritating vapor thus not commonly used for induction. They cause coronary vasodilatation and respiratory depression.

Desflurane: It has an extremely low blood-gas coefficient of 0.42. Due to its low fat-blood solubility, it has a very fast emergence from the anesthesia. It has the potency to induce tachycardia along with stimulation of the sympathetic nervous system with fast variations in inhaled concentration that might compromise a cardiovascular patient. It is not suitable to be used as an anesthetic agent as it possesses a fetid odor and which can be very agonizing to the pulmonary tissues and respiratory tract. It has a MAC of 6%, the least potent but the most expensive of the volatile agent. It causes dysphoria in pediatric patients.[8]

Sevoflurane: It is a new drug and the most commonly used volatile anesthetic agent used in ambulatory and office-based anesthesia. It is stable, nonflammable has a pleasant smell, and a MAC value of 2%. It is the most commonly used agent because it causes less irritation, unlike the other gases. It is metabolized by the liver releasing fluoride ions thus can be nephrotoxic. It may cause respiratory depression, muscle relaxation, is a myocardial depressant, and can cause a rise in cerebral blood flow and a decline in cerebral metabolism.[8]

The advantages of this drug are it has a rapid onset and offset of effect, nonirritant, sweet odor, rapid induction and recovery, suitable for pediatric patients and does not lead to the production of carbon monoxide with dry soda lime. The drawbacks of this agent include; it is less potent than the corresponding halogenated agents; children might experience postoperative agitation; only 5% of the drug is metabolized resulting in an elevation of fluoride levels and associated risk of renal toxicity.[8]

Conclusions

Inhalational anesthesia is the most commonly used agent in hospitals and ambulatory surgery operating rooms as it provides multiple delivery method and allows the anesthesiologist to choose from a varied and appropriate anesthetics for a given patient in a dental setup.

Artificial Intelligence and How it Renovates the World of Dentistry

Rabina Mohanty

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India.

Abstract

In the era of information and technology with the importance that data have in our daily life, advanced intelligence systemsare the new necessity to process and integrate those data and help us understand it efficiently. Artificial Intelligence (AI) with its computational and data processing powers provides a way to demonstrate intelligence which helps taking intelligent and effective decisions easy and effortlessly. This behavior of artificial intelligence has made it ever so significant in the field of dentistry. Using artificial intelligence in the field of dentistry would reduce cost and time of diagnosis, probability of medical error, and has the potential to improve the dental health of the public and in turn improve patient care. It assists dentists to be more proficient in their trade. This article tries to throw some light on the usefulness of artificial intelligence and how it can impact the world of dentistry in the upcoming future.

Keywords: *Artificial Intelligence; Dentistry; Applications; Diagnosis.*

Introduction

Artificial Intelligence (AI), the term coincided in 1956, is intelligence demonstrated by machines by accepting percepts from the environment and performs certain actions. This branch of computer science imitates the cognitive functions, such as learning and problem solving,similar to a way that the human mind or natural intelligence performs. The technology involves a set of complex mathematical algorithms which with a given set of data, analyzes and reaches to an intelligent conclusion. Apart from providing an intelligent conclusion, it also makes itself learn by correlating and analyzing the data and the corresponding result pattern for a better and more accurate output in the next iterations that follows. This process is also termed as deep learning, which is a part of the Machine Learning technique and entirely based on analyzing, inferring, and learning from complex forms of data.[1]

In the field of AI, there are so many variables, debates, and questions that it is simply impossible to have a single universally accepted definition for it. How exactly intelligence be defined or measured? What should make a machine intelligent? To understand the complete picture of AI, we need to know what intelligence exactly means and how we can relate it to a machine.

What is Intelligence?: From the simplest behavior to the most complex thinking can be attributed to intelligence. The AI and all the research around it mostly signify on certain components of intelligence such as learning, reasoning, unraveling, and adaptability using algorithms that are specifically designed to perform these actions using real-time data from different sources.[2]

a. The learning aspect of intelligence comes from information processing. This gives a dynamic feel to the intelligence of a machine that otherwise would be static and symbolic. There are different ways to make a machine learn, such as trial and error, generalization – learning from experience.

Corresponding Author:
Rabina Mohanty
Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: mohanty.rubina30@gmail.com

b. The reasoning aspect points to the decision making factor. Any intelligent machine needs to draw an appropriate conclusion based on the situation. A conclusion can be deductive or inductive. The deductive conclusion is based on the facts that guarantee a true conclusion, while the inductive conclusion is based on the previous examples that provide support to the conclusion.

c. Unraveling is the approach of solving a complicated problem by formulating them into several simpler problems. These smaller problems are then solved through a range of possible actions to arrive at a predefined solution.

d. The adaptability factor helps a machine termed as 'intelligent' to adapt based on changing situation by compiling information and reaching to an apt decision.

Now that we have gained a good understanding of artificial intelligence, let us see how it is being used and the opportunities where it can be applied in the future in the field of dentistry.[2]

How is AI currently used in dentistry?: Artificial Intelligence is a big revolution in the field of technology which is rapidly progressing and improving at the same time, thanks to all the extensive R & D being done in the field of machine learning. Medical science along with the field of dentistry has seen a substantial uptake of this technology. Every field of medical science has been integrated with this power of technology to help make it better and more efficient.[1-3]

Diagnostic capability is a primary work that dentists have to perform on any problem. In general, diagnosis is done through several investigating techniques such as X-rays, CT scans, MRIs. The results are then interpreted by a dentist to reach to a conclusion. Now what if, the analysis is being done by an 'intelligent' machine and directly provides probable conclusions to the dentist? The dentist can simply take a suited action. This is achieved through image processing and recognition using artificial intelligence algorithms and making a machine learn and determine as to what exactly a particular or a set of image(s) indicates. This reduces error probability, helps to identify even minor deviations from normal, eliminates differences in subjective diagnosis, decreases overall time by removing the predictable tasks and these would provide a much better patient care. Artificial Intelligence also helps in analyzing and predicting any possible genetic disorder that could lead to a bigger concern like oral cancer.[2,4]

Clinical decision support systems (CDSS) are complex algorithms that assist health care personal in clinical decision-making tasks. A working definition for CDSS was proposed by Robert Hayward which says – "Clinical decision support systems link health observations with health knowledge to influence health choices by clinicians for improved health care". The involvement of computers and software that are integrated with available medical records of individuals has become a necessity in dentistry. The CDSS can assist in that part efficiently. It consists of a link between the vast medical knowledge block and an interpretation process that are a set of researched-based rules. An example of such a system is the one used to forecasts the genetic disorder and differences by using a form of genetic mutation algorithm. Thus a CDSS effectively helps in reducing the gap between a doctor, medical knowledge, and a patient.[2,4]

Artificial Intelligence provides the platform to integrate data from several domains such as the dental history of the patient, prior scans images and tests,socio-demographic details, pre-existing health conditions. Processing these data will provide a better understanding of the problem to a dentist and in turn, helps take an appropriate route for diagnosis. Artificial intelligence helps streamline a large number of routine activities such as scheduling and reminding appointments, patient record keeping, diagnostic assistance systems, self-monitoring, and management by patients. As part of a health monitoring system, AI provides a much deeper learning about any underlying health conditions and diseases, the impact of medicine on the patient.[5]

There is a vastapplications of artificial intelligence in the field of dental surgery. With the advancement of robotics handed surgery and in combination with the machine learning algorithms, almost all of the complex human operating motions and intelligence can be programmed and simulated in an environment where a dentist can perform those surgeries and have expertise on them without actually risking any real patient. This also assists surgeons for better planning and execution time of the procedures. Although virtual reality provides a simulated environment, it still is a great way of learning and gaining practical experience for inexperienced surgeons. The effect visualization makes it more real than anything.[6]

Augmented reality is another aspect where there is a growing contribution by artificial intelligence and it has slowly started its impact in the field of medicine. The augmented reality has helped reduce the complexity in the process of delivering aesthetic prostheses. With the help of AI systems integrated with augmented reality, patients can now check the prosthesis virtually and see how it fits them. This helps the patient and the dentist to make any number of changes and the final prosthesis outcome will be more accurate as per the indicated specifications. Augmented reality helps in obtaining accurate facial measurements, bone structures which assist dentists as a surgical guide for implants.[7]

Artificial Intelligence has also helped to enhance the learning methodologies and skills of dentists around the world. It has been successfully integrated into the dental education system to enhance the theoretical as well as practical learnings and trainings in the field of dentistry. The AI technology has the facility to envision and create a virtual reality (VR) environment that would help simulate different complex surgical techniques. Dentists can achieve expertise in various techniques of surgeries without actually operating on a real clinical patient. They can learn to design the best possible prosthesis using an AI-supported designing tool. Professors can efficiently impart quality education through a simulated environment. This method of learning is very effective, has no risks (no error-prone), a better way to practice, and an in-depth transfer of knowledge and information.[7,8]

Forensic Odontology is another segment where the usage of AI and its advancements has been done. This involves an examination of the dental forensic evidence found at a crime scene and thus this holds a larger interest for justice. It becomes extremely critical to properly and accurately analyze the evidences. Systems enabled with AI technologies and algorithms can be very helpful in this scenario. A varied array of image processing techniques integrated with AI algorithms will help provide an accurate and systematic overview of human age estimation and facial identification that can be used to track the probably criminal involved. The enhanced system can be integrated with neural networks to learn and effectively predict the age and possible facial structure.[9,10]

Future for dentistry: Rise of AI

In this paper, a brief explanation by relating the usage of artificial intelligence in every possible aspect of dentistry. Artificial Intelligence (AI) has indeed similarly revolutionized the field of dentistry that it has impacted the field of technology. It has showcased a wide range of applications and exceptional accomplishments in the field of medical science in general. From enhanced clinical decision-making process to easier diagnosis, from improved patient care to an efficient way of performing complex dental surgeries, in every way AI has helped not only to improve the existing process but also assist dentists to become better. Having said that, this technology is on many levels still improving and every day something new gets added to it for better. There is a minimum doubt that in the future it will have a major impact throughout every aspect of dental care and be an integral part of it. Although the human knowledge, intellect, and decision making cannot be replaced completely, the main purpose of using AI integrated systems is to assist dentists to perform efficient diagnosis, accurate and risk-free surgeries, and better dental care for patients.

Infections of the Surgical Site: An Overview

Mohammed Wasif

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Surgical site infection is a type of nosocomial infection that not only increases the medical expenses of the patient but also the risk of fatality. It is of major concern as the patient has come for treatment of diseases and getting a new infection due to negligence in following sterilization and asepsis protocols during surgery. Therefore the article enlists the method on how to manage SSI.

Keywords: *Surgical site infections, risk factors, intra-operative, and post-operative management protocols.*

Introduction

Surgical site infections or SSIs are among the principal hospital-acquired infections. As per the latest studies its occurrence is around two to eleven percent of the total surgical operations. SSIs cause an increase in health care expenditures, an increase in hospital stay, and increased death rates.[1]

Categorization of SSI:

1. **SSIs are categorized into:**

Superficial–start in less than thirty days post-surgery, affect the skin as well as subcutaneous tissue;

Deep–start post thirty days or in less than one year (on condition that a foreign particle got into the fascial spaces and muscle;

Infection of the organ or body spaces found near the incision area – occurs in less than thirty days to one year (if a foreign particle got into it).

2. Wounds of the surgical site are categorized into 4 categories based on how hygienic or dirty the wounds are:

Corresponding Author:
Dr. Mohammed Wasif
Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India
e-mail: mwasifcool7@gmail.com

Type 1 type of wounds: clean wound where the occurrence of infection is less than two percent;

Type 2 types of wounds: clean or dirtied wound where the occurrence of infection is less than ten percent;

Type 3 type of wounds: dirtied wound where the occurrence of infection is nearly twenty percent;

Type 4: dirty or infected wound where the occurrence of infection is less than forty percent.[2]

Microorganisms responsible for SSI:

- *Staphylococcus epidermidis* (Commonly seen but only causes disease sometimes)
- *Staphylococcus aureus* (Rarely occurs, disease-causing in nature)
- *Staphylococcus warneri* (Rarely occurs, sometimes disease-causing in nature)
- *Streptococcus pyogenes* (Rarely occurs, disease-causing in nature)
- *Streptococcus mitis* (Commonly occurring, causes disease sometimes)
- *Propionibacterium acnes* (Commonly occurring, sometimes causes diseases)
- *Corynebacterium* spp. (Commonly occurring, sometimes causes diseases)
- *Acinetobacter johnsonii* (Commonly occurring, sometimes causes diseases)

- *Pseudomonas aeruginosa* (Rarely occurring, sometimes causes diseases)[3]

Components affecting SSI:

Factors depending on the patient: Age of the patient, nutrition of the patient, uncontrolled diabetic patients, regular Smokers,obese patients, parasitic infestations, colonization with drug-resistant disease-causing microbes, Immuno-compromised individuals,Time period of hospital stays prior surgery and post-surgery.

Factors depending on Surgery: Sanitization of the skin, removal of hair from the skin, peri-operative antibiotic dosage, time period of surgery, improper instrument sterilization, air ventilation or conditioning, foreign particle inside the wound, drainage of the surgical site, insufficient hemostasis, significant surgical trauma.[4]

Prevention of SSI:

Preoperative phase:

Surgical site shaving:

It has been seen that the use of bladed razors makesmicro-injuries on the epithelium. Therefore it increases the chances of SSI. Hence hair removal is usually done with the help of an electrical razor which has a one-time use tip which is used just before the patient is sent to the operating room.[5]

Nutritional status of the patient: Nutrition deficiency or improper nutrition hurts the patient's condition and surgical results. Two method could be used for assessment of the person's nutritional status:

- Nutritional-Risk Screening
- Nutritional-Risk Index[6]

An assessment of the association involving malnutrition

And SSI usually includes the mode and degree of surgical interference.

Obesity (BMI greater than thirty) influences the healing of the by various means. The subcutaneous tissue blood supply in overweight patients may not be enough and it may not supply proper O2 whereas tissue healing has an increased metabolic requirement and insufficient O2 supply reduces the speed of the entire process. Cells that provide immunity have an increased O2 demand, which is used for the production of anti-microbial oxygen compounds.[7]

Immuno-suppressive treatment: An examination conducted by Berthold et al shows that the immuno-suppressive treatment damages healing of the wound and raises the chances of occurrence of infection. Stoppage of immune-suppression may cause aggravation of the disease which was already present. The guidelines given by The Society for Healthcare Epidemiology (America), recommended the stoppage of immunosuppressive therapy before and after surgery as long as it is possible.[8]

Use of antibiotics for prevention of SSI: Prophylactic therapy of antibiotics is usually given for clean or dirtied wounds and clean wounds with foreign particles. Usually, for a clean wound, we use cephazolin or cefuroxime or vancomycin. For contaminated wounds, the person must not be usually given a prophylactic treatment but a full antibiotic course.[9]

Intraoperative phase:

Operating room: When a patient who has undergone surgery goes through the process of healing, for it to happen without complications of infection, the patient should be placed in hygienic surroundings. The correct planned operating room must have regions that constantly increase in sterility. The hospital staff must walk amidst areas where scrubbing takes place to reduce contamination of the OR environment with disease-causing microbes. The essential step when considering planning of OR is the differentiation of the clean and the dirty areas of the room from each other.

Sanitization of the surgical area: The objective is to decrease the pathogens which naturally occur inside the superficial layer of skin, and restrict the growth tendency of disease-causing organisms pre-surgery and post-surgery. Frequently substances used for skin decontamination before surgery consists of an alcohol solution of chlorhexidine gluconate as well as povidone-iodine. Chlorhexidine gets absorbed by proteins that contain phosphorous inside the cell wall of the bacteria. At bacterio-static quantity, the solution gets into and destroys the membrane of the cell which causes seepage of structures of the cytoplasm. When it reaches bactericidal quantity, it gets into the cell of the bacteria and permanently attaches itself with Adenosine-triphosphate of the cell as well as nucleic acids. Chlorhexidine has fungi-static and fungicidal properties and usually kills

viruses of some types. The least amount required to stop bacterial virulence is usually lesser for Gram-positivebacteria compared to Gram-negativebacteria because chlorhexidine shows more likeness to the Gram-positivebacterial wall of the cell. Povidone-iodine comprises a normal solution containing one percent iodine which is free. Iodine seeps inside the cell wall causing oxygenation of cysteine as well as iodination of the other amino-acid compounds as well as fatty acids which are not saturated which results in a decrease in protein production a well as the injury of the cell wall. Iodine, which is useful for treating infections due to Gram-positivebacteria and Gram-negativebacteria and a couple of bacteria that form spores, Mycobacteria, virus, and also fungi. Dissolving chlorhexidine along with povidone-iodine/ethanol/isopropylethanol increases bactericidal action. The alcohol damages proteins as well as increases the killing of the bacterial cell. It's effectiveness in opposition to *Staphylococcus aureus* which is methicillin-resistant, Enterococci which is vancomycin-resistant, and *Mycobacterium-tuberculosis*.

Studies have been conducted which compare chlorhexidine and povidone-iodine confirmed that both the materials demonstrate comparable anti-bacterial action. Chlorhexidine operates for an increased duration of time by combining with the skin as well as the proteins of the mucous membrane. As opposed to povidone-iodine, its function is unchanged when in contact with blood/any other type of body fluid. There are statements regarding the effectiveness of chlorhexidine as well as povidone-iodine which are contradictory. Considering the meta-analysis which was done by Lee et al (which also includes the nine randomized controlled trials), the better usefulness provided by chlorhexidine can be concluded but the significance of the examination has been argued upon since multiple studies have compared alcohol chlorhexidine solution and povidone-iodine solitarily. During meta-analysis which was done by Priviter et al which was for comparisons between alcohol solution of chlorhexidine as well as povidone-iodine, it was established that usage of chlorhexidine results in the decreased occurrence of SSI.[10]

Sanitization of hands: The bacteria which are found on the naked hand of the medical personnel may be leading to the causation of infections that are acquired at the hospital. The Gram-negativebacilli as well as Staphylococcus-aureus are the primary components of skin bacteria. Chlorhexidine-solution usually provides surgical sterility through a decreasing number of bacteria. Chlorhexidine has been depicted as a wide spectrum and increased duration of antibacterial action, while alcohol quickly begins taking action. Substances that contain chlorhexidine as well as alcohol mix the property of quick initiation of alcohol along with the increased duration of the consequence of chlorhexidine. Hence are considered most successful.[11]

Phase after surgery: Post-operation wound cleanliness is important. The best method is considered to be the 'no-touch' method which is to avoid touching the wound as well as dressings with non-sterilized hands. Sterile saline must be utilized for sponging or washing the wound. After 48 hours post-surgery, the patient should wash or herself with mild detergent (soap) preferably having antimicrobial properties. It's usually not advised to utilize local antimicrobials or topical antimicrobials to decrease the chances of occurrence of infection. Clinically, the infection presents itself as: Localized reddishness of skin,tenderness,increase in temperature of the site,fluid-filled spaces, pus containing discharge.

In treating SSI, importance is given to opening the area of infection as well as draining the purulent areas. Infections of deeper tissues require draining the area but infection of superficial tissues requires only limited draining of the area which is affected. Fibrins/suture as well as the staple is gotten rid of/tissue debriding must be done to remove the dead cell of the wound. SSI is usually treated with different types of antimicrobials which depend on open the surgeon's choice (for example, solution of povidone-iodine H2O/octenidine-dihydrochloride). The concentrations antiseptics which are commonly in use are almost a hundred times more when compared with the minimal inhibitory concentration of the same compound. Hence these substances kill the bacteria which have developed slight resistance against these antiseptics. The 2014 guidelines of Infectious Diseases Society of America, the usage of antibiotics is not necessary if there is a minimum infiltrate results from inflammation which is lesser than five centimeters near the surgical site with none of the signs of general infection established as fever which is less than thirty-nine degrees Celsius as well as the rate of the heartbeat which is less than hundred and ten per minute. Although, it is mandatory to recommend the initiation and anti-biotics if inflammation near the surgical site becomes greater than five centimeters as well as the sign of general inflammations occur. While making a choice of the 1st-line of therapy, localized epidemiological

situations, and the Gram-staining process of smears of the wound must also be taken into consideration.

Indications for microbiological studies for SSI patients include: Intense screening, the requirement of an anti-biotic therapy,the inclusion of evaluation of drug-resistant disease-causing bacteria,allergic reactions of any kind to the first-line of therapy. In case of there are suspects regarding infections which are caused by staphylococci, cefazoline, cefuroxime/cloxacillin may be useful. For the infections which are caused by MRSA, it is correct to use linezolid or glycopeptide. When there are suspects regarding infection caused by Gram-negativebacteria, the first-line of antibiotics are usually 2nd or 3rd generation cephalosporins or fluoroquinolone. When dealing with the complications of deep as well as non-healing wound, negative pressure treatment is usually taken into consideration. The negative pressure allows the proper supply of blood to the site of wound by increasing the formation of new blood capillaries and thus increases the rate of formation of tissue which is granulomatous. Treatment by negatively applying pressure in case of the wound which is infected is considered safe but it usually precedes debridement and initiation of target antibiotic treatment.[12]

Conclusion

Surgical site infection is a type of nosocomial infection that not only increases the medical expenses of the patient but also the risk of fatality. It is of major concern as the patient has come for treatment of diseases and getting a new infection due to negligence in following sterilization and asepsis protocols during surgery. Therefore the article enlists the method on how to manage SSI.

Pulpotomy

Rojalin Jena

Intern, Institute of Dental Science, Siksha O Anusandhana (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A pulpotomy is a way of preserving primary teeth from carious lesions and damage before the natural exfoliation. It is also the most controversial treatment in pediatric dentistry. The success rate of pulp therapy in the primary tooth depends mostly on early pulp diagnosis, pulp vitality prevention, pulp vascularization & periradicular status. New biomaterials that are more biocompatible have changed the frame of mind towards the prevention of cariously exposed teeth.

Keywords: *Pulpotomy, Pulp vitality, Pulp Therapy, Primary tooth, Carious lesion.*

Introduction

Pulp therapy is a medical intervention that is done for the preservation of cariously affected primary tooth until its normal exfoliation because the loss of primary tooth before natural exfoliation can lead to esthetic & functional problems & malocclusion. It has been the most debatable & controversial mode of treatment in pediatric dentistry for more than a decade, but the procedure of pulpotomy has evolved slowly & continued to accelerate in past few years which are now more acceptable in the present days.[1] Two different method can be used to perform pulpotomy:

a. Non-pharmacotherapy – treatment include leaser & electrosurgery

b. Pharmacotherapy – treatment such as replacing the cariously affected pulp tissue with biocompatible medicaments like ferric sulfate, MTA, glutaraldehyde, sodium hypochlorite enriched collagen solution, etc.

Treatment or management of a cariously affected primary tooth where the carious lesion has already reached the pulpal region requires a proper knowledgeable approach for pulpotomy, and the success rate of the procedure depends on the proper diagnosis of the pulp status before doing the therapy. Post-operative and preparatory data collected before the therapy is interpreted and mostly focuses on determining whether the pulp of the carious affected tooth is normal, reversibly inflamed, irreversibly inflamed, or necrotic. If the pulp is diagnosed to be necrotic or irreversibly inflamed then the treatment done is either a pulpotomy or extraction would be appropriate. If the pulp is diagnosed to be vital or reversibly inflamed then the vital pulp therapy technique of pulpotomy or indirect pulp treatment is indicated. In this article, the discussion is limited to the vital pulp therapy procedure of pulpotomy for primary teeth.[2]

Definition: Complete removal of the coronal portion of the dental pulp followed by placement of a suitable dressing or medicament that will promote healing and preserve the vitality of the tooth. A pulpotomy is defined as the amputation of vital pulp from the coronal chamber followed by placement of a medicament over the radicular pulp stumps to stimulate repair, fixation, or mummification of the remaining vital radicular pulp. A pulpotomy is a procedure in which the entire coronal pulp is removed, to remove all infected pulp tissue; the radicular pulp is then treated in different ways, according to the technique employed. A pulpotomy is the removal of the coronal portion of the pulp and the treatment of radicular pulp in an attempt to maintain the tooth and its supporting structure in a state of health. Procedures involving removal of vital partially inflamed

e-mail: rojalinjena841@gmail.com

coronal pulp and tissues and placing a dressing over the amputated pulp stumps and then placing the final restoration.[3]

Objectives: The main objectives of pulpotomy are the preservation of the vitality of the radicular pulpal tissue, removal of cariously infected coronal pulp tissue, treatment of remaining pulp with the placement of proper and suitable biocompatible medicaments, neutralization of further infectious process, avoiding degeneration of pulpal changes and avoiding dystrophy of the peri-radicular region.

Classification[4]

1) Vital pulpotomy

a) Devitalisation pulpotomy (mummification, cauterization)
   - Formocresol pulpotomy
   - Electrosurgical pulpotomy
   - Laser pulpotomy

b) Preservation (minimal devitalization, Non-induction)
   - Glutaraldehyde
   - Ferric sulfate

c) Regeneration (inductive, reparative)
   - Calcium hydroxide
   - Bone morph genetic protein
   - Mineral trioxide aggregate

2) Non-vital pulpotomy
   a) Beechwood cresol
   b) Formocresol

Devitalization: Is the first and foremost approach in the pulpotomy in primary teeth, with the vital pulp tissue destroyed, which includes formocresol, glutaraldehyde, electrosurgery, and laser. It is done with the intention of "mummifying" the radicular pulp tissue.

- Formocresol: It is the most popular medicament for pulpotomy in primary teeth for 70 years, which was introduced in the year 1932, with a success rate of 80%-90%.

Formocresol constitution: 19% of formaldehyde, 35% of cresol, and as a vehicle 15% of glycerin and water that is known as Buckley's solution. Formocresol prevents the destruction of the pulpal tissue by bonding with the protein.

- **Glutaraldehyde:** It is an alternative pulpotomy agent to formocresol for its superior fixative property, low antigenicity, and low toxicity. It was introduced by Kapel in the year 1979.

The application of 2%-4% of glutaraldehyde produces rapid surface fixation of the underlying pulpal tissue. A thin zone of compressed fixed tissue eosinophilic stain is formed under the region where the glutaraldehyde is applied, which blends with the vital normal tissue present apically.

- **Electrosurgery:** It is a non-pharmacological procedure for pulpotomy in primary teeth. In this process,a high frequency of the electric current is passed through the tissue cells to cut it, which forms a layer of coagulative necrosis and provides a barrier between the healthy radicular tissue and the biocompatible medicament placed in the pulp chamber.

- **Laser:** It was introduced in dentistry in the early 1960s. There are different types of lasers used in pediatric dentistry such as a laser which is used for diagnosis of carries development, argon laser for curing of composite, CO_2 lasers with the wavelength of 10600nm are used for soft tissue surgeries, YAG lasers are also used for cutting soft tissues. Erbium laser is used in hard tissues for cavity preparation. In pulpotomy, the use of lasers helps in the early preservation of vital tissues near the apex of the tooth, hemostasis and there is no vibration neither any odor, which leads to satisfaction of children and the parents.[5,6]

Preservation: In this method, the pulpal tissue is preserved by ferric sulfate and sodium hypochlorite. In this method, the pulp tissue is minimally insulated. Ferric sulfate and sodium hypochlorite help in retention of vital tissue and conserves the radicular pulp without including the reparative dentine and it also maintains the normal histological appearance of the radicular pulp.

- **Ferric sulfate:** Ferric sulfate in pulpotomy acts as a coagulative and hemostatic agent. The clinical success rate for this is 90%-95% and the radiographical success rate is 70%-80%.

The major failure of ferric sulfate is a high percentage of internal resorption. But as ferric sulfate is a less

expensive solution with no toxicity and carcinogenicity, it is recommended as a suitable substitute for formocresol.

- **Sodium hypochlorite:** It is mostly used as an irrigant solution due to its antimicrobial activity, tissue dissolving activity, detergent action, hemostasis, and the ability to neutralize toxic products.

Sodium hypochlorite can also be used as a medicament in pulpotomy but only a few clinical trials are done to evaluate the efficacy of sodium hypochlorite in pulpotomy.

Regeneration: Regeneration is the procedure which includes the application of biomaterials and biocompatible medicaments as a pulpotomy agent that has cell inductive capacity that helps in either replacing the lost cells or help to induce the existing cells to differentiate into hard tissue forming elements.[7,8]

Regeneration procedure helps in the formation of reparative dentine and the preservation of healthy pulpal tissue. Many pulpotomy agents are used in this method such as calcium hydroxide, mineral trioxide aggregate, and calcium-enriched mixture cement.[7-9]

- Calcium hydroxide: It is a pulpotomy agentthat generates information of new dentin when applied tothe pulp tissue. It is also used as a medicament for direct pulp capping and indirect pulp capping in both primary tooth and permanent teeth. Calcium hydroxide also acts as a bactericidal agent and helps in the stimulation of dentine bridge formation. Calcium hydroxide sometimes results in the development of chronic pulpal inflammation and internal resorption, so it is controversial to use it as a pulpotomy agent in a primary tooth.[7-9]
- **Mineral trioxide aggregate:** It as a member of hydraulic calcium silicate cement and it consists of tricalcium silicate, bismuth oxide, tetra calcium alumina-ferrite, and calcium sulfate dehydrate. First mineral trioxide aggregate had a grey coloration but then in 2002, a new formula was introduced with white coloration. When it is mixed with water it forms a colloid gel, which is similar to calcium hydroxide. MTA is a more preferable pulpotomy agent because it is more biocompatible; it has a bactericidal effect and also induces cementogenesis. Furthermore, it has the ability for sealing, dentinogenesis, and osteogenesis.[7-9]
- **Calcium enriched mixture cement:** It was first introduced as an endodontic filling material in dentistry. It mainly consists of calcium oxide, sulfur trioxide, phosphorus pentoxide, and silicon dioxide. The physical properties of this biomaterial are it is flowable, it has film thickness, primary settling time and it can set in an aqueous environment. This cement is highly biocompatible and can induce the formation of hard tissue and hydroxyapatite and it also has an antimicrobial effect that resists the entry of microbial agents.[7-9]

Factors that affect the prognosis of pulpotomy:

The factors that affect the prognosis of pulpotomy are as follows:

- Size of exposure
- Location of exposure
- Exposure to saliva
- Marginal leakage
- Age and status of pulp

Indication:

- Cariously involved primary tooth, which is rented enough to not to be extracted and can be preserved
- A vital tooth with healthy periodontium can undergo pulpotomy
- If there is any pain, it should not be spontaneous and should go along with the removal of the cause or stimulant of pain
- A tooth which can be restored and preserved can go for pulpotomy
- A tooth should have 2/3rd of its root length unaffected to undergo pulpotomy
- Hemorrhage from the amputation site should be pale red and it should be easily controlled
- There should be no abscess and fistula
- There should be no loss of inter-radicular bone
- It can also be done on a young permanent tooth with vital exposed pulp and incomplete formed apices[7-9]

Contra Indication:

- If the pain is spontaneous and does not persist after the removal of the stimulus then the tooth can undergo pulpotomy

- If there is the tenderness of percussion that tooth is not suitable for pulpotomy
- A mobile tooth is not suitable for pulpotomy
- If the root is resorbed for more than 1/3rd of the total root length, then it is not suitable for pulpotomy
- Sluggish hemorrhage from canal orifice which is uncontrollable and highly vicious
- When there is evidence of internal resorption and presence of inter radicular bone loss
- A tooth which is closed to their natural exfoliation is preferable for extraction more than pulpotomy
- Immuno-compromised patients are contraindicated for pulpotomy[7-10]

Conclusion

Preservation of primary tooth before the natural exfoliation and until the eruption of a permanent tooth is very important because the primary dentition is essential for the maintenance of the arch length, proper mastication, proper speech, and esthetic in children. Pulp affected by carious lesion and injured in trauma may threat pulp vitality, so appropriate treatment such as indirect pulp capping; direct pulp capping and pulpotomy are considered. A pulpotomy is the most common treatment plan for cariously affected tooth which consists of many method. Pulpotomy has three main procedures as devitalization, preservation, and regeneration. In pulpotomy, the affected pulpal tissue is removed and replaced by suitable biocompatible medicament which helps in the healing of the injured pulp and preservation of the vital pulp. Some of the medicaments used in pulpotomy are formocresol, glutaraldehyde, ferric sulfate, sodium hypochlorite, calcium hydroxide, calcium-enriched mixture cement, and mineral trioxide aggregate. From all the biomaterial medicament mineral trioxide aggregate is most suitable and successful for pulpotomy in a primary tooth. Many more clinical trials are being conducted so we may discover many more suitable agents for pulpotomy shortly.

Evolving Trends in Forensic Odontology

J. Shirisha

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Forensic odontologists have been playing an indispensable role in the sphere of forensics for over a hundred years. The various method used by them in identifying individuals from the human remains have been evolving over the years. Using dental remains is not just feasible but budget-friendly and time-saving as well. This article reviews the current trends in the branch of forensic dentistry while also highlighting the importance of antemortem records in comparison with post-mortem evidences.

Keywords: *Forensic odontology, identification,antemortem, postmortem, trends.*

Introduction

Forensic odontology is a subspecialty of dentistry that deals with the implementation of the art and science of dentistry within the criminal justice system. It mainly focuses on identifying deceased victims and unknown perpetrators. Forensic odontologists collect dental evidences from the crime scene, examine them and present them in the court of law.[1]

Teeth are the hardest and the most resistant tissues in the human body. Teeth are capable of standing firm against various natural disasters, major accidents, burials, crimes,or other severe exposures like broiling temperatures, humidness, and pressure changes. They do not decay easily and the teeth pattern is unique to each individual which is why they are very useful in identifying a person. The techniques used in forensic odontology has evolved through the evolution of humankind. This article aims to provide an overview of the most recent trends.[2]

Corresponding Author:
J. Shirisha

e-mail- janpareddyshirisha97@gmail.com

Evolving Trends in Conventional Method Used in Forensic Odontology:

DNA finger typing: DNA analysis is one of the most recent trends in forensic dentistry. Teeth being strong and resistant to trauma provides an excellent source for DNA finger-typing. The genome can be extracted from the pulpal tissue and crossmatched to identify the victim. Even an amount of DNA as negligible as 1 nanogram can be amplified to easily differentiate an individual with the help of the PCR (Polymerase chain reaction) technique. The amplified DNA is then compared to the post-mortem samples like blood, combs, clothes, bedsheets, etc. This method has gained popularity in forensics.[3]

Types of DNA:

a) Genomic-DNA – Found within the nucleus

b) Mitochondrial-DNA - Used when the retrieved DNA-sample is insufficient or degraded

Stages in DNA extraction:

a) Cell membrane is ruptured

b) Proteins are denatured using chelating agents and inactivated using proteinases

c) DNA is extracted using organic phenol, Chelex or isopropyl alcohol

"Advanced techniques in DNA typing:

- Restriction Fragment Length Polymorphism Typing

- Short Tandem Repeat (STR) Analysis
- Y-Chromosome Analysis
- X-Chromosome STR
- Single Nucleotide Polymorphism Analysis
- DNA methylation analysis"

Bite mark analysis: Bite marks are often found on the skin of victims in brutal events like sexual assaults, child molestation and abuse and other such crimes. Sometimes the victims while defending themselves, bite the perpetrator which leaves a mark on the attacker. The marks on males are found on the hands, forelimbs and shoulders whereas on women they're usually found on the bust and rear end. Unique characteristics like missing, broken, rotated teeth or supernumerary teeth along with the arch width can be determined. This helps in age determination as well. They have been categorized by Mac Donalds as "tooth pressure marks", "tongue pressure marks" and "tooth scrape marks".[4]

Method

Most of the bites are hardly discernible by the naked eyes and hence UV-illumination method is used to detect the bites.

1. The marks are analyzed by comparing a suspect's bite marks to those found at the crime scene with the help of transparent overlays. These overlays are usually hand traced using study-casts, wax-impressions, xenographs or other techniques like image-perception.
2. DNA can be retrieved from the saliva from the marks. This is one of the trends. salivary DNA recovery and bacterial genotyping from the bite marks are the most recent ones and have become the backbone of forensic investigation.
3. Another recent method is genotyping from bacteria from the marks.

The analysis of bite marks is not very accurate since the skin has many contortions and indentations. Therefore, they're usually used conjointly with other method of investigations to achieve a more accurate inference.[5-7]

Dental Record Maintenance: The dental records are legalized documents which contain the data of the patients. The dentist must maintain these records which are very useful in identifying the deceased victim or the criminals in medicolegal cases and forensics. The records also help in following up on the patients. They have been of great use in many disasters such as the 11th September WTC attacks and the tsunami of the Indian Ocean. The antemortem records are compared with the post mortem affirmations or other pieces of evidence found at the crime scene. These records have an account of all the complaints, medical histories, clinical examinations, diagnoses, dental-treatments, prognoses of the patients. These are usually penned down in forms and stored in huge shelves inside a storeroom. However, with the advent of technology, storing data in computers makes it easier for transferring and networking documents without much hassle. In America and other states of Europe, maintaining teeth records is mandated by law. The case is not the same in a third world country like India where people including many dentists are not aware of this practice and its uses. [8,9]

Dental imaging: The first application of radiology in forensics dates back to the year 1898, which is 3 years after the first radiograph was devised by C. Roentgen. Since then they have been playing a vital role in post mortem examinations. The post mortem radiographs are superimposed on the ante mortem images and then the comparison is made. Facial snapshots and videos show features of individuals in detail and hence are very useful in identification purposes. Orthodontists can help in determining the various oral tissues that form the smile of a person with the help of radiographs and photographs.

*Identification of victims***:** Antemortem computed tomography pictures layout many details which help in reproducing a duplicate photograph of the deceased person, taking into consideration that points of craniometry can be accurately located and calculations can be made. Every person has a unique design of their frontal-sinus which can also be put in service in identifying the victims.[10]

*Age estimation of adults from dental radiograph***:** With an increase in age, the proportions of the pulpal tooth cavity reduces as the consequence of secondary dentinal deposition. This takes place along with a reduction in the pulpal size. Hence, the pulp-tooth ratio can be determined to estimate the age of a person. The 3rd finger's middle-phalanx radiographs also indicate the skeletal maturity of a child.

To determine the cause of death: Radiographs may provide evidence of bullets or foreign bodies in the soft tissues following firearm incidence and explosion. After air crash accidents, the cause of the crash may be elucidated by the presence of radio-opaque objects in the soft tissues.[11-13]

Dental profiling: Profiles of individuals before their deaths can be designed with the help of radiographs. The post mortem anterior teeth play a major role in profile designing as they can be remodeled to estimate their alignment and angulations. The triad of factors taken into account are age, gender and ethnicity.[11-13]

Radiographs must be curated before the head and neck necropsy. Ideally, they should be taken at the crime scene. Proper labeling with IDs, location and date is mandatory and helps in the future.[11-13]

Rugoscopy: Rugoscopy is the study of palatal rugae. It is an emerging tool used for personnel identification in forensics. They have three to seven folds of irregular connective tissue known as 'plica palatine' located on the anterior third of the palate. These are unique to each individual. They are quite reliable as they are safeguarded by tongue and buccal fat and remain unruffled by any trauma. This method is preferred when teeth are absent.Several impression materials such as alginate, impression compounds, etc are used to record the pattern. Then the casts are poured and the rugae are compared to those of the suspects.

Other method used to examine the rugae markings comprise of:

- Photographs
- Clcorrugoscopy (overlay print)
- Stereoscopy (creates a 3D image of the rugae)
- Stereophotogrammetry"
- Computer-software like RUGFP-ID

Studies have shown that there is no sexual dimorphism in the rugae patterns which is why they cannot be used to determine gender. Although the patterns are unique to each individual, some errors may be found as they can change with age, orthodontic treatments, and other surgeries.

Cheiloscopy: Cheiloscopy (*Cheilos* meaning lips and *scope* meaning examination) is a forensic investigation technique dealing with the identification of humans based on their lip prints. Just like fingerprints, the grooves present on one's lips (sulci labiorum) are unique to each individual. Lip prints should be obtained within 24 hours of death from the deceased person's lips or from objects like cups, glasses, phones, clothing, etc. at the crime scene. The prints are clear-cut in closed mouth and when the mouth is open the prints are ill-defined and hard to decipher. The prints can be inaccurate if the lips wear a thick layer of lipstick or balm or in pathological conditions like mucoceles, traumatic ulcerations, loss of support in absence of anterior teeth.

Suzuki and Tsuchihashi's Classification of lip prints (1970):

- Type I: "Prominent grooves running vertically across the lip
- Type I': Straight grooves which disappear half-way
- Type II: Fork grooves
- Type III: Intersecting grooves
- Type IV: Reticulate grooves
- Type V: Undermined"

Cheiloscopy plays a major role in age determination. They have been proven to be superior to fingerprinting in determining gender. According to the Vahanwala-Parekh study,a study conducted by Vahanwala-Parekh,

- Type I and Ia patterns were primarily found in females in the third and fourth quadrants
- Type II pattern was dominant in males in the second quadrant Individuals with different patterns in all quadrants were common in males, whereas having the same pattern in all quadrants were seen in females.

Lip prints can be procured by cellophane/scotch tapes which are sensitive to pressure. Of late, biometrics scanning of lips has gained traction.[14]

Recent concepts in forensic dental identification:

Denture identification method: If the injured/ deceased person has been found to wear dentures, then the identification process becomes effortless, provided that the dentures are marked. Marking the dental prostheses is not practiced in India where people are not cognizant about the merits of marking dentures. [15]

Method

- Superficial marking: involves etching and embossing on the surface of the denture. The backdrop with this is that the markings fade with time and hence not permanent.
- Inclusive marking: This involves metal identification-bands, lead paper-labels, micro-labels, T bars, bar codes, etching by lasers, radiofrequency ID tags, polyethylene lenticular cards, photoelectric microchips.

Every country has its own special identification numbering system for its citizens. In America, the dentures are labeled with the social-security digits whereas in Australia citizens have their tax numbers which are labeled on dentures. In India, this practice is yet to be started and when it does, we can effectively use our unique Aadhar QR bar code to label on the dentures.

Comparison Microscopes: Comparison-microscopes, as the name suggests, help in comparing different specimens simultaneously. The device comprises of 2 microscopes attached by an optical-bridge. This bridge has a split-view window. This device allows easy comparability between a piece of evidence-specimen and the smear of a suspect.

Determination of both sex and age can be easily done using this device. Sex can be determined with the absence or presence of Y-chromosome and age can be found out by examining teeth for annuli of cementum. With age, cementum forms ring-like annuli in teeth just like the trees. This phenomenon called, cementum aging, can be examined under the microscope for estimating the age of an individual. The virtual comparison- microscopes have excellent accuracy and hence are an evolving trend in forensics. They can also identify bullets.

Facial reconstruction: When a person's face gets damaged beyond identification, this field of forensics comes into play in fabricating a facsimile of the person's premortem face. The skull does not decompose easily and hence it plays a crucial role along with the soft tissues over the bone. The method can be both 2D and 3D.[12-16]

Method

- Manual**:** Impressions of the skull are taken, casts poured, face is manually sculpted with modelingclay. The facial-features are chiseled on the model and hair is added.
- Computer-assisted**:** Virtually sculpting a face on computerised software using various imaging techniques that give an idea about the soft-tissue depth. The various imaging method are cephalometry, CT, CBCT, MRI, lasers, digital stereophotogrammetry and fusion imaging.

Face being the most distinct feature of humans is of utmost importance when it comes to identification techniques. Although reconstruction may not produce the exact copy of faces but it has proven to be a splendid.[12-16]

Tongue Prints: Tongue prints just like finger and lip prints are unique to each individual. Not just prints, the differences in the texture, size, colour and shape can be visually inspected. This method of personnel identification is burgeoning now in forensics. It has been recently added to the family of biometrics.

These prints can be recorded with impression-materials like alginate, casts are poured and the model of the tongue is prepared for studying the details and comparisons are made. For this technique to be successful, the antemortem images of the tongue should be available in the form of digital databases. It was found in a study that males had septate tongues whereas females had sharper tips. Hence, approximate gender estimation is also possible using this method. The presence of pathologies on the tongue may cause errors.[12-16]

Conclusion

Forensic odontology is a budding field of dentistry which has evolved manifolds over the years and has a great scope for further development. The anatomy of the tooth is unique to each individual and its resistant nature even in harsh conditions has made it an excellent and reliable source for personnel identification. However, the various method devised for the same will have little or no use if there is an absence of premortem records of the person as without them the post mortem records cannot be compared and identified. In many western countries, dental record keeping has been mandated by the law. Therefore, in our country too, the government should encourage this practice and the researches related to it while paving the way for the implementation of several new technologies in the field of forensic dentistry.

Complication & Management of Local Anesthesia: A Systemic Review

Alisha Pradhan

Intern, Institute of Dental Sciences, Siksha O Anusandhan University (Deemed to be University) Bhubaneswar-751003, Odisha, India

Abstract

Local anesthetics are widely used in the dentistry world for various procedures. The local anesthesia is very much effective and also safe but they have also risks which practitioners should be aware off and this article reviews the different complication regarding the use of local anesthesia. Different complications occur which include systematic and regional complications that can occur with the use of local anesthesia. The various complications include ocular complications, methemoglobinemia, toxicity, and paraesthesia, etc. Knowing the risk factors involved with local anesthesia relatively decreases the adverse outcome and helps the patient by improving health care.

Keywords: *Local Anesthesia, Paraesthesia, systemic and regional complication, Toxicity.*

Introduction

In the year 1860s, the first local anesthesia or anesthetic was isolated from the coca leaves by a German personcalled as Albert Niemann. Local anesthesia is widely used for dental procedures throughout the globe and lidocaine is currently the widely used local dental anesthetic solution in most of the countries of the world. One can define local anesthesia as the temporary loss of sensation or pain in a single particular part of the human body that has been produced by an injected or topically applied agent without suppressing the level of consciousness.[1, 2] The dental anesthetics include two classifications, which are described as esters that include procaine and benzocaine, and amides which consist of lidocaine, prilocaine, mepivacaine and articaine. Commercially available local anesthetic agents have a pH of 3.5- 5.5 and also have a shelf life of 3 to 4 years. This type of pH is very low to the drug pKa which all the vitally all the drugs are present in the more stable, water-soluble and charged form. Generally, the composition of local anesthetics includes lignocaine hydrochloride, a reducing agent that is sodium metabisulfite, a preserving agent that is methylparaben, and a diluting agent which includes distilled water.[3]

e-mail- alishapradhan626@gmail.com

Mechanism of action of local anesthesia:

The steps following the mechanism of action includes the:

- The anesthetic which are ionized by binding to the sodium channel
- The entry of the sodium channel is blocked in these different channels
- Blockage of sodium channels prevents the propagation of the action potential
- As the lack of propagation blocks the sensation as the signal is not transferred to the brain.[1-3]

Testing the success of Local Anesthesia:

Testing for a successful Local anesthesia should be done by the:

Subjective testing that includes asking the patient to describe the area that is altered in sensation which is usually positive with the nerve block and mandibular injections and anterior maxillary. Objective testing that includes the use of a probe or pulp testing or percussion. When probe the soft tissue always one should consider the supplementary nerve supply and 1A is positive with the onset time for the 1A is 2-3 minutes and for the NB is 3-4 minutes usually. Pulpal local anesthesia had a longer onset time as compared to the soft tissue anesthesia.[4]

Local Complications

The local complication included during the use of local anesthesia are:

Needle Breakage: It is one of the common complications that occur due to the bending of the needle, sudden movement of the patient, the entire needle is entered into the soft tissue, or using a smaller needle-like 40 gauge. Prevention includes using large gauge needles, especially in the case of the posterior superior alveolar nerve and inferior alveolar nerve and one should not insert the needles into tissues to its hub and take preventive not to redirect a needle once it's injected into the soft tissue. When a needle breaks and it is visible stay calm and instructs the patient not to move and left his/her mouth open. If the fragment is visible remove it from hemostat or Magill intubation forceps. If the fragment is not visible calmly inform the patient, inform an oral surgeon, and take a radiograph and determine its position whether it is superficial or not or leave it and follow up.[4-6]

Ocular Complications: There are different complication regarding ocular that includes Mydriasis that is pupillary dilation, Amaurosis which is temporary blindness, ptosis i.e. drooping of eyelid and diplopia which means double vision. The causes for these complications include inadvertent arterial injection with retrograde blood flow and orbital injection that includes inadvertent injection into orbit through the inferior orbital fissure. Prevention includes aspiration before the actual injection and inject slowly. The treatment includes make the patient reassure that is transient; cover the affected eye with gauze dressing. Refer the patient to an ophthalmologist for the evaluation if it lasts for more than 6 months and make follow up. [4-6]

Paraesthesia: This type of complication arises due to trauma of nerve, insertion of the needle to inside the foramen can also lead to the paraesthesia. Local anesthesia solution which is contaminated by sterilizing solution and the alcohol can produce irritation that results in the edema and increased pressure in the region of nerves which leads to paraesthesia. Also, the hemorrhage leads to an increase in the pressure paraesthesia. One can prevent this complication by proper care and handling of the injection and also the cartridge. In most of the cases having paraesthesia, it resolves within 8 weeks without treatment. A sequence followed for this complication includes-Reassuring the patient party; properly examine the patient and regular follow up for at least 2 months; If the sensory problem persists, consult a neurologist and an oral surgeon.[4-6]

Facial Nerve Paralysis: It occurs due to the when anesthesia is introduced into the deep lobe of the parotid gland. The cause for this local complication includes transient FNP that is due to the local anesthesia into the capsule of the parotid gland that is present in the posterior border of the mandibular ramus. It is usually occurring during the Vazirani alkiosi injection nerve block or alveolar nerve block. Prevention can be done by proper care to the needle while inserting and cartridge. The management includes reassuring the patient, contact lenses should be removed and eye patches should be applied to the affected eye or one can manually close the lower part of the eyelid periodically that will keep the cornea lubricated.[4-6]

Trismus: It can be defined as the pain and difficulty in the opening of the mouth that often occurs after the inferior alveolar nerve block and superior nerve block. The onset period is 1-6 days post-treatment. It is caused by the trauma to blood vessels or muscles area in the infratemporal fossa. It also occurs due to the local anesthesia solution contaminated by alcohol or cold sterilizing solutions that gives or produces the irritation of the muscles. Low-grade infection can often lead to Trismus. The prevention measure includes using the sterile, sharp, and disposable needle. Proper handling and care to the injection and cartridge. Avoiding repeating off the atraumatic injection. Management includes the heat therapy, warm saline rinse, Using of the analgesic like aspirin 325mg, If necessary then muscle relaxation, diazepam 10mg BID. Physiotherapy for 5 min each in every 3-4 hours. If the infection occurs then antibiotic is prescribed for 7 days. Surgical intervention can be done in some cases. The recovery range is between 4-20 days.[4-6]

Soft-Tissue Injury: It is trauma to the lips or the tongue that is produced by the biting or chewing of these tissues while anesthetized, especially occurs in the case of children. In Prevention A cotton roll can be placed between the lips and teeth & warn the patient with a self-adherent warning sticker. It can be managed by analgesic for pain, antibiotics if there is infection, warm saline rinse to decrease the swelling. Petroleum jelly should be used to control the lesion and minimize the irritation.[4-6]

Hematoma: It occurs due to the effusion of the blood into the extravascular spaces and results from inadvertently a blood vessel. It is caused by the nicking to the vein or artery. It mostly occurs with the IANB and PSA nerve. The practitioner should have a proper knowledge of anatomy, using the shorter needle for PSA nerve block. One should minimize the number of needle penetration. The Management includes the direct pressure applied in the site of bleeding. Applying cold moist towels to the affected area for 20 minutes every hour. Make sure to advise the patient regarding the limitation and soreness of mouth opening possibility.[4-6]

Pain on Injection: It mostly occurs due to the carelessness of the practitioners and mostly the palatal injection hurts. Dull of needle due to multiple injections. It can also be due to the rapid deposition of the local anesthetic solution. Prevention is Adhere to the proper technique of the insertion process including both the physiological and anatomical. Sharp needles should be used and topical anesthetic should be applied with injecting the needle slowly.[4-6]

Infection: It is caused due to the contamination of needle but in this modern world, it has become rare due to the introduction of sterile disposable needle and the glass cartridge. The managing includes the antibiotic, penicillin 250 mg QID. [4-6]

Edema: The cause for this local complication includes trauma, infection, allergy hemorrhage, or injection of the irritating solution like alcohol and cold solution. Management includes a minimal degree of edema – by giving analgesic for pain and will disappear in several days. If the edema occurs in severe form then antibiotics should be prescribed.[7-9]

Systemic Complications: The systemic complications include the overdose factor and the Allergy factor.

Overdose: The overdose reaction occurs when the drug access to the circulatory system. There is a constant absorption of drugs from the sites of the admission into the circulatory system and a steady removal by the liver of the blood. [7-9]

There are various predisposing factors which includes generally 2 factors:

- Patient Factors- This includes age, weight, medications that is an important one, gender, genetics, etc.
- Drug Factors- it includes concentration, dose, rate of injection, presence of the vasoconstrictors, and route of administration.

The preventive measures include using an aspiration syringe, using the needle which should not be smaller than 25 gauge. The aspiration should be done at least two planes before insertion. The anesthesia should be given very slowly and calmly.

Clinical Manifestation: The surgeon should notice the slurred speech, apprehension, talkativeness, excitability, and stutter. It also includes the sweating, vomiting, failure in following commands. Blood pressure is elevated with heart rate and respiratory rate. One can also notice the CNS depression and myocardial depression.[7-9]

Management: The basic emergency management includes–Position; Circulation; Breathing; Airway; Definitive Care. The sequence can be followed as P-C-A-B-D. The management in the case of mild overdose includes reassure the patient and administrate oxygen via the nasal canal and then monitor the record the vital signs. The anticonvulsants via IV should be administrated i.e. diazepam 5mg/min and the emergency medical assistance should be done before the discharge of the patient. In the case of severe overdose when the patient is unconscious then the following steps to be followed– Protect the patient, immediately call the emergency medical assistance, and most important continuing the Basic life support (BLS). Administration of anticonvulsants that is diazepam 5mg/min, if the seizure protract more than 5 minutes.[7-9]

Allergy: It is a type of systemic complication. It occurs due to the hypersensitive state that is acquired through the exposure of a particular allergen. The allergic reactions cover a broad spectrum of OD

clinically manifestations that range from the mild to the delayed response in the occurring as long as 48 hours after the exposure of the allergen to a mark of immediate and dangerous reaction that develops within seconds of the exposure. The predisposing factors include sodium bisulfate, Epinephrine, Latex, and topical anesthesia. The clinical manifestation includes: Generalized Anaphylaxis; Different Dermatological reactions; Respiratory Reactions.[16]

The clinical manifestation for the dermatological reaction includes urticaria and angioedema and the clinical manifestation of respiratory reactions includes bronchospasm that includes dyspnea, wheezing, cyanosis, Tachycardia which is life-threatening, anxiety, respiratory distress, and the laryngeal edema includes extension of edema and life dangering emergency. The clinical manifestations of generalized anaphylaxis include different skin reactions, smooth muscle spasm of gastrointestinal and the genitourinary tracts with bronchospasm and respiratory distress and sometimes cardiovascular collapse can persist or occurs. [10]

The management process in the skin reaction includes giving oral histamine blocker 50mg diphenhydramine with observation for at least 1 hour and medical consultation should be done. The management of respiratory reaction includes the administration of the oxygen at flow 5-5 liters per minute. If needed epinephrine 0.3 via IM with repeated 10-20 minutes. IM histamine blocker 50mg diphenhydramine should be given. Medical consultation should be taken and an oral histamine blocker should be prescribed for 3 days. The management of generalized anaphylaxis includes the medical assistance in the very first form with the epinephrine dose of the 0.3 IM for 10-20 minutes repeated. Administer of oxygen should be given with an Intramuscular histamine blocker or one can give the corticosteroid IM or IV. Monitoring of the vital signs should be recorded every 5 minutes in case of the unconscious patient.[10]

Conclusion

Today in the world of medicines and advancement new uses of the drugs and local anesthetic agents are been used and with the advancement in medical science, the complication of the drugs are increasing. The various ways should always be understood by the surgeon and the professionals to avoid the life-threatening risks for a patient. One should have skillful knowledge and a good mind set up to acquire or know the various hazards or complications from using local anesthesia. However in countries like India where numerous quacks are frequently practicing, which is challenging for our society as it produces a maximum risk of life treatment for the patient. The people should be aware and the mass awareness should be created to tackle this problem and a patient should always check the original practitioner's license followed by its different treatment. However, it's very challenging in our country due to the expensive dental procedures. A professional should always keep in mind that what are the risk factors and its consequence followed by simplicity and transparency in the treatment. A careful and proper treatment will lead to happiness and put forward a bright smile on the patient's face that will enhance the quality and prospective life in the society.

Oral Hygiene Practice and Oral Health Status among Tribal Children of Odisha, India

Biswabandita Mohanty[1], Susant Mohanty[2], Antarmayee Panigrahi[3]

[1]BDS, Post-Graduate Trainee, Department of Paediatric & Preventive Dentistry, Institute of Dental Sciences, [2]MDS, Professor and Head, [3]MDS, Reader, Department of Paediatric and Preventive Dentistry, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Objectives: The study aimed to assess the oral hygiene levels among tribal children belonging to a specific tribe in the state of Odisha, India and to correlate their teeth cleaning aids used for maintaining oral hygiene and the levels of oral hygiene.

Method: Oral hygiene status of a total of 1000 children between 8-13 years of age (boys 467, girls 533) were included in the study. A simplified oral hygiene index (OHI) developed by Greene and Vermillion consisting of two major components Debris index-simplified and calculus index-simplified was used for examining the OHI-S. Oral Hygiene Index- Simplified; the scores are as follows: Good: 0.0-1.2; Fair: 1.3-3.0; Poor: 3.1-6.0.

Results: The simplified debris index is good for 42.2% of children using toothpaste and toothbrush, 12% of children using indigenous powder with fingers, 3.4% of children using a twig and none of the children using gudakhu. The simplified calculus index is good for 66.1% of children using toothpaste and toothbrush, 12% of children using indigenous powder with fingers, 5.8% of children using a twig. The simplified oral hygiene index is good for 68.5% of children using toothpaste and toothbrush, 12% of children using indigenous powder with fingers, 4.5% of children using a twig and 38.9% of the children have good oral hygiene index who are using gudakhu.

Conclusions: Data showed that the oral hygiene index scores are mostly poor in the children using the indigenous method of oral hygiene practice. This data could be used as baseline information for health authorities and dental professionals for planning strategies for oral health programs in this tribal population as using addiction-prone tobacco pastes can lead to irreparable damage later in life.

Keywords: *Tribes, Oral hygiene Index Simplified, Tooth cleaning aids.*

Introduction

According to several studies diseases of periodontium had been prevailing since ages. There is a lot of effort made to combat those diseases but it is still prevailing among backward classes due to variations from normal oral hygiene routines and procedures.[1] Even in this contemporary world, some people are away from the civilization buried in their dark ignorant logic and tied to the misbeliefs and superstations following old and obsolete modes and modalities of lifestyle and health care practices. Among them are the "Tribes" of our country.[2] There are around 75 types of major tribal communities hailing in our country and they are again divided into many subgroups and clans. They have been mostly found in 15 states and union territories and are segregated into various clans depending upon their cultural practices.[3] From among those the state of Odisha nurtures about 36 different types of tribal populations

Corresponding Author:
Susant Mohanty
MDS, Professor and Head, Department of Paediatric and Preventive Dentistry, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: dr.susantmohanty@gmail.com

including Kondha, Kolha, Munda, Bhumiya, Bonda, Mohali, Loharas, Sauras, Shantal, Gond, Gadava.[4] The vast repository of tribal population is found in the Mayurbhanj district of Odisha. Those population groups are characterized by lower-income and high treatment needs. Therefore, there is a need to access oral hygiene practice and oral health status among those tribes. The objective of this study was to assess the oral hygiene levels among tribal children and to correlate the teeth cleaning aids used for maintaining oral hygiene and the levels of oral health.

Methodology

A total of 1000 children between 8-13 years of age (boys 467, girls 533) were included in the study. The oral hygiene status of the children was examined using a simplified oral hygiene index (Oral Hygiene Index-Simplified).[4] OHI-S was developed in 1964 by Greene and Vermillion and has two components Debris index-simplified and calculus index-simplified. Oral Hygiene Index- Simplified; the scores are as follows: Good: 0.0-1.2; Fair: 1.3-3.0; Poor: 3.1-6.0.

Results

A total of 1000 school going tribal children were examined by a single examiner, among these children, 578 (57.8%) brushing their teeth with toothbrush and paste, 379 children (37.9%) with twigs, 25 Indigenous powders with finger (2.5%), 18 Gudakhu with fingers (1.8%) (Table 1).Association of oral hygiene levels among children using different teeth cleaning aids. The simplified debris index is good for 42.2% of children using toothpaste and toothbrush. It is good for 12% of children using indigenous powder with fingers, good for 3.4% of children using a twig and none of the children have good debris index who are using gudakhu. Thus better debris index is significantly associated with children using toothbrush and toothpaste (p=0.000) than the children using other method of teeth cleaning. Overall 260 (26%) children have good, 734 (73.4%) have fair and 6 (0.6%) have poor debris index. This is an area of concern.

The simplified calculus index is good for 66.1% of children using toothpaste and toothbrush. It is good for 12% of children using indigenous powder with fingers, good for 5.8% of children using a twig and 38.9% of the children have good calculus index who are using gudakhu. Thus better calculus index is significantly associated with children using toothbrush and toothpaste (p=0.000) than the children using other method of teeth cleaning. Overall 414 (41.4%) children have good, 192 (19.2%) have fair and 394 (39.4%) have poor calculus index. This is an area of concern and require intervention.

The simplified oral hygiene index is good for 68.5% of children using toothpaste and toothbrush. It is good for 12% of children using indigenous powder with fingers, good for 4.5% of children using a twig and 38.9% of the children have good oral hygiene index who are using gudakhu. Thus better calculus index is significantly associated with children using toothbrush and toothpaste followed by gudakhu (p=0.000) than the children using other method of teeth cleaning. Overall 423 (42.3%) children have good, 233 (23.3%) have fair and 344 (34.4%) have poor oral hygiene index. (Table 2), which is an area of concern and require intervention.

Table 1: Distribution of primary teeth cleaning aid

Primary teeth cleaning aid	No.	%
Toothbrush and toothpaste	578	57.8
Indigenous powders with finger	25	2.5
Twig	379	37.9
Gudakhu with fingers	18	1.8
Total	**1000**	**100**

Table 2: Association of primary teeth cleaning aid with oral hygiene level

Oral hygiene index parameters	Primary teeth cleaning aid	Good		Fair		Poor		Total		Fisher's Exact 'p' value
		No.	%	No.	%	No.	%	No.	%	
Debris index simplified	Tooth brush and tooth paste	244	42.2	334	57.8	0	0	578	100	0.000
	Indigenous powders with finger	3	12	22	88	0	0	25	100	
	Twig	13	3.4	360	95	6	1.6	379	100	
	Gudakhu with fingers	0	0	18	100	0	0	18	100	
	Total	260	26	734	73.4	6	0.6	1000	100	

Oral hygiene index parameters	Primary teeth cleaning aid	Good		Fair		Poor		Total		Fisher's Exact 'p' value
		No.	%	No.	%	No.	%	No.	%	
Calculus index simplified	Tooth brush and tooth paste	382	66.1	170	29.4	26	4.5	578	100	0.000

	Total	423	42.3	233	23.3	344	34.4	1000	100	

Discussion

The oral hygiene index is found to be mostly good among the children using toothbrush and toothpaste, they have a fair debris index and a good calculus index whereas the children using twigs and various indigenous powders like charcoal, sand, clay, etc. have a poor oral hygiene index. The children using gudakhu have a fair oral hygiene index. This result is similar to the result found by P. Krishnam Raju et al, 12% of children using twigs have poor oral hygiene index score whereas only 3% of children using toothpaste and toothbrush have poor oral hygiene[5] according to a study by Rao and Bharambe the children using twigs and Manjans for cleaning teeth have higher calculus index along with gingival bleeding and periodontal abscess.[6] These results are governed by many factors such as socioeconomic status, awareness, attitude of the child, and the caregivers towards the oral hygiene. The children who belonged to a lower socio-economic background can't even afford for twigs those children mostly used charcoal, ash, etc. the oral hygiene condition of those children is very poor, they use charcoal with fingers so, they ought to have a poor oral hygiene. The children who use toothbrushes and toothpaste even if they don't know proper brushing techniques still due to swiping motion of toothbrush there is removal of debris and plaque which indeed prevents the calculus formation leading to good oral hygiene scores. In contradiction, certain other studies by Naheeda et al and Tanwar A. et al found the indigenous method to be more effective in oral hygiene maintenance than a toothbrush and toothpaste.[7] The reason of variation could be the use of different indices and use of twigs of different plants, as in the studies by Naheeda et al and Tanwar A. et al the participants mostly used meswak or neem twigs but in our study, the children mostly used twigs from Sal tree (*Shorea robusta*). Neem and Meshwak have antimicrobial properties as proved by certain studies such as a study by Al-Otaibi M et al where they found that *A. actinomycetemcomitans* were significantly more reduced by meswak ($p<0.05$) than by tooth brushing.[8] These results were supported by us in vitro results which, indicated that extracts from *Salvadora persica* might interfere with the growth and leukotoxicity of *A. actinomycetemcomitans*. Sal bark does not have any such antimicrobial properties.

Conclusion

The oral hygiene index scores are mostly poor in the children using the indigenous method of oral hygiene practice with the calculus index being significantly high, in children using toothpaste and toothbrush mostly had a fair to good oral hygiene score with low calculus index. From the above-mentioned result, it is quite clear that the entire tribal population not only children but also their caregivers need awareness programs, screening, and treatment camps to increase basic oral health knowledge. Anti-tobacco campaigns have also become a need of an hour among those populations. Hence, the oral hygiene behavior in children require emergency attention as coarse granular materials, addiction-prone tobacco pastes can lead to irreparable damage later in life.

Dental Implants in Pediatric Dentistry: A Review Article

Sristi Das

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Loss of teeth in children is commonly caused due to traumatic exposure or anodontia. It can lead to loss of masticatory function, altered speech, lack of self confidence and mal-alignment of teeth overtime. This hampers the esthetic and psychosocial development of children. Management of missing teeth can be done using removable prosthesis or fixed prosthesis and implants. The removable prosthesis can lead to residual ridge resorption and several periodontal problems and can cause oral hygiene maintenance issues in a child for which dental implants are considered to be an ideal mode of treatment for tooth loss. Placing an implant in a growing child can cause undue effects on maxillary and mandibular skeletal growth for which the dentist must plan a treatment taking into account the total number of missing teeth, degree of skeletal growth and related psychological stress to the child.

Keywords: *Dental Implant, Anodontia, Maxillary and mandibular skeletal growth, Child.*

Introduction

The absence of one or a few teeth manifested due to genetic condition, trauma, or any disease is known as hypodontia or oligodontia. Total anodontia is the congenital absence of all teeth in permanent or primary dentition.[1]The most commonly missing teeth are third molars and they don't require replacement. Mandibular second premolars are the second most commonly missing teeth followed by maxillary lateral incisors and maxillary second premolars.[1]The commonest cause for loss of tooth is trauma, especially the loss of anterior teeth. Its predisposing factors are incompetent lips and proclination of maxillary anterior."Avulsion Is defined as the complete and total displacement of a tooth from its socket" [1]. The most commonly avulsed teeth are maxillary central incisors.

The management of multiple tooth loss can be done by partial coverage fixed prosthesis such as resin-bonded restorations or removable prosthesis. The management of loss of a single tooth or avulsion is done as conservatively as possible in a young child. It is done by deploying treatment like replantation, attempting revascularization, apexification, and root canal treatment. The above-mentioned treatment for loss of multiple teeth has certain drawbacks. In both cases, removable and fixed dentures, the child's compliance is necessary. Maintenance of oral hygiene becomes an issue. It predisposes to several periodontal problems followed by bone resorption ultimately. Apart from that, new prosthesis needs to be fabricated from time to time, to make up for craniofacial growth.

Implants can be considered as an ideal method of treatment for tooth loss in young children, as it restores the function of missing teeth by preserving the alveolar bone and also provides excellent esthetics. However, it requires a proper understanding of growth and growth assessment by the dentist to establish a successful implant in a young patient.[2]

Growth: The maxillary and mandibular growth is multidirectional and occurs in sagittal, vertical, and transverse planes. It occurs in varying paces, periods of slow pace growth followed by accelerated growth called the growth spurts. The teeth maintain their position in the arches by following this pace of growth through

Corresponding Author:

e-mail: 1161996.situ@gmail.com

remodeling and drifting within the alveolar bone. Functional forces are balanced by a stable inter-arch occlusal relationship achieved gradually as transition from primary to permanent dentition.[3]

Maxillary Growth: The maxillary growth occurs by displacement, growth at sutures, and surface remodeling"[2]. The displacement is of two types- primary and secondary. The primary displacement occurs by the growth of maxillary tuberosity in a posterior direction that results in the whole maxilla being carried anteriorly.[2] The secondary displacement occurs due to the growth of the cranial base that leads to displacement of the nasomaxillary complex in a downward and forward direction. The transverse growth of the maxilla is facilitated by growth at median sutures. This leads to forward and downward relocation of maxilla. Sagittal growth occurs by surface remodeling of the anterior surface of the maxilla. It brings the maxilla even more downwards and forwards.[3]

The vertical growth of the maxilla occurs by bone resorption on the lateral wall of the nose and floor of the nasal cavity followed by bone deposition on the palatal side. Also, when the teeth start erupting, there is bone deposition at the alveolar margins that increases maxillary height.[2-5]

Vertical growth is the last to complete, at around the age of 17 to 18 years in girls and even later in boys. Hence the maxillary implants tend to perforate the nasal floor even after puberty when the permanent teeth have erupted already. Mikel Westwood and Duncan James, in their study, concluded that the implants placed in the maxillary anterior region are at less risk of submersion, due to the angulation changes it undergoes. It is because of the less maxillary vertical growth and also less bone loss when the implant is placed within less time of tooth removal.[6]

Mandibular Growth:

Of the facial bones, the mandible undergoes the largest amount of growth postnatally and also exhibits the largest variability in morphology"[2]. Mandible that appears as a single bone in adults can be divided developmentally and functionally into various skeletal subunits that are namely-

Body of mandible, Alveolar process, Coronoid process, Condylar process, Angular process, Ramus, Lingual tuberosity, and the Chin[2].

- There is drifting of the ramus in the posterior direction by sequential bone resorption on the anterior part of the ramus and bone deposition on the posterior part of the ramus.
- "The displacement of the ramus results in the conversion of former ramal bone into the posterior part of the body of the mandible"[2]. By this process, there's lengthening of the body of the ramus.
- There is a flaring of the angle of the mandible as the person grows older. This occurs by sequential bone resorption on the posterior inferior aspect of the lingual side and bone deposition on the anterosuperior aspect of the lingual side of the angle of the mandible. Contrary to this, on the buccal aspect of the angle of the mandible, bone resorption occurs in the anterosuperior part and bone deposition occurs in the posteroinferior part.
- There is a posterior movement of lingual tuberosity by deposition on its posterior facing surface. It lies towards the midline of the ramus protruding in a lingual direction. "There's a large resorption field just below the lingual tuberosity. Resorption occurs producing a large depression called lingual fossa. Resorption in the fossa and deposition on the medial surface of tuberosity combined makes the lingual tuberosity more prominent.[2]
- "Alveolar process develops in response to the presence of tooth buds. As the teeth erupt, the alveolar process develops and increases in height by bone deposition at the margins"[2]. This leads to overall growth in the vertical height of the mandible.
- The growth of the chin is influenced by sexual and specific genetic factors. A fully developed chin is only seen in a man. Usually, males have a more prominent chin as compared to the females.
- The head of the condyle is covered by the Condylar cartilage to help withstand the compressive forces that occur at the joint. The mandibular growth occurs by bone deposition at the Condylar cartilage. "Also there is growth of soft tissues (muscles and connective tissues) that carry the mandible forwards, away from the cranial base. Following this, bone growth occurs at the Condyle to maintain contact with the cranial base. The Condylar growth rate increases at puberty reaching a peak between 12½ to 14 years. The growth ceases around 20 years of age[2].

- The Coronoid process grows by bone deposition on the lingual surfaces of the Coronoid processes. Also, the vertical dimension of the Coronoid process increases by the enlarging 'V' principle.

In the mandible, the amount of anterior implant exposure or submergence of a posterior implant depends on the direction and amount of rotation during growth[9]. The implants in the mandibular anterior tooth region are at a risk of getting exposed due to the infra dental resorption, at the time of formation of the chin in adolescents. The implants in the mandibular posterior tooth region are at a risk of submerging due to the appositional growth of the alveolar bone.Cronin et. al. studied mandibular growth related to the implants in children with a strong rotational growth pattern. With erupting posterior teeth, alveolar growth continued to maintain the occlusal plane. This resulted in the implant being deeply buried within the mandibular alveolar process. They suggested that successful mandibular implants are favored by a lack of complicated structure. [5-10]

Treatment approach for quadrant-wise implant placement:

Maxillary Anterior Region: It is an important area of consideration due to higher chances of traumatic tooth loss and frequent congenital tooth absence. Substantial growth is seen in vertical and anteroposterior dimensions. The vertical growth is maximum in this quadrant, as compared to all other quadrants. Hence, premature placement of implants can lead to growth cessation and requirement for lengthening transmucosal implant connection. Hence, the placement of implants should be delayed upto the age of 15 years in girls and 17 years in boys.

Maxillary Posterior Region: Maxillary posterior quadrant has similar growth factors as described for the maxillary anterior-posterior area. An additional growth factor transfers maxillary growth at midpalatal suture, which produces rotational growth that anteriorizes the position of maxillary molars. Placement of osseointegrated dental implants in the maxillary posterior quadrant is best delayed until the age of 15 years and 17 years of age in females and malesrespectively[4].

Mandibular Anterior Region: It is the best site for the placement of an osseointegrated implant before skeletal maturation. The mandibular anterior quadrant presents fewer growth variables. The closure of mandibular symphyseal suture occurs during the first two years of life. Prosthesis supported by dental implants in the anterior mandibular region should be of a retrievable designed to allow for an average increase of dental height of 5-6 mm as well as the anteroposterior growth.[4]

Mandibular Posterior Region: The dynamic growth and development of the posterior mandible in the transverse and anteroposterior dimensions coupled with its rotational growth presents multiple treatment concerns. Placement of osseointegrated implants in the posterior mandibular quadrant is best delayed until skeletal maturation.[4]

Discussion and Conclusion

Using implants in growing children has its advantages but only when it's placed at the right age, take into consideration the growth assessment of the patient. Various studies have suggested that use of implants, due to developmental changes of jaws and teeth in children, should be performed with high precision and systemic evaluation, and, if possible, be postponed up to the age of 15 years for girls and 18 years for boys and be within a long-term process. The dentist needs to take into account various factors that might lead to implant failure. Precise diagnosis, treatment planning, and extensive knowledge in the field of implants and pediatric dentistry are crucial for the dentist for the establishment of a successful implant. The evaluation of some factors, including causes of anodontia, patient's sex, range of skeletal growth, prosthesis design, the range and quality of residual bone ridge, keeping hygiene and satisfying parents' and patients' demands should be taken into consideration for the final decision making on implant positioning. In the end, the dentist decides to restore the function of the lost tooth and guard the patient's self-esteem, keeping in mind the patient's comfort and ease of maintenance of the prosthesis.

Abstract

Dental clinics can play a crucial role in spreading the SARS-CoV-2 infections because of the nature of close contact with the patient's oral cavity and aerosol generating essential dental procedures. Dental practices in regions affected with SARS-CoV-2 are needed to take utmost precautions and follow strict effective infection control protocols even when the movement control/lockdown is gradually lifted post pandemic. Thus, we aim to summarise the current research findings on SARS-CoV-2 in dental settings and relevant international guidelines and recommended management protocols for the dental clinica. The knowledge on the viral properties of SARS-CoV-2 and epidemiologic characteristics are essential to implement proper mitigation strategies against transmission of Covid-19 infections via dental clinics.

Keywords: *SARS-CoV-2, Covid-19, dental clinic, dentistry.*

Introduction

The ongoing pandemic caused by severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) has caused more than 2,60,00,00 cases and claimed over 180000 deaths worldwide as of April 23, 2020.(1) On Feb 11, WHO named this disease as "Corona Virus Disease (COVID-19)" and later the International Committee on Taxonomy of Viruses (ICTV) named this virus as "SARS-CoV-2" based on the phylogenetic and taxonomic analysis(2). The characteristic symptoms of the Covid-19 illness are fever, myalgia and cough with headache, diarrhoea and haemoptysis as less frequent symptoms.(2,3)

Previous outbreaks of coronavirus infections included severe acute respiratory syndrome (SARS) and the Middle East respiratory syndrome (MERS), emerged as a significant public health threat and were controlled effectively, though SARS-CoV-2 behaviour does not match its predecessors. After the initial pandemic wave, the behaviour of the SARS-CoV-2 and possibility of another seasonal epidemic wave are not yet elucidated.(3,4)

Properties of SARS-CoV-2: Coronaviruses belong to the family of RNA viruses *Coronaviridae* and order

e-mail: divyagopinath@imu.edu.my

Nidovirales.[5] Among four genera of coronaviruses, α-CoV and β-CoV mainly infect the humans and mammals.[6] Many subtypes have been known to cause respiratory diseases in humans.[7,8] Unfortunately, the fatal diseases were reported only by the SARS-CoV and the Middle-East respiratory syndrome coronavirus (MERS-CoV), which belong to β-CoV.[9] The envelope of coronaviruses is coated by surface glycoprotein that leads to their characteristic crown-like (Latin: corona) appearance of the particle. Coronaviruses share a typical genome in which the replicase gene covers the 5′-two thirds of the genome.[10] Spike proteins in their envelope help to bind receptors on host cells and helps in entering into the cells.[10,11]

Oral Cavity as Target of SARS-CoV-2: Angiotensin-converting enzyme 2 (ACE2),expressed in human airway epithelialcells, oral mucosa, especially tongue epithelium and epithelial cells of minor salivary glands are the most important receptor for SARS-CoV-2highlightingthe possibility of salivary glands being a potential reservoir of SARS-CoV-2.[12, 13]Therefore the probability of oral mucosa and salivaacting as a reservoir of viral particles in asymptomatic Covid-19 patients cannot be ignored.Moreover,peak infectivity was noticed before the patient is symptomatic.[4]Positive rate of SARS-CoV-2RNA detection in hospitalized patients' saliva was as high as 91.7%.[14]

SARS-CoV-2 Transmission in Dental Clinics: Common routes of SARS-CoV-2 are through direct transmission (sneeze cough and droplets) and contact transmission (oral, nasal, and ocular mucous membrane).[15]Besides, experts have suggested that it can be transmitted directly or indirectly through saliva owing to the consistent detection of SARS-CoV-2 in saliva.(14)The incubation period of SARS-CoV-2 is reported to be 5 -6 days on average; nevertheless, it can be as long as 14 days which is currently considered as observation/quarantine period for exposed/potentially exposed individuals.[16] Dental practitioners encounter close contact with patient's oral cavity for extended hours during various aerosol/splatter generating procedures (AGP) or non AGP. Splatters (larger than 50μm) and aerosols (less than 50 μm) are particle droplets of saliva, blood and microorganisms generated while using rotary dental and surgical instruments and air-water syringes.[13,17] Travelling for short distances, splatter settle over inanimate surfaces and exposed parts of the dentist or the patient whereas aerosols remain airborne for extended periods and may be inhaled.[18,19] Humidity and temperature have also been shown to be significant determinants of particle size and viability of other airborne viruses.[11,19] It has been shown that SARS-CoV-1 and 2 can remain infectious from 2 hours up to 9 days at room temperature depending upon the relative humidity.[20] Having air-conditioned settings, these factors can play an important role in the survival of viruses in dental clinics.

Suggested Advisory to Dental Clinics: Reopening of dental clinic requires several careful considerations which starts right from giving appointment till the patient leaves the dental clinic.

a) **Appointment through tele screening:** Web/app-based technologies should be explored for initial screening, followed by scheduling appointment of patients to distribute the patients throughout the clinical hour avoiding gathering. Investigation of the patient details should always start with answering a set of questionnaires (Figure 1)asked by trained personnel during teleconsultation. "Yes" to any of the questions would categorize the patient as a probable suspect. Thedentist can defer the treatment procedure in such patients until a minimum of 14 days to a maximum of 24 days. Such patients should be advised for self-quarantine and consulting physicians. "No" to all questions would qualify the patient for scheduling the appointment.

b) **Patient evaluation at the reception of the dental clinic:** Once the patient scheduled for appointment arrives at the clinic, there will be a sign on the door with the dental assistant's phone number. Calling the dental assistant before entering the clinic is essential. The patient should enter the dental clinic after washing hands in the basin kept outside the dental clinic. At the reception, reaffirmation of the questions should be done, followed by the patient's signature. The dental assistant should record the body temperature by the non-contact thermometer or infrared thermal sensors. Except for minors and specially-abled patients, no accompanying person is allowed with the patient. In these cases, the accompanying person also has to go through the screening test. Point of care rapid screening kit may be incorporated at this stage. Reception area of the dental clinic should adequately display respiratory etiquettes and hand hygiene through several posters available at "www.cdc.gov/flu/protect/covercough.htm" and "www.cdc.gov/ncidod/dhqp/pdf/Infdis/RespiratoryPoster.pdf",

c) Clinical examination in the dental clinic: Standard precaution, as mentioned in the Centre for Disease Control and Prevention (CDC)(21), such as hand hygiene,Personal protective equipment (PPE), handling contaminated materials or equipment to prevent cross-contamination, using engineering and work practice controls, respiratory hygiene and cough etiquettes and safe injection practices. [21,22] Choice of antiseptic agents, duration and technique of hand scrubbing, techniques for drying and gloving can influence the effectiveness of the surgical hand antisepsis. CDC's 2002 guidelines and WHO provides complete information on hand hygiene.[23]

Owing to the modes of transmission of Covid-19, three categories of precaution such as droplet, contact and airborne are recommended for every patient. Therefore, gloves, masks, eye protection with side shields, protective fluid repellent gowns and N95 respirators are required while examining the patient's oral cavity. Extraoral radiographs are preferable to intraoral ones. Extra barrier should be followed when intraoral imaging is essential.

d) Treatment procedure: Only essential staff should be allowed in the room during operative procedures. AGP demand strict use of personal protective equipment. Although CDC 2007 guidelines donot recommend eyewear for closely examining the patients it may be used by the dentist during splatter or AGP.[22]Selection of PPE depends upon the type of clinical exposure anticipated, durability and appropriateness of task as well as fit. Respiratory protection is the most important component of PPE which can be achieved through particulate respirators, half or full-face elastomeric respirators and powered air-purifying respirators (PAPR). WHO recommends the use of a particulate respirator as a U.S. National Institute for Occupational Safety and Health (NIOSH)-certified N95, European Union (E.U.) standard FFP2, or equivalent when performing AGPof managing critically ill patient[24]which should be followed in a dental clinic. There is no evidence regarding the safety of either N95 or the equivalent FFP2 or even higher grade respirators while performing the aerosol-generating procedure in a suspected case of COVID-19. EUFFP3 respirators conforming to European standard 149 offers a filtration rate of 99% of all particles measuring up to 0.6micron. [25]SARS-CoV-2 measures around 0.12micronand aerosol particles range from 3-100nm. Therefore, the safety of these respirators in protecting dentist from SARS-CoV-2 during aerosol-generating procedures is questionable. Uses of such respirators require adequate training through annual respiratory program. Higher level of protection may be achieved through PAPR while performing AGP. PAPR as opposed to N95 does not require testing, can be worn with facial hair, reduced patient anxiety but high cost makes it unaffordable by the dentist, especially in India. For additional information dentist may explore http://www.cdc.gov/niosh/npptl/respirators/respsars.html and http://www.cdc.gov/niosh/topics/respirators. Donning and doffing should follow OSHA guidelines at http://www.osha.gov/SLTC/dentistry/index.html.) Donning of PPE should start with the gown followed by respirator/mask, goggles or face shield, and gloves. Sequence for doffing starts with gloves followed by face shields/goggles, gown and mask/respirators. Optimizing the availability of PPE is essential. Healthy subjects wearing PPE are reported to show hyperthermia, tachycardia, hypercapnia developing stress and work intolerance among dentists.[26]

Efforts to reduce bio-aerosol can be achieved by isolation of the operative site by rubber dam, pre-procedural mouth rinse and air cleaning systems. Cochran et al[27]28 have demonstrated a 90% reduction in bio-aerosol though protective eye wear and head cap are compulsory while using rubber dam.[29]Conditions where rubberdam placement is not feasible, pre-procedural mouth rinse with 1% hydrogen peroxide and 0.2% povidone-iodine can reduce the bio-aerosol. [30]

High volume evacuator (HVE) and high-efficiency particulate arrester (HEPA) filters are suggested method for controlling airborne infection in the dental clinic. Avasthi et al. [31][32] in 2018 have reported a substantial efficiency of HVE filter in reducing bio-aerosol whereas Desarda et al.[33] have contradicted this. Ergonomic limitations of HVE can be overcome by Nubird HVE.[34] HEPA filter is 99.97% effective in reducing aerosol particles measuring 0.3 μm in diameter though less used being expensive and difficult to clean. Aerosol contamination due to dental unit waterlines can be overcome by chemical and non-chemical treatment of dental unit waterline biofilmanddental chair unit design modifications.[35]

e) Disinfection of patient care items: Critical items can be single-use disposable or heat sterilized. Heat sterilization or high-level disinfection after every use is required for semi-critical items. Barrier protection should be used at a minimum. Non-critical items can be disinfected by FDA-cleared sterilant or high-level disinfectants and EPA-registered disinfectants.[36] SARS-CoV-2is a lipid virus having least resistance to germicidal chemicals.[37] Therefore,regular disinfection and sterilization should minimize the viability of SARS-CoV-2 on these patient-care items.

f) Disinfection of clinic and waste management: Surface disinfectants like 62%–71% ethanol, 0.5% hydrogen peroxide, and 0.1% (1 g/L) sodium hypochlorite (20) and otheroxidizing disinfectants may be used to decontaminate the clinical contact surfaces after each patient. Dental waste consisting of majorly extracted teeth; saliva/blood-soaked gauze surgically removed tissues and contaminated sharp items should be disposed in a leak-resistant biohazard bag with secured closure.[38]

Preparedness of Dental Practitioners: We propose a checklist to evaluate the preparedness of the dentist to resumeclinic (Figure 2). Dental procedure in the current scenario will be more expensive than before to afford strict disinfection program as well as PPE for almost every patient. Reducing taxes on dental materials and equipment, reduction of electricity tariffs and free sanitization programme in dental clinic and reducing the premium of health insurance for dentists at least till the emergence of a vaccination programme, are few considerations which the representatives of dental organizations should put forward to Government.

Tele-screening questionnaire for scheduling appointment

Name of the interviewer: **Date of call:**

Name of the patient: **Age/Gender:**

Date of birth:

Address with contact number:

Screening questionnaire	Yes	No	Assessment of emergency	Yes	No
Have you ever been diagnosed with COVID-19?			Chief complaint:		
If yes, date of last negative test result:					
Do you have travel history to known Hot-Spots?			Pain?		
Have you been exposed to a known COVID-19 positive person?			Pain level:		
Do you have Fever?			Pain since when:		
Do you have Cough/Sore Throat?			Swollen gum/face?		
Are you facing any difficulty in breathing?			Trouble swallowing?		
Are you having any body ache?			Trouble opening mouth?		
Are you suffering from Diarrhoea or GI Discomfort?			Trauma?		
Have you observed any diminished sense of smell or taste recently?			Ulcer?		
Do you share a workplace, classroom or household or come in contact with large gatherings regularly?			If yes, ulcer since when:		
			Bleeding?		

Figure 1- Questionnaire for tele screening

Dental practitioner's preparedness assessment

1. Education and job specific training to all employees at Dental office	Yes	No
Signs and symptoms of Covid19		
Techniques of hand washing, respiratory etiquettes and wearing face masks		
Self-monitoring for Covid19 specific symptoms		
Process of reporting suspected or confirmed cases of Covid19		
Patient placement		
2. Facilities at reception area of the clinic	**Yes**	**No**
Notification for patients to take appointment through tele-screening process		
Adequate signs posted regarding respiratory etiquettes, social distancing, mask wearing and symptoms of respiratory infection		
Provision of face mask		
Alcohol based hand sanitizers		
Tissue papers and no-touch receptacles for their disposal		
Social distancing in the waiting area		
3. Availability of Items to maintain Standard precaution for infection prevention	**Yes**	**No**
Gloves		
Fluid repellent coveralls		
Eye protection		
Hand wash		
EPA approved disinfectants		
4. Availability of Items to maintain Transmission based precaution for infection prevention	**Yes**	**No**
High level respirators		
Rubber dam		
Mouth rinse		
Dental unit waterline maintenance		
Air filtration system		
5. Adequate training in donning and doffing of PPE		
6. Registered for annual respiratory protection program

Effect of Modern (Junk) Food in Dental Caries

Manisha Nayak

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

In this modern age, 21st-century people are attracted more towards the outside oily and calories rich junk food than homemade healthy food. Especially this group includes children and youth. Either due to the taste of tongue or due to circumstances like hostel life, they are attracted to these unhealthy fast or junk food. These junk foods are bad for physical health and especially for oral health. Under this topic, we shall discuss the influence of junk food in dental caries which is increasing day by day especially in children and young people due to their modern lifestyle.

Keywords: *Dental caries, junk food, sugar, carbohydrates, starch, acids microorganisms, fermentation, decaying.*

Introduction

We have to get knowledge about "which are junk food?" and its "consistency" We should have a precise idea about "what is dental caries?" and "how it is initiated?" And "what is the role of junk food in initiating or extending dental caries?"[1]

Junk food: Junk food is the unhealthy food that is high in calories consisting of sugar or fat and also have a little amount of dietary fibres, protein, vitamins, minerals or other important nutritional value. Even, so high protein food like meat prepared with saturated fat may be considered as junk food. The ubiquitous supply of junk foods in our food environment is our day to day lifestyle and becomes our day to day food habit. It is seen nowadays that students from high socioeconomic status, they are more junk food consumers. Children from middle eastern culture having a background of high junk food consumers. Junk food consumers are more likely to consume due to some habits like: Eat dinner in front of the television; Receive sweet rewards; Allows to consume snacks anytime; Have soft drinks available at home; A television in their bedroom or dinner hall.[2]

Table 1. Junk food types

Sugar Rich	Spicy and Salty	High-Calorie Food
Candies	Pizzas	Fried chicken
Potato chips	Pavvaji	Fried paneer
Chocolates	Burgers	Oily Breads
Ice-cream	Gupchup	Coffee
Soft drinks	Chats	Diary products
Pastries	Momo	Fruit juice with added sugar
Cookies, cakes	Bada, Samosa	

Dental Caries: Dental caries is an irreversible microbial disease of the calcified tissues of the teeth, characterised by de3mineralization of the inorganic part and destruction of the organic substance of the teeth,which often leads to Cavitation. It's the truth that this junk food affects your oral health. You may ask "HOW? If I brush or floss regularly?" But only brushing or flossing is not enough to prevent these sticky and solid food retention on the tooth surface and its reaction on it. Brushing only maintain the oral hygiene. Pizzas, burgers and French fries these foods are rich in starch and carbohydrate which is the main source for caries. If we don't brush or floss after eating these junk foods, then it will help these caries causing bacteria to grow and proceed to decay of tooth eventually. These also help in the formation of plaque and tartar which cause

e-mail: nayakmanisha999@gmail.com

gum disease. Dry fruits and fruit juice with added sugars due to its natural sugars and artificially added sugar in packed fruit juice help the bacteria to grow freely. And carbohydrate drinks like soda,cold drinks cause harm to their teeth because of two constituents i.e sugar and acids. Due to high acids in carbohydrate drinks cause eroding and wearing down of enamel and make the tooth prone to erosion and decay. Excess salts and sugars are added to the packed food by the food companies to preserve it for a long time and to reach to its optimum taste. These factors help in long time retention of the debris and acid surface along the tooth surfaces and increase the rate of caries. How caries initiated in tooth due to retention of the excess sugar, carbohydrate, and extra salted food is a question.[4,5]

Table 2. Consistency of these unhealthy junk foods[3]

Sugar drinks	Adding sugar is one of the worst ingredients in the modern diet. Sugary drinks increase your total carbohydrate intake. It may cause insulin resistance diabetes type 2, nonalcoholic fatty liver disease, other heart disease or obesity
Pizzas and Burgers	Highly refined dough Heavily processed meat extremely high in calories and high in starch
White bread	These are unhealthy or bad for health if consumed in high amounts because it is highly rich in refined wheat and which is low in fibers and essentials
Fried Packaged food	It contains high calories and also chemicals like acrylamides, acrolein, heterocyclic amines, oxysterols, polycyclic aromatic hydrocarbons(PAHs), AGEs
Pastries, Cookies, and Cakes	If we take it in excess then it is unhealthy. They are made up of refined wheat flour, added fat and refined sugars and also high in unhealthy transfats and preservatives and no essential nutrients and calories.
French fries and potato chips:	Highly riched in carbohydrates so also riched in calories. These also contain carcinogenic acrylamide
Packed Fruit juice:	We know fruit juice has its natural carbohydrate or sugar but now a day outside packed fruit juice have added sugars and preservatives which is unhealthy.
Agave Nectar	Agave nectar is a sweetener agent that is highly refined and fructose-rich.
Ice-cream:	This diary product is highly rich in carbohydrates and also in calories, and easy to overeat
Candy bars, Chocolates:	Candy bars are incredibly unhealthy. They are high in refined wheat flour, sugar, and processed fats while very low in essential nutrients. These are also high in carbohydrates.
High calories coffee drinks	The good effects of coffee which help in prevention against serious diseases like type 2 diabetes, Parkinson's disease. But nowadays for mouthwatering we are adding creamers, syrups, sugars and additives, that are frequently highly rich in carbohydrates and unhealthy highly for body like other sugar-sweetened beverages.
Excess salty and spicy foods:	Pavvaji, gupchups, chats, momoetc are highly riched in carbohydrates, salts and chilly

According to "miller's chemo-parasitic theory" or "acidogenic theory" in the first stage decalcification of enamel and dentin occurs & in second stage softened residue dissolution due to acid and microorganism. For dental caries two factors are responsible first is Oral microorganism & Second is Acids produced from the fermentation of starch or carbohydrate available sticky and solid carbohydrate and starch remaining products on tooth surfaces. Bread, sugar, and another carbohydrate-rich food remain stick to the remaining tooth surfaces for long periods, they will start fermentation with the help of some microorganisms present in our saliva that produce acids. These acids formed from fermentation helps in the decalcification of enamel and dentin and proceed to decay of tooth.[6]

There are two types of microorganisms,one is acidogenic and another is proteolytic.

In simple language dental caries is the combination of microorganism which produces acids and proteolysis,

acid produced, tooth surface and remaining carbohydrates and starches.

(Bacteria) + (sugar) + (tooth) → (acids) → dental caries

Functions of carbohydrates: Both raw sugar and cooked sugar cause dental caries but cooked sugar produces more acids. The carbohydrates present in saliva are not available for microorganisms, because these carbohydrates bound to proteins and other carbohydrates. The presence of carbohydrates and starch on tooth surfaces depends on how many times taken,how much taken which forms taken and in which path it is taken. Monosaccharides and disaccharides are much available on tooth surfaces for acid production. But glucose and sucrose are easily soluble in the stomach tube and intravenously so not available for fermentation.[7]

Functions of microorganisms: As we know two types of micro organisms is acidogenic and proteolytic. Those bacteria which are responsible for acid production and dental caries: *S. mutans, L. acidophilus, Actinomyces.* These bacteria either in isolated or in combined form involved in this fermentation and dental caries process.

Functions of acids: Fermentation or enzymatic breakdown of carbohydrate and sugar may produce lactic acid along with butyric acid. There are two types of enzymes "heterofermentative" and "homofermentative". *Streptococci* and *lactobacilli* which are homo fermentative mostly produce lactic acid in anaerobic conditions. Those which are heterofermentative produce varieties of intermediate acid products. Like pyruvic acid in the presence of lactic acid dehydrogenase produce formic acid and acetyl CoA along with intermediate acid propionic, butyric acid, succinic acid and ethanol. To adhere to these acids on the tooth surfaces, plaque plays a great role. Monosaccharide and disaccharide reduce pH so that it will be suitable for the acid to remain on the tooth surface for a long time. Actinomyces in anaerobic condition becomes homofermentative and produces lactic acid but in the presence of CO_2, it becomes heterofermentative. The amount of acid production depends on the growth of the number of bacteria and the types present.[8-10]

Steps to take after taking junk food to prevent caries: We know that junk food is not only bad for our oral health but also our physical health. So consume these unhealthy foods as less as possible. After taking this junk food we should wash our mouth with water. And we should brush and floss your tooth after taking this junk food so that this food will not remain on tooth surfaces for a long time which will reduce the risk of caries. We can also use mouth wash along these.

Conclusion

For your relaxation, I want to say that fast food is not harmful when it is taken under control. The problem happens, when it is taken in a large amount and frequency. The result of fast food taken and its complications for oral health is right in front of you.

Adenocystic Carcinoma of Salivary Gland: A Literature Review

Santosh Kumar Subudhi[1], Sthitaprajna Lenka[1], Kalyan Sundar Pal[2], Satchidananda Meher[2], Aditi Ava Rath[2]

[1]Professor, [2]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery,Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha: 751003, India

Abstract

Adenoid cystic carcinoma is a rare salivary gland tumor that has a consistent slow growth rate and has destructive biological behavior because of its deep peripheral tissue invasion and higher recurrence rate and tendency of distant metastasis. The involvement of adjacent vital structures may lead to death. Its clinical presentation also causes difficulty in diagnosis. Surgical resection following radiotherapy is the main treatment modality of Adenoid cystic carcinoma. Even after successful therapy of the primary tumor, there is a high rate of local recurrence and in contrast to other epithelial malignancies, it has a very poor prognosis. The survival rate is good for the initial 5 years but it falls after 5 years follow up.

Keywords: *Adenoid cystic carcinoma, Malignant neoplasm, Distant metastases, Perineural invasion.*

Introduction

Robin, Lorain, and Laboulbene were first described Adenoid cystic carcinoma in two articles published in 1853 and 1854 reporting on two nasal tumors and one parotid.[1] Cribriform arrangement of the cells invasion of adjacent structure and spread through the nerve also described by them. ‘‘Cylindroma’’ was the term suggested by Billroth in 1856 suggested the for tumor and Spies coined the current name of ‘‘adenoid cystic carcinoma’’ in 1930. It comprises 1% of all malignancies of the head and neck region and about 10% of all salivary gland tumors. It is the most common malignant tumor of minor salivary glands and is also one of the most common cancers of the major salivary glands. ACC not only involves the salivary gland but also involve the lacrimal gland, ceruminous gland, paranasal air sinuses, larynx, and trachea. Initially,the tumor was described benign and mixed tumors. The layer was establishedas malignant. Currently, ACCis recognizedas an extremely difficult malignancy to treat. Conleyand Ding mandescribed it as one of the most biologically destructive and unpredictable tumors of the head and neck. It has a high, almost inevitable, predisposition torecur if a patient, lives long enough, and this occurs even when radical excision has been performed.[2]

Clinical presentation:

Location: Nearly 10% of all salivary gland neoplasm are adenoid cystic carcinoma which most commonly involves the minor salivary glands (in 60% cases). Whereas in the head and neck region the parotid gland is the single most common site for the tumor involvement. Minor salivary gland adenoid cystic carcinoma commonly affects the minor salivary gland present intraorally, most commonly the palate.

Age: There is no age predilection but more common in adults with a peak of incidence at the 4th to 6th decade of life. Sometimes children may also be affected. It is found that in children major salivary glands are common sites for the tumor whereas in adult minor salivary glands are commonly affects than the major salivary gland.[3-5]

Corresponding Author:

Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha: 751003, India
e-mail: aditirath@rediffmail.com

Gender: There is slight female predilection (F:M = 1.2:1). Although other different study shows that there is no significant gender predilection for the tumor.

Clinical Features: Any non-ulcerating tumor in a major or minor salivary gland recognized for months or years, causing mild discomfort or pain and associated with paresthesias, is highly suggestive of adenoid carcinoma until proven otherwise".There are no distinct signs and symptom of ACC to identify it clinically exactly. Different studies revealed that ACC is a persistent slow-growing tumor with a recurrent growth pattern. It has a long clinical course and distant metastases occur at a late stage. On the advancement of the malignancy in an advanced stage, there are chances of involvement of adjacent nerve. Generally, 2nd division of the trigeminal nerve is involved causing paresthesia and pain along the distribution of the nerve. Radiological and histopathological study reports along with clinical reports are correlated for final diagnosis.[3-5]

There is multiple contradictory behavior of ACC. **First**, slow growth, but progressive, relentless course. **Second**, clearance of the margin is achievable but multiple local recurrences occur**. Third**, regional metastases to cervical lymphnodesareuncommon, but the incidence of distant metastasis to lung, live, bone is quite common, and **Forth**,survival rate is high for the first 5 years,but in case of 10-to 20-yearsurvivalrate, it is quite low. [3-5]

Histological features: Histopathological study of the tumor reveals it consists of a mixture of ductal and epithelial cells and they are arranged in three different patterns. They are namely 1.Cribriform, 2.tubular, and 3.solid. the cells having little cytoplasm with angulated and hyperchromatic nuclei. Mitotic figures are less present in the tubular and cribriform pattern and found more in the solid strand pattern which is associated with very poor prognosis. Huang et al. concluded in his study that the location of the tumor, clinical staging, and the histopathological variant are the factors that determine the prognosis and patient survival. [6]

Histopathologically adenoid cystic carcinoma can be graded as below

Grade I: The tumor consists only of cribriform and tubular

Grade II: A mixture of cribriform, tubular, and solid growth patterns, with a solid growth pattern of less than 30% of the tumor.

Grade III: Tumors with predominantly solid features (>30% or more of the tumor).

Immunohistochemically, ACC was consistently positive for cytokeratin [AE1/3, CK 34βE12, CK5/6, CK7, CK14, CK18] p63, CA19-9, c-KIT (CD117), PDGFRA, MUC1, and Ki-67. ACC was consistently negative for CK8, CK20, desmin, S100 protein, CD34, chromogranin, MUC2,MUC5AC, and MUC6. Some ACCs were positive for CK CAM5.2, CK19, EMA, CEA, vimentin, α-smooth muscle actin, p53, CD10, and synaptophysin.[7]

Perineural Invasion: Neoplastic invasion of nerves was reported first in 1842 by Cruveilheir. It is direct spread from the primary tumor and it is continuous microscopically though appears discontinuous macroscopical view. This invasion occurs at the level of perineural and endoneurial plane through the path of least resistance. Lymphatic channels in these tissue planes have very little to no role in this aspect. Most commonly involve the 2nd and 3rd division of the trigeminal nerve but may also involve the descending portion of the facial nerve and other smaller branches. It is considered that Gasserian ganglion is the most commonly affected site while the cavernous sinus is less commonly affected. As per different literature the latency between involvement of the nerve and onset of the neurological symptoms and diagnosis time ranges between months to 3 years. In the case of ACC of nasopharynx cranial nerve involvement is more common. It is considered as an indicator of poor prognosis as there is a chance of involvement of the cranial cavity, skull base, orbital cavity, and pterygopalatine fossa. The relationship between the distant metastases and perineural invasion is controversial sill now. Researchers considered perineural invasion as a significant factor for prognosis and distant metastases of the primary tumor. It is also supported by other studies.[8]

Distant Metastases: It is difficult to estimate the incidence of distant metastasis in ACC, but it usually ranges from 35 to 50%.Incidence of distance metastases employing hematogenous spread is quite common in ACC and creates challenges in successful treatment of the same. Distant hematogenous spread is quite common in the case of ACC in contrast to the regional lymph node spread of other types of malignancies. These metastases occur in a very unpredictable way and can involve the

lung, liver, bone, and other soft tissue. Pulmonary or lung metastasis is quite common. These metastatic of primary ACC remain asymptomatic for a longer period especially the pulmonary metastasis which has very slow progress. On the other hand metastases to the bone have a very rapid and fatal course. The successful treatment of an ACC with well-controlled local disease is not possible because of these distance metastases. As per Spiro "the incidence of distant metastasis at other sites is likely to be more frequent, as no further investigations are done once lung metastasis is detected. In 40-60% cases, distant metastases are most common in lung, bone, and soft tissues. distance metastases should be considered as a separate disease process and for the same, the effort to control the primary tumor control should not be hampered.[8-10]

Management: Optimal management of the ACC of the head-neck region is not well established. Management depends on the site of the involvement, staging of the tumor, histological grading, metastatic involvement, and biological behavior of the tumor. It is difficult to treat an ACC because of its unreliable behavior, multiple and late local recurrence. Generally, surgical resection with a clear margin along with radiotherapy is most commonly employed for the treatment of ACC. Before delivery of the treatment throughout the workup and complication of each treatment procedure should be evaluated. Care should be taken to preserve the normal function of different anatomical structures as far as possible. Indications for surgery are: 1.bony involvement, 2. Tumors that are not sensitive to radiotherapy, 3. Recurrent lesion at the primary site, 4.side effect is radiotherapy is greater. Radiotherapy for the treatment of ACC has not been used solely as these tumors are radiosensitive but not radiocurative. The primary response to the radiotherapy is assuring but in later stage recurrence rate is higher. As per a study "patients receiving radiation alone, 96% had tumor regression but 93% relapsed, and half of them relapsed in 18 months.[11]

The use of chemotherapeutic agents in the treatment of ACC is controversial because of its poorly defined and limited role. Generally administered for palliative care.[41,42,43-45] Few studies proved that the use of cyclophosphamide, doxorubicin, cisplatin are useful and have some activity as a single agent or in combination during surgical management of the ACC of the parotid gland, facial nerve should be preserved if there is no involvement of the nerve present. For that presurgical evaluation of the nerve function should be done when the submandibular gland involved supraomohyoid neck dissection to be done along with the resection of the tumor. Post-operative radiotherapy is given following surgery in both cases. Local radical excision and postoperative radiotherapy should be done in the case of minor salivary glands ACC. Postoperative radiotherapy reduces the chances of recurrence but survival benefits are not demonstrated.[12]

Prognosis: There are many prognostic factors of ACC. They are 1. Size 2. primary site, 3. involvement of adjacent structures, 4. lymphnode metastases, 5. clinical staging, 6. treatment modality, 7. positive margins of surgical resection, 8. perineural invasion, and 9. histological subtype. It has been noted that the prognosis of minor salivary gland ACC is worse than those ACC of the major salivary glands. In the case of minor salivary gland tumor, peripheral extra glandular soft tissue and bone are readily infiltrated by the tumor and cause increased dissemination of the tumor which makes the complete excision of the tumor more difficult. Again the cribriform subtype of ACC has the best prognosis whereas the solid subtype has the worst and the prognosis for tubular form is intermediate. Another study reported that there was no significant relationship between the morphologic type of ACC and locoregional control. But they found that there was a high rate of distant metastases in the case of cribriform and solid variety. "Authors found that positive margins did not influence survival, but are implicated in increased treatment failure. However, many others reported the presence of surgical positive margins as a parameter for survival and tumor control." Some authors describe a close relation between perineural invasion and the degree of extension of the primary tumor. While some others reported the perineural invasion as a negative survival predictor. Poor prognosis was often associated with perineural invasion. Ki-67 antigen expression, DNA ploidy, nucleolarorganizing regions, S-phase value are some tumor markers that are associate with poor prognosis.[8-12]

Conclusion

Adenoid cystic carcinoma is one hard to treat malignancy because of its aggressive clinical behavior. Early diagnosis is necessary to reduce the morbidity and successful management. Follow up at regular intervals is necessary to prevent the local and distant recurrence of the same. Surgical resection of the lesion along with radiotherapy proved to be beneficial for the management

of this type of malignancy. Radiotherapy helps to reduce recurrence.

Glandular Odontogenic Cyst

Arpita Kar

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A cyst is a Pathological cavity which consists of solid, semi-solid or gaseous contents which are not created by the accumulation of pus and which may or may not be lined by epithelium. The cysts of the jaw are divided into two categories namely epithelial and non-epithelial. The epithelial cysts are further classified into developmental and inflammatory. Based on their origin the developmental cysts are further classified into odontogenic and non-odontogenic cysts. Hence the odontogenic cysts are described as jaw cysts originating from the odontogenic epithelium. A glandular odontogenic cyst (GOC) is a developmental cyst. A glandular odontogenic cyst (GOC) is a sparse entity of odontogenic origination. A glandular odontogenic cyst is known for its hostile behaviour, unforeseeable nature, indeterminate clinical features and high recurring potentiality. The aggressive behaviour may be attributed to the cell kinetics of the lining epithelium or the conservative treatment approach. Apart from the aforementioned peculiarities, GOC is also notorious for impersonating clinicopathological lesions such as Botryoid odontogenic cyst, which is also a regionally aggressive polycystic form of a lateral periodontal cyst and central mucoepidermoid tumour further complicating the diagnosis. These features further establish Glandular odontogenic cyst as an independent biological entity. This article focuses on discussing the various aspects of the rare entity that is a glandular odontogenic cyst in terms of histopathological features, radiological features, diagnostic criteria, clinical features, cytological investigations, differential diagnosis and treatment approach.

Keywords: *Cyst, Glandular odontogenic cyst, Central mucoepidermoid tumour, Fluorescent In Situ Hybridization (FISH).*

Introduction

A glandular odontogenic cyst (GOC) is a developmental cyst derived from the dental lamina. It is also known as sialoodontogenic cyst having many similarities with the lateral periodontal cyst except for the multilocular radiolucency. Gardner et al (1988) coined the term GOC and suggested that it's histological attributes and biological conduct are fairly evident for it to be regarded as a separate entity. It is a rare aggressive lesion with a recurring potential.[1] In 1992 in WHO typing of odontogenic Tumours GOC was defined as "a cyst arising in the tooth-bearing areas of the jaw characterized by an epithelial lining with cuboidal or columnar cells both at the surface and lining crypts or cyst-like spaces within the thickness of the epithelium. "It is the rare lesion, that can show aggressive behaviour, accounting for about 0.012-1.3% of all jaw bone cysts. According to Padayachee and Van Wyk, 1987 the quintessential characteristics of the cyst include that it shows multilocular radiolucent appearance, it is infrabony, can recur if not adequately excised, spaces created by cysts are lined by non keratinized same as that of reduced enamel epithelium with epithelial concretions, mucous and columnar cells form an indispensable portion of the epithelium unit. [2]

Diagnostic Criteria: According to Kaplan et al certain characteristics, features were classified into major and minor criteria based on the incident of occurrence of each feature in formerly reported cases. The presence

of major criteria is obligatory whereas the presence of minor criteria confirms the diagnosis. The major criteria include squamous epithelium of differing thickness with the presence of cuboidal shaped eosinophilic or hobnail cells and goblet cells along with the glandular structures. The squamous cell lining also shows spheres or whorls with the absence of basal palisading. The minor criteria include the papillary proliferation of epithelial lining multicystic appearance and presence of clear cells in the epithelium.[3]

Histopathology: Histologically, it is lined by non keratinized epithelium with mucous material within the spaces created by the cyst being an important feature. The superficial epithelial cells are columnar to cuboidal with cilia. Numerous mucus cells and gland-like structures are also seen in the epithelium. The histopathological features of GOC play a pivotal role in diagnosis as they resemble a wide variety of lesions including lateral periodontal cyst, Dentigerous cyst, Intraosseous mucoepidermoid carcinoma. Therefore careful and detailed microscopic examination plays a key role in diagnosis.[4]

Clinical Features: Clinically it presents as a slow-growing, aggressive lesion commonly associated with the mandible (Four times more commonly seen in the lower jaw in comparison to the upper jaw) with a preference for the anterior region. Clinically it is seen most commonly occurring in middle-aged people, It is rarely seen in children below 20 years. Most commonly seen in the lower jaw with a strong preference for the anterior area. The size of the cyst is variable ranging from smaller lesions lesser than 1 cm in diameter to larger destructive lesions involving the whole jaw. It presents initially as an asymptomatic swelling in case of small cysts. In the case of large cysts it can become destructive due to clinical expansion or if it is secondarily infected or if there is compression of neurovascular bundles.[5]

Investigation: The investigation includes immunohistochemical staining with Cytokeratins (CKs 7 8 10 14 19). Another prominent investigation which plays a key role in segregation of GOC and low-grade mucoepidermoid carcinoma, a relatively close entity resembling GOC is Fluorescent In Situ Hybridization (FISH). The immunohistochemical stains can play a pivotal role in the recognition of tumour cell type and origin. Mucoepidermoid Carcinomas show Mastermind – like 2 (MAML2) gene redistributions characterized by translocation t(11;19) (q21;p13) whereas FISH investigations have shown that glandular odontogenic cyst doesn't show MAML2 gene redistributions. Periodic Acid Schiff (PAS) Periodic Acid Diastase (PAS-D) and mucucarmine stains play a pivotal role in highlighting glycogen-rich and mucin-secreting cells.[6]

Radiological Features: Radiologically Glandular odontogenic cyst shows well-defined margins and multilocular radiolucency along with a sclerotic rim and scalloping of the borders. The scalloping can be seen in interdentally and inter radicular spaces. Other radiological features include minute root resorption, cortical perforation and expansion, tooth displacement. In some cases, the absence of impacted tooth has been reported. It often exhibits honeycomb appearance. A radiopathological link can play a significant role in definitive diagnosis.[7]

Radiographic diagnostic aids include preoperative orthopantomogram as well as postoperative orthopantomogram to check for the recurrence as the cyst has high recurring potential. Some other advanced radiographic diagnostic aids include Digital Volumetric Tomography (DVT). CT scans are also advised as they serve precise details about locularity of the entity, cortical integrity, expansion of the lesion and collusion of the contiguous soft tissue.[8]

Differential Diagnosis: The differential diagnosis of glandular odontogenic cyst involves both benign and malignant lesions. Glandular odontogenic cyst imitates a wide clinicopathologic spectrum ranging from a lateral periodontal cyst to a catastrophic malignant neoplasm such as central mucoepidermoid carcinoma. Hence the differential diagnosis for GOC may include Dentigerous cyst, unicystic Ameloblastoma, Intraosseous mucoepidermoid carcinoma, a lateral periodontal cyst. Intraosseous mucoepidermoid carcinoma is a rare malignant neoplasm of the salivary glands with a predilection for the lower jaw.[9,10] Cellular atypia and solid microcystic epithelial proliferation are Pathological findings in Intraosseous mucoepidermoid carcinoma but not in GOC.Also, GOC shows positive immunostaining for CK-18, CK-19 and Ki-67 and decreased positivity for p-53, which helps to differentiate GOC from Intraosseous mucoepidermoid carcinoma. The dentigerous cyst does not exhibit cuboidal surface cells, nodular thickening and gland-like spaces. Another differentiating feature is the higher recurrence rates of GOC than Dentigerous cyst. Lateral periodontal cyst lacks cuboidal cells and mucin pools and presents as a unilocular lesion radiologically.

GOC presents as a multilocular radiolucency usually with a well defined sclerotic rim. Some cases of GOC show Ameloblastomatous changes similar to unicystic Ameloblastoma. In such cases the histologic changes which resemble unicystic Ameloblastoma. Also, few radiographic features such as lobulated margins, perforation of the cortex and root resorption of the adjacent tooth are similar but the clinical findings are distinctive.[11-13]

Treatment: The treatment modality differs based on the size and aggressiveness of the lesion. The treatment modality varies from minor surgical processes such as enucleation and curettage to major surgical processes such as peripheral osteotomy, marginal resection. The treatment of choice has been enucleation or curettage. Treatment of small unilocular lesion by enucleation is advised. In large uni- or multilocular lesions, an initial biopsy is advocated. Marginal resection is also considered as a reliable method of treatment. Due to its recurring potential and aggressive behaviour in some cases, en bloc resection is advised especially for the multilocular lesions. The recurrence rate is more prevalent in multilocular cysts with cortical perforations while in smaller unilocular lesions conservative treatment approach is adapted which includes curettage with adjuvant Carnoy's solution. Excision of soft tissue adjacent to cortical bone perforation and peripheral bone osteotomy with a large round bur to remove the remaining epithelium of cyst and application of liquid nitrogen to the remaining bony cavity. Endodontic treatment of the offending tooth followed by apicoectomy can be done. The number of reported cases has increased significantly in recent years Due to increased knowledge of surgeons and pathologists about this entity.[14-15]

Conclusion

A glandular odontogenic cyst is an unusual cystic lesion with a tendency to recur and showing locally aggressive behaviour. The cyst exhibits non-distinctive clinical-radiological which may mimic many other lesions. The radiographic appearance of the cyst can be variable and not pathognomonic. A concluding diagnosis can be achieved by a careful histopathological examination. Close follow up for the patient is suggested owing to the high recurring potential of the lesion. The recurrence mainly occurs due to faulty diagnosis, inefficient removal of cyst and absence of proper follow-up.

Caries Risk Assessment-Protocols and Paraphernalia

Swati Patnaik

Associate Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Measures of caries control involve identifying the disease process and the risk factors; this is achieved by first performing a caries risk assessment for the patient in order to identify his/her risk factors for caries development. With a better understanding of the caries process, there comes a change in operative dentistry. Although there is considerable variability between dentists, there is more emphasis on preventive dentistry than ever before. The shift in emphasis appears to be occurring in dental schools in which curriculum and practical skills are focused more on caries risk assessment, modern management of the caries disease. This paper reviews about the various caries risk assessment approaches and models and stresses on the need for a risk assessment based approach.

Keywords: *Dental caries, Risk assessment, Basic protocols, Management.*

Introduction

Dental caries is a major oral health burden and is the commonest dental disease seen throughout the world. Dental caries has been linked to food habits, lifestyle changes, oral hygiene etc. Recent advances in the field of dentistry regarding caries detection and management, preach CRA to be the need of the hour. The American Academy of Paediatric Dentistry (**AAPD**) has recognized caries-risk assessment and management protocols as a tool to assist clinicians with decisions regarding treatment based upon caries risk and patient compliance and are essential elements of contemporary clinical care for infants, children, and adolescents.

Awareness about caries risk assessment is essential as it helps the dentist assess caries susceptibility and carious lesions at an earlier stage, which indirectly helps in educating & motivating the patient in maintaining a good oral hygiene and also reduces the amount, extensiveness of invasive treatments. A caries risk assessment tool saves both the dentist's and the patients chair side time for further appointments.

Hence, a set guideline has to be followed to educate healthcare providers and other interested parties in preventive dentistry and aid in clinical decision making regarding diagnostic, fluoride, dietary and restorative protocols [1].

Caries Risk Assessment: Caries risk assessment (CRA) is the process of collecting data regarding various factors (e.g. bacterial level) and indicators (e.g. previous caries experience) to predict caries activity in the immediate future[2].

Formal CRA has been described as a four-step process:

1. Identification of measurable risk factors;
2. Development of a multifactorial tool;
3. Risk assessment to determine a patient's risk profile; and
4. Application of preventive measures tailored to the risk profile[3].

The risk assessment tool should estimate caries risk, identify the primary etiological factors, provide an inventory of the patient's current preventive practices,

Corresponding Author:
Dr. Swati Patnaik
Associate Professor, Department of Public Health Dentistry, Institute of Dental Sciences, S 'O' a Deemed to be University

and serve as a guide for selecting specialized preventive care tailored to that individual's needs.[4,5,6] Research has shown that experienced clinicians are often able to assess caries risk very quickly and accurately.[7,8,9]

Performing a CRA assists practitioners in providing, patients with appropriate levels of preventive care and to avoid unnecessary procedures[10,11]. If dental professionals were able to identify, in advance, individuals at the greatest risk of developing dental caries, the cost of caries prevention procedures could be markedly reduced and their efficiency greatly increase Dental caries management by formal risk assessment represents a significant change in the profession and should be incorporated into daily practice as dictated by practices of evidence-based standards of care. CRA should be routinely built into preliminary and recall examinations as the findings help to guide the patient's designated course of treatment. This is especially important before extensive prosthodontics, restorative, and orthodontic treatment is undertaken to ensure a favourable prognosis[13, 14].

Need for having CRA:

CRA may be valuable in the clinical management of caries by helping dental clinicians to:

1. Categorize the level of the patient's risk of developing caries to control the intensity of treatment rendered.
2. Pinpoint main etiological factors that contribute to the development of decay and thus determine appropriate form of therapy.
3. Assist in restorative treatment decisions (e.g. choice of restorative material).
4. Improve prognosis of planned therapeutic care.
5. Provide information on what additional diagnostic tests and screening are required.
6. Educate and motivate patients to improve and maintain optimum oral health.
7. Guide timing of subsequent recall appointments.

CRA tools screen people based on risk factors and predictors and classify patients into one of three risk categories- low, moderate, or high[6,15,16] If new caries has developed since the last examination, the patient is categorized either as moderate or high risk depending on the time elapsed since the last examination, and the number and severity of carious lesions[17]. Diagnosing a moderate risk group accuratelyis the greatest challenge. These patients, along with people who are at risk without any apparent signs or symptoms of disease, benefit the most from identification from CRA[18,19].

Although dental caries has long been established to be a disease of multifactorial ethology, many of the traditional caries prediction models have focused on individual factors associated with high caries activity[20]. More recently, the multifactorial etiology of caries points in the direction of constructing a more promising risk assessment model that includes the various factors that contribute to the development of caries as: host resistance, cariogenicity of the diet, and microbial pathogens.[2, 21, 22]

Caries risk assessment model: There are two frameworks that can be used for the development of CRA instruments: *the risk model and the prediction model*. The risk model, or sometimes called the etiologic model, is employed when one wants to identify the risk factors for the disease to implement the most effective prevention and treatment interventions. It detects only true risk factors and is typically simple to use, but it is not intended to predict future caries risk. Because of its simplicity and stability across different subgroups of the population, it is often used for screening in public health domains[23, 24].

In contrast, a prediction model uses both risk factors and risk predictors to maximize its ability to identify low and high risk individuals (i.e. maximize sensitivity and specificity). Risk factors (e.g. *Streptococcus mutans* counts) are often more costly to measure; however, they tend to be more reliable in caries prediction. Caries-risk assessment models involve a combination of factors that include diet, fluoride exposure, a susceptible host, and micro-flora that interplay with a variety of social, cultural, and behavioural factors. Caries risk assessment is the determination of the likelihood of the incidence of caries (i.e., the number of new cavitated or incipient lesions) during a certain time period or the likelihood that there will be a change in the size or activity of lesions already present. With the ability to detect caries in its earliest stages (i.e., white spot lesions), health care providers can help prevent cavitation. It can be done using cariograms, risk assessment forms designed by various institutes (AAPD, CAMBRA).

Selection of Risk Assessment Instrument

The principle of risk assessments is that individuals

with elevated levels of risk factors will receive more aggressive preventive interventions. Because of this, examiners must be cautious in how they categorize patients in the various risk levels. One must decide at what stage a risk factor changes from low to moderate to high risk categorization. This can prove to be a difficult task as many etiological factors do not have a clear demarcation between absence and presence, but normally range from excellent to poor (e.g. oral hygiene) or from low to high (e.g. *Lactobacillus* counts).

In creating a CRA tool, a balance between sensitivity (percentage of truly diseased persons who test positively) and specificity (percentage of persons without the disease who test negatively) must be made.[24] In doing so, a balance is struck between the number of false positives (i.e. patients assumed to be high risk but do not develop caries) and false negatives (i.e. patients assumed to be low risk but develop caries). It is imperative that the values of sensitivity and specificity remain high to ensure that a patient labelled as high risk truly has the disease and the threat of identifying low risk individuals as diseased should be minimal.

Because it is impractical to believe that a diagnostic test would have sensitivity (Se) and specificity (Sp) values of 100%, different criteria and cut-off points have been established by researchers investigating caries risk[26,27]. Wilson and Ashley suggested that Se and Sp values each be set at 80% to be considered an acceptable test for caries risk. Alternatively, it has been recommended by Fleiss and Kingman that the combined Se and Sp of a risk model should be at least 160%, which has become the gold standard amongst many researchers. Unfortunately, this benchmark value has only been achieved by a small number of caries prediction instruments.[23]

Several tools have been used to assess the cries risk. A few of them have been enlisted below:

Caries risk assessment form was introduced by the ADA[28]. The clinical judgment of the dentist may justify a change of the patient's risk level (increased or decreased) based on review of this form and other pertinent information. For example, missing teeth may not be regarded as high risk for a follow up patient; or other risk factors not listed may be present.

The assessment cannot address every aspect of a patient's health, and should not be used as a replacement for the dentist's inquiry and judgment. Additional or more focused assessment may be appropriate for patients with specific health concerns. As with other forms, this assessment may be only a starting point for evaluating the patient's health status. The ADA plans to periodically update this tool based on:

1. Member feedback regarding its usefulness, and;
2. Advances in science. ADA member-users are encouraged to share their opinions regarding this tool with the Council on Dental Practice.

Two forms have been devised to assist the caries risk assessment, for the age group of less than 6 yrs. of age and that of above 6 yrs. of age. Apart from the forms, one of the most important tool of CRA is cariogram. The details have not been discussed in this article.

Public Health Significance: If the CRA tool is to be used at the public health level for mass screenings, it may be advantageous to have a higher specificity as, Public health administrators would want to avoid false positives in order to avoid over treatment of individuals that do not necessarily require the preventive services. This is especially crucial in environments where resources are scarce. On the contrary, it may be more advantageous from an ethical and economic standpoint to increase the sensitivity of the test in order to avoid false negatives. Failure to identify those at risk for caries development may result in unnecessary treatment in the future that may be more costly and painful to the patient due to the progression of undiagnosed disease. Although increasing the sensitivity may result in over treatment of some patients, if the clinician uses an appropriate preventive strategy, this would result in little to no harm to the patient in that dental caries would not be permitted to start or progress.[12]

Caries risk assessment by dentists: In recent years, a lot of importance has been attached to formal caries risk assessment to guide treatment planning decisions and recall intervals for individual patients, and various risk assessment tools and checklists have been developed for this purpose. With an established protocol on caries risk assessment, the factors that contribute to a child having caries are identified, and modifiable risk factors can be addressed. The Caries Risk Assessment Checklist (CRAC) has been developed by the Irish public dental service to encourage a formal, risk-based approach to the management of caries in Irish school-children. Given that the Guideline Development Group considered all children to be at risk of developing caries, it was decided at the outset that the checklist would only record high caries risk status.[20-24]

Re-assessment of caries risk: Caries risk assessment is a continuous process, as an individual's risk status can change over time. In the public dental service, intervals between dental assessments for most children are measured in years rather than months. A guideline on dental recall, which was developed for the NHS in the UK by the National Institute for Health and Clinical Excellence (NICE), recommended that the "*interval between oral health reviews should be determined specifically for each patient and tailored to meet his or her needs, on the basis of an assessment of disease levels and risk of or from dental disease*." The guideline also recommended that "*the longest interval between oral health reviews for patients younger than 18 years should be 12 months*" based on evidence that the rate of progression of dental caries can be more rapid in children and adolescents than in older people, and seems to be faster in primary teeth than in permanent teeth.[20-24]

Conclusion

Caries risk assessment, based on a child's age, biological factors, protective factors, and clinical findings, should be a routine component of new and periodic examinations by oral healthcare providers. There is not enough information at present to have caries risk assessment analyses, estimating children at low, moderate, and high caries risk by a preponderance of risk and protective factors will enable a more evidence-based approach to dentists' referrals, as well as establish periodicity and intensity of diagnostic, preventive, and restorative services.

Osteomyelitis of Jaw: A Review

Ronisa Swain

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Osteomyelitis of the jaw in dental practice has seen to be decreased due to the increasing awareness among the general population about oral hygiene and the various treatment modalities available in dentistry. Often the maxillofacial region is involved due to improper treatment, compromised immunity, fracture, or any other reason. It is due to the inoculation of bacteria because of multiple factors. The diagnosis is based on clinical findings, radiographs, and lab findings. Osteomyelitis is managed by both conservative and surgical management. With the availability of more potent antimicrobials and treatment under aseptic conditions, management of osteomyelitis has been possible.

Keywords: *Osteomyelitis, Sequestra, radiography, management.*

Introduction

Once being a dreaded disease in the pre-antibiotics era, the incidence of osteomyelitis of jaws has become less, because of awareness, availability of antimicrobials, and better dental health services. The word 'osseous' is from Latin origin which means bony, 'osteon' from Greek origin meaning bone, 'myelos' means marrow, and 'it is' means inflammation.[1]

Osteomyelitis may be defined as an inflammatory condition of the bone, that begins as an infection of the medullary cavity and Haversian system of the cortex and extends to involve the periosteum of the affected area. It is an inflammatory process with the tendency to progress. Because of poorly vascularized cortical plates, mandible shows a higher incidence of osteomyelitis.[2-5] Mandible gets its blood supply from the inferior alveolar neurovascular bundle. Maxilla being less dense shows less incidence as it is highly vascularized and gets its blood supply from numerous feeder vessels. Maxillary posterior region is less affected than the mandibular posterior region. Even in mandible,the most common sites are body, symphysis, angle, ascending ramus, and the condyle. The severity and high frequency of odontogenic infections in daily dental practice and the heavy bacterial load of the oral cavity is one of the major reasons why osteomyelitis of the jaw is more common than any other skeletal bone.[2-5]

Staphylococcus aureus or *Mycobacteria* are the most specific bacteria causing infection, other causes may include trauma, radiation, or certain drugs.[6] Diminished host defense mechanism whether local or systemic contributes to its emergence. Diabetes, malignancies, autoimmune diseases, malnutrition are some of the other causes that may associate with osteomyelitis.[3] Osteomyelitis can be described by inflammation of the mouth, exposed bone in the mouth which fails to heal, unhealing extraction socket, presence of fistula from mouth to lower skin, or development of sequestra.[7,8] It starts as an infection of the medullary cavity, spreads to the Haversian system, and gradually involves the periosteum of the infected area leading to severe tissue and bone destruction.[9-11] There is progressive inflammatory osteoclasia and ossification.[6] Radiation related osteomyelitis shows a delayed onset and tooth extraction and implant placement is also contraindicated in that area which has been irradiated.[12]

Predisposing Factors: The predisposing factors of osteomyelitis are: (1) A delayed host defense mechanism or any condition that affects the host resistance, (2) Lack of vascularity of the host bone at a local or systemic level, and (3) virulence of microorganisms. The host defense system gets by the presence of any immunocompromising condition like Diabetes mellitus, leukemia, malnutrition, agranulocytosis, severe anemia, chronic alcoholism, drug abuse, sickle cell disease, typhoid, chemotherapy, irradiation, steroid use, hepatitis, HIV, glomerulonephritis, systemic lupus erythematosus, etc.[1,3,13] The vascularity of the host bone is altered due to therapeutic irradiation, Paget's disease, bone malignancy, fibrous dysplasia, osteoporosis, mercury; arsenic, and bismuth causing metallic bone necrosis. In the maxilla, osteomyelitis can occur due to any pansinusitis or facial cellulitis. Due to the lysosomal activity,certain organisms form thrombi. A protective barrier is formed around the infective foci by the pathogen born bioactive peptides and the chemoattracted leukocytic purulence which leads to lysosomal and enzymatic destruction of the tissues along with microvascular thrombi formation. The organisms further proliferate in the host medium but remain protected from the host defense mechanism. [1,3,13]

Etiology:

Odontogenic infection arising from pulpal, periapical, pericoronal tissues, infected cyst, socket, or tumor are one of the major cause of osteomyelitis. Trauma is the second most common cause especially compound fracture and any iatrogenic surgery.Oro-facial infections derived from periostitis following the gingival recession, infected lymph nodes from furuncles, peritonsillar abscess, lacerations are also seen to cause osteomyelitis. Furuncle on the face, upper respiratory tract infection, mastoiditis, wound on the skin, middle ear infection, systemic tuberculosis cause infection to spread via hematogenous route.[1,14]

Pathogenesis: The primary hematogenous osteomyelitis is very rare but can be seen at a very young. In adults, the primary cause being the inoculation of bacteria in the jaw bone. This insult results in the initiation of an inflammatory process or cascade. In a normal or healthy host, this may self-heal or self-limit itself, but in a compromised host it can lead to a process that is no more considered physiologic but pathologic. With increased inflammation, there is increased blood flow to that area and increased hyperemia. Further leucocytes are recruited to fight against the infection.[3] Pus formation occurs and a continuous supply of bacteria and cellular debris occurs that cannot be eliminated by the body host defense mechanism. When the pus and the inflammatory process starts in the bone marrow, the intramedullary pressure increases, and the blood supply decreases to this region. The pus then travels via Haversian and Volkmann's canals to spread through-out the medullary and cortical bone. Once the pus has entered the cortical bone and gets collected under the periosteum, the local conditions are aggravated by compromising the blood supply to that area.[3] Finally, the pus exits the soft tissue by intraoral or extraoral fistulas.[3] Osteomyelitis starts by bacterial invasion in the cancellous bone, followed by acute inflammation hyperemia, increased capillary permeability, and infiltration of granulocyte. It is an infectious process of the medullary myeloid cavity and only the mandible and the calvarium has myeloid compartment.[1]

Microbiology

Aerobic streptococci (alpha-hemolytic streptococci, *streptococci viridans*), anaerobic streptococci; and other anaerobes, such as Peptostreptococci, Fusobacteria, and Bacteroides cause many cases of osteomyelitis. Sometimes, anaerobic or microaerophilic cocci, Gram-negative organisms such as *Klebsiella, Pseudomonas,* and *Proteus* are also found. *M. tuberculosis, T. pallidum,* and *Actinomyces* species cause some specific kind of osteomyelitis. Marx et al. (1992), identified Actinomycoses, *Eikenella,* and *Arachnia* as pathogens of some other refractory osteomyelitis.[1,3, 14]

Classification:

Table 1. Classification of osteomyelitis of jaw

Historically accepted classification based on the clinical course: Hundson's classification of osteomyelitis of jaw:	**Acute forms** Contiguous focus: trauma, surgery, and odontogenic infection • Progressive: burns, sinusitis, and vascular insufficiency • Hematogenous (metastatic): developing skeleton (children)
	Chronic forms • Recurrent multifocal: Developing skeleton (children), Escalated osteogenic activity (< age 25 years) • Garre's: Unique proliferative subperiosteal reaction, Developing skeleton (children to young adults) • Suppurative or Non-suppurative: Inadequately treated forms, Systematically compromised forms, and Refractory forms (CROML: Chronic Refractive Osteomyelitis) • Diffuse sclerosing: Fastidious organisms, and Compromised host or pathogen interface.
Classification is based on the pathogenesis of altered vascular perfusion as a major contributing factor to the presence and persistence of osteomyelitis as a clinical disease. (Vibhagool et al 1993).	**There are three types:** • Hematogenous osteomyelitis • Osteomyelitis secondary to a contiguous focus of infection • Osteomyelitis associated with or without peripheral vascular disease
Classification based on the presence or absence of suppuration	**Suppurative osteomyelitis** a. Acute suppurative (pyogenic) osteomyelitis b. Chronic suppurative (pyogenic) osteomyelitis i. primary ii. secondary c. Infantile osteomyelitis
	Nonsuppurative osteomyelitis a. Chronic sclerosing osteomyelitis i. Focal sclerosing osteomyelitis ii. Diffuse sclerosing osteomyelitis b. Garre's sclerosing osteomyelitis c. Actinomycotic osteomyelitis d. Radiation osteomyelitis (osteoradionecrosis) e. Specific infective osteomyelitis i. Tuberculosis ii. Syphilis
Classification and Staging system of osteomyelitis developed by Clerny et al. and Vibhagool	**Anatomic type:** **Stage I** Medullary osteomyelitis It involved medullary bone. Without cortical involvement, usually hematogenous **Stage II** Superficial osteomyelitis Less than 2 cm of the bony defect without cancellous bone **Stage III** Localized osteomyelitis Less than 2 cm bony defect seen on the radiograph, the defect does not appear to involve both cortices **Stage IV** Diffuse osteomyelitis The defect is less than 2 cm Pathological fracture, infection, and nonunion
	Physiological type: A Host: Normal host; B Host: Systemic compromise (Bs); local compromise (Bl); C Host: Treatment is worse than the disease

Systemic or local factors that affect immune surveillance, metabolism, and local vascularity.

a. Systemic (Bs): Malnutrition, renal or hepatic failure, diabetes mellitus, chronic hypoxia, immune deficiency or suppression, malignancy, extremes of age, autoimmune disease, and tobacco and alcohol abuse.

b. Local (Bl): Chronic lymphedema, venous stasis, major vessel disease, arteritis, extensive scarring, radiation fibrosis, small vessel disease, and loss of local sensation.

Clinical Presentation: The classical clinical features are pain, swelling, and erythema of the overlying tissues, fever, paresthesia of the inferior alveolar nerve, paresthesia of lower lip, adenopathy, trismus, malaise, fistulas, and sometimes pathologic fracture.[1-7] The pain is a generally deep and boring type. In the case of Acute osteomyelitis swelling and erythema is very common to see which indicates the cellulitic phase of the inflammatory process under the bone. Fever often accompanies it but in the case of chronic osteomyelitis, it is not seen. Due to the inflammatory process, there is continuous pressure on the inferior alveolar nerve, hence, paresthesia of the inferior alveolar nerve is the characteristic feature of osteomyelitis. In the case of inflammation in the muscle of mastication of the maxillofacial region, there is trismus. The patient gradually feels weak and malaise and may associate with any other systemic disease. Generally intraoral and extraoral fistulas are seen in the case of chronic osteomyelitis.[3]

In Acute osteomyelitis, the early cases are characterized by generalized symptoms like fever; malaise; nausea; vomiting; anorexia, deep-seated boring and continuous pain, intermittent paresthesia or anesthesia of lower lip, facial cellulitis or indurated swelling of moderate size, thrombosis of inferior alveolar vasa nervorum, rise in pressure from edema in the inferior alveolar canal, teeth are tender to percussion and loose and trismus. In established cases there is deep pain, malaise, fever, dehydration, anorexia, tender on percussion of the teeth in that area, teeth become loose, purulent discharge through sinuses, presence of fetid odor, trismus may be present, acidosis, toxemia, regional lymphadenopathy.[1,2]

In chronic cases, there is pain and tenderness but the pain is minimal, non-healing bony and soft tissue wounds with induration of the soft tissue, intraoral or extraoral draining fistula, thickened or wooden characteristic of bone, enlargement of the mandible because of deposition of subperiosteal new bone, a pathological fracture may occur. [1,2]

Lab findings: The laboratory studies show slightly raised ESR (Erythrocyte sedimentation rate), elevated C-reactive protein (CRP), moderate leukocytosis (PMNL), anemia, and albuminuria In acute cases leukocytosis is common but in chronic cases, it is not common.

Histopathology of biopsies shows scattered inflammatory infiltration, mainly lymphocytes, histiocytes, plasma cells, and neutrophil granulocytes, increased osteoblast, thickened bony trabecula, and fibrous marrow replacement.[8-15s]

Radiographic findings:

The following method can be used for radiographic analysis:

Conventional radiography: The radiographic changes can be appreciated after 3 weeks of the onset of osteomyelitis. At least 40-60% of bone destruction should be there to mark any radiographic changes. This alteration is seen 4-8 days after the onset of acute osteomyelitis. In the early stages, areas of sclerosis and osteolysis with varying degrees of periosteal reaction is seen as mixed radiodensities. There is a "mottled appearance"due to the widening of marrow space and enlargement of Volkmann's canals. The irregular lines and zones of radiolucency give "moth-eaten appearance" due to the presence of granulation tissues between the livings and dead bone. In later stages, gradually the cortical bone gets involved and an island of cortical bone gets mobilized by the osteolytic process which is devitalized and is favorable for the precipitation of calcium. These separated devitalized calcified bone with resorbed periphery act as a foreign body and are prominent in the radiograph which is called a sequestrum. The subperiosteal new bone is seen as opaque lines over the cortex called Involucrum. A "fingerprint" or "onion peel appearance" is seen at the place where the new bone is superimposed upon the jaw.[1-4]

Imaging: This includes computerized tomography (CT), Positron emission tomography (PET), radioisotope scanning. Computed tomography gives a more clear picture of the involved calcified bone and the cortical plates. There is less radiation exposure to the patient.

Radioisotope Tc-99m methylene diphosphonate bone scanning helps to identify the margins of calcified tissue involvement, but, it has very poor resolution. Positron emission tomography (PET) recently have been more promising for evaluating metabolic activities. It uses radioisotopes of physiologically active compounds like glucose, ammonia, fluoride and the changes can be seen as early as 3 days.[1]

Treatment: The treatment of osteomyelitis requires both medical and surgical approach. Very rarely it requires intravenous antibiotic therapy like in the case of infantile osteomyelitis [3]. Based on the histopathological features i.e. gram stain results of the exudate or suspected pathogen, empirical antibiotic treatment should be started.Culture and sensitive reports may take time but guide the surgeon for treating the patient.[3]

In general, treatment[1] consists of:

i) Debridement

ii) Control of infection: acute infection is controlled through antibiotic therapy. However, as there is no circulation in the necrotic bone so the antibiotic does not reach.

iii) Hospitalization

iv) Other supportive treatment: a) hydration: fluid therapy, b) high protein and vitamin diet.

v) Analgesics: Narcotic and non-narcotic analgesics. Bupivacaine (Marcaine), alcohol nerve blocks, nerve avulsion, rhizotomy.

vi) Good oral hygiene: oral rinses, such as 1% sodium fluoride gel, 1% chlorhexidine gluconate, and plain water help to prevent radiation-induced caries from the xerostomia and mucositis by providing some local augmentation of the host immune antimicrobial activity.

vii) Frequent irrigations of wounds.

viii) Exposed dead bone: small pieces of bone may become loose and can be removed easily.

ix) Hahn and Corgill in 1967 gave the treatment of small areas by drilling multiple holes into vital bone as a means to encourage sequestration.

x) Sequestrectomy is performed intraorally, because of skin and vascular damage resulting from irradiation.

xi) Pathological fractures are not so common. These may occur from minor injuries. The fractures do not heal readily. Excision of necrotic ends of both fragments and replacement with a large graft is the best treatment. Reconstruction of bone defects usually warrants major soft tissue flap revascularization support.

xii) If there is persistent pain, infection, or pathological fracture, bone resection is performed. It is done intraorally to avoid orocutaneous fistula in radiation compromised skin.

xiii) Hyperbaric oxygen therapy is a useful adjunct. It increases the tissue oxygenation levels which helps to fight any anaerobic bacteria present in these wounds.[1]

Surgical Options: The classic treatment is sequestrectomy and sauterization. The main aim is to remove the necrotic or less vascularised bony sequestra and improve the blood flow. In sequestrectomy infected and avascular pieces of bone are removed, it is generally the cortical plates in the infected area. In saucerization adjacent, bony cortices are removed up to a good bleeding bone and an open pack is given for healing by secondary intention. Decortication is also done in which removal of dense, basically chronically infected and poorly vascularized bony cortex is performed and a vascular periosteum adjacent to the medullary bone is placed to increase the blood supply.[3]

Conclusion

Osteomyelitis of the jaw is an inflammatory condition that is multifactorial. A dentist should be aware of the predisposing conditions and know how to manage the condition.

Accidental Periodontitis Induced by Orthodontic Treatment: A Review

Sadaf Nayab

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, 751003, Odisha, India

Abstract

This article aims to encapsulate the effect of appliances on the periodontal health of patients undergoing orthodontic treatment. While orthodontic treatment provides benefits to a wide range of intra-oral and extra-oral issues starting from aesthetics to mastication, there are some major setbacks in terms of relapse if the treatment is not carried out with a proper plan. Therefore, with limitations in maintaining a desired oral hygiene, which breeds various periodontal problems, iatrogenic causes further narrow down a good prognosis which is desired at the end of an orthodontic treatment or in fact, any medical procedure. This is a review of the unnatural and natural impact of orthodontic treatment on the tissues periodontium and the treatments associated with it.

Keywords: *Orthodontics, Chronic Periodontitis, Iatrogenic effects, Periodontal Health.*

Introduction

The earliest evidence-based history of dental practice can be found in the era of Indus Valley Civilisation which dates back to 7000 BC.[1] The journey from a 6500-year-old jawbone with a cavity within the dentin layer with beeswax as a filling, to the first dental journal being published in 1839 and now, the use of advanced and efficient techniques for diagnosis and treatment has been remarkable. But the emergence and evolution of orthodontic treatment has been one of the most significant breakthroughs in this field as it fulfills the requirements and comprehends with both, the occlusal and facial abnormalities both at the same time to a fairly acceptable state.[2]

The earliest attempt to the correction of a teeth irregularity was done by Pliny the Elder by mechanical filing of elongated teeth to bring them to proper alignment in the period of 23-79 AD.[2] In the year 1619, Fabricius[3] suggested the extraction of tooth for correction of crowding. It was the introduction of 'brace' the 'bandeau' by Pierre Fauchard[4] also known as the father of modern dentistry, that increased the pace of orthodontics exponentially as it paved the way for all the appliances and their appendages invented later with his discovery that 'the malalignment of teeth can be corrected as teeth would follow the pattern of the brace'[5]. With time, the advancement in orthodontics have made adaptations which brought changes in function and esthetics, function being its prime priority.

However, the most significant part of an orthodontic treatment still is to keep the integrity of the entire dentition intact in the best way possible to make sure that there is no ailment to the patient in the infinite future. Orthodontic treatment involves the movement of the entire tooth from one location to another which is why the periodontium, along with the tooth, plays a crucial role in the beginning, during, and end of the treatment. This also suggests that the standard appliances used, which include orthodontic braces, archwires, and elastic bands should be used befittingly to obtain the desired results.[4,5]

Therefore, to accommodate with the changing

Corresponding Author:

e-mail: nayabsadafids15@gmail.com

concepts of function and esthetics with a varying range of patients having their oral hygiene practices, this kind of treatment has its risks and complications amongst all the benefits, some of which are unwanted side effects, which include decalcification of enamel and discoloration of teeth and some are extensive conditions like periodontitis, pseudo pockets, root resorption and bone loss due to iatrogenic causes.[6]

Potential upshots of orthodontic wires on the tissues of the periodontium: It was in the 1980s when the earliest cases of periodontal destruction due to orthodontic wires were given attention.[7] The diverse use of elastics ranges from correction of Angle's Class II and Class III malocclusion, correction of malposed tooth, crossbite, and midline diastema to the non-surgical removal of tooth in case of hematological diseases like Haemophilia. The main cause of elastics being used so widely among dentists for the patients is its cost-effective nature and ease of placement and removal.

While plaque is considered to be the most important factor determining the periodontal health of the patient, placement of elastic bands and the archwires play a key role in the same during an ongoing treatment. Experimental studies on animals have shown that orthodontic forces & tooth movements do not induce gingivitis in the absence of plaque.[8] However similar forces can induce angular bone defects in the presence of plaque. Orthodontic tooth movements like tipping & intrusion can cause attachment loss in the presence of plaque.[9] Any neglect from either the practitioner or the patient during this treatment can be a cause of various periodontal problems with periodontitis being one of the complicated ones. Hence at the beginning of an orthodontic treatment, a patient must be made aware of the maintenance of oral hygiene throughout and after the treatment concludes to avoid long term diseases like chronic periodontitis and a probability of relapse.

Figure 1: Gingival Inflammation and plaque accumulation during orthodontic treatment. Source.[17]

Incorrect placement of orthodontic brackets: When an orthodontic treatment is carried out sufficing the periodontal needs, the results are excellent but it's the iatrogenic nature of the use of elastics along with the hygiene which causes undesired outcomes, periodontitis being a common one. What most of the practitioners fail to understand is that the errors start to occur with the placement of the braces itself. A wrong placement of molar bands, mainly on a subgingival level, besides with accumulation of food particles has the potential to intrude the alveolar bone[10], which further aids in the characteristic osseous defects caused by extensive inflammation and gingival recession.[11] The magnitude of forces also plays a key role in the relationship between periodontal tissues and orthodontic forces as it is seen that the extent in magnitude of orthodontic forces affects the rate of root resorption.

Attachment Loss: Elastic bands, due to their shape memory tend to retain back to their original place, and hence there is a dire need of thorough inspection of their position when they are placed in a patient's mouth especially when there is no specific placement mechanism. This is why the bands tend to creep down the narrower end of the crown of the tooth.[12] and move thereby apically creating an expected periodontal ligament destruction resulting in bone loss due to periodontitis and subsequently, the extrusive movement of the tooth. This happens because the elastic bands act as foreign material causing an inflammatory reaction of the soft tissues leading to the weakening of periodontal attachment. Incidentally, the apical extension of the band is, however, independent of microbial colonies present in plaque.

Effects on gingival embrasures: One of the main criteria that decide the esthetics of a patient is the gingival embrasures, which are the V-shaped spaces present inter proximally around the proximal contact present in between the adjacent teeth[13], the embrasures present on the anterior teeth playing the important role. The treatment of patients with already existing periodontitis is a cause of concern as such patients are at risk of further bone loss and loss of tooth with due course of time. Prevention of black triangles on esthetic zones and preservation of interdental papilla are to be taken into consideration as a priority during the treatment. The gingival recession associated are not dependent on the orthodontic treatment but are dependent on the type of forces applied for tooth movement. Some factors like thickness or cortical plates, type of load distribution,

type of forces, tipping in general, and morphology of teeth like lower incisors also contribute to the formation of gingival recession as an adjunct to the treatment.

Tooth Mobility: The biology of movement follows the sequential pattern of bone resorption and bone deposition in the pressure side and tension side respectively. This process shows the widening of periodontal ligament space in radiographic examination.[14] Hence this phase is a result of temporary mobility of the tooth. But extensive bone loss or an extended long term treatment with ill-maintained oral hygiene may cause exfoliation if it is not given attention by the practitioner. When the forces applied are extremely large in magnitude, it causes greater undermining resorption and hence the mobility of the tooth is to a greater extent. This could be avoided by the forces and changes associated with it are monitored and if there is mobility.[15]

All movements should be temporarily discontinued until the movement reduces to a moderate level.

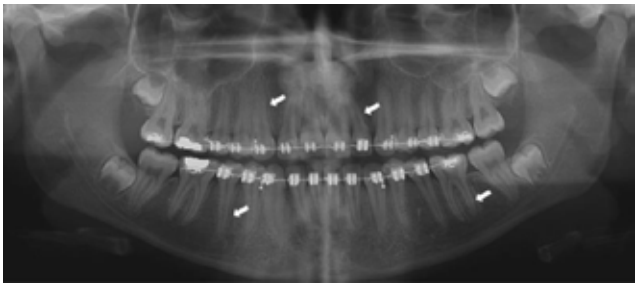

Figure 2: Radiograph demonstrating widening pf PDL due to excessive orthodontic forces[18]

The image shown above represents a panoramic radiograph representing the increase of periodontal ligament space on the application of orthodontic forces during an orthodontic treatment. As the strain on the periodontal ligaments increase, the PDL space widens leading to the gradual mobility of tooth and associated periodontal issues.

Iatrogenic Damage: This is one of the rare causes of chronic illness which is very significant as its existence might be unknown for a long time and the diagnosis and treatment are hence delayed, with outcomes sometimes beyond repair. There are not many cases regarding a specific error but the unknown persistence of discarded or broken elastic wire inside the periodontium is a leading cause of chronic periodontitis, abscess, and mobility on a long term basis.[16] Another cause may be the apical migration of an elastic band which later on gets covered by the surrounding gingiva without the knowledge of the patient and later leads to periodontal destruction inside the root of the tooth giving the clinical manifestations years later. The timing of diagnosis of such conditions is crucial as the treatment plan is solely dependent on it and the intensity of the diseases associated with this becomes severe with time. The diagnostic time may vary from months to years, but it the practitioner's call to manage it as soon as it is diagnosed and confirmed.

Treatments for periodontitis in orthodontic treatment: The first and foremost thing after such a condition is suspected there is a temporary discontinuation of the orthodontic treatment and involving a periodontist for creating a detailed treatment plan with a proper case history describing the duration of the ongoing treatment and the incidence of the disease. This helps the practitioner decide the extent and severity of the disease and eases the route of the treatment plan. After there is a confirmed diagnosis of such condition, the treatment depends on the prognosis of the tooth which is predicted by radiographic images and gingival examination. For cases with moderated recession careful scaling and root planing is done to ensure the absence of any foreign substance to aid the healing for the treatment to be carried out smoothly. The treatment plan follows that of the usual periodontal problems, from recession to mobility with its varying grades and hence the treatment modalities include scaling, root planning, splinting, gingival surgeries which include flap surgery which is done in cases where furcation is involved which is followed by subsequent repositioning of the tooth. All of this done along with a post-surgical antibiotic therapy which includes drugs lie Amoxicillin and a prophylactic dose of Chlorhexidine mouthwash for maintenance of oral hygiene.[16] All of this is performed on adults with consent and due information about the success rate of the surgery and the prognosis of the tooth and the same procedure is followed when a minor is getting treatment but here, the parents of the patient are informed accordingly. The success of this type of situation is purely based on the maintenance and thorough monitoring of the patient with regular intervals of recall. During every appointment during the revisits, oral prophylaxis and reinforcement of oral hygiene instructions are the building bricks for a good prognosis. All the clinical parameters like periodontal pocket depth, bleeding on probing, mobility is regularly checked. If there is a relatively low mobility or the loss of attachment reduces significantly with time, reduction in

erythema can be observed with increased firmness. After the periodontal health improves to a satisfactory state, the orthodontist is now ready to move further along with the desired treatment plan for the orthodontic correction only after consulting with the concerned periodontist.

Conclusion

An orthodontist must always ensure the state of a periodontal condition of the patient before heading for a treatment as the treatment as such provides a good boost to patients by providing a better functioning dentition and desired profiles for the individual who needs it and by this it also ensures self-confidence, lifestyle and a good self-esteem. But amongst this, the risks associated are a reality that cannot be ignored. The complications of such treatments possess a multifactorial process including the practitioner, patient, the treatment procedure itself, and the appliances associated with it. An orthodontic treatment of an individual goes hand in hand with the periodontal health. Therefore it's the role of the practitioner to be keenly involved in the treatment procedure and detect any source of error, if at all that exists, as early as possible to achieve the expected results. The improper use of any appliance or its appendage can cause periodontitis and can enhance bone loss in the long run during or even after the treatment is finished. For such cases, a detailed clinical examination and a meticulous treatment plan is necessary because it is the correct diagnosis and treatment which practically decided the fate of the defect caused. If done timely, a patient can be benefitted from early diagnosis as well as the correct management. Not everything is the responsibility of the practitioner, especially when the treatment is for a long duration and requires compliance from the patients themselves. Therefore, the importance of the treatment should be informed by the practitioner so that it is taken seriously. It is often considered that the orthodontist should explain the need and function of the appliance being used for the treatment because it helps the patients understand the need of keeping the integrity of the nature of the management by being vigilant themselves and also be informed about their treatment status. If children are the patients, the parents should actively participate in getting educated about the need of maintaining good hygiene while the treatment goes on while the orthodontist handles the rest.

As there is always a scope of marginal error, it is required that the practitioner informs their patients to report any unusual activity in their oral cavity as this could be the sign of the problem which lies underneath. Lastly, a good coordination among fellow practitioners is highly required which benefits both the patients and the practitioners by making them aware about such problems which may or may not have an iatrogenic cause just so that when the time comes, a practitioner is ready to diagnose it on time, deal with the situation and most probably manages it on time.

Space Maintainer: A Review

Subhashree Samal

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Space maintainers are useful incases of deciduous teeth to protect the dentition from malposition,impaction, crowding,etc. They can also be used inmixeddentition. Various types of space maintainersare there for Particular treatment. This is mainly aimed atthe management of space in children. This article mainly aims at Bandandloop,Distal shoe, and trans palatal arch space maintainers.

Keywords: *Band and loop, Distal shoe, Trans palatal arch space maintainers, Removable space maintainers.*

Introduction

Early loss of primary dentition occurs very commonly in children due to various causes like maintenance of oral hygiene, dental caries is the most common one. Deciduous dentition is very important in child growth and development in terms of speech, mastication, and the good eruption of permanent dentition. When the natural process of teeth exfoliation is disrupted due to various causes like early loss of deciduous teeth, proximalcaries, early childhood caries, avulsion, periapicalpathology, systemic causes like hyperthyroidism, downs syndrome,etc. It may result in the mesial movement oft he dentition, resulting in loss of arch length which may cause malalignment of adult teeth in form of crowding, impaction,supra-eruption, rotation, ectopiceruption, crossbite, overjet, etc. A space maintainer is a mechanical device that preserves the natural space after the early loss of deciduous dentition. Space Maintenance of arch length management of occlusal planes etc. It can also be used for esthetic purposes.[1]

Space Maintainers Classified By Various Method: Hitch cock classified them into removable/fixed/semi-fixed, banded/non-banded, functional/non-functional, active/passive. Raymond C. Thurrowis classified into Removable, Lingual arch, Individual tooth. Hinrichsen classified into Fixed space maintainers (Bar type, Loop type, Lingual arch type distal shoe, Band, and loop) and Removable space maintainers (Acrylic partial dentures).

Various indications of spacemaintainers include when there is early loss of deciduous teeth shows signs of closing or if there is any chance of orthodontics treatment or if the permanent teeth are not ready for eruption. There should be a minimum of 1mm of bone coverage.[2]

Various contra indication of space maintainers includes if bone coverage is absent or if the root of permanent teeth is the only 2/3rd or when the permanent teeth have not erupted and space needs to be closed or the mesiodistal width of the crown of the deciduous tooth is less than the permanent teeth.[1,2]

Basic requirements of space maintainers include: The space maintainers should have good proximal dimensions to occupy the space created by the teeth. The space maintainers should be functional. It should not interrupt with the eruption of the opposite teeth. It should be strong enough to withstand the force. It should not harm the adjacent tooth. It should be easy to clean. It should not interfere in the normal growth and function of the tooth.[3,4]

Band And Loop Space Maintainers: It is a fixed type of space maintainer and used in the forms of loop bands, tailored bands, preformed seamless bends. It

Corresponding Author:
Subhashree Samal
Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: samalsubhashree63@gmail.com

should possess the following; It should fit the teeth properly, it should not extend below the gingival margin, the band material it should be enough strong to resist the forces in the mouth. It should not tarnish. There should be no occlusal interruption.[3,4]

Preparation of Band space maintainers: Separation of teeth done by Brasswire, elastic threads. Band formation can bed one by a direct method which includes; Band pinching,festooning,trimming, folded flap. It can be also done by indirect method/preformed bands. Welding-by welding the bands are joined by soldering. Band and loop appliances are used when there is more than one tooth is a loss in the quadrant, it can replace occlusal function.[3,4]

Benefits of Band and loop: It can be cleaned easily. It maintains the vertical dimensions. It can be warm sometimes. Space can be created for the eruption of permanent teeth. It prevents tongue thrusting habits. It is cheaper and can be fabricated easily.[3,4]

Demerits of Bandand loop: It may be easily lost or broken by the patients. Some patients may not wear this. Side word jaw growth may be restricted. It may cause tissue irritation. It could not restore the occlusal function of the lost tooth.[3,4]

Indications of Band and loop: It is used in case of esthetic purpose, when the abutment tooth is not supportive, in case of cleft palate patients, in case of delaying permanent tooth eruption, if the permanent tooth does not erupt properly when there is several loss of primary teeth.

Contra indications of Band and loop: When the patient is not co-operative, patients are allergic to acrylic material, epileptic patients.[3,4]

Trans Palatal Arch Appliances: This applianceis mainly used for stabilizing the upper first permanent molars. It provides rigidity. It protects the first permanent molar from rotation.

Indications of Trans-palatal arch: The best indication is when one side of the arch is firmly fixed and various deciduous teeth are missing on the opposite side. It also indicated when the deciduous molars bilaterally missing. It can not be used when both permanent molars are mesially directed. In that case, Nance palatal arch is recommended.[5,6]

Benefits of Trans-palatal arch: Due to the absence of an acrylic base there is less tissue irritation and could be clean easily so preferred for oral hygiene maintenance.[5,6]

The demerit of Trans -palatal arch: This appliance fails to remain passive. Due to this, there are chances of vertical and transverse movement of permanent molars that can happen.

Construction of Trans-palatal arch: A round wire of 0.036 inches is bent to make the palatal surface of the band. Then the mesial part of the palatal side of the band is constructed then the wire is bent to the distal part to form the joint. Then soldering is done and the wire is heated to make it passive.[5,6]

Distal Shoe Appliance:

This is the most ancient type of Space maintainers. It is used as a guiding device for the eruption of the first permanent molar mostly of the mandible . This is usually not used in the maxillary arch. Its arm managed the Leeway space of the second premolar and guides the eruption of the permanent molar. For that reason,it is designed to have a horizontal bar and intra alveolar extension which is used as a guiding plane. It should be used by the patients regularly until the eruption of the first permanent molar. Otherwise if not used regularly it shows negative effects.[7,8]

Indications of Distal shoe appliance: Early loss or extraction of a second deciduous molar before the eruption of the first permanent molar. It is used in the case of root resorption and periapical bone destruction of the second deciduous molar before the eruption of the first permanent molar. In the case of advanced dental caries in the second deciduous molar. Ectopic eruption of first permanent molar teeth. Ankylosis of deciduous second molar teeth.[7,8]

Contra indications of Distal shoe appliance: Lack of abutment teeth due to several loss of teeth. In the case of uncooperative patients. When the first permanent molar is absent. In the case of systemic diseases such as Diabetes mellitus. In the case of cardiac diseases, kidney diseases, juvenile diabetes, rheumatic fever, hemophilia require antibiotic treatment before dental treatment. In case of congenital missing of the first permanent molar.[7,8]

Crown Distal shoe appliance: It is also known as Willet's appliances or intra–alveolar appliances. This helps in guiding the path of eruption of the first permanent molar.

Indications of crown Distal shoe: Early loss of second deciduous molar before the eruption of the first permanent molar but first deciduous molar should be present as an abutment tooth.

Contraindications of crown Distal shoe: In the case of medically compromised patients and in patients who do not have good oral hygiene.

Stepsinthe placement of Crown Distal shoe appliance: First IOPA is taken of second deciduous molar and first permanent molar. Then the abutment tooth is prepared. Then perform metal crown is made on the abutment tooth. Then the cast is poured and the working model is prepared. Dimensions of the second premolar are measured on the IOPA then the horizontal arm of the Distal shoe is prepared. The vertical height should be 1 mm downwards the mesial marginal ridge of the first permanent molar. The primary second molar is trimmed and the desired horizontal length is marked.[9,10]

Fabrication and placement of Distal shoe Spacemaintainers: A cobalt-chromium bar or stainless steel of 0.9 mm wire is used. The wire is bent to the desired shape. The vertical height of the horizontal wire of the Distal shoe should not touch the opposite tooth. Then soldering is done and the metal crown is polished. In the next appointment, the second deciduous molar is extracted and the bleeding is managed. The infection of the crown is controlled. Then the metal crown and Distal shoe are tried in the mouth. Then an IOPA is taken and the location of the Distal shoe concerning the erupting first permanent molar is confirmed. Then final managements are done if required and then the metal crown with the Distal shoe is placed on the abutment tooth.[9,10]

Removable Space Maintainer:

It is used as a partial denture.

Active Removable Space Maintainers: Here a labial bow is made for the anterior teeth on the working model. The side which is affected by the U shaped wire is bent to protect the alveolar ridge between the first premolar and molar.[8-10]

Acrylicpartial Denture: It is indicated when there is several loss of teeth in the mandibular or maxillary arch. This is used when there is a bilateral loss of more than one tooth and can be used for the eruption of the tooth . It is constructed with stainless steel wire 0.036 inches on deciduous canines and permanent molars. It can also be used in permanent incisors when they are in an active state of eruption.[8-10]

Benefits of Removablespacemaintainers: It managesthemesiodistal space. It also maintains the vertical shape. Do not interfere with mastication. It helps in the improvement of esthetic in the anterior region. It does not interfere with speech. It helps in protection from oral habits.[8-10]

Demerits of Removable space maintainers: It is difficult in uncooperative and medically compromised patients.

Indications of Removable space maintainers: When there is an absence of more than two deciduous molars it is indicated. When there is an absence of more than one deciduous tooth bilaterally. In cases of absence of anterior teeth.[8-10]

Conclusion

This article mainly highlights the types of Space maintainers. Space maintainers are mainly very essential in children before eruption of permanent teeth as it maintains good oral hygiene. It helps in the preservation of deciduous teeth from deleterious oral habits and dental complications such as malalignment of teeth, rotation, crowding,etc. at a young age. Space maintainers help in the preservation of space when the teeth are prematurely lost. It helps in maintaining good esthetics in children. It also controls orthodontics complications which may occur in the future .Thus Space maintainers help in the better eruption of permanent dentition.

A Comparative Study on Effect of Motivation and Hope on the Well-being of Geriatric Population

Apoorva Sharma[1], Shikha Srivastava[2]

[1]B.A. (Hons) Student, [2]Program Chair and Head, Department of Applied Psychology, School of Liberal Arts, Galgotias University, Greater Noida, Uttar Pradesh India

Abstract

Introduction: For the last decade, the physical and the mental health has been the concern and most interest among the researchers. This relationship is most discussed among geriatric population, because of the various challenge's posed by the old age at various levels. Here in this study we have how motivation and hope enhances the living wellbeing.

Aim: To measure the effect of motivation level, hope and well-being of geriatric population

Methodology: The present study was conducted in Delhi – NCR societies. Overall sample size of the study was 60 elderly population both male and female. Hypertension elderly (n =30) and Healthy elderly (n =30). The study was conducted using Elderly Motivational Scale, Adult Hope Scale and Ryffs Psychological Well-Being Scale.

Conclusion: The well-being of hypertension group (experimental group) is at a higher side than healthy elderly group (control group).

Keyword: *Elderly, Hypertension, Motivational Scale, mental Health,hope.*

Introduction

Old Age: Old age refers to ages nearing or surpassing the life expectancy of human beings, and is thus the end of the human life cycle. Terms and euphemisms include old people, the elderly, seniors, senior citizens, older adults, and the elders.

The Psychology of Aging Today: While the population over the age of 65 is growing considerably, their lifestyle has also evolved. Older citizens might live independently, work into advanced age, and take an active role in any number of groups in their communities. According to the American Psychological Association, there are also mental health conditions that are more prevalent in those of advanced age

There are number of scenarios possible regarding senior lifestyle and health:

Mental Capacity: Mental capacity is always a concern for seniors because they are susceptible to different factors, such as dementia, which can hinder their ability to care for themselves mentally. Other possible health issues, such as stroke, can cause issues with mental acuity. Many seniors who face deterioration of mental faculties will need care on daily basis.

Physical Health: With age, there can be obstacles to physical health. Depending on the severity, physical limitations may cause seniors to lose some or much of their former independence

Emotional Wellbeing: Emotional wellbeing can be a wide-reaching issue. Seniors often face traumatic changes, such as loss of loved ones and their own failing health. These severe environmental stresses can lead to depression and other psychological hardships.

Financial Stability: Because people are living longer and healthier lives, the old modes of saving for retirement often fall short of what seniors will need. Financial stability is a large concern for seniors and

their families' once regular income ceases, especially for active seniors who may live many years longer than their savings was geared to sustain.

Literature Review: Over the last couple of decades, there has been a growing of researches that has been focused on geriatric and their motivation, well-being, and level of hope in their life.

Kenneth E. Mobily (1982)[1] did a study on "Physical & Occupational Therapy in Geriatrics" which focused on of physical activity as one ages is not solely a function of age. Rather, there is data to support the contention that the elderly refrain from exercise because of environmental and personal as well as motivational conflicts.

Stevens-Ratchford, Regena (2000)[2] did a study on Occupational Engagement: Motivation for Older Adult Participation which focused on guiding participation in developmental tasks that enhance aging well can be a motivational strategy for rehabilitation.

JoNell Strough, Wändi Bruin, and Ellen Peters (2015)[3] did a study on "New perspectives for motivating better decisions in older adults" which focused on promising intervention strategies for motivating older recipients motivation to make better decisions.

Lindanor Jacó Chaves1 and Claudia Aranha Gill (2015)[4] did a study on "Older peoples concepts of spirituality, related to aging and quality of life" they aimed to investigate and analyze the concepts that older people have of spirituality and how this concept affects their quality of life. It is a descriptive, exploratory, quantitative-qualitative study, with a sample of 12 participants over the age of 60.

Stephen Jivraj, James Nazroo, Bram Vanhoutte, Tarani Chandola (2015)[5] did a study on "Aging and Subjective Well-Being in Later Life" which found that older cohorts enjoy higher levels of SWB than their younger counterparts when under similar circumstances, they experience sharper declines, especially in the very oldest cohorts. Stephanie V and Rachel Cooper (2015) did a study on Physical Activity and Mental Well-being in a Cohort Aged 60–64 Years which focused to investigate associations of monitored total PA under free-living conditions, self-reported leisure-time, and walking for pleasure with mental well-being at age 60–64 years

Budhiraja, Ankita; Midha, Punam (2015)[6] did a study on Hope and Spirituality as Portals to Subjective Well-Being among Geriatrics which aimed to assess the level of hope, spirituality and subjective well-being among geriatrics.

Antonella Delle Fave, Marta Bassi, Elena S. Boccaletti did a study on Promoting Well-Being in Old Age (2018): [7] The Psychological Benefits of Two Training Programs of Adapted Physical Activity found that people aged 67–85 who do physical activities promote mental health, opportunities for elderly people to socialize and improve emotional functioning.

Ena Yadav, Srishti Chanana (2018)[8] did a study on Emotional Regulation and Well-Being among Elderly. The results of the study point out that the relationship between perceived wellbeing and emotional regulation is comprehended to be bidirectional. Emotional regulation may also have protective role in wellbeing since regulation of emotions is essential for adaptive functioning, whereas suboptimal or dysfunctional.

Aim: Aim of this present study is to measure the effect of motivation level, hope and well-being of geriatric population .A comparative study will be done between elderly with hypertension elderly (experimental group) and healthy elderly (control group).

Method

Sample: Total sample of the present study consisted (N=60) among geriatric population in Noida. The sample comprises of hypertension elderly as experimental group (n=30) and healthy elderly as control group (n=30) which were randomly selected from different areas of Delhi NCR. The elderly population with hypertension were diagnosed by medical doctor more than six months ago. Elderly's ages were ranged above 60 years

Tools: The following measures were used in the present piece of research work.

1. **Elderly Motivation Scale:** Elderly Motivation Scale assesses the intrinsic and extrinsic motivation of elderly individuals. It assesses 4 constructs: intrinsic,self-motivation - determined and non-self-determined extrinsic motivation, and a motivation.

2 **Adult Hope Scale:** For measuring elderly's hope level, a scale developed by Snyder, C. R., Harris, C., Anderson, J. R., Holleran, S. A., Irving, L. M., Sigmon, S. T was used. Hope scales can be

used to determine client's perceived motivations for pursuing their goals (agency thought) and their ability to identify workable routes to goal attainment (pathway thought). According to Snyder et al., (1991), hope is the "stuff" that facilitates change. The adult hope scale contains 12 items. Four items measure pathways thinking, four items measure agency thinking, and four items are fillers. Participants respond to each item using an 8-point scale ranging from false to definitely true and the scale takes only a few minutes to complete.

The scale has been found to be inversely correlated with several measures such as the Beck Depression Inventory.

3 **Ryff's Psychological Well-Being Scale:** Psychological well-being of elderly was assessed by using Ryff's Psychological Well-Being Scale developed by psychologist Carol D.Ryff, the scale contained 42 items.

Procedure: The study was conducted between hypertension (experimental group) and healthy elderly's (control group). Data was collected on 30 hypertension (experimental group) and 30 healthy elderly's (control group) using Elderly Motivational Scale, Adult Hope Scale and Ryffs Psychological Well-Being Scale. Rapport was established between the administrator and the subjects. Also, the environment was made friendly so that subjects would feel comfortable and does not hesitate while marking their responses. All subjects include in the present study were given assurance that information provided by them will be kept confidential and will be used for research purpose only. It was also told to the participants to fill demographic details, informed consent was taken, instructions were given clearly, and if any confusion was there it was made clear to the subject. Initially the subject was feeling nervous but as they interacted with the administrator and rapport was established, they felt more and more confident while responding to the items. Elderly Motivational Scale, Adult Hope Scale and Ryffs Psychological Well-Being Scale was handed over to the subject for administration. All the data I collected from the subjects was appropriate as in individual who performed the test were mentally fit. Subjects who were not mentally fit their data was excluded from the study.

The individual scores were obtained, and the responses were scored according to the manual. The data was tabulated for giving statistical analysis and for obtaining the result. Finally, the results were discussed, and the formulated hypotheses were tested.

Discussion

The present study was conducted in Delhi–NCR societies. Overall sample size of the study was 60 elderly population both male and female. Hypertension elderly (n =30) and Healthy elderly (n =30). The objective of the study was to compare-

1. The difference of well – being in hypertension elderly and healthy elderly
2. The difference of motivation level in hypertension elderly and healthy elderly and
3. The difference of hope level in hypertension elderly and healthy elderly.
4. The difference in hypertension elderly and healthy elderly.

To fulfil the objectives two groups were taken 30 hypertension elderly (experimental group) and 30 healthy elderly (control group). Raw scores of 30 hypertension elderly and 30 healthy elderly were obtained from Elderly Motivational Scale, Adult Hope Scale and Ryff Well-being Scale Questionnaires. T-test was used in motivational scale and hope scale to measure group difference. Also, ANOVA was conducted in well-being scale to measure group difference.

According to the first hypothesis there was significant difference between the well-being of geriatric pathological group and non – pathological group. As the result shows that elderly with hypertension had higher well – being than healthy elderly's. This was found after analyzing the raw scores of the questionnaire and applying ANOVA shown on table1 on page 48, the mean scores of both groups differ a lot. American College of Cardiology (2018) studied that psychological well-being can improve overall heart health. This means that elderly with hypertension who have high level of optimism may lead a better diet, regular exercise and lower stress.

The second hypothesis was found to be non–significant difference between the motivational level of geriatric pathological group and non-pathological group. As the results at each domain health activities activities related to your biological needs, activities related to your relationships with others, activities to religion, activities related to leisure and activities related to information were found non – significant. This was

found after analyzing the raw scores of the questionnaire and applying t-test shown on table1 on page 49-55, the mean scores of both groups were quite similar. This might be due to small sample size or large number of questions in the questionnaire. Phillips (2004) [9] studied that motivation helps elderly maintain their physical health. Strough (2015) [3] studied that motivation helps to make better decisions in elderly.

The third hypothesis was found non – significant difference between the level of hope in geriatric pathological group and non-pathological group. This was found after analyzing the raw scores of the questionnaire and applying t-test shown on table1 on page 56, the mean scores of both of the groups were quite similar. . This might be due to small sample size or improper rating done by the elderly's. Ankita Budhiraja and Punam Midha (2015)[6] studied that hope and spirituality helps subjective well-being in geriatrics.

The final hypothesis shows that there is significant difference between geriatric pathological and non-pathological group. These findings confirm that both the groups are distinctive in nature.

Conclusion

The current study has highlighted following main findings:

1. The well-being of hypertension group (experimental group) is at a higher side than healthy elderly group (control group).
2. The motivation level of both the groups are quite similar hypertension group (experimental group) and healthy elderly group (control group).
3. The hope level of both the groups are quite similar hypertension group (experimental group) and healthy elderly group (control group).

Ethical Clearance: Consent was taken from all the participants

Source of Funding: Self

Conflict of Interest: No

Challenges of Allied Healthcare Professionals in India–Establishing the Council is Need of the Hour

Alka Rawekar[1], Shashank Gotarkar[2], Swapnil Patond[3], Sarika Dakhode[2]

[1]Professor Physiology and Dean, School of Allied Health Sciences, Datta Meghe Institute of Medical Sciences (DU), [2]Assistant Professor, Dept. of Community Medicine, Jawaharlal Nehru Medical College, [3]Associate Professor, Dept. of Forensic Medicine, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M) Wardha.

Abstract

There is a supply-demand gap of about 65 lakh allied health professionals in India. With India facing a heavy burden of disease with many challenges as achieving millennium development goals, shortage of skilled manpower will be a great hurdle for the health care delivery system. In such a situation, Allied Health workers can play a major role in providing holistic health services to the community. Though many institutions or Universities in India are generating allied healthcare professionals, there is no uniformity in the outcome of such professionals. There is no standardization of this professional till date. Hence, to establish a Centralized council is a need of an hour so that all such programs will come under a common platform and generated manpower will be able to provide the necessary services to the community. In this article, some suggestions are provided to improve the quality of AHPs, like estimation of workforce according to WHO requirement, uniformity in curricula, common nomenclature for all programs, creating job opportunities in private and public sectors etc.

Keywords: *Allied healthcare professionals, demand-supply, WHO, outcome.*

Introduction

Nurses, midwives and other health workers are of great significance in delivering the health care as primary health care services are not doctor-dependent. Allied healthcare professionals (AHPs) play pivotal roles in the health system. The importance of Allied Healthcare Professionals can be observed in the operation theatres, various diagnostic laboratories, blood banks, Intensive Care Units (ICUs), dialysis units, trauma care, ophthalmic OT; the list is quite exhaustive. The life of a person is handled by these allied health professionals. Operating the machines, repairing the machines, handling the patients, accuracy in diagnostic laboratory testing need skills. Any mistake can be life-threatening. That is why everyone now insists for trained staff to handle such machines either in operation theatres, ICUs or laboratories. Technology is now in an advanced position. But to operate, the person should be technically as well as scientifically sound and perfect. These technologists are to be competent enough to handle those machineries. Even in secondary and tertiary care, skilled support services should be provided by suitably trained nurses and allied health professionals.

The outbreak of COVID-19 throughout the world (From December 2019 onwards) outstretched the importance of allied Health Professionals. According to the interim guidelines published by WHO mentioned that all countries should increase their level of preparedness, alert, and response to identify, manage, and care for

new cases of COVID-19; where the laboratory testing is an integral part of this strategy. It is added that good laboratory practices which produce accurate results are key to assure that laboratory testing benefits the public health response. It further stated that the availability of timely and accurate results can be threatened when testing demands outstrip capacity[1].

Advances in science and technology have encouraged the major shift in health care over the past few decades resulting in wider understanding of the fact that health service delivery must go beyond just doctors or nurses and involve teamwork among clinicians and non-clinicians or 'allied healthcare staff.' Better utilization of the whole range of the skills of allied Health Professionals (AHPs), is the key to health-sector reforms in India, particularly because of the shortage of doctors and nurses in semi-urban and rural areas.

NEED for AHPs: The report 'From Paramedics to Allied Health Professionals: Landscaping the Journey and Way Forward' that was published in 2012, marked the variance in education and training practices for the allied and healthcare courses offered by institutions across the country[2].

According to the World Health Statistics 2011 figures, the density per 10000 people in India is six doctors and 13 nurses and midwives working out to a doctor to population ratio of 0.5: 1000 in comparison to 0.3 in Thailand, 0.4 in Sri Lanka, 1.6 in China, 5.4 in the UK, and 5.5 in the United States of America. A recent Public Health Foundation of India (PHFI) study reveals a supply-demand gap of about 65 lakh allied health professionals.[2]

Health workforce requirements for universal health coverage and the sustainable development goals incorporated in Human Resources for Health Observer Series No 17, illustrated the total number of health workers by cadre and income group country estimated for 2013 and forecasted for 2030 as follows[3]:

	Cadre of Health Workers (Other than Physician and Nurses and midwives)			Total Health Workers		
	2013	**2030**	**% Change**	**2013**	**2030**	**% Change**
Lower Middle (Income group) countries	3550824	6685479	88%	10018004	18266529	82%

This figure demands about 80% change in the number of total health workforce.

In view of gaping shortages of doctors in providing healthcare, allied healthcare professionals (AHPs) can play a prominent role in providing holistic health services to Indian community. There is a need to establish a centralized policy to fill the gaps and ensure the availability of the appropriate human resources for quality care at primary, secondary as well as tertiary levels in India.

Classification of health workers: The US Department of Health and Human services defines AHPs as 'experts in a multitude of therapeutic, diagnostic and preventive intervention.

According to WHO, the international classification of health workers is mainly based on the International Standard Classification of Occupations (ISCO, 2008 revision)[4].

The classification of health workers maps occupation categories into five broad groupings: a) health professionals, b) health associate professionals, c) personal care workers in health services, d) health management and support personnel, and e) other health service providers not elsewhere classified.

1. Health professionals: It includes Paramedical practitioners, Dieticians and nutritionists, Audiologists and speech therapists, Optometrists and ophthalmic opticians, category of Health professionals not elsewhere classified other than all medical, nursing or physiotherapy practitioners.
2. Health Associate Professionals: Includes Medical imaging and therapeutic equipment technicians, Medical and pathology laboratory technicians, Pharmaceutical technicians and assistants, Medical and dental prosthetic technicians, Dental assistants and therapists, Medical records and health information technicians, Community health

workers, Dispensing opticians, Medical assistants, Environmental and occupational health inspectors and associates, Ambulance workers and a category of Health associate professionals not elsewhere classified

3. Personal Care Workers In Health Services: Includes Health care assistants, Home-based personal care workers and Personal care workers in health services not elsewhere classified
4. Health Management and Support Personnel: Includes Health service managers, Health management personnel not elsewhere classified, Life science professionals, Social work and counselling professionals, Life science technicians, Medical secretaries, and a category of Non-health professionals not elsewhere classified
5. Health Service Providers Not Elsewhere Classified: Includes Armed forces occupations.

Challenges of AHPs: Currently, due to the nonexistence of a central regulatory body for allied health professionals in India, they are divided into smaller groups, and regulated as independent bodies either by institutions or University. For instance, the rules or norms of professional practice vary from extremely professional to dispersed groups with no uniformity.

A representative of the MoHFW (Ministry of Health and Family Welfare, India) explained the Parliamentary Standing Committee on Health and Family Welfare about the circumstances that necessitated the firming up of a Bill to set up the new council. He noted the following problem areas and hence require regulatory body[2]:

- Para-medical professions are not regulated;
- Entry-level qualifications are different at different levels
- Level of knowledge and skills is not uniform, since the period of training differs from place to place and has no uniformity
- Course curricula are not uniform
- Fee structure and facilities in these institutions are not regulated and
- Ethical standards are not uniform and are not being enforced

The lack of planned courses and institutions, non-uniformity in nomenclature for the existing courses, diverse standards of practice and lack of qualified faculty pose a threat to the quality of education and skills of the AHPs in India.

Allied Healthcare Council of India: The Union Cabinet of India chaired by Prime Minister on November 22,2018, had approved the Allied and Healthcare Professions Bill, 2018, for regulation and standardisation of education and services by allied and healthcare professionals. The Bill has the provision for setting up of an Allied and Healthcare Council of India and corresponding State Allied and Healthcare Councils which will play the role of a standard-setter and facilitator for professions of Allied and Healthcare. Since then, more than one year has passed, but no interim council has been established[5].

Discussion

At present, the shortage of quality human resources is one of the major challenges faced by the public health domain in India. Bhore committee report of 1946 underscored the significance and importance of health care as it initiated the concept of integrated development and comprehensive healthcare[6].Acknowledging the shortage of clinicians, the Mudaliar Committee report in 1962, emphasized the need for redesigning health service delivery with better roles for paramedical personnel, leading to better utilization of doctors and nurses. Sixty years later, the recommendation still remains pertinent to reforms in the Indian public health sector as allied health workers can reduce costs and augment the quality of care [7].

The health service delivery is not just a honour of clinicians, nurses or midwives but it is a team effort, obtaining the expertise of both clinicians as well as non-clinicians. These healthcare professionals or health-service providers have been historically identified as paramedical staff or health technicians.

Many new health professions as physicians' assistants, clinical nutritionists and dietetics, optometrists, respiratory therapists or operation theatre technologists have emerged over the past several decades to support some of the work that clinicians used to perform. Somewhere these technologists are helping the clinicians that their work-skills are conducted without the physician's control and supervision (cardiovascular technologist) as other professional workers seek their own identity and autonomy.

With advancements in technology over the past few decades, the quality of medical care has vastly improved across the world. This has thrown up fresh challenges for public health. Today, there is an urgent need for competent people who can handle highly sophisticated medical machinery. In fact, diagnosis has become so dependent on technology that the role of allied health staff has become vital in delivering successful treatment.

Another very pertinent issue that is equally important in India is that students are not aware of all the allied health courses available in the medical education system.

Health care gain footing from more than 20 years of research on team performance and training and that these principles should be integrated into the practice of health care and the training of health professionals. Modernisation of the healthcare system has initiated a team-based healthcare delivery model[8]. The process of teamwork is inherently interdisciplinary which requires division of labour among the medical, nursing and allied health fraternity. Poor teamwork skills have been found to contribute to patient-care incidents[9]. Health teams are mainly the 'performer teams' due to their dynamic work conditions, wherein teamwork, coordination and collaboration are the prerequisites for optimum results. Teamwork now becomes the essential component of achieving high reliability for health care organizations. The team training can provide great insights and techniques for improving performance within such organizations.

There are some initiatives undertaken by Government of India as the Ministry of Health and Family Welfare has commissioned a Centrally Sponsored Scheme for the establishment of one National and five Regional Institutes of Allied Health Sciences and to support State Government Medical Colleges for conducting allied health science courses. The first phase of the initiative undertook a massive review of the allied health landscape in the country and proposed the development of the allied health system through the establishment of an interim body called 'National Board for Allied Health Sciences'. This process will eventually ensure the quality and standardization of the allied healthcare education and professions in the country [10].

Expanding the explanation for comprehensive healthcare, interdisciplinary collaboration can create new paths to health care problems that transcend conventional, discipline-specific method, procedures, and techniques. As proposed by Carl I. Fertman, a four-pronged approach can be used to prepare allied health students to become interdisciplinary team members in rural areas. It described in-class instruction, Web-based modules, service-learning programs, and faculty development workshops to develop and practice interdisciplinary health promotion skills in rural communities [11].

Since AHPs play a vital role in the holistic care of the patient, ensuring that they are skilled and trained efficiently, it will help to reduce the total cost of care, improve the quality and accessibility to healthcare service[10].

Rising healthcare costs provide opportunity for public and professional debate about the most effective way of providing weekend allied health care services. Some manager's perceived weekend allied health services to improve patient quality of care [12].

Healthcare delivery requires acute medical or surgical emergencies; hence weekend service provision may not be practicable. The resources may be better spent to improve the patient outcome in areas where emergency is not required such as Rehabilitation wards.

Suggestions to improve the quality of AHPs in India: The continuously changing health needs and service requirements influence the allied healthcare system in terms of both education and service provision.

Despite the huge demand of job opportunities from this sector, the allied health sciences field is highly fragmented. The government currently provides limited options for employment. It is hence essential to address the following issues [13].

1. Estimation of workforce needed both for public and private sector and create the job opportunities for them with special considerations for geographical and epidemiological needs
2. Establish a clearly defined cadre structure for AHPs based on a combination of educational qualifications and years of work experience with a distinct career pathway for three tracks: clinical practice, academic faculty and research and development.
3. Identify and establish common terminologies/ nomenclature for the various allied healthcare professionals as per the classification prescribed by (ISCO, 2008) for India.

4. The entry level for AHPs to be made uniform and centralized
5. Undertake reforms for uniformity in curricula of various programs
6. Undertake reforms for uniformity in training which include not only for cognitive but also for real and virtual skill training
7. Fees structure to be made rationalised for public and private sector
8. Minimum standards to be set for infrastructure and associated requirement like library, ICT enabled classrooms etc
9. Create a centralized portal of an allied health science knowledge community through networking, real-time data and innovative research which will be responsible for all knowledge activities in allied health.
10. Every medical college should be given the responsibility to generate the allied healthcare workforce in proportion to the number of undergraduate medical/health students.

Conclusion

For better quality of healthcare delivery in India, there should be genuine effort to address all these above issues. As such there is no regulatory body in India, the outcome of all these students become ambiguous. These are skill based programs, the certification of the skills remains questionable. Over the period, more and more allied health professionals are adding to the society but due to lack of quality assurance, the healthcare system is struggling. According to the theories of learning, students should be scientifically and appropriately trained for all the skill based competencies. If the quality is compromised, the training remains questionable. Such passed out graduates or postgraduates again training the new entrants and the cycle goes on.

Youth are getting attracted to these courses as they are job providing courses. But over-production of ill-trained personnel will lead to the manpower who cannot handle the health system appropriately. Due to their critical role in today's healthcare delivery system, it is necessary to build capacity among allied health professionals and ensure that they are appropriately skilled. Although they play important roles in the system, a lack of recognition and standardization of the courses, immensely impacts the quality of the profession.

Hence, setting of the Allied Health council in India is need of the hour so that AHPs can be appropriately, ethically and logically woven into the fabric of the Healthcare delivery system in India.

The Study of Location of Mandibular Foramen in Dry Adult Human Mandible

Chimurkar Vilas[1], Patond Swapnil[2], Anjankar Vaibhav[3], Pande Varsha[4]

[1]Professor & Head, Department Anatomy, [2]Associate Professor, Department of Forensic Medicine, [3]Associate Professor, Department Anatomy, [4]Assistant Professor, Department Anatomy, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Wardha, Maharashtra, India

Abstract

Human mandible is only a movable bone forms lower jaw of the skull. It articulates with the temporal bone at the synovial temporomandibular joint, Mandible consists of a horizontal horse shoe shaped body and two broad rami projecting upward from the posterior end of body. Each ramus of mandible presents two surfaces, external and internal. The aim of the study is to identify the location of mandibular foramen in relation to the limits of mandibular ramus and to correlate the data with the other research works. In the present study 200 dry adult human mandibles of unknown sex and age were collected from the Dept. of Anatomy, J.N.M.C. Sawangi (M) Wardha, DMIMS (DU) and the students of first M.B.B.S of J.N.M.C. Sawangi (M), Wardha, Maharashtra and various measurements were noted. According to the results of the study, it is concluded that there is variability of the mandibular foramen of the two mandibular rami in the same person. There is variable difference between the locations of mandibular foramen in the dry human mandibles of the same zone. It may be due to differences in the age, sex and development in population. This study is mainly concentrated on finding the location of mandibular foramen by measuring its distance from various landmarks on mandibular ramus.

Keyword: *Mandible, Mandibular Foramen, Ramus of Mandible, Dry mandible.*

Introduction

In humans mandible is only a movable bone forms lower jaw of the skull. It articulates with the temporal bone at the synovial temporomandibular joint. Mandible consists of a horizontal horse shoe shaped body and two broad rami projecting upward from the posterior end of body. Each ramus of mandible presents two surfaces, external and internal.

Near the centre of internal surface of each ramus presents mandibular foramen guarded bytongue like projection known as lingula. Mandibular foramen continuous as mandibular canal in the ramus of mandible and then in the body of mandible fora short distance. Mandibular canal conveys the inferior alveolar nerve and vessels. Inferior alveolar nerve is a branch of posterior division of mandibular nerve. Inferior alveolar nerve innervates the lower jaw, teeth and periodontal tissue. Inferior alveolar nerve also innervates soft tissue of the premolars, incisors, canines and skin of chin. Inferior alveolar nerve is blocked during anaesthesia in various dental surgeries and facial reconstruction.[1]

In dental surgeries technique failure during anaesthesia of inferior alveolar nerve is due to inappropriate setting of needle because of inaccurate location of mandibular foramen.[2] Anatomical variation of the location of the mandibular foramen may result in failure in dental and maxillofacial procedures and may lead to clinical complications if not properly identified.[3]

In advanced surgical techniques for the correction of craniofacial anomalies and pre –post operative procedures the knowledge of location of mandibular foramen is must.[4] For this purpose the qualitative and quantitative measurements are required.

It is now clear that facial reconstruction from the skull remnants in forensic medicine for medicolegal purpose is more accurate when the mandible is present. Measurements are equally important in the identification as well as facial reconstruction for medicolegal purpose in forensic medicine as well as in Anthropological study of different races. The study of various morphological features o mandible can be useful to determine age, sex and race of the individual in various medico-legal cases as well as in other anthropological studies.[5]

Despite numerous studies have been conducted on Morphometric measurements for location of the mandibular foramen in the various countries and the other regions of India, it is observed that there are differences in the data collected by various researchers. So it is important to study the location of the mandibular foramen in more no of mandibles of different regions to provide valuable and precise information to our clinician and dental professionals.[6]

The aim of the study is to identify the location of mandibular foramen in relation to the limits of mandibular ramus.

Aims and Objectives: To determine the location of mandibular foramen on dry adult human mandibles to provide informative data to be used for dental and other health professionals in various surgeries and procedures.

The aim of the study is to identify the location of mandibular foramen in relation to the limits of mandibular ramus.

To correlate the data with the other research works.

Material and Method

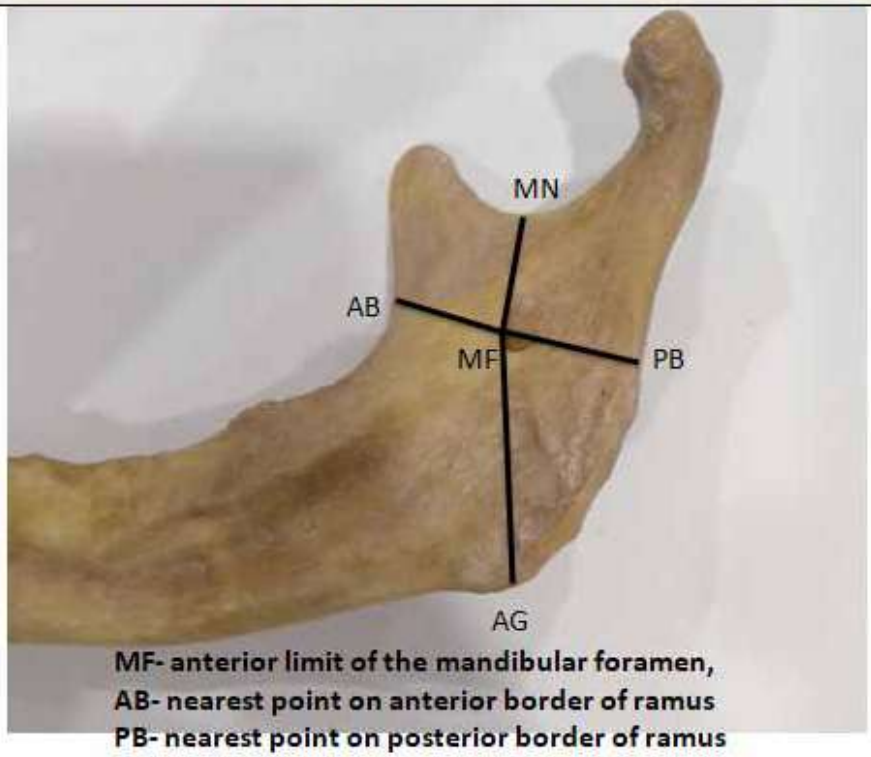
200 dry adult human mandibles of unknown sex and age from the Dept. of Anatomy, J.N.M.C.Sawangi (M) Wardha, DMIMS (DU) and from the students of first M.B.B.S ofJ.N.M.C.Sawangi (M), Wardha, Maharashtra were collected. The damaged bones and those, having pathological abnormalities, congenital anomalies were excluded. The mean distance of mandibular foramen from anterior border of ramus, posterior border of ramus, mandibular arch and the angle of the mandible (ramus). Both right and left sides are used for measurements. A digital vernier calliper of 0.001mm accuracy is used for taking measurements. Each distance measured thrice and mean is taken to avoid error. The measurements were recorded to the nearest millimetre. The mean and SD were calculated for left and right sides.

Fallowing measurements were noted:

1. MF- AB:A distance from the centre of the anterior limit of the mandibular foramen (MF)to the nearest point on anterior border of ramus (AB).
2. MF-PB: A distance from the centre of the anterior limit of the mandibular foramen (MF) to the nearest point on posterior border of ramus (PB).
3. MF-MN: A distance from the centre of the anterior limit of the mandibular foramen (MF) to the nearest point on mandibular notch (MN).
4. MF –AG: A distance from the centre of the anterior limit of the mandibular foramen (MF) to the nearest point on angle of mandible.

MF- Mandibular foramen

AB- Anterior border of ramus



PB- Posterior border of ramus

MN- Mandibular notch

AG- Angle of mandible

Figure 1 showing various measurements from anterior limit of mandibular foramen

Image showing various measurements from anterior limit of mandibular foramen

Observations:

Table 1: Measurement of the Mandibular foramen from anterior border.

Total no. of mandibles	Side	Mean (mm)	SD (mm)	P-Value
200	Right (200)	17.58	0.98	6.06 P=0.0001,S
	Left (200)	17.22	0.94	

Table 2: Measurement of the Mandibular foramen from posterior border.

Total no. of mandibles	Side	Mean (mm)	SD (mm)	P-Value
200	Right (200)	13.61	1.18	6.22 P=0.0001,S
	Left (200)	13.30	1.00	

Table 3: Measurement of the Mandibular foramen from mandibular notch.

Total no. of mandibles	Side	Mean (mm)	SD (mm)	P-Value
200	Right (200)	19.54	2.01	8.28 P=0.0001,S
	Left (200)	19.84	2.07	

Table 4: Measurements of mandibular foramen from angle of mandible.

Total no. of mandibles	Side	Mean (mm)	SD (mm)	P-Value
200	Right (200)	26.86	1.77	5.03 P=0.0001,S
	Left (200)	27.31	2.41	

Statistical analysis was done by using descriptive and inferential statistics using Student's paired t test and software used in the analysis was SPSS 24.0 version and $p<0.05$ is considered as level of significance.

Results:

In the present study, the position of the mandibular foramen in 200 dry human mandibles of unknown age and sex were located by measuring the distance between mandibular foramen from anterior border of ramus, posterior border of ramus, mandibular notch and angle of mandible. Measurements were taken on both the sides of mandible.

According to the study it is seen that, there is no symmetry between the location of mandibular foramen on right and left side of the same mandible.

In this study, the mean distance of MF from the anterior border is 17.58 mm on right side and 17.22 mm. on left side. The mean distance of MF from the posterior border is 13.61 mm on right side and 13.30 mm. on left side. So the mandibular foramen is more nearer to the posterior border than the anterior border of ramus. The mean distance of MF from the mandibular angle is 26.86 mm on right side and 27.31 mm. on left side. So the mandibular foramen is more nearer to the mandibular angle on right side than on the left side. The mean distance of MF from the mandibular notch is 19.54 mm on right side and 19.84 mm. on left side. So mandibular foramen is significantly nearer from mandibular notch on right side than on left side.

The location of mandibular foramen with reference to various landmarks varies mandible to mandible.

Discussion

The location of mandibular foramen is very important to achieve inferior alveolar nerve block in dental surgeries of lower jaw like osteotomy, orthognathic reconstruction and dental implant .[1]Morphometry of mandible vary from mandible to mandible and with age. Malka Ashkenazi et al, (2011) stated that, the distance of mandibular foramen from the anterior and posterior border of ramus increases significantly with age.[7]Variations in the number of canal can be explained because of early development.

It is stated that the mandibular foramen is located below occlusal plane by 6 years, at occlusal plane or slightly above by the age of 13 years.[8]

The distance from mandibular notch to the mandibular foramen is an important reference point for identifying the location of the mandibular foramen during orthognathic surgery.[9]

Some adult study show that the mandibular foramen is located posterior to the midline of ramus Hayward et.al 1977, Hetson et al 1988.[10,11] The other studies show that the location of mandibular foramen is located at the midline of the ramus Sweet 1947, Monheim 1969, Nicholson 1985). Mc Donald et.al (2004) recommended the injection of the mandibular block more posteriorly in children than adult.

In this study, the mean distance of MF from the anterior border is 17.58 mm on right side and 17.22 mm. on left side. The mean distance of MF from the posterior border is 13.61 mm on right side and 13.30 mm. on left side. So the mandibular foramen is more nearer to the posterior border than the anterior border of ramus. The mean distance of MF from the mandibular angle is 26.86 mm on right side and 27.31 mm. on left side. So the mandibular foramen is more nearer to the mandibular angle on right side than on the left side. The mean distance of MF from the mandibular notch is 19.54 mm on right side and 19.84 mm. on left side. So mandibular foramen is significantly nearer from mandibular notch on right side than on left side.

According to Padmavathi G et.al .(2014) studied the mandibles from south Indian population found that the mean distance of MF from the anterior border is 16.9 mm on right side and 16.8 mm. on left side. The mean distance of MF from the posterior border is 12.10 mm on right side and 11.7 mm. on left side. The mean distance of MF from the mandibular angle is 22.20 mm on right side and 22.60mm on left side. The mean distance of MF from the mandibular notch is 22.30 mm on right side and 22.00 mm. on left side.[12]

According to Rajkumari K, et. al(2017)studied the mandibles from Imphal, Manipur population found that the mean distance of MF from the anterior border is 16.77mm on right side and 16.90mm. on left side. The mean distance of MF from the posterior border is 11.05mm on right side and 11.21 mm. on left side. The mean distance of MF from the mandibular angle is 21.02mm on right side and 21.80mm on left side. The mean distance of MF from the mandibular notch is 22.93mm on right side and 23.15mm. on left side.[13]

Table 5: Showing the location of mandibular foramen by different authors in different regions of India. (Mean distance in mm)

Author	Region	Side of mandible	MF-AB mm.	MF-PB mm.	MF-MN mm.	MF-AG mm.
Padmavathi G, et. al.(2014)	South India.	Right	16.90	12.10	22.30	22.20
		Left	16.80	11.70	22.00	22.60
Rajkumari K, et. al.(2017)	Imphal, Manipur.	Right	16.77	11.05	22.93	21.02
		Left	16.90	11.21	23.15	21.80
Amjad S.et. al.(2018)	Jalna, Maharashtra.	Right	15.6	12.0	17.70	23.0
		Left	15.3	11.10	17.0	24.0
Sandhya, et. al.(2019)	Ranchi, Jharkhand.	Right	16.00	10.21	20.48	-
		Left	16.27	10.28	20.15	-
Present study(2020)	Wardha, Maharashtra.	Right	17.58	13.61	19.54	26.86
		Left	17.22	13.30	19.84	27.31

According to Amjad S.et. al(2018), studied the mandibles from Jalna, Maharashtra and found out that, the mean distance of MF from the anterior border is 15.6mm on right side and 15.3mm on left side. The mean distance of MF from the posterior border is 12.0mm on right side and 11.10 mm. on left side. The mean distance of MF from the mandibular angle is 23.0mm on right side and 24.0mm on left side. The mean distance of MF from the mandibular notch is 17.70mm on right side and 17.0mm on left side.[14]

According to Sandhya, et. al.(2019)studied the mandibles from Ranchi, Jharkhand population found that the mean distance of MF from the anterior border is 16.00 mm on right side and 16.27mm. on left side. The mean distance of MF from the posterior border is 10.21mm on right side and 10.28mm on left side. The mean distance of MF from the mandibular notch is 20.48mm on right side and 20.15mm. on left side.[15]

So when the studies in table 5 correlates with the present study, the measurements of south Indian and Maharashtra population are showing some similarity than the population of Jharkhand and Manipur . Anatomic variations may be due to developmental perspective, racial discrepancies and craniofacial growth .[9]

Conclusion

The basic anatomy of the mandible and location of mandibular foramen is essential to medical and dental professionals for various surgeries as well as inferior alveolar nerve block.

According to the results of the study, it is concluded that there is variability of the mandibular foramen of the two mandibular rami in the same person. There is variable difference between the locations of mandibular foramen in the dry human mandibles of the same zone. It may be due to differences in the age, sex and development in population. This study is mainly concentrated on finding the location of mandibular foramen by measuring its distance from various landmarks on mandibular ramus.

Quantitative data analysisis an effective and reliable tool of demonstration and localisation of mandibular foramen in dry human mandibles. On the basis of present study it will be possible and helpful for monitoring and interpreting the maximum possible location of mandibular foramen.

A Study of Rhodamine-6G Stain Expression for Detection and Association of Copper Content in Potentially Malignant Disorders and Squamous Cell Carcinoma

Himanshu Singh[1], Sushruth Nayak[2], Prachi Nayak[3]

[1]Senior Lecturer, Department of Oral Pathology & Microbiology, Index Institute of Dental Sciences, Indore, Madhya Pradesh-452016, [2]Professor & Head, Department of Oral Pathology & Microbiology, [3]Reader, Department of Oral Pathology & Microbiology, M.M. College of Dental Sciences & Research, M.M (Deemed to be University), Mullana (Ambala)-133207, Haryana

Abstract

Aim and Objective: To assess the expression of Rhodamine-6G stain in potentially malignant disorders and SCC and to determine association of copper in potentially malignant disorders and OSCC.

Materials and Method: Sections from ten tissue blocks of each normal oral mucosa, oral leukoplakia, oral sub mucous fibrosis (OSMF), well differentiated squamous cell carcinoma (WDSCC) and moderately differentiated squamous cell carcinoma (MDSCC) was taken and stained with Rhodamine-6g stain. After adequate staining, all the samples were assessed using Fluorescence microscope for the color intensity and depth of penetration of copper and compared.

Results: It showed significant Pearson chi square values of 0.157 for color intensity of copper and 0.019 for depth of penetration of copper. Pearson correlation was calculated which showed significant value for leukoplakia (0.055)* in comparison to OSMF (0.429), WDSCC (-.395) and MDSCC (0.372).

Conclusions: Increase levels of copper in leukoplakia would be because of the fact that copper helps in activating many angiogenic factors which further helps in tumor progression from premalignant to malignancy.

Keywords: *Rhodamine-6G, Leukoplakia, Oral Sub mucous Fibrosis, Squamous cell carcinoma, Copper content, Fluorescent Microscopy.*

Introduction

Trace elements are important constituents of biological enzyme systems. They are found to play a central role in a various physiological metabolic process and in the pathology of various diseases of these elements, copper has been studied more extensively for its role in various bodily processes.[1,2] In absence or deficiency of copper, various enzymes in the body are not be able to perform their metabolic functions, as they require metallic ions such as copper to get activated. For example, ceruloplasmin, tyrosinase and cytochrome oxidase. These enzymes play an essential role in various redox reactions, free radical formation and maintenance of cellular protein homeostasis.[3,4] A number of angiogenic factors, for example TNF-α, IL-1 and VEGF are activated by copper which on further binding to endothelial cells result in their proliferation. During the progression of the cancerous lesion, copper level is reported to be unbalanced.[5]

Occurrence of cancer, precancer and other tumor-like lesions in oral cavity is very high now-a-days in the developing countries.[6] The reason for the high incidence is not fully known, however it may be due to various contributing factors like smoking, chewing tobacco, sharp impinging prosthesis among others.

In existing literature, serology and whole blood analysis for tracer elements has been correlated with various diseases and their pathogenesis. Very few studies have been conducted using the tissue sections with respect to potentially malignant disorders and OSCC. Therefore, a retrospective study was conducted to analyze the presence or absence of copper content in potentially malignant as well as in malignant lesions using Rhodamine-6G stain and also to evaluate its significance as a diagnostic tool in disease progression.

Materials and Method

The current study was carried out in the Department of Oral Pathology, after taking the approval from Institutional Research and ethical Committee at M.M. College of Dental Sciences & Research, M.M. (Deemed to be University), Mullana.

Formalin fixed and paraffin embedded blocks of previously diagnosed cases were obtained from archives of the department. Normal healthy gingival tissues were obtained from the excess gingival tissue which were excised and discarded during periodontal flap surgery and extraction after taking the informed consent from the patients. The study groups were divided into three:

Group A: Control Group [Normal oral mucosa (n=10)]

Group B: Potentially Malignant Disorders (PMD)

- Leukoplakia (n=10)
- Oral sub mucous fibrosis (n=10)

Group C: Carcinoma

- Well-differentiated SCC (n=10)
- Moderately-differentiated SCC (n=10)

The slides were prepared by sectioning the paraffin embedded tissues with the help of manual rotary microtome. Tissues sections were than subjected to Rhodamine-6G staining procedure. They were assessed using Nikon Research (Eclipse 80i) fluorescent microscope and compared based on quantitative expression in various study groups.

Results

The criteria were set for the color intensity and depth of penetration as mild, moderate and severe. Analysis of color intensity and depth of penetration of copper was done in oral leukoplakia, OSMF, Well Differentiated SCC and Moderately Differentiated SCC. In the criteria for color intensity, out of 10 cases of oral leukoplakia, mild and moderate intensity were shown by 04 cases each, whereas severe intensity were seen in 02 cases. Out of 10 cases of oral sub mucous fibrosis, mild color intensity was seen in 07 cases, moderate color intensity was seen in 03 cases, whereas no case showed severe color intensity. In Well differentiated Squamous cell carcinoma cases, mild color intensity was seen in 02 cases, moderate color intensity was seen in 06 cases and only 02 cases showed severe color intensity. In Moderately differentiated Squamous cell carcinoma, out of 10 cases, mild color intensity was seen in 07 cases, moderate color intensity was seen in 01 case and 02 cases showed severe color intensity.

In the criteria for depth of penetration of copper, out of 10 cases of oral leukoplakia, no case showed mild depth of penetration, whereas moderate depth of penetration were seen in 04 cases and severe depth of penetration were seen in 06 cases. In oral sub mucous fibrosis, out of 10 cases, mild depth of penetration were seen in 03 cases, no case showed moderate depth of penetration, whereas 07 cases showed severe depth of penetration. In well differentiated squamous cell carcinoma, out of 10 cases, no case showed mild depth of penetration, moderate depth of penetration was seen in 02 cases and 08 cases showed severe depth of penetration. In Moderately differentiated Squamous cell carcinoma, out of 10 samples, no cases showed mild depth of penetration, whereas 05 cases each showed moderate and severe depth of penetration.

Categorical data was collected and chi square test was done for both color intensity and depth of penetration for the study samples. All the normal healthy tissues showed the absence of copper content (Figure 1). Tissue samples of oral leukoplakia (Figure 2), oral sub mucous fibrosis (Figure 3), Well-differentiated squamous cell carcinoma (Figure 4) and Moderately-differentiated squamous cell carcinoma (Figure 5) showed the presence of copper in epithelium and connective tissue. The test showed significant Pearson chi square values of 0.157 for color intensity of copper and 0.019 for depth of penetration of copper. Pearson correlation was done which showed

significant value for leukoplakia (0.055)* in comparison to OSMF (0.429), well differentiated SCC (-.395) and moderately differentiated SCC (0.372).

Discussion

Trace elements are an important constituents of biological enzyme systems. They are found to play a key role in numerous physiological metabolic processes and also in various pathological diseases. Among these trace elements, copper has been studied more extensively for its role in various bodily processes.[1,2]

In the absence or deficiency of copper various enzymes in the body are not be able to perform their metabolic functions, as they require them to get activated. For example, ceruloplasmin, tyrosinase and cytochrome oxidase. These enzymes play an essential role in various redox reactions, free radical formation and maintenance of cellular protein homeostasis.[3,4]

The present study was aimed at assessing the expression of Rhodamine-6G stain under the fluorescent microscope in potentially malignant disorders and SCC and to determine its association with copper. A total of 40 study samples were taken for the study from the archival blocks from the department of Oral Pathology. For comparison, 10 normal healthy gingival tissues were obtained after taking the informed consent from the patients, from excess gingival tissue excised and discarded during periodontal flap surgery and extraction.

Criteria for scoring the color intensity and depth of penetration were set. For color intensity, criteria were set as mild, moderate and severe and the color intensity of copper in cases of oral Leukoplakia, OSMF and squamous cell carcinoma were observed.

Categorical data was collected and the Pearson chi square test was done for both color intensity and depth of penetration for the study samples. All the normal healthy tissues showed the absence of copper content. The test showed significant Pearson chi square values of 0.157 for color intensity of copper and 0.019 for depth of penetration of copper. Pearson correlation was calculated which showed significant value for leukoplakia (0.055)* in comparison to OSMF (0.429), WDSCC (-.395) and MDSCC (0.372).

A study done by Swain N and Ray JG found that copper content was increasingly higher from leukoplakia to cancer group.[7] Ayinampudi BK and Narsimhan M, observed significant increase in salivary copper levels in leukoplakia.[8] Similar findings were observed in our study with Rhodamine 6G staining technique on paraffin embedded tissue sections in comparison to the latter.

Toke et.al in their study found increased levels of serum copper as well as serum zinc in malignant patients as compared to the potentially malignant disorders.[9] Their findings were different to what is seen in our study.

Study done by Shetty SR et.al observed significant raise in the serum copper values in OSMF patients in contrast to controls.[10] According to Joshi PS et al. higher mean values for copper was seen in cases of oral sub mucous fibrosis (2.00) in comparison to leukoplakia and squamous cell carcinoma.[11] Our findings in the present study were different in comparison with the above study which showed no significance values for OSMF and SCC but rather showed highly significant values for oral leukoplakia.

Khanna SS and Karjodkar FR in their study found mean serum copper values were notably high in patients sera with premalignant as well as malignant lesions. In comparison, in our study only premalignant lesion (leukoplakia) showed significant values for copper.[12]

Ehud J et.al revealed that copper levels were raised in malignancy in comparison to zinc whose levels were found to be decreased.[13] Their findings were similar to the findings in the present study in relation to the depth of penetration of copper which showed increase levels in SCC.

Irons RD et.al[14] in their study revealed the presence of abnormal tissue copper levels in histopathological sections of liver using the Rhodamine staining technique, whose findings were similar to the present study. Varghese I et.al[15] found significant reduction in levels of copper in OSMF and SCC in comparison to leukoplakia which was similar to the present findings.

Conclusion

Increase levels of copper in leukoplakia would be because of the fact that copper helps in activating many angiogenic factors which further helps in tumor progression from premalignant to malignancy. During this progression copper level is reported to be increased and unbalanced. Since the chances of oral leukoplakia progressing to cancer is more as compared to other potentially malignant disorders, our study has showed significant values for copper in leukoplakia as compared to OSMF and SCC.

Regular follow up of all the potentially malignant lesions with periodic estimation for copper content using Rhodamine 6G staining technique as potential marker in assessing the disease progression should be helpful in correlating the progression from potentially malignant stage to malignancy.

Effectiveness of Deep Brain Stimulation in Iraqi Patients with Parkinson Disease

Bassam Mahmood Flamerz Arkawazi[1], Anwer Noori Hafdh[2], Zaki Noah Hasan[3], Awfa Aktham Abdullateef[4]

[1]Assistant Professor of Neurosurgery/Alkindy College of Medicine/University of Baghdad, [2]Consultant Neurosurgeon/Neurosurgical Teaching Hospital/Baghdad/Iraq, 3Professor of Neurology/Alkindy College of Medicine/University of Baghdad, [4]Neurosciences Hospital/Baghdad/Iraq

Abstract

Background: Surgical treatment for advanced Parkinson disease (PD) is considered when medical therapy fails to control the symptoms.

Objective: Assessment of effectiveness of deep brain stimulation (DBS) in controlling motor manifestations of advanced PD.

Patients and Method: Twenty patients (14 male and 6 female) whom fulfill the requirements for DBS surgery, were included in this study. All patients were on Levodopa (L-dopa), procyclidine, pramipexol, and amantadine medications. The study conducted between March 2017 and March 2018 in the neurosurgical teaching hospital and neuroscience hospitalin Baghdad/Iraq. Unified Parkinson's Disease Rating Scale(UPDRS) was used before and after surgery.

Results: There was a statistically significant improvement in the tremor, rigidity, and bradykinesia.

Conclusion: Most disabling axial symptoms of gait and postural instability, that failed to respond to medical therapy, will show effective response to the bilateral STN stimulation in advanced PD cases.

Keywords: *Parkinson disease, deep brain stimulation, subthalamic nucleus.*

Introduction

PD is a chronic degenerative disease of the basal ganglia, it includes both motor function and non-motor clinical manifestations, treated symptomatically by dopamine replacement .Every year, an average of nine-thousand DBS procedures are done for patients with PD around the world.(1) Ninety percent of PD are sporadic, while the monogenic forms of the disease account for approximately 3–5%.(2)

e-mail: bassamarkawazi@kmc.uobaghdad.edu.iq

Perhaps not since neurosurgery introduced to thecommunity,by Harvey Cushing, has there been a surgical treatmentthat has got the intention of the neurosurgeons and the thoughts of the patientsto the extent that DBS did. Since its introduction in its current form 30 years ago, DBS remains innovative in the mind of many and is acknowledged as underutilized.(3)

Benabid's clinic first reported DBS for the management of PD in 1993. After FDA authorizationfor essential tremor on 1997, DBS was widespread used. It was first admitted to Iraq in 2007, and all the implantations were carried out in the neurosciences hospital in Baghdad/Iraq. (4)

DBS provides for the PDpatients a remarkable therapeutic effect. It generates measurable electrical stimulation pulses at the goal target in the brain which

leads to intrusion with neural activity and creating areversible lesion in the implanted target nucleus whichresults, eventually, in improvement of motor characteristics of PD (bradykinesia, rigidity, and tremor).(5)

However,risingdataimplies that "DBS is more than just a neuromodulatory switch to control debilitating motor symptoms". Chronic DBS has been revealed to stimulatecontinuingreformation of neuronal circuits throughout enhanced synaptic plasticity and neurogenesis. Thus DBS can cause slowing of disease progression and increase survival in some PD cases.(6)

Symptomatic treatment using dopamine replacement remedycontinued to be the most useful management of PD since L-dopa was initially brought to use since the 1960s. In the end, they were coupled with motor fluctuations and L-dopa-induced dyskinesia. In a community-based study, the mean times of onset of dyskinesia were 6.6 years.(7)

In the lack of disease-modifying therapies, the presentmanagement of PD is principallyconcentrated on minimizing motor symptoms by drugs that augment intracerebral dopamine level (e.g. L-dopa, MAO-B inhibitor) or excite dopamine receptors (e.g. Dopamine agonist). On the continuing, side effects of dopaminergic treatment, counting on/off motor fluctuations and dyskinesias, commonly occur. (8) DBS of subcortical nuclei such as the subthalamic nucleus (STN),globus pallidus internus(GPI), and infrequently ventralis intermedius nucleus (VIM), can be presented as a conventional treatment for properly selected patients with L-dopa-responsive motor symptoms who suffer from disabling drug-associated side effects.(9)

The progress in DBS for movement disorders can be grouped in terms of the steps of the DBS workflow, which consist of selection of patients, selection of target and imaging, selection of hardware, surgical technique, and postoperative programming and maintenance.

Advances in every of the exceeding domains are continuing and to improve the excellence and effectiveness of DBS for movement disorders. (3,5,10,11).

Aim of the study: Assessment of effectiveness of DBS in controlling motor manifestations of advanced PD.

Patients and Method

Patients Selection: This is a prospective clinical study that incorporated 20 patients (14 male and 6 female) for whom DBS was implanted at the neurosurgical and the neurosciences teaching hospitals in Baghdad/Iraq, from March 2017 to March 2018 for bilateral stimulation of the STN. The patients were fulfilling the Movement Disorder Society Clinical Diagnostic Criteria for PD. (12)

The DBS were implanted using a fusion system of the CT and MRI images (Stealth Station- Medtronic®) to identify the site of the STN in relation to the mid-commissural point.

All the patient were right handed, and all of them were on L-dopa, procyclidine, pramipexol, and amantadine medications. In addition, intraoperative neuronal electrical activity recording was made.

All of the patients were followed for 2 months after staring of stimulation.

The inclusion criteria were:

1. Diagnosis of idiopathic PD and duration > 5 years.
2. Intolerable L-dopa related motor complications despite of optimal adjustment of antiparkinsonian drugs.
3. Improvement of motor symptoms > 50 % during L-dopa test
4. Age below 70 years.
5. No surgical contraindications.
6. No cognitive abnormality or significant continuing psychiatric illness.
7. No medical co-morbidity
8. Normal brain MRI

The severity of the disease is assessed before and after DBS implantation using UPDRS, which is a 50 question assessment of both motor and non-motor symptoms of PD.

Any patient who did not fulfill the above criteria was not a candidate for DBS implantation (e.g. severe brain atrophy, brain lesions, coagulopathy, anticoagulation therapy, immunosuppression, active psychosis, major depression with suicidal thoughts, personality disorder impairing compliance, drug abuse impairing compliance,

and poor general health conditions like severe ischemic heart disease, hypertension, and diabetes).

As a routine of the workup, the general preoperative list of diagnostic tests including hematology, biochemistry, serology, ECG, CXR and standard brain MRI were done for each patient.

The severity of the disorder was assessed, and the motor fluctuation were evaluated after the diagnosis of idiopathic PD. Also drug related dyskinesia were evaluated according to the UPDRS.[13]

Every patient should have new set of MRI studies. Closed MRI(3 Tessla) were used in our study.

The patientsresumed their preoperativedrugs regimenstraight away postoperatively to keep away from dopaminergic withdrawal symptoms.

CT scans and/or MRI were done for all the patients postoperativelyto review the electrode position and the intracranial condition. Additionally, plain X-rays were obtained to review the position and geometry of the leads and hardware. Modification of the drugs may be needed according to the patients' clinical condition. If stable, patients were allowed to return home as early as 24 hours following the surgery.

The process of programming of the patient susually started 7 days after the implantation so as to bypass the phase of lesioning result of the surgery.

Statistical Analysis: Descriptive analysis in the form of percentage was calculated using Microsoft Office Excel Worksheet and presented in the relevant tables shown below. Chi-Square test was used for statistical analysis by utilizing the Statistical Package for Social Sciences (SPSS) version 17(p value< 0.05 was considered significant).

Results

The explanatory data of the patients incorporated in this study are demonstrated in table 1.

Table 1: Descriptive data of the patients before DBS

Patient number	Gender	Age (years)	Tremor UPDRS score	Rigidity UPDRS score	Bradykinesia UPDRS score
1	Female	60	4	3	3
2	Female	33	3	3	4
3	Female	55	3	3	2
4	Male	57	3	3	4
5	Male	60	3	2	2
6	Female	56	2	2	3
7	Male	55	3	3	3

Complications: We had only 2 cases of surgical wound infection who responded well to conservative treatment by antibiotics and meticulous dressing.

Discussion

DBS has become an already established surgical option for medically intractable PD.[14] After the implantation, the motor symptoms improves comparatively to the pre-implantation response to L-dopa. The reduction of the disabling motor symptoms eventually leads to a significant reduce in the dopaminergic drugs doses with subsequent drop of drug – related dyskinesia.[15,16]

GPI and STN stimulation showed similar efficacy rates. However other studies claimed that STN stimulation is possibly superior in controlling the symptoms of PD. Choosing STN stimulation over the GPI is frequently based according to the foundational, surgeon, and programming practices and preferences. There is a more reliabletendency for major reduction in dopaminergic drugs consumption andl esser current requirement with consequential longer battery time, with the STN stimulation.[17,18,19]

In our study we followed 20 patients(14 males and 6 female), with age range from 33 to 69 years.

Lopiano et al reported improvement in tremor, bradykinesia, rigidity, dyskinesia, and motor fluctuations symptoms after DBS for PD, while hypophonic speech, dysphagia, micrographia, freezing of gait (especially if occurring in the “on” state), cognitive dysfunction, and dysautonomia did not show improvement.[13]

In our study there was a significant improvement in rigidity, tremor, and bradykinesia.

Paul Krack et al reported that in the first few days after DBS implantation, the complications related to the device were rare (less than 1%). One patient had an infection that was managed bytransitorytaking away of the subcutaneous extension lead and IPG, three deaths, one patient developed an intra-operative intracerebral hemorrhage and remained bedridden and died three years after surgery, one patient died 11 months after surgery due to myocardial infarction, and one patient had severe depression and suicidal thoughts three months before the implantation and eventually committed suicide six months after surgery.[20] This is not comparable to our results because of the bigger number of cases and extended period of follow up by Paul Krack et al.

Paul Krack et al, in five years follow up on patients with PD who had bilateral DBS-STN, found a significant decrease in the requirement for L-dopa (or equivalent drug) postoperatively (11of 42 patients did not took L-dopa anymore, and 3 patients did not took any dopaminergic drugs).[20]

Conclusions

The advantages of DBS in advanced PD is symptomatic control rather than therapeutic effects. The fate or progress of the illness will not be changed. DBS is completely reversible in comparison with the other ablative procedures. Most disabling hypokinetic manifestations, that failed to respond to medical therapy, will show effective response to the bilateral STN stimulation in advanced PD cases.

Abstract

Trichomonas vaginalis is a flagellated protozoan parasite that causes a disease called trichomoniasis in humans. It affects the urogenital tract and is one of the most important causes of non-viral genitourinary sexually transmitted infection (STI). The host's immune response plays a very important role in the onset of pathological symptoms and their differences between infected people. During the period from July to December 2019, 30 samples were collected, 20 of infected women with *T. vaginalis* and 10 samples as a control group from reviews of external women's clinics in Kirkuk city, whose ages ranged between 18-56 years so this study was designed to know the effect of infection with *T. vaginalis* parasite on some immunological parameters such as the role of humoral immune response based on the production of immunoglobulins IgM, IgG, IgA against the parasite and there estimation in serum by using Enzyme Linked Immunosorbent Assay (ELISA) technique as well as estimating the C-Reactive protein concentration as an indication of systemic inflammation and of serum iron level . The results of the current study showed a "significant" increase in the level of immunoglobulins IgM, IgG in serum of women infected with *T. vaginalis* compared to the control group, as the level of IgM (8. 2 ± 2.9 ng/dl), (6.3 ± 0.5 ng/dl) Consequently, at the level ($p < 0.05$), the level of IgG was (8.16 ± 2.20 ng/dl), (6.53 ± 1.69 ng/dl) for the infected women and the control group, respectively. As for the level of IgA, the results showed non-significant increase in the affected women compared with control group (8.22 ± 3.1 ng/dl), (7.82 ± 2.8 ng/dl), respectively. The results of estimating the CRP concentration showed a significant increase in the infected women compared to the control group (5.76± 1.56 mg/dl), (4.61± 0.66 mg/dl), respectively. While the results of measuring the level of iron showed a significant decrease among infected women and the control group (38.79 ±8.23 mg/dl), (93.83± 34.76 mg/dl), respectively. We conclude from the above that infection with *T.vaginals* stimulates the humoral immune response and affects on immunoglobulins levels, CRP concentration and Iron serum level.

Keywords: *T. vaginalis, lgM, IgG, IgA, CRP, Iron level.*

Introduction

Trichomonas vaginalis It is one of the flagellated protozoan parasite that causes Trichomoniasis by affecting the urinary genital tract in humans and is one of the most important causes of non- viral genitourinary sexually transmitted infection (STI) with a prevalence rate of 180 million annually according to WHO estimates(1). *T. vaginalis* has only trophozoite stage with a size of (7-32 μm) and is pear shaped. It possesses 5 flagellates, 4 of which are forward with a fifth flagella that bends back along the undulating membrane and lacks the cyst stage and possesses a central nucleus and Axostyle, Trophozoite is divided by binary fission. The parasite is an aerotolerant anaerobes that dissolves whole carbohydrates into short chains of organic acids Especially (acetate and lactate) Regardless of the presence of oxygen. The parasite produces hydrogen

molecules in the absence of oxygen, and this reaction occurs in hydrogenosomes that like mitochondria (which are not present) in *T. vaginalis*, which are energy-producing organelles surrounded by two membranes[2].

T. vaginalis live in the vagina and urethra of the female and in the prostate, seminal vesicles and urethra in the male. The incubation period ranges from 4-28 days, and the normal acidity of the vagina pH 4.0-4.5 inhibits infection, but when the parasite moves to the vagina, pH will change in the vagina to the alkalinity pH 5-6 due to metabolic processes of the parasite, which promotes the growth and duplication of it[3].

As for the clinical symptoms of trichomoniasis, they have a wide range, ranging from asymptomatic in more than 50% of women to moderate and severe infections. The main causes of the different symptoms are due to the virulence factors of the parasite, the genetic difference and the immune response of the host to the parasite[4]. The symptoms are white to green secretions, frothy discharges, mucopurulent accompanied by severe itching and burning in the affected area, and small hemorrhagic spots in the vaginal and cervical mucosa of the uterus known as strawberry cervix [5].

Innate immunity and adaptive immunity play an important role in developing trichomoniasis, as innate immunity includes many defensive physical barriers that prevent the transmission of the parasite to the genital tract and include epithelial cells, mucous and acidic pH in the vagina which is caused by the Lactic acid produced by commensal bacteria such as *Lactobacillus spp* in healthy women[6].

Humoral immunity is an important role in the immune response against trichomoniasis. Local and specific antibodies have been established in the serum of patients with the parasite as well as in experimental studies, as a high level of IgM, IgG, IgA[7] has been observed. During the latter 40 years have been relying on method and techniques to measure the level of the these immunoglobulins and their classes such as radioimmunoassay and ELISA to find out the role of humoral immunity in eliminating pathogens that enter the body[8].

C-Reactive Protein is a protein produced from the liver to the blood circulation and stimulates its production by many cytokines such as IL6 and TNFα and plays an important role in the immune response to pathogens that enter the body and is considered as an indication of systemic infections and evidence of the acute phase and severity of infection, also in chronic infection but to a lesser degree than in acute infections, and vaginitis which caused by *T. vaginalis* is a form of systemic inflammation response[9].

Iron is an essential ingredient for living organisms, including humans and parasites, because it is necessary for biological processes including oxygen transport, DNA formation, and electron transport[10]. Also, some parasites such as *Trichomonas vaginalis*, Giardia *lamblia* and *Entamoeba histolytica* need iron in high concentrations ranging from (5-200 μm) to their growth compared to other prokaryotic and eukaryotic organisms.

Iron is very necessary in the pathogenesis of *T. vaginalis* as it contributes to cytoadherence in the surface of the epithelial cells of the vagina and regulates the genetic expression of adhesion proteins and its role was confirmed by culture experiment to find the relationship between the virulence of *T. vaginalis* and the role of iron in that[11].

Therefore, this study was designed to know the effect of parasite infection on some immunological parameters such as immunoglobulins IgM, IgG, IgA, CRP concentration, iron level in infected women and comparison with control group.

Materials and Method

During the period from July to December 2019, 30 samples were collected, 20 of infected women with *T . vaginalis* and 10 samples as a control group from reviews of external women's clinics in the Kirkuk city, whose ages ranged between 18-56 years and vaginal swabs were taken from posterior vaginal fornix and put it on tube Contains 1ml of normal saline and samples were examined within few minutes with a wet mount examination. A drop of the mixture was placed on a clean slide, then a cover slip was placed on it and examined under 100X and 400X magnification forces to observe a pear shaped trophozoite with jerky motility [12].

Five milliliters of blood samples were collected from infected women with *T. vaginalis* and control group and serum was obtained by making a centrifuge 3000 rpm for 3 minutes and keeping serum by freezing one section at -20°C to measure the CRP concentration as well as the iron level and the other section -70°C to measure The level of immunoglobulins IgM, IgG, IgA for both groups.

The level of immunoglobulin M (IgM) was measured in serum of infected women and the control group by using (Human IgM ELISA Kit), the principle of this method is based on Sandwich ELISA from (Bethyl Laboratories, Inc. USA) and the attached instructions have been followed by the manufacturer.

The level of immunoglobulin G (IgG) was measured in serum for infected women and the control group by using (Human IgG ELISA Kit), the principle of this method is based on Sandwich ELISA from (Bethyl Laboratories, Inc. USA) and the attached instructions have been followed by the manufacturer.

The level of immunoglobulin A (IgA) was measured in the serum for infected women and the control group by using (Human IgA ELISA Kit), the principle of this method is based on Sandwich ELISA from (Bethyl Laboratories, Inc. USA) and the attached instructions have been followed by the manufacturer.

CRP concentration was measured by (CRP Direct Latex Reagent kit) from (LINEAR CHEMICALS, Barcelona, Spain) and the instructions included with the kit were followed.

The iron level was measured by Iron Colorimetric Assay kit (Ferrozine method) from (LINEAR CHEMICALS, Barcelona, Spain) and the instructions included with the kit were followed. Furthermore, this study was approved and conducted by the Scientific Committee at the College of Nursing/University of Kirkuk/Iraq.

Statistical Analysis: Statistical analysis was performed using (t-test) under a significant level (0.05)[13].

Results and Discussion

1. **Estimation of immunoglobulin levels IgM, lgG and IgA:** Table 1. shows the level of immunoglobulins in the serum of women infected with parasite compared to the control group, as the results of the current study showed a significant increase in the level of IgM in the serum of women with *T. vaginalis* compared to the control group (8.2 ± 2.9 ng/dl), (6.3 ± 0.5 ng/dl), respectively. This finding is consistent with [14] who, through their studies, found a higher IgM level in the serum of mice infected with the parasite compared to the control group, also[15] found through their study a rise in the IgM level in the serum of women infected with the parasite and comparison with the control group indicating that acute infection with *T.vaginalis* stimulate the humoral immune response because IgM is indicator of acute period of infection. In addition, this is leads to knowledge of insights and trends for preventing parasite infection or developing treatment [16].

The results of the current study also showed a significant increase in the level of IgG in the serum of women infected with *T. vaginalis* compared to the control group (8.16 ± 2.20 ng/dl), (6.53 ± 1.69 ng/dl). This result is consistent with [14] who found, through their studies, a high level of IgG in the serum of mice infested with the parasite compared to the control group as well as with [17] who demonstrated through their study a rise in the level of IgG in the serum of women infected with parasite compared to the control group, which indicates that chronic infections are common especially in married women due to repeated infection and leave it without treatment .Moreover, to the fact that most of the infected women are asymptomatic when infected with *T. vaginalis*. In addition to what has been mentioned, the role of immunoglobulin, especially IgG, has a significant role in humoral immunity to control the parasitic infection[18].

The results of the current study also showed a significant increase in the level of IgA in the serum of women with *T. vaginalis* compared to the control group (8.22 ± 3.1ng/dl), (7.82 ± 2.8 ng/dl), respectively, and this result is consistent with [18] as well as with [17], As our study showed that there are no significant differences between the patients and the control group, and the reason for this result is that IgA rises in acute cases of the disease and returns to its normal level in chronic cases, and because most of the cases with *T. vaginalis* are chronic cases as mentioned Above. As the immune response depends on humoral immunity and begins as a local inflammation at the place of invasion and pathogen presence, WBC is attracted to the site of infection and produces cytokines, which in turn stimulate the production of specific immunoglobulins, especially IgA, which is considered one of the main media specialized in host defenses present in the secretions. The proteinase secreted by the parasite *T. vaginalis* is excreted in the vaginal and serum secretions and reduces the level of immunoglobulins over time and this effect on humoral immunity is one of the most important reasons for the difficulty in forming a vaccine against *T.* vaginalis [19].

Table 1. Immunoglobulins levels in women infected with *T. vaginalis* and control group

Mean ± SD (ng/dl) Control group n=10	Mean ± SD (ng/dl) Patients n=20	Immunoglobulins levels In serum
6.3±0.5	8.2±2.9	IgM
6.53±1.69	8.16±2.20	IgG
7.82±2.8	8.22±3.1	IgA

2. **C-Reactive Protein concentration:** The results of the current study showed a significant increase in the CRP concentration in the serum of women with T vaginalis compared to the control group (5.76 ± 1.65 mg/dl), (4.61 ± 0.66 respectively) (Table 2) and this is consistent with [20]. The high concentration of CRP in the serum in women with the parasite represents a strong link between localized vaginal infection and the response of the body's systems to infection, as CRP is produced from the liver in large quantities and transmitted to blood circulation and rises in bacterial, fungal and parasitic infections and is considered as an indication of the presence of infections in the body, it is not A diagnostic test, but it is used to link signs and symptoms.

Infection with *T. vaginalis* stimulates the cellular immune response, as the parasite causes vaginitis in females and urethritis in the male. The high CRP in the serum of infected women indicates that the reactions of the immune response to the parasite have exceeded the boundaries of the mucosal genital tract in the host[8].

Table 2. CRP concentration in women infected with *T. vaginalis* and control group

Mean ± SD mg/dl	Number of samples	CRP Concentration Group
5.76±1.56	20	Patients
4.61±0.66	10	Control

3. **Serum Iron level:** The results of the current study showed a significant decrease in the iron level in the serum of women with *Trichomonas vaginalis* compared with the control group (38.79 ±8.23 mg/dl), (93.83±34.76 mg/dl), respectively (Table 3), and this result is compatible with[21]. Note that the normal level of serum Iron level is (50-170 mg/dl), and the reason for this is that iron is a key component in pathogenesis of the parasite as the level of adhesion to human cervical cell line, or what is called Hella cells, changes with iron levels, because *T. vaginalis* isolates from an iron-rich medium show a high level of adhesion and the reason is because the parasite has developed many mechanisms for adhesion, including Lipophosphoglycan, which is a major adhesion factor for parasite. In addition to Adhesion Proteins (AP), Fibronectin binding protein (FN), Laminine –binding protein, these proteins have the ability to interact with the parasite through their own receptors on its surface. Moreover, the presence of four types of important proteins in the adhesion process, namely (Ap33, Ap23 Ap51 Ap65), which iron plays a very important role in the process of gene expression and translation of these proteins [22]. There are many experiments proven by scientists [23] on the role of iron in the pathogenicity of the parasite, as they cultured *T. vaginalis* in the Trypticase yeast media (TYM) which provided with iron, While the parasite's isolates from an iron-deficient medium failed to produce any pathogenicity[24]. The source of the iron for the parasite comes from hemolysis of red blood cells from lesions formed by the parasite in addition to iron from the menstrual blood cycle[25].

Table 3. Serum Iron level in women infected with *T. vaginalis* and control group

Mean±SD mg/dl	Number of samples	Serum Iron level Group
38.79±8.23	20	Patients
93.83±34.76	10	Control

In conclusion, infection with *T. vaginalis* affects on some immunological parameters levels which indicate the role of humoral immune response against trichomonasis, also the infection decreases serum iron level due to important role of iron in pathogenicity and cytoadherence of *T. vaginalis*.

Heuristic "Bottom-up": COVID-19

Taranjeet Duggal[1], Ayush Sundriyal[2], Abhishek Kakkar[2], Neeti Mittal[2]

[1]Professor, Amity Business School, Noida, [2]Research Scholar, Amity Business School, Noida

Abstract

Background: COVID 19, a global pandemic has led to the disruption all over the world. Not only the COVID outbreak but the measures taken to straighten the curve led to the psychological distress amongst people. The disruption in daily routine which changed People's lifestyle, the changed business working environment while COVID and post COVID. The concept to adapt to the new normal still seems abrupt.

Method: This present study was done amongst Indian youth and working professionals (age 18-28) in order to understand their psychological well-being in these COVID times. With collection of data through an online questionnaire more than 350 people participated. The instrument used was DASS-21 and a self-conceptualized VIRUS scale. All statistical analysis was computed through SPSS 21.

Conclusion: This paper aims to contribute through exploration into the stressors and how the COVID situation has brought about vexation, immediate concern, routine disruption and uncertainty about future. Through these four factors we obtain results that elaborates on what will affect their life's the most, highlighting the need for post-COVID interventional strategies in business environments and in one's lifestyle.

Keywords: *Covid-19, DASS21, Mental Health.*

Introduction

The novel coronavirus has taken over our normal lives, this virus has transmitted globally and transformed the normal of the world. We can only talk about the new normal, the daily update of the increasing cases has a great psychological effect on the human mind. COVID-19 has wired youth to fear, uncertainty, dragging people with frustration and sadness. Reports have proven other pandemics have played a similar role like the SARS and H1N1 over human behavior showing signs of distress and anxiety. Generally, more than 25% of the population in China faced high- level stress traits (Wang et al., 2020)[(1)]. The state of mind and the behavior during these times are due to misinterpretation of the set-offs by themedia.

These reports are similar to what was described during the time of the SARS epidemic moreover, the experience and the idea of contracting the COVID-19 have put pressure and increased psychological suffering. In any epidemic, physical health suffers but a significant amount of damage is caused to mental health too. Trauma, panic, anxiety, and suicidal thoughts during an outbreak of such disease are common psychological distress caused in an individual (Tucci et al., 2017; Taylor et al., 2008).[(2)(3)]

Anxiety can be understood as a sense of worry, tension, physical changes such as trembling, dizziness, or increased blood pressure or change in a heartbeat. Anxiety can lead to many issues which can lead to limited socialization and limitations in daily life activities. If caused within the larger population, it can lead to panic buying which leads to exhaustion of resources. Many people tend to get affected mentally due to a pandemic and can cause high anxiety which affects the emotional well-being adversely. Thus, it is critical to manage mental well-being. Research has shown that approximately 1/5th of the people experiences severe to very severe anxiety and in terms of gender, females

tend to feel more anxious than male (Moghanibashi-Mansourieh,2020)[4].

As a preventive measure, the government of India decided to implement a lockdown and people were home quarantined which drastically changed people's lives. However, mental health degradation was not because of the control measures (lockdown/Quarantine) but due to the changes it caused in daily life (Li et al., 2020) [5]. It has been found that disruption in daily routine can lead to a variety of mental disorders. Due to the prolonged Lockdown as a countermeasure against coronavirus, there has been a disruption in the lifestyle of people which may increase the emotional distress amongst people and can result in developing psychological distress (mental illness) even amongst those healthy individuals with no prior medical history (Zhang and Ma, 2020)[6]. It has been said that people end up suffering more mentally than the number of people who are physically injured after such an outbreak. The psychological wellbeing is affected immensely and may last for a longer duration. (Allsopp et al., 2019) [7].

Psychology is extremely relevant in understanding how people cope or react in such times. The experience of the COVID-19 is changing our lives. The disruptions faced in such unfamiliar living situations – work, financial worries and relationships. Change in lifestyle has led to **vexation** in our relationships with lack of physical meeting or touch and at the same time the trauma of the virus has created frustration, **immediate concern** about the lockdown, the idea of panic buying being prevalent, **routine disruption** coming to our lives lack social meetings or any daily activity be it work or school, overall facing uncertainty about the future not knowing the timeline of this virus which is complexed, the exceptional circumstances have created an ambiguity and major procrastinations among individuals.

The COVID 19 pandemic has caused distress in many people's lives and left many people vulnerable to mental health issues and has led to suicidal behavior. Mental health consequences are likely to be present for longer and peak later than the actual pandemic. This paper talks about the sensitive topics - depression, anxiety and stress among youth. Crippling bouts of COVID-19 began to take over the youth's mind, leading to mental stress. This is the study of negative mental health outcomes (depression, anxiety, and stress) and psychological distress (VIRUS stressors). The question here arises that during this lockdown how seriously these negative health outcomes affected the respondent. Negative outcomes include impaired performance (unproductive feel), poor quality of life, the uncertainty of the future, fear all around due to increasing cases of COVID, and others.

Research Objectives:

1. To study the level of stress, anxiety and depression in the Indian environment due to Covid- 19.
2. To Study the Factors affecting the mental health
3. To study the psychological stress (unpleasant feeling or emotions that have an impact on the level of functioning/negative views or perception we are attached toCOVID-19)

Review of the Literature: Outbreaks of diseases and pandemics have been found to create distress and have shown major mental illness (Bao et Al 2020) [8]. There is the future scope for research and exploration with a clinical scope. Pandemics and outbreaks are catalysts to the global mortality rate (Verikios2016) [9]. Various factors including gender, explicit experience with COVID19 infection, Isolation, and exposure to media can make one vulnerable to Mental illness and can cause psychological distress (Li et al., 2020) [5].

Chinese individuals' psychological wellbeing has fallen apart, a higher prevalence rate of depression (50.7%), Sleep-deprived (36.1%), anxiety (44.7%), and stress-related problems (73.4%). Lack of information related to COVID 19 led to these higher rates of mental health issues in China. Generally, at the beginning phases of a pandemic, individuals have little data about the nature of the disease, treatment, casualty rate, and so forth fueling the fear (Xiang et al.2020)[10]. Isolation can induce fatigue, outrage, nervousness, loneliness, boredom, and depression. Economic damage and widespread lockdown led to much psychological distress amongst people. Added to this is the plenty of falsehood information circulating on the internet and social networking media that led to a lot of uneasiness. Circulating this misinformation can contribute tot he spread of illness and that is very much common for COVID-19.

Although there is no current evidence as to the direct effects of SARS-COV-2 on mental wellbeing, there has been a significant increase in psychological distress such as anxiety and depression along with more negative impacts on the health of the general public (Vindegaard

and Eriksen Benros, 2020)[11].In addition, it causes severe psychological anxiety (Chen et al., 2020)[12], which could adversely affect the quality of life and can influence individuals working and social functioning (Monson, Caron, McCloskey, and Brunet, 2017)[13]. As specialists all over the world work hard to find effective vaccines and antibodies against COVID-19, the mental effect of the disease is to a great extentdisregarded.

Pandemics like these do not only affect physical wellbeing; they in general influence the quality of living not only on an individual level but as a whole; causing widespread panic, xenophobia, social dysfunction, and social stigma. The first suicidal case in India of a 50-year-old man was reported dead fearing that he had contracted coronavirus. So, he locked his family and killed himself (Goyal, Chauhan, Chhikara, Gupta & Singh, 2020)[14] As the worldwide prevalence increased, people started hoarding medical supplies and basic necessity which caused havoc in many countries, people started isolating themselves due to the fear of the COVID and restricted their social interaction to minimal, People got health conscious but it was so anxiety-driven that even a mild condition like cold which is just one of the symptoms of the illness led to an increase in psychological distress (Duan and Zhu, 2020)([15] When contrasted with before the outbreak situation, information is still scarce on the effect of mental wellness in the general population (Sonderskovetal., 2020)[16]. Researchers have found no major distinction in anxiety, depression, and stress level sin the period with numerous new cases compared with the period of many recovering (Wang et al., 2020)([1]. Long-lasting impacts of COVID 19 should be expected, it is known from the earlier experience of SARS-CoV-1, that those who were affected by it (for example; due to isolation) had mental side effects a long time (several months) even after the controlover the epidemic.

At any point when a country is struck by large-scale and deadly disasters of different types, the quality of psychological well-being is affected, and various issues related to mental health can emerge which can differ across different periods. Any significant outbreak will negatively affect people and society. Terrorist attacks like one at the Pentagon and anthrax attacks demonstrated how important it is to re-establish the resources and mobilize them in order to respond quickly to the disaster-related mental health needs of the affected individual (Dodgen, LaDue and Kaul, 2002)[17] When the SARS plague hit, mental health was affected not exclusively due to the working condition of the workplace but also due to the thoughts of close ones getting affected by the virus which generated psychological trauma (Wu et al., 2009)[18] Most COVID-19 patients experienced PTSD (Post-traumatic stress disorder) before even leaving the hospital, and these side effects may prompt negative results in their day to day life after COVID for example, lower personal satisfaction and performance of work. Following the episode SARS in 2003, the predominance of Post-traumatic stress disorder (PTSD) in SARS survivors was 9.79% in their initial recovery stage (Fang, Zhe, andShuran, 2004)[19] and Post-SARS assessment (approximately after 30 months) it was 25.6%. (Mak, Chu, Pan, Yiu, and Chan, 2009)[20]

One survey showed that respondents aged 12-21 had severe impacts on their mental health due to the prolonged lockdown. This age bunch mostly consisted of school students and undergraduates who were affected because of the school closure, uncertainty about their exams, and making arrangements for online education. Young individuals have had their education and career interrupted and are anxious about the future. UGC has given a few rules to Higher Education Institutes, to deal with the Mental Health, Psychosocial concerns and Well Being of Students Community during and after COVID-19 Pandemic. Loss of work and monetary stressors are recognized as the major factors which can lead to suicide. (Stuckler, Basu, Suhrcke, Couttsand McKee, 2009) [21] Studies have shown that adults who were not working reported worse health. Studies have shown a high and perhaps even alarming prevalence of depressive symptoms in both developed and developing countries (Al-faris et al., 2012) [22]. It is demonstrated through a study that 3% to 9% of adolescents are found to be depressed anytime, and 20% of them report a lifetime pervasiveness of depression toward the end of the adolescence (Zuckerbrot and Jensen, 2006) [23]. Malaysian report uncovered that nearly 1 out of 5 Malaysian adolescence is found to be depressed (Kaur et al., 2014) [24]. Teenagers who felt lonely more often than others or continually felt alone over a period of 1 year are 3 times more likely to be characterized as depressed by the DASS21 assessment and that social isolation was one of the major reasons for depression in 11-to 14-year-olds. Longer duration of depression and more frequent episodes can lead to poor work performance, poor coping skills, and various negative traits such as low self-esteem and low positivity. It can also affect your relationships with your loved ones (Pettit, Lewinsohn, Roberts, Seeley, and Monteith, 2008) [25]. 7 out of 10

US adults experience anxiety/stress at a moderate level every day, as indicated by an ongoing report led by the Anxietyand Depression Association of America. Whiles tress is considered to bean inevitable part of life, it is present and very much becoming prevalent in students (Gallagher, 2008; Mackenzieetal., 2011).[26][27] Younger peopled is playa high risk of psychological problems (Huang & Zhao, 2020)[28].

Mental health professionals should be advised to instruct people about the psychological consequences, they should promote healthy mental behaviors. People should be encouraged to reduce their exposure to negative information. And in order to maintain social distancing people should use more virtual networks (Banerjee, 2020) [29]. Furthermore, the need of the hour is to create mental health interventions that can be communicated to general health care workers and volunteers and these strategies can be spread amongst workers (*Rajkumar*, 2020)[30]. Psychological distresses should be identified at the initial stage for allowing the efficient implementation of interventional strategies.

Research Methodology: Research Goal: The goal of the present study is to evaluate the potential sources of depression, anxiety, and stress correlating with the stressors of VIRUS (vexation, immediate concern, routine disruption, and uncertainty about future).

These were addressed by surveying a sample with a mix of young adults and working professionals (age group 18-28 yrs) from varied sources using the DASS 21 scale with VIRUS stressors.

Data Collection: The primary method of data collection was used, an online questionnaire was distributed. More than 350 people participated.

Given the established measure of the DASS21 Lovibondversion of it, the survey consisted of a demographics section, a list of stressors (VIRUS), and 21 questions.

The first portion of the survey constituted the most inevitable part of life, stressors that were pertinent in the times of a pandemic Covid-19. The responses were recorded on a Likert scale (0-3). It was estimated individuals would exhibit increased levels of those stressors.

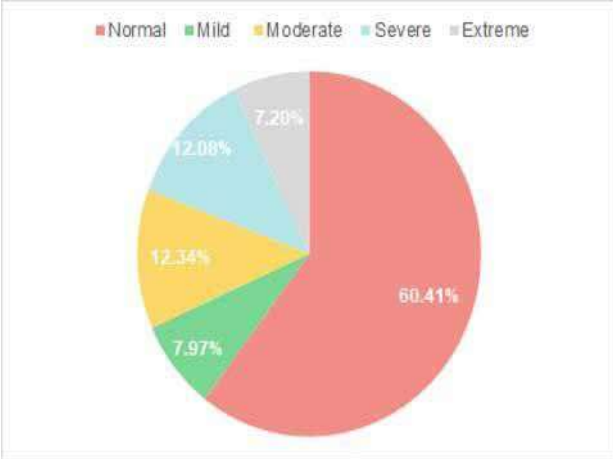
DASS21 measured the prevalence of the symptoms on a 4-point Likert scale 0-3. A score of 0 indicated that the item "did not apply to them," and a score of 3 meant that the participant considered the question to apply "very much, or most of the time" (Gomez, n.d.).

Virus Stressors:

Vexation: Feeling imprisoned at home, relationship with loved ones and being unproductive

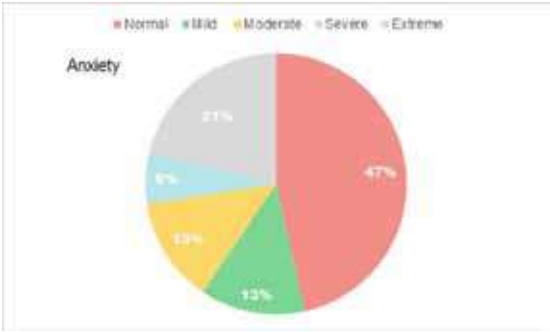
Immediate concern: Feeling afraid if something awful might happen, an increasing number of Covid-19 cases, and changed lifestyle

Routine disruption: Spending more time on gadgets for media consumption, learning new courses or exploring E-platforms



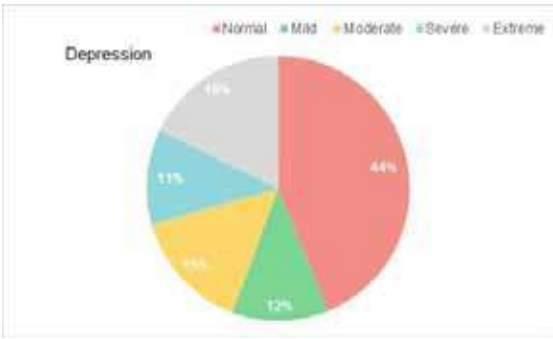
Uncertainty about future: Academics and graduation timeline, market disruptions, and financial challenges

Data Analysis method: After the data were collected and inserted in SPSS software, they were analyzed descriptive statistics (mean and standard deviation) and inferential statistics (independent t-test and analysis).



Data Analysis: The Findings suggest a correlation disclosed that VIRUS stressor sf or each aspect had a significant positive correlation.

DASS 21-The tallies of DASS 21 positions each partaker's depression, anxiety, and stress levels, assorting each area as either "normal," "mild," "moderate," "severe," or "extremely severe." Out of those analyzed,60.41% accounted for symptoms of severe levels of stress,47% signaled severe anxiety, and 44% severe depression.



A. Stress

B. Anxiety

C. Depression

Our sample was able to filter out top 7 sources of concern, based on the DASS moderate and extreme cases were Uncertainty about Future (Market disruptions & Financial challenges), Routine disruption (Spending more time on gadgets for media consumption, Sleep-deprived al the time & Learning new courses), Immediate Concern (Increasing cases of COVID 19) and Being Unproductive.

A succession of ANOVAs with VIRUS as an independent factor and the DASS-21 scales as the dependent factors showed a significant effect of the scales, including:

Table 1: Stress and Virus (R2 =0.357, F=17.16, P < 0.01)

Stress	Coefficients
Feeling imprisoned at home	0.730
Being Unproductive	0.853
Spending more time on gadgets for media consumption	0.884

Table 1 speaks about the body's response to the circumstance where we feel imprisoned at home threatens the feeling of self. Individuals are vulnerable to widespread concern and are feeling more lonely. Stress is researched to be beneficial for being productive, the unproductive stress is making individuals overwhelmed. There is a lack of accomplishment in these times. Major setback being exposure to gadgets, there is a growing addiction to technology and an overdose to media.

Table 2: Depression and Virus (R2=0.384,F=19.29, P < 0.01),

Depression	Coefficients
Feeling imprisoned at home	0.672
Changed Lifestyle	1.061

Table 2 gives data on Mental health, that has brought about a status among individuals hence they feel worthless and trapped at home, this feeling has affected their outlook towards life. Individuals are not able to accept the change and take a toll on their mental health.

Table 3: Anxiety and Virus (r2=0.304, F= 13.515, P < 0.01)

Anxiety	Coefficients
Changed Lifestyle	0.851
Market Depression	0.882

Post regression analysis in Table 3 we observe with Anxiety and VIRUS factors show that economic fissures have created uncertainty about the market conditions among individuals. The possibility of job loss, salary cut, and the steps taken in the macro environment have created a feeling of anxiety.

Obsessive thoughts regarding the COVID are giving headaches and other common symptoms. These negative thoughts have created an irritable environment causing mental fatigue.

Table 4: Correlation

Variables	Depression	Anxiety	Stress
Relationship with loved ones	.006	.32	.22
Changed lifestyle	.01	.45	.07
Market disruptions	.040	.114	.203
Learning new courses or exploring E- platforms	.282	.975	.179

Table 4 presents Correlations between the DASS-21 scales and VIRUS as variables Referring to Table 1 using correlation the sig. value is .000, which is less than the alpha values 0.01. Therefore, thereexists a significant relationship between feeling imprisoned at home, being unproductive, feeling afraid if something

awful might happen, changed lifestyle, sleep-deprived at all the time, academics, relationship with loved ones, increasing number of Covid-19 cases, spending more time on gadgets, graduation timeline, financial challenges, learning or exploring new courses, and market disruptions with DASS.

Discussion and Conclusion

Our emotional resources are used up in trying to cope with challenging situations. We currently have two viruses to tackle, one being COVID, and other which we all are infected in some way or another when it comes to COVID VIRUS:

Vexation due to imprisonment at home, families are suffering relationship turmoil's and the morale is low due to the unproductive lifestyle. **Immediate concern** has created a mental health crisis, there is a feeling of helplessness and uncertainty, the increasing number of Covid-19 cases has added to manage this fear of the unknown and the changes in lifestyle such as norms of distancing and a not-so-luxurious life. **Routine disruption**, the fight against this virus is long, spending more time on gadgets for media consumption, giving time to self- improvement as learning new courses, or exploring E-platforms. **Uncertainty about the future,** be it economic uncertainty, academics and graduation timeline, market disruptions, and financial challenges.

DASS-21 is the assessment and clinically validated screening instrument of depression, anxiety, and stress among youth. This scale assesses the person's perception of life and interest in certain things. In COVID-19 times, we tried to assess the mental health among youth. This study evaluates the measures of depression, anxiety, and stress in young adults with the factors of concern for our sample, based on Covid-19 VIRUS correlating with depression, anxiety and stress were Vexation or Frustration (feeling imprisoned at home, being unproductive), Immediate concern (feeling afraid of the dire future, increasing number of coronavirus cases), Routine Disruption (spending more time on gadgets, sleep-deprived), & Uncertainty about future (academic and graduation timeline, financial challenges). There is a significant relationship between VIRUS and DAS (depression, anxiety, and stress).

The preliminary objective of this paper was to confine potential sources of depression, anxiety, and stress, respectively each item specified in the study had a significant positive correlation with scores of depression, anxiety, and stress. Out of the 4 parameters of VIRUS, vexation, or frustration (being imprisoned, and unproductive), evaluate the gravity of the symptoms of depression, anxiety, and stress. This paper included 12 factors under these parameters of VIRUS. There exists a negative impact on mental health problems due to spending too much

time on gadgets and sleep-deprived. Financial difficulties and academic concerns (future uncertainty) correlate with extreme levels of these mental health problems. The negative perception of fear of awful happenings and an increasing number of cases of coronavirus, causing an increase in depression, anxiety, and stress.

Present results coincide with previous research that shows multiplied incidences of mental health problems in times of a pandemic. Publications have taken up the psychological brunt of the virus on the masses, established on information from previous disease outbreaks and papers (Zandifar and Badrfam, 2020)[31] that show social isolation contributes towards mental illness. (Shigemura et al., 2020)[32]Showing the fiscal impact of the virus and mental health.

This paper is able to add the importance and role of educating the masses about the psychological effects of any pandemic, this will evolve the mindset and bring about the survival instinct to find strategies to handle the present-day crisis. We have analyzed the negative screens of DAS responsible to affect mental stability among youth. Further exploration can be piloted in this area to understand the Interventional strategies of post-COVID (In business and normal lifestyle).

Abstract

The Galvanic vestibular stimulation (GVS)is proven to be a promising tool to improve vestibular functioning. Decline in vestibular functioning in the elderly results in decreased capacity to identify weak signal which may lead to postural instability. Postural sway is produced when GVS is given over mastoid process. In this study our aim is to determine whether GVS can be utilized to maximize the effect of balance training programme among elderly individuals. Ambulatory community dwelling elderly (N=150, age 65.67±3.4 yrs) were randomly assigned to a control group (Group A, n=50, age 65.54±3.4 yrs), Placebo group (Group B, n=50, age 65.5±3.3 yrs) and an experimental group (Group C, n=50, age 65.98±3.5 yrs). Group A was not given any intervention while group B was given placebo stimulation along with balance training and group C was given noisy galvanic vestibular stimulation along with balance training program. Pre, mid and post data were recorded for overall stability index (OSI) (Biodex Balance Master) and Timed up and gotest (TUG) and analyzed. Compared to control group there was a significant improvement in overall stability and mobility in placebo and experimental groups. Significant difference was observed in improvement in experimental group compared with placebo group for both,OSI and TUG. Early improvement in stability and mobility was also observed in experimental group but similar results were not obtained in control and placebo groups. The outcome of this study suggests that GVS can be utilized therapeutically to optimize the efficacy of balance training clinically.

Keywords: *Fall, Postural Stability, Mobility, Vestibular Stimulation.*

Introduction

Older individuals constitute over 7.4% of the total population of India, and the elderly are a rapidly growing demographic.[1] Falls and fall associated secondary injuries in elderly are a serious concern, and a foremost cause of mortality and morbidity in them.[2] About one-third of community-dwelling elderly have a tendency to incur a falls, and 50% of those who fall have recurrent falls.[3–5] The Fall Mortality Rate is 2.1 in India.[16] Multiple factors contributing to fall risk, including physical, environmental, and behavioral have been identified. The role of the vestibular system for maintenance of upright posture is well understood. Age associated changes such as loss of muscle girth, loss of vestibular hair cells, degenerative musculoskeletal transformation or the onset of chronic diseases and their consequences are closely related with reduction in static and dynamic balance, and likely to cause falls.[7–9] Early identification of vestibular deficits and instability, with appropriate intervention may help in reducing the incidence of falls and associated risk.

Balance training exercises are designed to improve postural stability, mobility, and activities of daily living. Balance programme includes exercises helps to

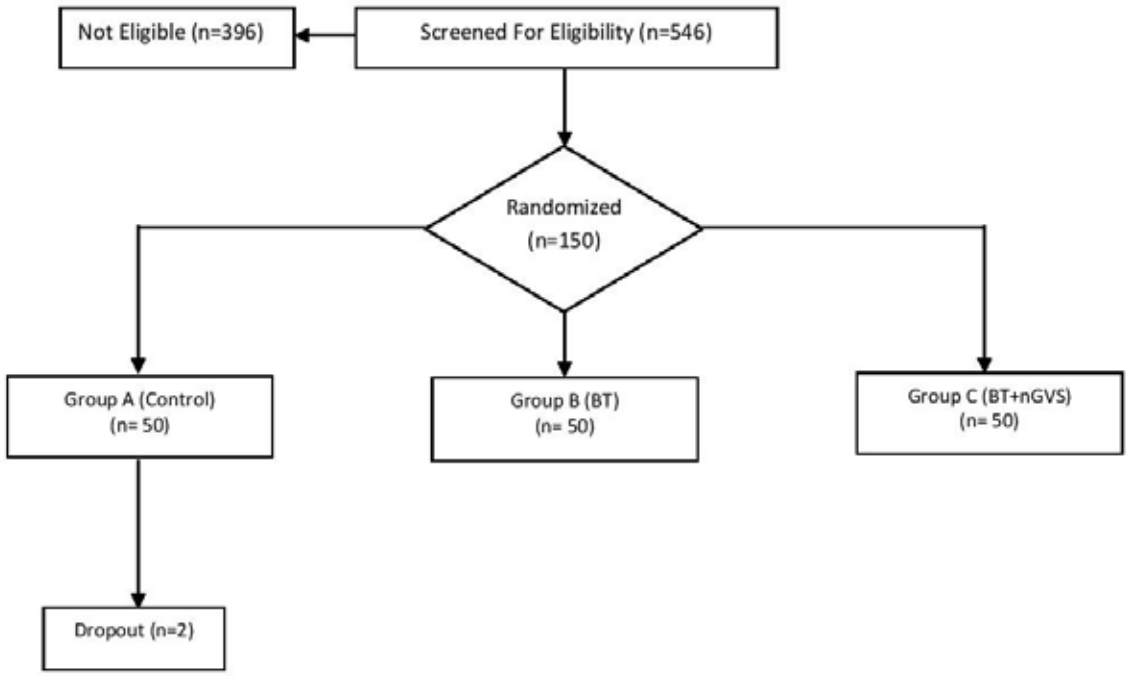
control equilibrium. Balance exercises are repetitive and progressed gradually to help to improve balance by reducing postural sway and irrelevant motor responses.[10] The maintenance of upright posture involves complex sensory systems including the vestibular system. Vestibular system is the main processing unit to maintain postural stability. As the age progresses, reduction in function of the vestibular system is well identified. Physical therapy is an established treatment for vestibular system dysfunction.[11]. However recent studies on noisy Galvanic Vestibular Stimulation (nGVS) are proven to be a promising treatment. During Galvanic Vestibular Stimulation, a small electrical current is delivered through surface electrodes over the mastoid process.[12] This transcutaneous electric current activates and induces continuous firing of the vestibular afferents.[13] In response to GVS, the capacity to identify a weak signal or to process incoming sensory information may be enhanced by adding white noise.[14]

Stimulating an individual's vestibular afferents during standing causes leaning in different directions depending upon the polarity of the electrodes.[13] Induction of a change in the electrical excitability of the vestibular nerves stimulates the vestibular nuclei and networks of the right hemisphere when the anode is attached to the left mastoid and the cathode on the right (known as LGVS), while the reverse electrode positioning (RGVS) leads to a bilateral activation.[15] Specifically, anodal and cathodal currents can be used to artificially decrease and increase the firing rates of the vestibular afferents. A standing subject tends to sway towards the anodal stimulus and/or away from the cathodal stimulus.[16] Another study shows that the sway response increases in direct proportion with the stimulus intensity when constant galvanic current is given.[17] Bilateral activation of vestibular cortices is obtained by applying left-cathodal/right-anodal GVS.[18]

Previous studies show that M1 a-transcranial direct current stimulation along with treadmill based gait training reduces the anterior posterior and medial lateral sway that significantly improved static balance along with functional performance in cerebral palsy children.[19] GVS when delivered to adults in quite-standing with open eyes, results in reduction in sway length and sway velocity.[20,21] It also produces similar results in bilateral vestibulopathy during quite-standing with closed eyes.[22,23]

In another study stochastic vestibular stimulation during walking resulted in increase in the gait speed and changes in stride length in healthy adults.[24,25] Sensitivity of the vestibular system to normal vestibular inputs can be increased by adding noise to subthreshold stochastic vestibular stimulation. This increase in the sensitivity is important to postural stability in more challenging situations. Studies suggested that noisy vestibular stimulation alters visuomotor activity and motor circuit functioning in Parkinsonism. This sensorimotor integration and performance might be associated to change in oscillation related to processing of information and error.[26]It has been shown that more erect posture is maintained after mechanical perturbation when appropriate galvanic current is given over the mastoid process.[27]

Thus the objective of this study was to determine the effect of noisy Galvanic vestibular stimulation on postural stability and mobility among elderly by performing a randomized control trialand to determine whether GVS can be utilized to maximize the effect of balance training programme among elderly individuals.



Method

This study employed a repeated measure design and a randomized controlled trial. A total of 150 participants were recruited from various Physiotherapy Centers in Noida, India and randomly allocated to three groups.

Inclusion criteria included individuals of both gender with age between (60 – 75) years, can walk in the community independently, able to perform the balance tests without assistive device and able to participate in a series of balance classes. All participants provided with patient information sheet.

Our study excluded subjects with the history of, any orthopedic surgery in the lower limbs, psychoactive medication in past six months, persons with progressive neurologic disorder that could affect balance and gait, orthostatic hypotension, unstable medical condition, diabetes for more than five years, vision less than 6/6 in either eye (even if corrected),fall in past 6 months and patient with high risk of fall (Tinetti<19)

Figure 1: Recruitment of study participants

A total of 546 volunteers were initially screened for the study out of which 150 who met the inclusion criteria were included in the study. Participants were randomly assigned into three groups after being fully informed about the nature of the research and taking written informed consent. (Fig 1) The first group was the control group A that included 50 subjects, 48 subjects (2 dropouts) were retested at the interval of 3rd and 6th weeks without any intervention.

50 subjects were allocated to Placebo group B who received placebo stimulation along with balance training and the remaining 50 subjects were allocated to the Treatment Group C who received noisy Galvanic Vestibular stimulation (nGVS) along with balance training.

A structured interview was conducted to collect socio demographic information including age and gender. Medical history was obtained by a physician who also recorded the presence of any symptoms associated with balance dysfunction.

All the study participants after group allocation were assessed pre, mid and post for postural stability on the Biodex Balance System and Timed Up and Go. Three trials of 20 seconds each were conducted for postural stability and mean of which was considered the final reading (as recommended in the manual described by the developers of the tool). Interval of one minute was given between each trial. Subjects sway over a fixed plate was monitored to calculate Overall Stability Index (OSI). During each trial participants were instructed to remain standing without support with eyes open. Value of OSI depends upon the rate of oscillation of the platform, lower values indicate good stability as lesser the oscillation lower will be degree of sway. For TUG every participant was given first practice trial which was not timed and then mean of three trials were considered as final value.

The intervention given in group B and C included a sixweek program of active stretching, postural control, endurance walking, and repetitive muscle coordination exercises. The actual frequency, repetitions, and resistance intensity of the exercises were adjusted according to individual ratings of perceived exertion.[28] During first week, subjects were made to exercise at a fairly low level (equivalent to 11 on the 16-point Borg ratings of perceived exertion scale). In follow up training, exercise at a moderate level of intensity (equivalent to 13 on the ratings of perceived exertion scale) were given. Balance exercises were given thrice a week for 6 weeks.

Group C Participants additionally received bi-polar binaural (left-cathodal/right-anodal) noisy Galvanic

Vestibular Stimulation of subliminal intensity for duration of 20 minutes during postural, dynamic stability and coordination exercises.

The tap water was used as a medium for lint cloth over the electrodes (60mm_40mm) and fastened with the elastic band over each mastoid to stimulate the vestibular afferents.

Statistical Analysis: All statistical analysis for Time-up and go procedure and Stability index parameters were performed with SAS 9.4 version software. Normality assumptions were tested using the Shapiro-Wilk test. All individual data parameters were tested for normality, and test variables followed a multivariate normal distribution in the population (as per the assumptions of Repeated measures ANOVA (RMA), as n>=25). The model considered here was based on an interaction effect between the treatment group and visits for between and within groups and for Least square mean estimates based on individual visits. Tukey's-Kramer method was used for adjusting p-values for multiple pair-wise comparisons for post-hoc analysis.

Summary statistics for demographics presented was based on the descriptive statistics N, Mean and standard deviation with three quartiles (Q1, Q2 and Q3) with minimum and maximum values. All statistical analysis was performed within 95% confidence interval,with alpha fixed at 5% level of significance for acceptance.

Results

All Male and Female subjects considered for this study were clustered between 60 to 74 years of age. The Mean & SD of the demographic data was comparable in the three groups. The average age was 65.5 and there were 47% females and 53% Males in the study. The average BMI was 26.44 (1.685), 26.01 (1.319), 25.99 (1.321) for Control, placebo and Treatment groups.

Time-Up and Go Test scores: The Least squares Mean values for Time-up and go (TUG) test showed a decline from Day-1 to Day-42 in both Treatment and Placebo groups compared to control group, suggesting an improvement from baseline to the end visit. There was a significant decrease in the TUG Score in treatment group **(0.604±0.017)**and in placebo group **(0.424±0.023)** at Day 42 compared to Day-1 ($p<0.0001$) and the post-hoc pair wise comparison test was statistically significant ($p<0.0001$).

Table 1: Pre, Mid and Post by shift difference - within Group – Time Up and Go Test

	Estimate	SE	95% CI	P-value
Treatment With Group Difference				
Pre-Mid vs. Mid-Post Difference	-0.100	0.016	[-0.13;-0.07]	<0.0001
Mid-Post vs. Pre-Post Difference	-0.352	0.019	[-0.39;-0.32]	<0.0001
Pre-Mid vs. Pre-Post Difference	-0.252	0.016	[-0.28;-0.22]	<0.0001
Placebo With Group Difference				
Pre-Mid vs. Mid-Post Difference	-0.200	0.016	[-0.23;-0.17]	<0.0001
Mid-Post vs. Pre-Post Difference	-0.312	0.020	[-0.35;-0.27]	<0.0001
Pre-Mid vs. Pre-Post Difference	-0.112	0.016	[-0.14;-0.08]	<0.0001
Control With Group Difference				
Pre-Mid vs. Mid-Post Difference	0.015	0.012	[-0.01; 0.04]	0.2222
Mid-Post vs. Pre-Post Difference	0.010	0.013	[-0.02; 0.04]	0.7262
Pre-Mid vs. Pre-Post Difference	-0.004	0.012	[-0.03; 0.02]	0.4226

A table (Table 1) shows the evaluation of Time-up and go test for the three treatment groups, shift difference between visits. The Pre-Post Difference is high in Treatment group compared to Placebo and control groups. The pairwise comparisons between the three shift difference tests is statistically significant, for within group shift difference from Baseline to stimulated points for Treatment and Placebo groups ($P<0.001$).

Both the Treatment and Placebo groups show shift difference more in "Mid-Post vs. Pre-Post Difference" and Treatment group is more when compared to placebo. The shift in the within group difference among these shift pairs shows statistical significance in both Treatment and Placebo groups.

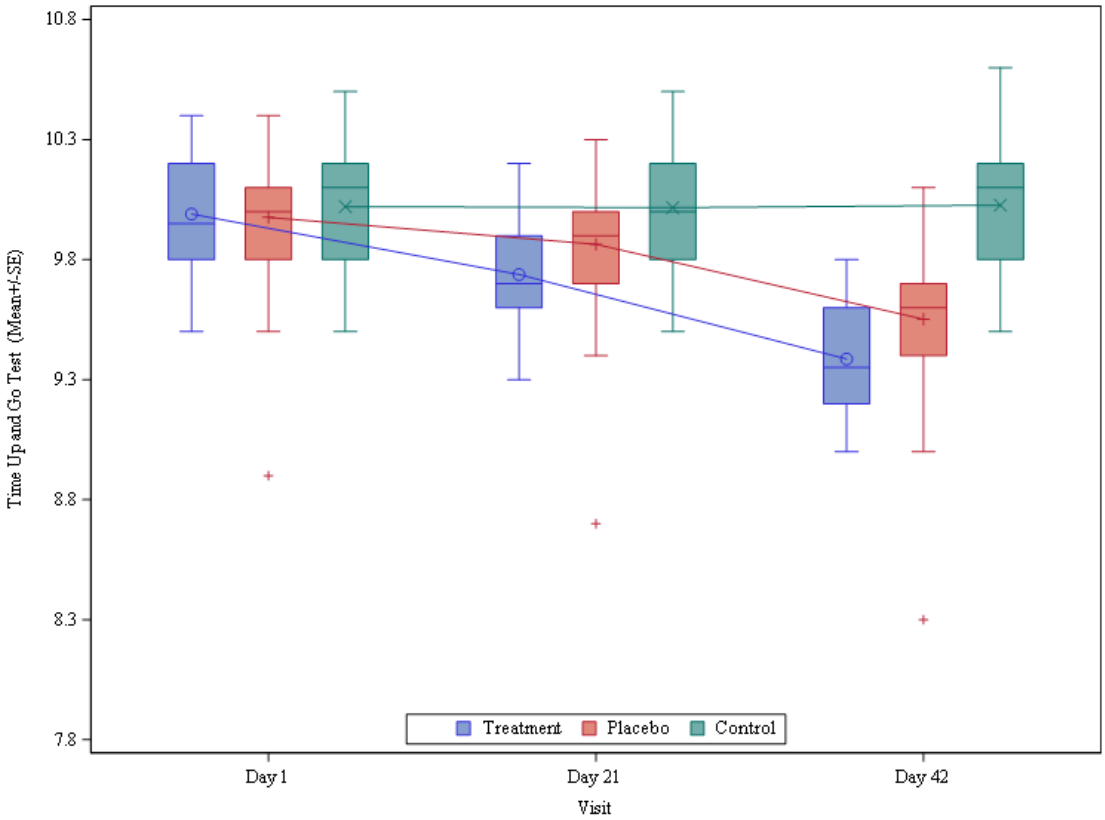


Figure 2: Box plot – By groups across the visits – Time Up and Go Test

A box plot presented in the Figure 2 compared the range and distribution of the Time up and Go Test at baseline (Day 1) and stimulated points (day 21 & Day 42). We observe that there is a greater variability for Treatment group and over time there is decrease at Day 21 and a visible decrease from mid-point to end of study in Treatment group compared to placebo and there is slight shift in increase in control group. The placebo group also has some outliers existing at all the three time points. Since the notches in the boxplots do not overlap, one can conclude with 95% confidence that the true medians do differ.

Table 2: Between the groups shift difference–Treatment estimates–Time Up and Go Test

	Estimate	SE	95% CI	P-value
Between Treatment group effects				
Treatment Pre-Mid vs Placebo Pre-Mid	0.140	0.021	[0.10; 0.18]	<0.0001
Treatment Pre-Mid vs Control Pre-Mid	0.247	0.021	[0.21; 0.29]	<0.0001
Placebo Pre-Mid vs Control Pre-Mid	0.107	0.021	[0.07; 0.15]	<0.0001
Treatment Mid-Post vs Placebo Mid-Post	0.040	0.021	[-0.00; 0.08]	0.0547
Treatment Mid-Post vs Control Mid-Post	0.362	0.022	[0.32; 0.40]	<0.0001
Placebo Mid-Post vs Control Mid-Post	0.322	0.021	[0.28; 0.36]	<0.0001
Treatment Pre-Post vs Placebo Pre-Post	0.180	0.021	[0.14; 0.22]	<0.0001
Treatment Pre-Post vs Control Pre-Post	0.610	0.022	[0.57; 0.65]	<0.0001
Placebo Pre-Post vs Control Pre-Post	0.430	0.021	[0.39; 0.47]	<0.0001

We also intend to identify the shift pairs between the treatment groups in Table 2, and in this table for "Treatment Mid-Post vs Placebo Mid-Post" had an Estimate difference of 0.040 with 0.021 Standard error with [0.00, 0.08] 95% confidence limits. This doesn't show statistical significance (P>0.005) and can conclude that these two shift difference groups show some significant difference. The other pair difference shows statistical significance and thus conclude that there is no significant difference between the considered paired shift differences and thus it justifies the previous table that the difference from Mid to post (Day 21- Day 42) for both Treatment and Placebo are tending near to same, with maximum difference between the stimulated points

Stability Index: Likewise, for TUG score, the Least squares Mean values for overall stability index (OSI) test showed a decline from Day-1 to Day-42 in both Treatment and Placebo groups, suggesting an improvement from baseline to end visit. There was a significant decrease in the Stability Index scorein treatment group **(0.604±0.017)** and in placebo group **(0.424±0.023)**at Day 42 compared to Day-1 (p<0.0001) and the post-hoc pair wise comparison test also project a statistical significance (p<0.0001).

Table 3: Pre, Mid and Post by shift difference - within Group - Stability Index

	Estimate	SE	95% CI	P-value
Treatment with Group Difference				
Pre-Mid vs. Mid-Post Difference	-0.100	0.016	[-0.13;-0.07]	<0.0001
Mid-Post vs. Pre-Post Difference	-0.352	0.019	[-0.39;-0.32]	<0.0001
Pre-Mid vs. Pre-Post Difference	-0.252	0.016	[-0.28;-0.22]	<0.0001
Placebo with Group Difference				
Pre-Mid vs. Mid-Post Difference	-0.196	0.016	[-0.23;-0.16]	<0.0001
Mid-Post vs. Pre-Post Difference	-0.308	0.021	[-0.35;-0.27]	<0.0001
Pre-Mid vs. Pre-Post Difference	-0.112	0.016	[-0.14;-0.08]	<0.0001
Control with Group Difference				
Pre-Mid vs. Mid-Post Difference	0.010	0.012	[-0.01; 0.03]	0.3894
Mid-Post vs. Pre-Post Difference	0.008	0.013	[-0.02; 0.03]	0.8631
Pre-Mid vs. Pre-Post Difference	-0.002	0.012	[-0.03; 0.02]	0.5238

Table 3 presented, to understand the pairwise comparisons between the three-shift difference and three groups been identified among shift points and groups for Stability Index score. The "pre-post" difference shows more difference among the other paired combinations in both Treatment and placebo groups.

Box plot in Figure 3 is plotted for stability index scores to compare the range and distribution of the Index score at baseline (Day 1) and stimulated points (Day 21 & Day 42). We observe that there is a greater variability for Treatment group and over time there is decrease at Day 21 and a visible decrease from mid-point to end of study in Treatment group compare to placebo and there is slight shift in increase in control group.

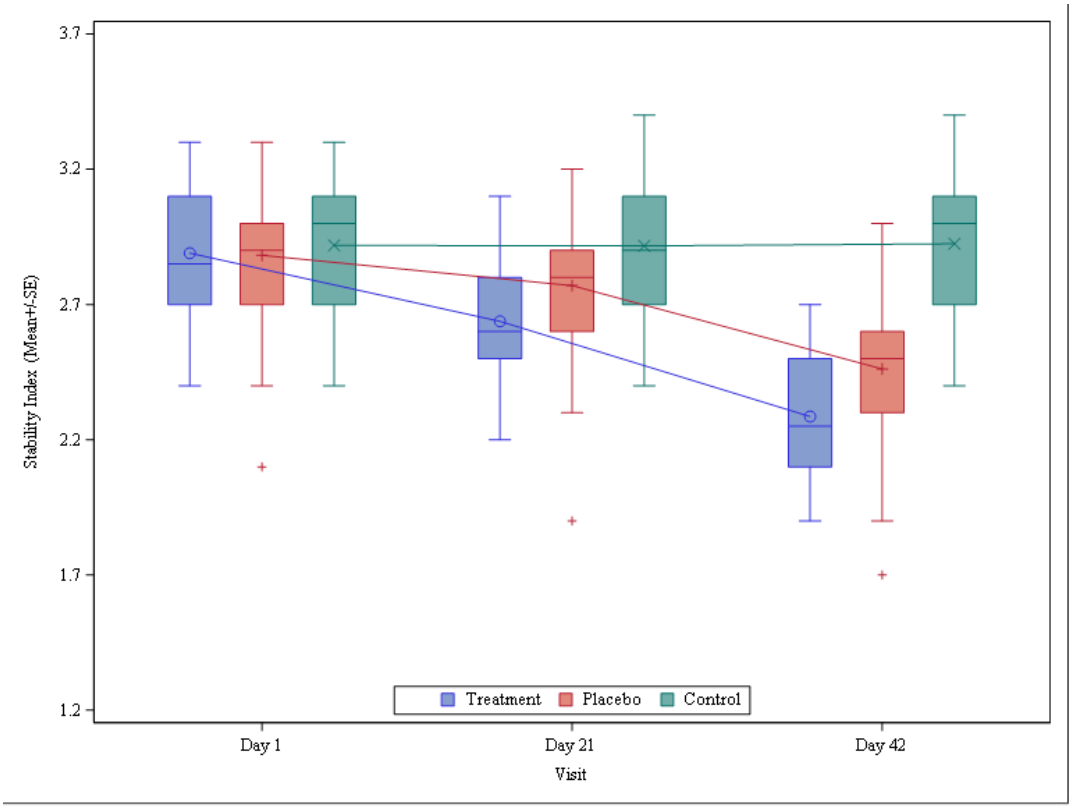

Figure 3 : Box plot – By groups across the visits – Stability Index

Table 4: Between the groups shift difference – Treatment estimates – Stability Index

	Estimate	SE	95% CI	P-value
Treatment Pre-Mid vs Placebo Pre-Mid	0.140	0.021	[0.10; 0.18]	<0.0001
Treatment Pre-Mid vs Control Pre-Mid	0.249	0.021	[0.21; 0.29]	<0.0001
Placebo Pre-Mid vs Control Pre-Mid	0.109	0.021	[0.07; 0.15]	<0.0001
Treatment Mid-Post vs Placebo Mid-Post	0.044	0.021	[0.00; 0.08]	0.0345
Treatment Mid-Post vs Control Mid-Post	0.360	0.021	[0.32; 0.40]	<0.0001
Placebo Mid-Post vs Control Mid-Post	0.316	0.021	[0.27; 0.36]	<0.0001
Treatment Pre-Post vs Placebo Pre-Post	0.184	0.021	[0.14; 0.22]	<0.0001
Treatment Pre-Post vs Control Pre-Post	0.610	0.021	[0.57; 0.65]	<0.0001
Placebo Pre-Post vs Control Pre-Post	0.426	0.021	[0.38; 0.47]	<0.0001

Table 4 shows the shift pairs between the treatment groups for "Treatment Mid-Post vs Placebo Mid-Post" had an Estimate difference of 0.044 with 0.021 Standard error with [0.00, 0.08] 95% confidence limits. This doesn't show statistical significance (P>0.005) and can conclude that these two shift difference groups show some significant difference. For stability score, the actual shift of improvement started from Mid (Day21) till Post(Day 42) for both Treatment and Placebo groups. "Placebo Pre-Mid vs Control Pre-Mid" had an Estimate difference of 0.109 which is slightly better than the "Treatment Pre-Mid vs Placebo Pre-Mid" also have estimated difference 0.140, however these are statistically significant and indicates that there is no significant difference between these two groups.

Discussion

In this study we evaluated the effect of vestibular stimulation on postural stability and mobility in the

elderly randomized into experimental, control and placebo groups. We measured change in postural stability with overall stability index (OSI) and change in mobility with TUG. Significant improvement was observed in overall stability and mobility in the placebo group after the placebo stimulation and balance training while there was no difference in the control group. It was also observed that in the treatment group postural stability and mobility was significantly improved after the vestibular stimulation and balance training while there was no difference in the control group. TUG and OSI indices both were significantly improved in placebo and experimental group. There was a significant difference in improvement between placebo and experimental group which indicates the usefulness of vestibular stimulation along with exercises.

Similar studies show that when direct current is given to vestibular afferents, it passes through vestibular nucleus and vestibular thalamus resulting in added activation of brain areas linked with multisensory input.[15] This could be the underlying mechanism for enhancement in the function of vestibular afferents which results in improvement in postural stability.[29]

Findings of this study suggest that GVS can be used during balance training which help the elderly to gain better control over postural stability and mobility. The mechanism underlying might be extensive neuroplastic nature of the vestibular system.[30] These neuroplastic changes are dependent upon age, visual and vestibular experiences[31,32]. Vestibular end-organs send message to vestibular nuclei, which excite motor neuron of ipsilateral extensors and inhibit motor neuron of reciprocal flexor of the limb via lateral vestibulospinal tract.[33] Studies on animal model suggested that stimulation to vestibular afferents can induce long term potentiation and long term depression of the field potential of vestibular nuclei.[34]

Studies also suggest that the activation of brain areas involved in vestibulospinal relay and vestibular sensory input lead to the decrease in sway of center of pressure during single session of GVS stimulation in community dwelling elderly.[20]

Till date many studies have investigated and advocated the immediate effects of GVS over postural stability and mobility. Some also talked about change in sway during stimulation. Early improvement seen in this study in treatment group compared to placebo group can be explained on the basis of finding of one study which suggested the moderate additional improvement in postural stability after second stimulation session which last for few hours even after cessation of stimuli.[35]

Studies suggested that three hours of stimulation have a better effect in postural stability compared to thirty minutes of stimulation but the difference is relatively small,[35] this stimulation probably increases the activation of voltage-gated ion channels in vestibular system and prolong activation might cause decrease in activation of these channels.

So in this study we used twenty minute repeated sessions considering the adaptation of neural system but further investigation is required to find out factors which explain the appropriate duration to produce lasting effects on balance and mobility in different population and various balance disorders.

In this study we delivered multiple sessions of stimulation thrice a week every alternate day. Previous studies discovered that when low intensity direct current stimulation was delivered transcranially to motor cortex, then increase in the duration of post stimulation effects of the first stimulus was observed.[36] The study also determined that timing of stimulation of motor cortex can control plasticity. Adequate interval between consecutive sessions might be the cause of improvement in the treatment group in this study.

Long term effects, minimal invasion and absence of adverse effects prove appropriateness of subliminal GVS for repetitive stimulations in treatment studies for improving postural stability and mobility in elderly.[12] Further studies are required to find out the exact duration and intensity of stimulation for optimal results in improving the balance among elderly.

Conclusion

The present study suggests that vestibular stimulation can significantly improve balance and mobility in elderly individual when given along with exercise training program. Our results shows overall stability improved when nGVS delivered along with exercise training. Finding of this study also suggest improvement in dynamic stability. We can also conclude on the basis of finding that early changes in the stability can be achieved when nGVS is delivered along with balance training exercises. The findings also suggest these effects are not due to the placebo effect of the vestibular stimulation.

Factors Affecting Recurrent Lateral Ankle Sprain in Athletes

Pooja Sharma[1], Shaurya Dayal[2]

[1]Assistant Professor, [2]Student, Amity Institute of Physiotherapy, Amity University Noida

Abstract

Background: Lateral ankle sprains are one of the most common sports injuries that an athlete may endure during their career. If not treated correctly, it often leads to recurrent twisting of the ankle joint, causing disruption of the ligaments in the ankle joint. Various anthropometric factors such as height, weight, BMI, as well as previous ankle sprain history are assessed as potential predictors of recurrent lateral ankle sprain. The potential factors are correlated with the Foot and Ankle Ability Measure- Sports Sub Scale to assess their contribution to a recurrent lateral ankle sprain in athletes. The FAAM Sport subscale is used to determine the functioning of the ankle joint, as recorded by the subjects themselves.

Methodology: The questionnaire is sent to the candidates who fall under the inclusion criteria, and they are asked to fill the questionnaire. The participants were between the age of 18-30 years. Both male, as well as female athletes were included in the study. Each athlete must have played at least 3 competitive sports in the last 1 year, and they must have a history of at least 1 lateral ankle sprain. The collected data is then compiled and analyzed.

Result: After the analysis of the data, previous ankle sprain history depicted maximum correlation with the FAAM- Sport Subscale, as well as an inverse relationship, with a reading of -2.89, and significance of 0.27. Height depicted an inverse relationship as well, with -.119 when compared to FAAM Sport Sub-scale. Weight also shows an inverse relationship (-0.053) when correlated with the FAAM Sport sub-scale. BMI does not show any correlation with the FAAM Sport Subscale (+0.002).

Conclusion: Previous ankle sprain history, height and weight depict an inverse relationship with the FAAM Sport Subscale, indicating that, as their score increases, the functioning of the ankle joint decreases, and hence becoming a potential factor for recurrent ankle sprains. BMI however, does not depict any correlation with the FAAM sport sub-scale.

Keywords: *Lateral ankle sprains, Anthropometric factors, BMI, The FAAM Sport subscale.*

Introduction

An ankle sprain occurs when the ligaments on the lateral aspect of the ankle complex get stretched or torn due to the rolling or twisting of an ankle joint. Lateral ankle injury is the most common problem in athletes. Female athletes are more prone to a lateral ankle twist as compared to males with a prevalence rate of 13.6 vs 6.90 for every 1000 people, respectively. It is also known as a supination or inversion ankle twist and it leads to the damaging of the ligaments in lateral aspect of ankle complex. Generally, a lateral ankle sprain is easily managed. However, if it is left untreated, it may lead to residual symptoms that may last 6-18 months.(1)

Ankle sprains are often partially treated. According to various studies, the rate of recurrence of lateral ankle sprain is more than 40%. The lack of adequate treatment and recurrent ankle sprains results in chronic ankle instability and osteoarthritis of the ankle joint. There are

e-mail: shaurya.dayal14@gmail.com

various risk factors that precede a lateral ankle sprain. Factors such as functional deficits in isokinetic strength of the ankle joint musculature, flexibility of the ligaments and muscles, proprioception, muscle reaction time, postural stability, gait biomechanics, the dominance of limb, history of previous lateral ankle sprains, and body mass index (BMI).[2]

Lateral ankle sprains usually occur due to an over-bearing hind-foot inversion which is accompanied with external or lateral rotation of the proximal segments during a task involving bearing of weight on the foot. Hind-foot supination is a multi-planar motion which is composed of ankle plantar-flexion, sub-talar inversion, and internal or medial rotation of the foot. These combined movement patterns result in the center of pressure (COP) moving externally on the plantar surface of the foot, as well as medially in relation to the ankle joint complex axis of rotation. In this position, a ground reaction force creates an external inversion moment at the ankle. Pronation moments can be elicited both externally, as with prophylactic ankle supporters, and internally, as with the peroneal musculature and lateral ankle ligaments,i.e., ATFL, CFL and PTFL in order to exert a counter force to the external supination moment. A net supination moment of sufficient magnitude will exert stress on the lateral ankle ligaments, potentially causing a significant strain or deformation of the ligaments. During an acute lateral ankle sprain, maximum level of ankle inversion may be reached as quickly as 40 ms after the initial contact with the ground.

Ankle joint is also known as the talo-crural joint. It is a synovial hinge joint formed by the mortise that is the distal end of the tibial and the fibular malleoli and the trochlear dome of the talus. It is covered by relatively thin and weak capsule. It is supported with ligaments medially and laterally. From the inner aspect, it is supported by the inner collateral ligament (deltoid ligament) and laterally by outer collateral ligament, which composes of the anterior talofibular ligament (ATFL), the calcaneofibular ligament(CFL) and the posterior talofibular ligament(PTFL).[3]

Ryan S. McCann et Al in 2018, conducted an examination to build up a prediction model for acute lateral ankle sprain in university ladies soccer players. They used different factors, for example, ankle sprain history, height, mass, and BMI. They hypothesised that school female soccer players with higher stature, mass, and BMI, and a history of ankle sprain would have higher odds of having a lateral ankle sprain. Ordinarily, an ankle sprain is supported when exaggerated ankle plantarflexion, subtalar inversion, and foot inward turn are available while decelerating. More prominent BMI, determined from stature and mass, likely builds the body, and reduces a person's capacity to external force. The essential finding of this examination is that height and history of ankle sprain were potential predictors of lateral ankle sprain among university ladies' soccer players. In particular, those competitors equivalent to or taller than 167.6 cm had 7.5 occasions more noteworthy chances of supporting a sidelong ankle sprain than those underneath 167.6 cm in tallness.[3]

Christopher R. Carcia et Al. in 2008, directed an investigation on the legitimacy of the Foot and Ankle Ability Measure in competitors with Chronic lower leg instability. The reason for this examination was to give verification of the legitimacy to the FAAM dependent on theory testing in competitors with an interminable ankle instability. Thirty National Collegiate Athletic Association Division II competitors (16 men, 14 ladies) from one college were considered for this investigation. The examination reasoned that the FAAM might be utilized to identify self-revealed practical deficiencies identified with constant ankle instability.[4]The current researches have depictedthat there are only a few predictors of lateral ankle sprain. However, no previous studies have given an insight at a model of lateral ankle sprain as a risk for athletes per say, but anthropometrics may be the key to potential injury. Lateral ankle sprains constitute approximately 7-10% of all admissions to Accident and prediction factors for that population.

Therefore, the objective of this research was to create an estimation model for recurrent ankle sprain injuries in athletes utilizing previous ankle sprain history, height, weight, and BMI as possible estimators.

Methodology

The inclusion criteria required the participants to be athletes between the age of 18-30 years. Both male, as well as female athletes were included in the study. Each athlete must have played at least 3 competitive sports in the last 1 year, and they must have a history of atleast 1 lateral ankle sprain. The exclusion criteria accounted for any history of lower limb surgeries, ankle fractures, medial ankle sprains or arthritis of the ankle joint. History of other lower limb injuries were excluded from the study. The subject should not have had a lateral ankle

sprain in the past 1 month. Subjects having signs and symptoms of neurological disorders were also excluded from the study.

An online survey was conducted on 67 subjects, comprising of 2 sections: FAAM ADL sub-scale and FAAM SPORTS Sub-scale. Only 46 participants were chosen on the basis of the inclusion and exclusion criteria. Each participant was asked to fill the consent form following which the required study was conducted. 50 male and female participants are included in the study between the ages of 18 to 30-yearold. All participants must be athletes. They are assessed on the basis of their height, using an inch tape, and weight using a general weighing machine. The resultant BMI is calculated in kg/m^2. Each participant fills the Foot and Ankle Ability Measure questionnaire. Participants reported whether or not they had ever sustained a previous ankle sprain.

Results

Spearmann Rho Correlation test was used to establish a relationship between lateral ankle sprain history, height, weight and BMI with FAAM SPORT sub-scale.

Table No. I: Spearman's Rho Correlation between FAAM Sport and Ankle Sprain History

			FAAM Sport	Ankle Sprain History
Spearman's rho	FAAM Sport	Correlation Coefficient	1.000	-.289*
		Sig. (1-tailed)	.	.027
		N	45	45
	Ankle Sprain History	Correlation Coefficient	-.289*	1.000
		Sig. (1-tailed)	.027	
		N	45	45

*. Correlation is significant at the 0.05 level (1-tailed).

Spearman Rho correlation was used for analysis between FAAM Sport and Ankle sprain history. When the Correlation coefficient is negative, it describes an inversely proportional relationship between the two variables. It signifies that, as the number of ankle sprains increase, the score on the FAAM Sport will reduce. Similarly, as the number of ankle sprains reduce, the score on the FAAM Sport will increase.

Table number 1 also depicts the significance of Ankle sprain history on the score of FAAM Sport. The correlation significance is measured when the value is below 0.05. As the value is lower than 0.05, it proves that ankle sprain history has a significant impact on the score of the FAAM Sport.

Table No. II: Spearman's Rho Correlation between FAAM Sport and Height

			FAAM Sport	Height
Spearman's rho	FAAM Sport	Correlation Coefficient	1.000	-.113
		Sig. (1-tailed)	.	.229
		N	45	45
	Height	Correlation Coefficient	-.113	1.000
		Sig. (1-tailed)	.229	.
		N	45	45

When the Correlation coefficient is negative, it describes an inversely proportional relationship between the two variables. It signifies that, as the height of an athlete increases, the score on the FAAM Sport will reduce. Similarly, as the height of the athlete decreases, the score on the FAAM Sport will increase.

Table No. III: Spearman's Rho Correlation between FAAM Sport and Weight

			FAAM Sport	Weight
Spearman's rho	FAAM Sport	Correlation Coefficient	1.000	-.053
		Sig. (1-tailed)	.	.365
		N	45	45
	Weight	Correlation Coefficient	-.053	1.000
		Sig. (1-tailed)	.365	.
		N	45	45

As shown in the table, the correlation between FAAM Sport and weight is inversely proportional, which means that, as the weight of an athlete increases, the score on the FAAM Sport will reduce. Similarly, as the weight of the athlete decreases, the score on the FAAM Sport will increase.

Table No. IV: Spearman's Rho Correlation between FAAM Sport and BMI

			FAAM Sport	BMI
Spearman's rho	FAAM Sport	Correlation Coefficient	1.000	.002
		Sig. (1-tailed)	.	.494
		N	45	45
	BMI	Correlation Coefficient	.002	1.000
		Sig. (1-tailed)	.494	.
		N	45	45

When the Correlation coefficient is positive, it describes a directly proportional relationship between the two variables. As shown in the table, the correlation between FAAM Sport and BMI is directly proportional,

which means that, as the BMI of an athlete, increases, the score on the FAAM Sport will also increase. Similarly, as the BMI of the athlete decreases, the score on the FAAM Sport will also decrease.

Discussion

The primary result of this study is that the participant's previous ankle sprain history was the most effective predictor of lateral ankle sprain among athletes. The study suggested that the score on the FAAM Sport sub-scale reduces as the incidences of ankle sprains increases. This result is confirmed by the study of Christopher R Garcia, et Al. in 2008 who have given a similar conclusion to their study. The score of the FAAM Sports subscale was greater in healthy individuals as compared to individuals that have past lateral ankle sprains. Kofotolis et al. in 2003 also examined a large selection of amateur soccer athletes and determined that those with a previous lateral ankle sprain had nearly twice the greater chances of sustaining an outer ankle sprain during the two years of subsequent observation. M. De Norhona in 2013, conducted a study on Intrinsic predictive factors for ankle sprains in active university students. He concluded that students with a previous ankle sprain history were twice as likely to suffer subsequent ankle sprains.[4]

According to this study, height was also correlated to recurrence of lateral ankle sprain. As the height of an individual athlete increases, the FAAM sports sub-scale depicted lower values. This finding supports previous studies reporting participant height as an effective predictor of ankle injuries. Waterman et al. in 2010 reported taller military academy cadets were at greater risk of sustaining an ankle sprain. Similarly, Milgrom et al. in 1991 found that taller infantry recruits were more prone to lateral ankle sprains.[5][6]

Another finding of the study described weight of an individual athlete to be correlated with recurrence of lateral ankle sprain. As the weight of an athlete increases, the tendency for a lateral ankle sprain increases and, the score on the FAAM sports sub-scale reduces. Tricia A Jubbard and Erik Wikstrom conducted a study in 2010 regarding the pathophysiology, predisposing factors, and management strategies of a lateral ankle sprain. The study concluded that weight was an intrinsic factor that contributed to Chronic ankle instability, among various other factors, like, height, proprioception, peroneus reaction time, etc.[7]

According to this study, BMI did not show a correlation or significance to recurrent lateral ankle sprains. As the BMI increases, the score on the FAAM sports sub-scale increases as well. This is confirmed by the study of M. De Norhona in 2013, who conducted a study on intrinsic risk factors of ankle sprains in active university students, who concluded that BMI does not play a significant role in causing recurrent lateral ankle sprains. Takumi Kobayashi et al. conducted a study on interior risk factors for non-contact lateral ankle sprains in collegiate athletes and he concluded that BMI does not show a correlation to recurrent lateral ankle sprains.[8]

Clinically, the strength of height and previous ankle sprain history as lateral ankle sprain predictors is their ease of assessment, but they are clearly limited by their lack of modifiability. Although they are not changeable, these simple outcomes may be important catalysts for targeted intervention. For example, preventative measures such as prophylactic ankle supports, proprioceptive training, core strengthening and postural control training are viable options for lateral ankle sprain prevention, and perhaps may be particularly valuable for taller athletes and those with a previous ankle sprain. As a lateral ankle sprain in athletes occurs through a variety of mechanisms, postural control training likely should be diversified to include static and dynamic balance exercises, dynamic stability following a jump landing or agility trainings involving change of direction and cutting, and external stimulus or perturbations.[3]

Future studies should examine various forms of neuromuscular control training and attempt to find the most effective protocol for lateral ankle sprain prevention in this population. Early identification of strong risk factors will allow clinicians to work more on preventive resources that have the highest chances of causing a lateral ankle sprain. This will help in cutting down costs of treatment and time significantly. Using of prophylactic ankle support and working on neuro-muscular strengthening, will further reduce the costs of treatment and the time that is spent on the same.

Certain notable limitations are present within this study. Firstly, this study was based on athletes of Delhi NCR only and it may not be applicable to athletes from other regions. Due to the ongoing COVID-19 pandemic, the studies were taken online. Furthermore, the sample size concise. Also, this study was focused only on anthropometric variables that may be the potential predictors of lateral ankle sprains in athletes. Future

studies should continue to explore lateral ankle sprain prediction in athletes using a larger sample size and other clinical tests that may be relevant to the mechanism of lateral ankle sprain injury such as postural control, flexibility, muscular strength, and self-reported function.

Conclusion

The history of lateral ankle sprain of an athlete is a significant factor to predict a potential recurrent ankle sprain. An increase in the number of ankle sprain will give a lower score on the FAAM sports Sub-scale. Height of an individual athlete depicts a correlation with an increased risk of lateral ankle sprain in athletes. As the height of the individual increases, the score of the FAAM sub-scale reduces. Weight of an individual athlete shows a correlation with an increased risk of a recurrent lateral ankle sprain. As the weight increases, the score on the FAAM Sport Sub-scale reduces. BMI did not show a correlation with recurrent ankle sprains.

Impact of COVID-19 Pandemic on the Mental Balance among Health Care Workers

Savita Pohekar[1], Ranjana Sharma[1], RuchiraAnkar[1]

[1]*Associate Professor, Medical-Surgical Nursing, DattaMeghe Institute of Medical Sciences, Sawangi (Meghe), Wardha, SRMMCON, Sawangi (Meghe), Wardha*

Abstract

The current outbreak of the latest coronavirus [COVID-19] has created a global crisis of unparalleled dimensions. As massive pandemics are significant community mental health threats.Services of health demand is increasing drastically. The pandemic has emotionally affected physicians, and the vast majority report they have one or more of the following effects: fear of illness, anxiety, tiredness, trouble sleeping, loneliness, depression, confusion, or irritability. Those in the front line are particularly affected by fear of family and personal infection, work-related pressure, and fatigue. Always, when contacting COVID-19 persons, they have been quarantined frequently. Greater workloads, loneliness and prejudice contribute to physical exhaustion, anxiety, emotional distress and sleep disturbance. In addition to the strategies used to prevent the spread of the virus, innovative strategies are required for health practitioners to tackle associated mental health concerns. In light of almost all of these issues must be taken even more seriously by the respective governments and stakeholders of persons affected by any psychological disturbance. This review summarizes the present health care professional's psychological disturbances and the strategies to improve their mental health.

Introduction

COVID-19 pandemic Corona Virus Disease is the current crisis in more than 200 countries in the world.[1] Corona virus disease Global pandemic (COVID-19) was announced in 2019 by the WHO.[2]The COVID 19 is actually causing a big health crisis in the world."Owing to this pandemic, mortality and morbidity have risen dramatically in the last few months[3].It's more than that 680,000 total cases with 31,920 deaths, 146,396 recovered over 202 countries.More than half the world's deaths and infections at the end of 28 March 2020, according to the World Health Organization (WHO) situation report, came from Europe.[4] Because the disease spreads quickly, the majority of the affected countries are unable to meet the demands of personal protective equipments and infrastructure requirements.[5] As per the ministry of health and family welfare, in India 595501 Active Cases,1328336 Cured/Discharged,40699 Deaths, till date 6th august 2020(6).Throughout the recent months, the general population has shown an increased mental health problem during this outbreak of COVID-19 infectionother than COVID-19 patients, elderly, teenagers, migrants and health professionals.[7] Worldwide, mental health is a major concern. It is a big burden for an individual and society worldwide."Overall neuropsychiatric causes for years lost due to disability are: anxiety disorder, schizophysiological disease and bipolar disorders, overuse of prescription medication, headache, abuse of other substances, Alzheimer's disease, alcohol and epilepsy.[8] Up to now. International organizations have not made concrete guidelines to address mental health problems during this COVID-19 pandemic, the global preference for the increasing numbers of infected populations and deaths".Most countries have, in fact, inadequate manpower and equipment to manage COVID-19. There is also a greater burden for healthcare providers in the fear of infection. They were frequently quarantined when they contacted COVID-19-confirmed individuals. Further stress, loneliness and prejudice contribute to physical fatigue, anxiety, emotional trouble and sleep problems.[9]

Impact on health professionals: The providers

of healthcare must face a growing workload in fear of infection, increased workload; alienation and prejudice contribute to physical fatigue, anxiety, sleep disorders and emotional disturbances[10]

A recent study by 1563 health workers reported over half that Depressive symptoms (50.7%), 44.7 %, and 36.1 % reported anxiety, Sturge of Sleep (Ho et al. 2020).Besides, there are insufficient facilities to offer advice and clinical distress, depression, and suicide assessment services to doctors who are dealing with infected patients, psychological distress, and suicidal tendency.(11) It is also relevant that many doctors postulate grow post-traumatic stress disorder, depression, anxiety, and burnout following pandemic cessation.(12) Previous studies suggest that nurses, emergency staff and health professionals have also shown elevated mental health problems during COVID-19 Emotional stress, disruptions and higher rates of depression and fear."The probability of infection is estimated to be much more at an exposure risk that causes fear of being transferred to loved ones and to children causes' burnouts and emotional and physical signs[13]

Unfortunately, a typical example of the highest-quality hypocrisy is that the mindset of society towards doctors and health staff in its neighborhood. At the appeal of our President, the nation cheered the health staffs while in the neighborhood they were ill-treating the same staff because of terror of catching an infection. There are many allegations that their tenants and neighbors have threatened health workers. The public has been threatened during the examinations and quarantine checks by health staff. It triggers mental disorders and burnout among health workers.[14]

The lack of appropriate protection is of great concern for medical staff. In an Indian nation that is populated profoundly and has no strong health infrastructure that causes concern.

Mental Balance Strategy Recommended:

Government action plan:

1.	Encourage the involvement of multidisciplinary mental health teams at regional, state and local level
2.	Relevant education in stress reduction, trauma, depression, and risk behavior protocols
3.	Ensure sufficient funding and facilities for mental health services
4.	Provide the public with official outlets for updated details
5.	Provide alternative service platforms (apps, blogs, telephones) for health care professionals
6.	Collect epidemiological evidence that will help future initiatives on prevention and mental health care policies

Individual management and approaches to mental health issues:

Mental health issues	Strategies to overcome
Feeling loneliness	**Keep relations:** • Create a virtual forum to help each other • Sit down and have fun in the conversation. • Virtual community parties, online book clubs, and co-working spaces where one can operate in the presence of others (virtually),established by the teams of staff
Anxiety	**Routine is your friend** • It facilitates anxiety reduction and allows you to respond more easily to this new reality. • Creates clear boundaries in both the physical and the head space between work and non-work time. • Finding something that doesn't work and isn't connected to viruses that bring you happiness. • Operating with consistent breaks in short bursts will help to preserve consistency • Restrict pandemic exposure, as too much information, can cause disturbances
Panic about COVID-19	**Be sure to live in the moment** • Take as it happens every day and concentrate on the things that you can handle. • Being mindful and meditating can be Simple instruments

Mental health issues	Strategies to overcome
Stress, burnout, and depression	• Recognize your life's causes of stress • Take care what you're eating and drinking. • Try eating a healthy diet and consume at least 3 meals a day • Get proper sleep • Control your breathing • Create time for fun • Improve study skills • Take care of yourself and others, maintain interaction with family and friends • Follow guidelines from the WHO and the government agencies • Track behavioral dysphoric states such as aggression and irritability • Do not disseminate information from unofficial sources • Understand that in uncertain circumstances stress and fear are natural • Set up a support network (although virtual) • Practice meditation and exercise • Effective use of method in psychiatry/psychology

Essential tips:

1. Regardless of how you live, changes to your normal social and professional circumstances can lead to a deep sense of isolation. Why not join others to remain connected? a few social networking groups to discuss topics you're interested in. Try arranging with friends and family or colleaguesa daily video conference, face-to-face interaction also helps to establish social links across the phone.
2. Structure your days and take daily breaks to reduce tension and adapt the current situation to your life. You should stick to the routine of an "office" as much as possible if you telework: get up at your ordinary time, get ready, get dressed, as if you are working (the fact that you stay in your pajamas may have a detrimental effect both on your moral standards and on your job). Try to set a simple but organized programming and stick to it all week long, if you have children in particular. Decide in advance when you should start and finish your working day and finish of your working day and Factor in your breaks (important) for coffee and lunch: Should not vacillate to set warning signals to remind yourself that your business day is over and to allow you to exit your computer. Use your entitlements to leave. Though you cannot go on holiday and just sit home, you must stop and pause for a few days for well-being and safety.
3. Plan the day as effectively as possible to banish feelings of powerlessness. The objective is to define goals and to assign those times to every mission. Finally, go over what you have accomplished and plan your goals for the next day. The duration of the mission cannot always be decided in advance. Be patient with yourself if you have not accomplished all of your targets and have set your targets for the next few days.
4. Hold your private and personal life apart to stay successful and maintain a healthy balance. Many of us don't have a home office full, so everybody at home, even if it is just a kitchen table, can set up a work space..Declare and delete all that. is not work-related from your office. Get what you need: loaders, head phones, notebooks, pen, tablets, and bottles of water, if necessary snacks. The goal is not 10 times a day to leave the office to find it. It is necessary to enter 'work' or 'home' mentally and do not mix both (for example, Schedule personal telephone calls during 'business' hours.
5. Take care of daily workouts for your physical and mental health. The number of exercise lessons, yoga and meditation, and others during the lock-down. The roof has gone through similar online options: take advantage of it. Create in your weekly schedule one or more workout or relaxation sessions. Seek to enjoy a little fresh air and sunlight every day, if possible, or sit at a window.

6. Choose carefully and purposefully your media resources. Many such low-quality details cause anxiety. Limit your attention to news and carefully pick your information sources. For example, decide to watch, hear, or read a summary of the news daily from a source of confidence and highly assessed, and ignore all else (particularly deactivate Smartphone notices).
7. Spend some time on creative hobbies to keep the energy levels up and stay optimistic. Even if your days are busy, time for creative activities is important. Do some art or crafts; Take a lesson online, plan dinner and party, etc. Be imaginative and discover new entertainment sources in your home
8. Take note of your daily meals and try to preserve your energy levels with a healthy, balanced, and diverse diet. Especially if you can't do as much physical activity as normal by locking down, eat light meals.[15]

Conclusion

According to government orders, during the lockout, emergency and basic healthcare services will proceed. It extends to all government hospitals, private hospitals, private health centers, testing centers, and consultation clinics in the world. COVID-19 poses significant threats to mental wellbeing. There is not enough work in the COVID-19 pandemic to resolve mental health problems. As death and Morbidities rates hit new heights day after day, mental health problems can raise exponentially, and loneliness and reclusiveness can continue, leisure opportunities will be reduced and the financial crisis is continuing. The intellect outlook of COVID-19 and the potential steps to deal with the pandemic is important to understand for their efficient management.

Abstract

Introduction: Fluoride toxicity causes irreversible damage to soft tissues like brain, liver, heart and lung**.** Fluoridetoxicity and hypoxiaexposure might alterhepatic oxygen sensing cell signaling mechanisms and a supplementation of antioxidant like l-ascorbic acid might have protective role.

Aim: To investigate the exposure of sodium fluoride or hypoxia alone or in combination with or without administration of L- ascorbic acid on biochemical and transcriptional pathways in hepato toxicity **.**

Materials and Method: Male albino rats were divided into 8 groups (n= 6/group), group I(control), group II (l-ascorbic acid, 50 mg/100g. b.wt), group III (hypoxia, 10% O_2), group IV (NaF;20 mg/kg b.wt/day; ip), group V (NaF + hypoxia, 10% O_2), group VI (l–ascorbic acid + hypoxia, 10% O_2), group VII (l-ascorbic acid + NaF) and group VIII (l-ascorbic acid + NaF + hypoxia, 10% O_2). The treatments were carried for 21 days. Gravimetry, serumoxidant and antioxidant status were assessed by using spectrophotometer, serum levels of vascular endothelial growth factor (VEGF) and nitric oxide synthase 3(NOS3) was done by ELISA technique. Histopathological evaluations of hepatic tissue were done. ANOVA followed by "Tukey" test were done for analysis of data in between the groups.

Results: Gravimetry and biochemical evaluation showed significant decrease in body weight hepatosomatic index, altered serum SOD, MDA, vitamin C, vitamin E, nitric oxide and hepatic vitamin Cin rats treated with hypoxia (group III), NaF (group IV) and NaF with hypoxia (group V). In case of l-ascorbic acid supplementation in group VI, VII and VIII showed remarkable improvement. Alteration in serum VEGF, NOS3 andhistopathology of liver in rats treated with hypoxia, NaFand hypoxia with NaFindicate hepatic dysfunction by oxidative and nitrosative stress, whereas l-ascorbic acid supplementation were found to be beneficial against fluoride and hypoxia induced alteration of hepatic function.

Conclusion: Supplementation of L-ascorbic acid is salubrious to combat both sodium fluoride and hypoxia induced oxidative & Nitrosative stress.

Introduction

Fluoride toxicity causes irreversible damage to soft tissues like brain, liver, heart and lung[1]. Fluoride

can cross cell membranes by simple diffusion and enter soft tissues. Fluoride induces necrosis and apoptosis[2]. Fluoridetoxicity and hypoxiaexposure alterhepatic oxygen sensing cell signaling transduction pathways. Weather fluoride induced toxicity and low oxygen microenvironment act through similar or different mechanisms is not known. Antioxidant supplementation is useful in fluorosis management and fluoride intoxication[3]. Hence the present study was schemed toassess therole of l-ascorbic acid as antioxidant on NaF and hypoxia or in combinationonhepato cellular oxidative stress in male albino rats.

Materials and Method

Healthy adult male albino Wistar rats weighing about 150 -180 gramswere procured from animal house. Acclimatized for one week to the laboratory conditions at 21-25ºC and fed with laboratory stock diet and water *ad libitum*..

Experimental Groups: Male albino rats were divided into 8 groups (n= 6 in each group), group I(control), group II (l-ascorbic acid,50 mg/100g. b.wt), group III (hypoxia, 10%O_2), group IV (NaF; 20 mg/ kg b .wt/day; ip), group V (NaF + Hypoxia, 10% O_2), group VI (l-ascorbic acid + hypoxia, 10% O_2), group VII (l-ascorbic acid + NaF) and group VIII(l-ascorbic acid + NaF + hypoxia, 10% O_2). The interventions were carried for 21 days.

NaF was injected intra peritoneally at a dose of 20mg/ kg body weight/day for 21 days [4]. L-ascorbic acid was administered orally by using force feeding needle with syringe for 21 days (50mg/100g body weight).

Exposure of Rats to hypoxia: Acrylic chamber was used to induce hypoxia. Rats in cage were kept in chamber and given mixture of 10% oxygen and 90% nitrogento inducechronic normobaric hypoxia for 21 days. Temperature was maintained at 22-27°C [4].

Gravimetry: Animals of all groups were weighed on the starting day of protocol and on the 21st day i.e. on the day of sacrifice using digital weighing balance. Percentage of body weight gain was determined. Liver was weighed after sacrifices at the end of experiment and further hepato somatic index was determined by using the following formula:

Hepato somatic index = Weight of heart × 100/Body weight

Sample Collection: At the end of 21st day all animals were kept for an overnight fast and blood was collected in plain tubes by doing retro-orbital puncture. These blood samples were centrifuged and serum was separated.

Oxidant and antioxidant parameters: Serumsuperoxide dismutase (SOD), malondialdehyde (MDA), nitric oxide was determined. Serum nitric oxide synthase 3 (NOS3) and vascular endothelial growth factor(VEGF) was estimated by ELISA kit. Serum vitamin C,vitamin E and hepatic vitamin C levels was estimated.

Histopathology Procedure: Animals of all groups were sacrificed by cervical dislocationat the end of 21 days experimental protocol. The liver was carefully collected, isolated immediately and fixed in freshly prepared 10 % formal in for 24 hours and thin sections were taken. Histopathological evaluations were done to identify changes in liver for treatment groups and compared with control. CPCSEA guidelines were carefully followed during experiments.

Statistical Analysis: SPSS software version 16.0 was used. One-way ANOVA followed by "Tukey" test were done to find out intergroup significant differences. All values were represented asmean ± SD. $p \leq 0.05$ considered as statistically significant.

Results

Table-1 shows significant decrease in % of body weight gain, liver weight and hepatosomatic index of rats exposed to hypoxia (group III), NaF (groupIV), hypoxia and NaF (group V) as compared to control (group I) at the end of 21st day. However simultaneous treatment with l-ascorbic acid showed greater % of body weight gain, liver weight and hepatosomatic index in group VI (l-ascorbic acid + hypoxia), group VII (l-ascorbic acid + NaF) and group VIII (l-ascorbic acid + NaF + hypoxia).

[Table-3]: Effect of l- ascorbic acid supplementation on sodium fluoride and hypoxia induced changes in antioxidant status.Group I(control), group II(l-ascorbic acid), group III(hypoxia), group IV(NaF), group V (hypoxia + NaF), groupVI (l-ascorbic acid +hypoxia), groupVII(l- ascorbic acid +NaF) and group VIII (l-ascorbic acid +hypoxia + NaF), values expressed as Mean ± SD, $p \leq 0.05$ is significant, values with different superscripts a,b, c,d,e are significantly different from each other

Fig-1shows significant increase in serum VEGF concentration inrats exposed to hypoxia (group III), NaF (groupIV), hypoxia and NaF (group V) as compared to respective controls. However simultaneous supplementation with l-ascorbic acid in group VI (l-ascorbic acid +hypoxia), group VII (l-ascorbic acid + NaF) and group VIII (l-ascorbic acid + NaF + hypoxia) rats showed significant improvements in serum VEGF concentration.

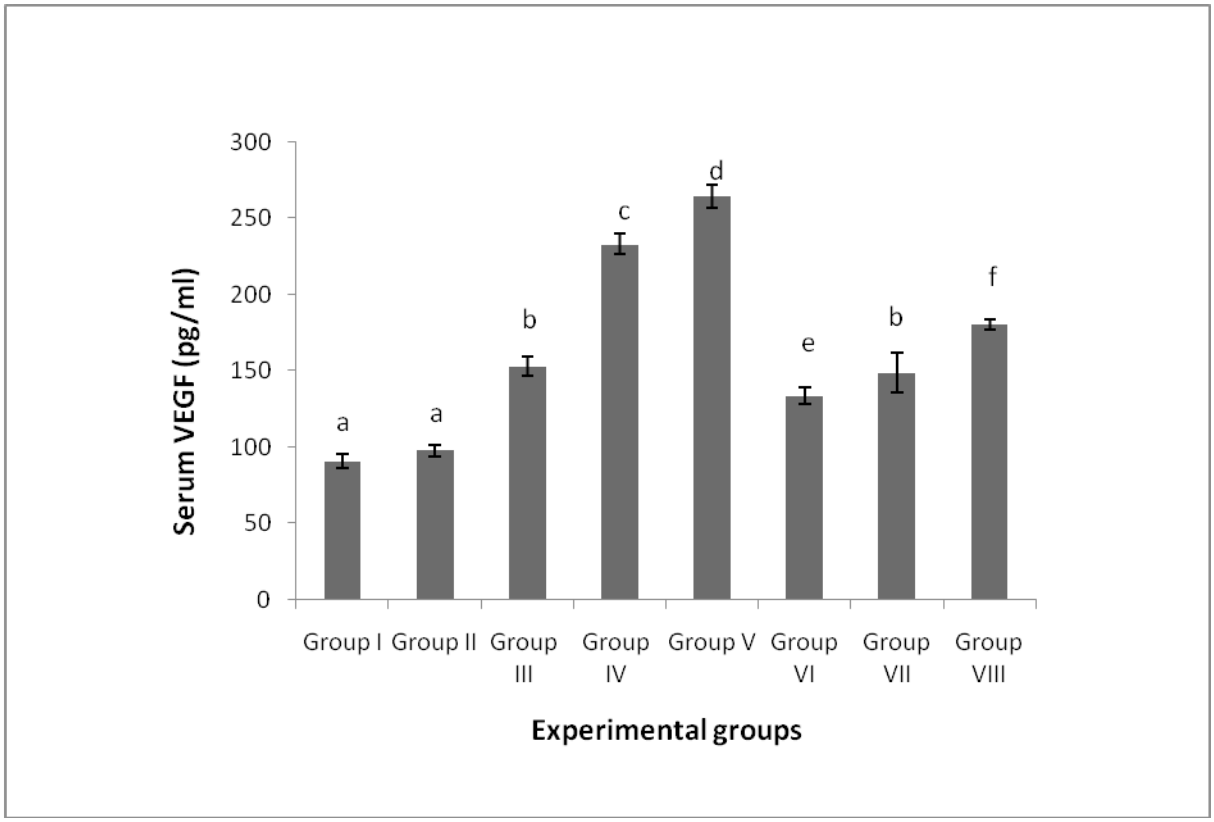

Fig. 1

[FIG-1]: Effect of l- ascorbic acid supplementation on sodium fluoride and hypoxia induced changes on serum VEGF level. Group I(control), group II(l-ascorbic acid), group III (hypoxia), group IV (NaF), group V (hypoxia + NaF), group VI (l-ascorbic acid + hypoxia), groupVII(l- ascorbic acid +NaF) and group VIII (l-ascorbic acid + hypoxia + NaF), values expressed as Mean ± SD, $p \leq 0.05$ is significant, values with different superscripts a,b, c,d,e,f are significantly different from each other

Fig-2 shows significant increase in serum NOS3 concentrations inrats exposed to hypoxia (group III), NaF (group IV), hypoxia and NaF (group V) as compared to respective controls. However simultaneous supplementation with l-ascorbic acid in group VI (l-ascorbic acid + hypoxia), group VII (l-ascorbic acid + NaF) and group VIII (l-ascorbic acid + NaF + hypoxia) rats showed significant improvements in serum NOS3 concentrations.

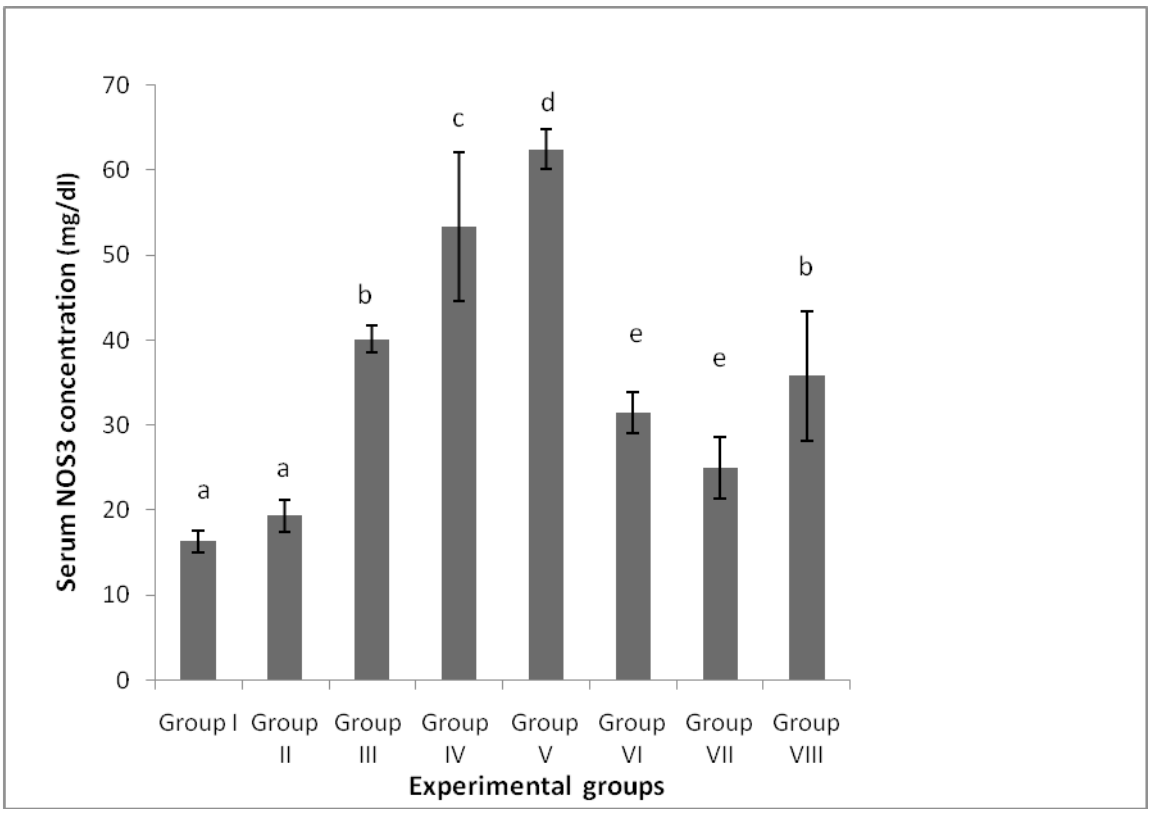

Fig. 2

[FIG-2]: Effect of l- ascorbic acid supplementation on sodium fluoride and hypoxia induced changes on serum NOS3 level. Group I(control), group II(l-ascorbic acid), group III(hypoxia), group IV(NaF), group V (hypoxia + NaF), groupVI (l-ascorbic acid +hypoxia), groupVII(l- ascorbic acid +NaF) and group VIII (l-ascorbic acid +hypoxia + NaF), values expressed as Mean ± SD, $p \leq 0.05$ is significant, values with different superscripts a,b, c,d,e,f are significantly different from each other

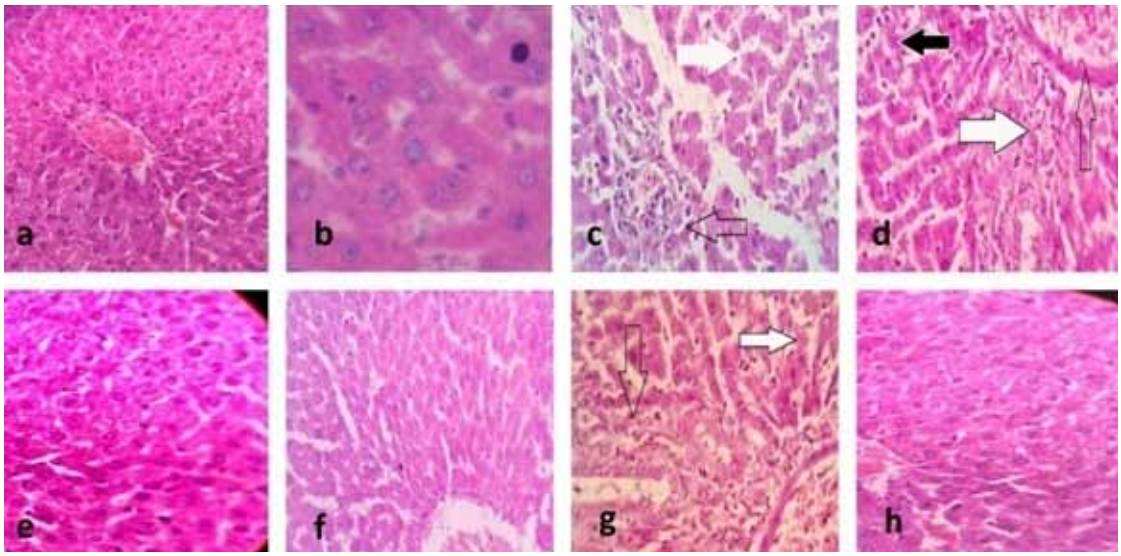

Fig. 3

Fig-3 (a-h) shows H & E stained sections of liver. Group I (control) and group II (l-ascorbic acid) showed normal architecture of liver (Fig- 3a & b). Group III (hypoxia) showed inflammation and sinusoidal congestion (Fig-3c), in group IV (NaF) showed focal necrosis, mononuclear infiltrate and central vein congestion (Fig-3d) and group V (hypoxia +NaF) also showed focal necrosis, mononuclear infiltrate and central vein congestion (Fig- 3e) whereas in case of l- ascorbic acid supplementation hepatic architecture appeared normal in group VI (l-ascorbic acid +hypoxia), group VII (l-ascorbic acid + NaF) and group VIII (l-ascorbic acid + NaF + hypoxia) rats (Fig-3f-h).

Discussion

Protective role of l-ascorbic acid on oxidative and nitrosativestress in hepatocytes were studied in hypoxia, sodium fluoride and in combination of hypoxia and sodium fluoride in experimental rats through evaluation of gravimetry, serum oxidant and antioxidant status along with histopathology of hepatictissues.

Gravimetry: Our study results shows decrease in body weight,change in % of body weight gain and hepatosomatic index in hypoxic and NaF administered rats or in combination of both. This decrease in body wt (%) and hepatosomatic index may be due to less food intake . NaF may cause inhibition of hunger centre in hypothalamus and fluoride also induces breakdown of tissue proteinsandlipids[5]. Supplementation with l-ascorbic acid showed % of body weight gain, liver weight gain and increased hepato somatic index due to protective actions of l-ascorbic acid in hypoxia and NaF induced alteration of tissue protein breakdown [6].

Oxidant and antioxidant status: In our study sodium fluoride induced and/or hypoxia exposed rats show increase in serum MDA and serum nitrite concentration due to oxidative stress. Oxidative stress is characterised by increase in reactive oxygen species (ROS) formation .ROS include free radicals like super oxide, peroxy nitrite and hydroxyl radicals. MDA is an indicator of lipid peroxidation and an important biomarker of oxidative stress[7]. Increase in nitrite concentration insodium fluoride induced and hypoxic rats may be due to over expression of NOS3 gene and increases production of nitric oxide(NO)[8,9]. our study results on supplementation of L-ascorbic acid on MDA and NO levels are indicative of preventing oxidative and nitrosative damage.

Our study also shows decrease in serum SOD, serum and hepatic vitamin C,serum vitamin E concentrations in sodium fluoride induced and/or hypoxia exposed rats. Sodium fluoride not only generates superoxide ions but also decreases enzymatic activity of SOD by binding to its active site .As a result SOD fails to detoxify hydroxyl ions. So inhibition of antioxidant enzyme SOD leads to oxidative damage at mitochondrial level and causes hepato cellular dysfunction[10]. Vitamin C combats superoxide in liver and also scavenges NO. Vitamin C also regenerates tetrahydrobiopterin (BH4). BH4 is important for NOS3 activity.Vitamin E with

lipid peroxyl molecule is oxidized to α -tocopheroxyl molecule. α-tocopheroxyl is recycled by L- ascorbic acid. Antioxidants like vitamin C and E protect against ROS damage[11,12]. On supplementation with L-ascorbic acid there was significant improvements in serum SOD, serum and hepatic vitamin C, serum vitamin E concentrations.

Serum NOS3 and VEGF concentrations: Our study results show that in sodium fluoride induced and/ or hypoxia exposed rats leads to increased serum VEGF and also NOS3 levels. Interestingly sodium fluoride toxicity mimics hypoxia like effects at hepatocellular level and increases ROS production. ROS induces directly NOS3 and VEGF gene expression. VEGF triggers hypoxic response and leads to upregulation of NOS3genes and enhances NO production .Increased NO levels itself down regulate VEGF expression.

Vitamin C supplementation has lead to decreased gene expression of NOS3 and VEGF in sodium fluoride induced and/or hypoxia exposed rats. This is due to decreased ROS production and NO levels to combat cellular hypoxia.

Histopathology of Hepatic tissues: Histological changes were observed inhypoxia exposed or NaF treated or in combination of hypoxia exposure and NaF treated rats. Sodium fluoride induced toxicity lead to disruption of hepatic architecture and lead to mononuclear infiltration and hepatic necrosis[1415]. In hypoxia exposure and NaF treated rats such changes have lead to hepato cellular damage.

Vitamin C supplementation prevented disruption of hepatic architecture and necrosis.

Conclusion

Both sodium fluoride and hypoxia enhances nitric oxide production by VEGF and NOS3 pathways leading to hepatocellular damage and apoptosis. The supplementation of L-ascorbic acid is salubrious to combat both sodium fluoride and hypoxia induced cell death in liver by oxidative & Nitrosative stress.

To Assess Knowledge, Attitude and Practice on the Use of Automated External Defibrillation (AED) by Emergency Medical Services (EMS) Providers in Pune, India

Parag Rishipathak[1], Shrimathy Vijayaraghavan[2], Anand Hinduja[3]

[1]Professor & Director, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India, [2]Medical Officer, Academics, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India, [3]Adjunct Faculty, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India

Abstract

Introduction: An Out of Hospital Cardiac Arrest (OHCA) is defined as the loss of cardiac mechanical function that occurs outside of the hospital setting and confirmed by the absence of signs of systemic circulation. OHCA has a very low survival rate. Timely provision CPR and Rapid Defibrillation during Cardiac Arrest requires adequately trained and qualified personnel. It is therefore important to understand the current level of Knowledge, Attitude and Practice (KAP) with regards to AED amongst EMS responders.

Objective: To assess Knowledge, Attitude and Practice on the Use of Automated External Defibrillation (AED) by Emergency Medical Services (EMS) Providers.

Methodology: The Knowledge, Attitude and Practice (KAP) study was conducted amongst 120 Emergency Medical Services Providers at SCHS, Pune, India. A previously tested and validated KAP questionnaire by Marcus EH Ong et.al[9] was utilized for the study. The final questionnaire consisted of 15 items spanning 3 parameters -5 items testing Knowledge, 8 items measuring Attitude and 2 items measuring Practice related to use of AED.

Discussion: The study was aimed at assessing the current knowledge, attitude and practices with regards to AED amongst EMS respondents. Most respondents reflected positive attitude towards utilizing AED in out of Hospital Cardiac Arrest patients.

Conclusion: The study reemphasizes the need for formal training on AED usage. Although the study is limited by its sample size, it provides broad perspective on the subject.

Keywords: *Out of Hospital Cardiac Arrest (OHCA), Automated External Defibrillator (AED), Emergency Medical Services(EMS), Knowledge, Attitude and Practices (KAP).*

Introduction

An Out of Hospital Cardiac Arrest (OHCA) is defined as the loss of cardiac mechanical function that occurs outside of the hospital setting and confirmed by the absence of signs of systemic circulation. Many OHCA patients develop early symptoms several hours before the event, which may lead them to seek medical help from primary care physicians (PCPs) or other out-of-hospital ambulatory care settings where he gets a cardiac arrest[1].

OHCA has a very low survival rate. With each minute delay in defibrillation from the onset of cardiac arrest, the probability of survival decreases by 10%.[2]

Corresponding Author:
Dr. Parag Rishipathak
Professor & Director, Symbiosis Centre for Health Skills, Symbiosis International (Deemed University), Pune, India
e-mail: director_schs@siu.edu.in

Cardio Pulmonary Resuscitation (CPR)is a simple but effective procedure that allows almost anyone to sustain life in the early critical minutes after cardiac arrest[3]. The administration of CPR immediately after the onset of cardiac arrest is associated with improved survival and better quality of life among survivors.

Apart from CPR, Early defibrillation is essential in management of cardiac arrest. An automated external defibrillator (AED) allows lay rescuers to advance defibrillation by starting treatment before emergency medical services (EMS) arrive on the scene.[4] They are easy to use, accurate, and can be used safely and effectively.[5]

Use of automated external defibrillators (AEDs) is now an important component of emergency medical systems, and recent advances in AED technology have allowed expansion of AED use to non-traditional first responders and even the lay public.[6]

A study conducted by Ross A pollock *etal*[7] in 2018 concluded that bystander AED use before EMS arrival in shockable rhythm was associated with better survival and functional outcomes.

The crucial key lies in prehospital management. Early defibrillation in the prehospital phase

Can significantly increase the chance of survival.[8] Emergency Medical Service Providers are very important link in the Chain of Survival. Timely provision CPR and Rapid Defibrillation during Cardiac Arrest requires adequately trained and qualified personnel.

It is therefore important to understand the current level of Knowledge, Attitude and Practice (KAP) with regards to AED amongst EMS responders. This can tide further interventions to improve the KAP levels and ensure better qualified EMS responders to deal with OHCA.

Objective

To assess Knowledge, Attitude and Practice on the Use of Automated External Defibrillation (AED) by Emergency Medical Services (EMS) Providers.

Methodology

The Knowledge, Attitude and Practice (KAP) study was conducted amongst 120 Emergency Medical Services Providers at SCHS, Pune, India. A previously tested and validated KAP questionnaire by Marcus EH Ong et.al[9] was utilized for the study. The original 29 item questionnaire intended for usage in General Practitioners was modified to suit the present study. The final questionnaire consisted of 15 items spanning 3 parameters -5 items testing Knowledge, 8 items measuring Attitude and 2 items measuring Practice related to use of AED.

Informed consent was obtained from the respondents. The respondents were instructed to answer every item on the questionnaire either in YES or NO in front of the respective statement of Knowledge, Attitude and Practice. All items were to be mandatorily filled. The students were given 30 minutes to answer the questionnaire and to submit it. Only completely filled questionnaire were accepted for data analysis. The data collected was tabulated and statistically analysed using SPSS version 23.

Any queries pertaining to questionnaire was clarified at the time of collection of data.

Results

It was observd that the average age of the respondents was between 21 to 25, and 88% of them were female. Further, 17% had a valid basic cardiac life support (BCLS) certificate, and 14% had a valid advanced cardiac life support (ACLS) certificate**.**

As seen in Figure 1.,In terms of Knowledge, 83% of the respondednts could write the AED abbreviation correctly while around 88% claimed that they know how to operate an AED.As many as 32% of the respondents answered incorrectly stating that AED required an operator to interpret ECG rhythm. Only 58% of the respondents had attended any formal AED training in the past.

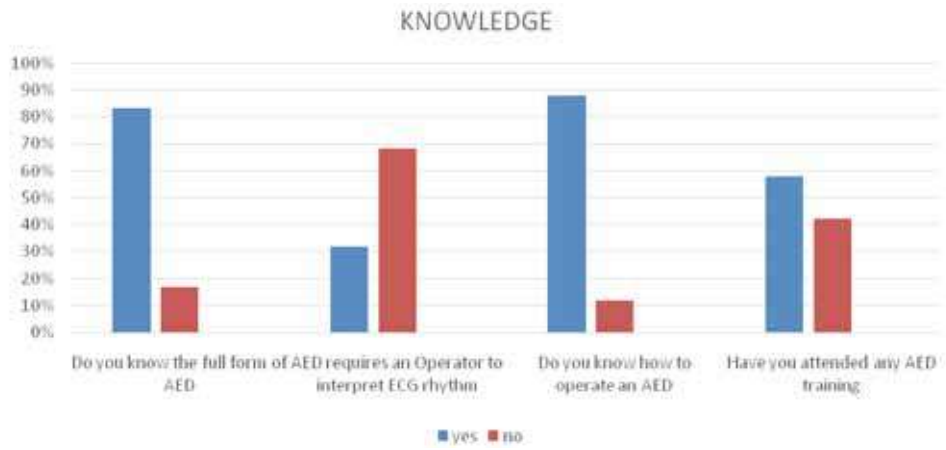

Figure 1.

As seen in Figure 1.,In terms of Knowledge, 83% of the respondednts could write the AED abbreviation correctly while around 88% claimed that they know how to operate an AED. As many as 32% of the respondents answered incorrectly stating that AED required an operator to interpret ECG rhythm. Only 58% of the respondents had attended any formal AED training in the past.

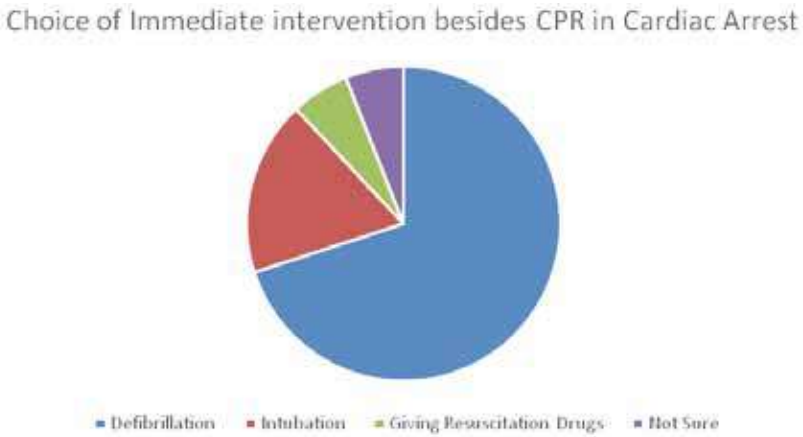

Figure 2.

As seen in figure 2. Majority (70%) of the respondents identified Defibrillation as the correct immediate intervention besides CPR in Cardiac Arrest.

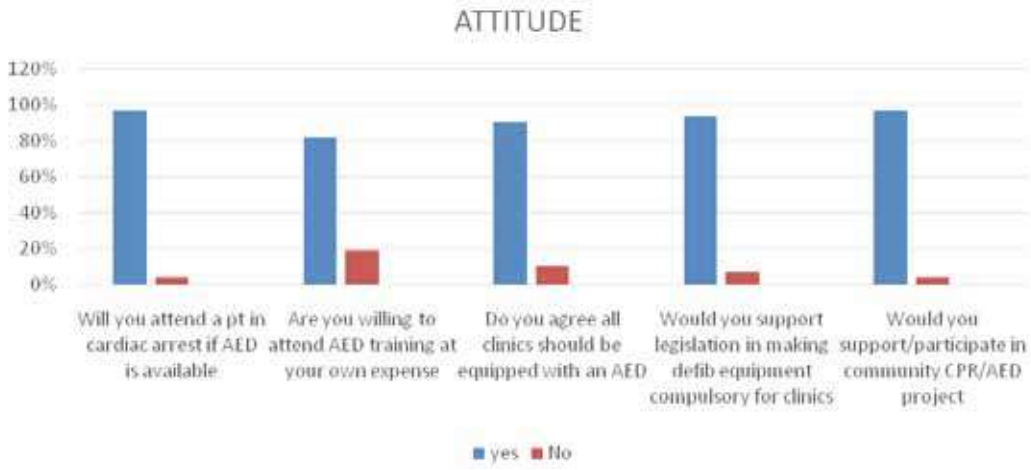

Figure 3.

As seen in figure 3., in terms of attitude 96% answered in affirmative when asked if they would attend a patient in cardiac arrest if AED is available. 90% agreed that all clinics should be equipped with AED and 92% supported the idea of bringing legislation in making defibrillatory equipment compulsory for clinics. Almost all (96%) respondents were willing to participate in community CPR/AED projects.

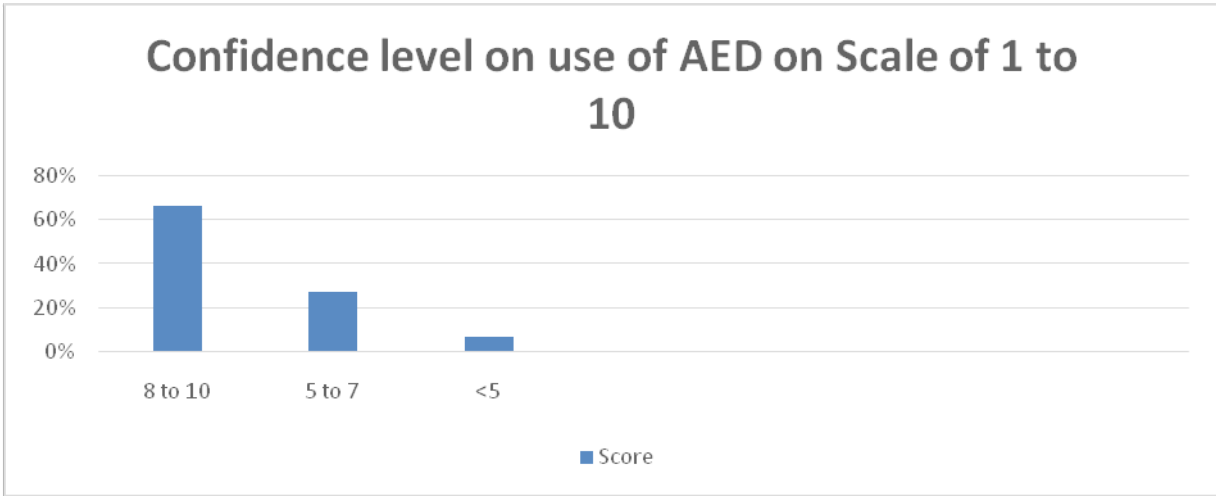

Figure 4

As depicted in figure 4,66% of the respondents exuded a high degree of confidece on the usage of AED.

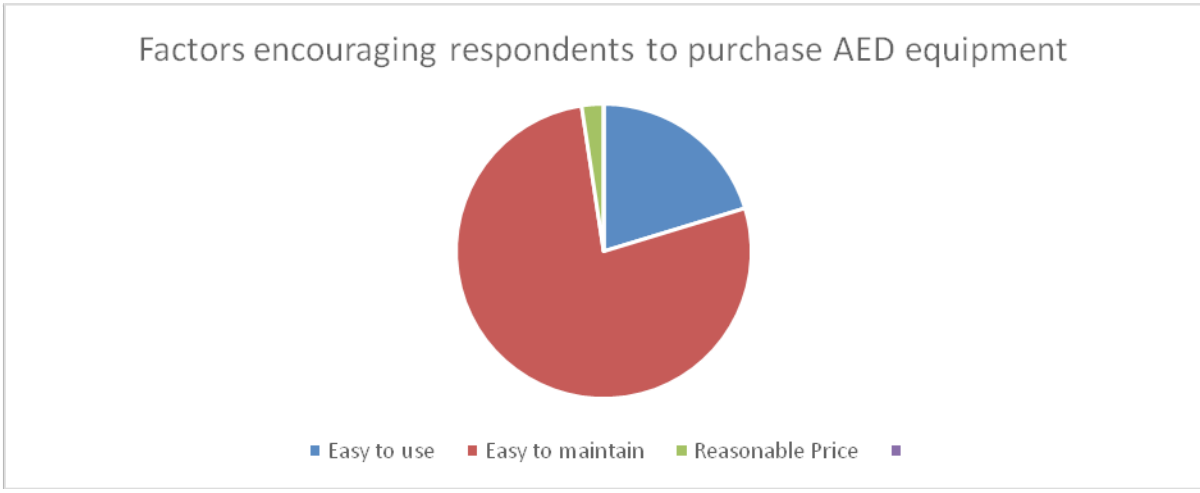

Figure 5.

As seen in figure 5.,84% of the respondents felt 'ease of use" as the key drive to purchase AED.

In terms of Knowledge, 62.2 % responded that they would perform mouth to mouth CPR.

77.04% of the rspondents suggested that they would go ahead with both compression and ventilation.

Discussion

The study was aimed at assessing the current knowledge, attitude and practices with regards to AED amongst EMS respondents.

The findings are encouraging in part while providing with valuable perspective for bringing improvements in certain areas. A sizable number of respondents

incorrectly percieved that percieved that AED requires operator to interpret ECG rhythm. This can be attributed to lack of formal training for AED as was found in the case of 58% of respondents. The optimum utilization of any equipment largely depends on the training of the operator. Training not only enhances knowledge, but also improves attitude towards usage and enhances utilization in emergency situations. It also helps in clearig misconceptions and allay fears.

Most respondents reflected positive attitude towards utilizing AED in out of Hospital Cardiac Arrest patients. The confidence level towards its utilization can be further improved by periodic hands on training. Majority respondents will in to attend AED training at their own expense and were optimistic about purchasing AED if they found it simple to use. Interestingly, price was not a significant factor while making a purchase decision. Respondents overwhelmingly supported the idea of legislation to make AED compulsory for clinics. This finding is important for policy makers on wider iimplementation of AEDs at clinic level in managing Out of Hospital Cardiac Arrest.

Majority of respondents appreciated the significance of ventilation during CPR and were ready to perform mouh to mouth ventilation. Given a choice between compression only and both compression and ventilation,majority of respondents chose both compression and ventilationas they found it more effective in comparison to compression only during CPR in Out of Hospital Cardiac Arrest.

Conclusion

The study amongst EMS responders throws light on the knowledge, attitude and practices with regards to AED usage. The study reemphasizes the need for formal training on AED usage. Although the study is limited by its sample size, it provides broad perspective on the subject. AED is a lifesaving modality in Out of Hospital Cardiac Arrest and optimizing its usage is the need of the hour.

Whither to Public Interest-The Curious Case of Compulsory Drug Licensing in Indian Pharmaceutical Industry

Rakesh Kumar Sehgal[1], R.L. Koul[2]

[1]Research Scholar, Ph.D (Law) (PT), Amity Law School, F-1 Block, Amity University Campus, Sector 125, Noida, Uttar Pradesh 201303, [2]Amity Law School, F-1 Block, Amity University Campus, Sector 125, Noida, Uttar Pradesh 201303

Abstract

Countries like India which are grappling with providing healthcare to heterogeneous and varied base of stakeholders including those at the bottom of pyramid have their own share of availability and affordability concerns in the healthcare sector for providing access of life saving drugs to the vast segment of Indian population and move towards the achievement of the Sustainable Developmental Goals (SDGs); in process addressing not only adequate availability of the primary health care but achieving the competition framework *vis- a- vis* patent control as the Original Patents which intend to protect innovation tangentially run across the consequential price determination power by monopolistic patented drug companies. Compulsory licensing of Patents provisions are used by the Governments as a means to correct anti-competitive practices to promote public interest or public health and in cases of emergency avoiding monopolies at the hands of patent holders to deter anti-competitive violations by engaging in unfair competition or abuse of dominant position in the market which aspect is so crucial to provide outreach of cheaper and quality drugs in common good.

Keywords: *Health Care Sector, Anti- competitive violations, Patent Holders, Compulsory Licensing.*

Introduction

The explosion of population and emergence of drug resistant communicable diseases like Tuberculosis and others like Malaria, HIV/AIDS epidemic, Cancer, Hepatitis C has made the task of providing cheaper health care in Indian market a frustrating experience despite increase in the domestic capacities of drug production, increased Government spending towards health care sector and alike. One has to take into account the learning outcomes out of the recent regulatory framework, wherein the epidemic diseases which have since resulted in the mutational form of the very disease itself; perhaps in majority of cases is the first (patented)version of the drugs being applied for curing such diseases is being provided whereas such diseases are being attempted to be controlled through second generation/further generic versions of the drugs in other developed countries under Compulsory Licensing; with the difference being the Patented version costing a significantly higher markup than those manufactured under Compulsory Licensing. Article 5 A(2) of the Paris Convention of 1883 provides that "Each country of the Union shall have the right to take legislative measures providing for the grant of compulsory licenses to prevent the abuses which might result from the exercise of the exclusive rights conferred by the patent, for example, failure to work"[(1)]. Largely seen as an interventionist measure, it seeks to calibrate rights of the patent holder with Governments obligation to ensure working of patents, ensuring availability at a reasonable price, protection of public health and nutrition and simultaneously encouraging technological invention.

Compulsory Licensing has emerged as one of the effective tools to prevent the monopolistic situations at the hands of patent holders and cause supply of generic drugs at affordable price addressing health care *viz-a viz* intellectual property and has found favor in developed nations such as European Union, Germany, Italy, United Kingdom, France, Norway and Russia to name a few. Compulsory Licensing of Patents has facilitated low priced pharmaceuticals and in process encouraging the local generic drug industry Developing countries like

India face the issue of delivery of healthcare technology, and challenge for policy makers has been to ensure acceptability and affordability on an equitable basis which could theoretically accrue through Compulsory Licensing and said aspect has been highlighted by the United Nations Human Rights Commission Report, 2001 as well[2]. The National Bureau of Economic Research (NBER) Working Paper indicates that compulsory licensing has a strong and persistent positive effect on domestic invention [3]. Even without any effects on innovation, compulsory licensing may create significant positive welfare effects on consumers in developing countries as a mechanism to maintain product variety. One needs to examine the relevance of compulsory license framework in Indian scenario more particularly the will of the regulatory architecture coupled with the response of the pharmaceutical industry to make use of the flexibilities available in context of the two domains namely patented production versus the manufacturing under Compulsory Licensing; having varying mandate; the State working with the social objective and the private sector having a business mandate .

A study indicates 65% of the Indian population still lacks access to essential medicines[4]. Share of drugs in OPD expenses were estimated at 63 per cent by NSSO 60th Round (January 2004)[5]. NSSO in their Report on 61st Round indicated this expenditure having increased to 82 per cent [6]. As per National Health Accounts, medicines accounted for 50-60 per cent of inpatient expenditure in rural and urban areas[7].As per the Report of National Health Accounts Estimates for India (2016-17), for the year 2016-17, total health expenditure for India is estimated at Rs 581023 crores (3.8% of the GDP and Rs. 4381 per capita)[8]. These reinforce the issues raised by the Parliamentary Committee for the need to increase the availability and accessibility of drugs to the poor in the country[9]. The National Pharmaceutical Policy 2002 recognizes the need to 'ensure abundant availability at reasonable prices of good quality essential pharmaceuticals of mass consumption'[10]. The National Pharmaceutical Policy 2006 while acknowledging the explosive growth in this sector between 1990 and 2010, and the accompanying low cost of medicines notes, that concerns regarding the accessibility and affordability of medicines remain[11]. The National Pharmaceutical Policy 2017 has aimed to realign the 'price control' orientation now to 'monitoring of price'[12].

Discussions

The 2001 Doha Declaration brought in a silver lining for Developing and Least Developed Countries as Declaration of the Trade Related Aspects of Intellectual Property Rights (TRIPS Agreement)and Public Health reiterated the flexibility of the member states to avail of the compulsory license to manufacture cheaper version of the patented drugs. Article 6 (b) of the said Declaration further highlighted the right of each Member State to grant Compulsory License and determination of grounds when such licenses are to be granted[13,14]. The Indian Patent Act 1970 (as amended in 2005) has been made fully compliant to incorporate these flexibilities[15].

The compulsory licensing as per Article 30 and 31 of TRIPS is very much WTO compliant for effecting in India. Article 31, while listing out 12 conditions/ circumstances highlights public non commercial use as one of the criteria's. Article 31(k) permits the grant of Compulsory licences to remedy anti-competitive practices. The DIPP paper of 2010 -made a reference to National Pharmaceutical Policy wherein the Drug Regulatory System has a National List of 354 essential drugs subjected to effective price control and limiting trade margins; that apart 74 drugs being under regulation has seen instances of regulatory contraventions[16]. Infact the developed countries with regard the Doha declaration having instituted two loop-holes as exceptions to the TRIPs agreement; one of them being parallel importing, where a "country may import patented drugs from another country where the patent-holding manufacturer sells them for less," and compulsory licensing. Developed countries and big pharmaceuticals are definitely against use of CL provisions[12]. No CLs have been issued in India under the amended Patents Act*(supra)*. In September 2007, three applications under section 92A of the Patents Act, 1970 were received for grant of compulsory licence for the manufacture and export of patented drugs to countries which reportedly did not have manufacturing capacity nor had insufficient capacity. The process envisaged under the Act was initiated. However, the applicant subsequently withdrew his applications

The Indian Patent Act deals with the issue of Compulsory Licensing through Section 84 (General CLs to be issued by Controller on application), Section 91 (Issue of CL by the Controller for the related Patent on application), Section 92 (issue of the CL by the Controller upon a Notification for National emergency/

extreme emergency or in case of Public Non Commercial Use) and Section 92 (A) (When insufficient or no manufacturing capacity is there to address pubic health problems).

Given the varied and a larger landscape under which Compulsory licenses provisions could be invoked, definitely there is a need to put in regulation justifying the elements of Section 92 of the Indian Patents Act i.e. national Emergency/extreme emergency/public non commercial use circumstances, which would mean further elaboration of provision of Section 92 (C) as per Para 43 of the Discussion Paper and the Guidelines should be made available both in case of Category 1 (production at lowest prices) and Category 2 (production at affordable prices) to ensure considerations of quality and availability, which would address the distribution aspects of the medicine to the desiring section of the society (*supra).* One also needs to examine the effective alternative to compulsory licensing wherein the patents could be opposed and more importantly questioning the drugmakers of "ever-green" provisions where pharmaceutical companies make subtle variations to the existing medicines to extend their patent monopolies for a larger duration

A cursory look at the provisions involved in the Indian Patent Act viz. Section 84, 89, 90, 92, 92A reveal that while CL provisions are yet to be tested; it may have technical administrative difficulties in view of the clear cut regulations not in place. (unlike section 84 which stresses for expiration of a 3 year period before a compulsory licensing application can be made, section 92A is silent on this. MoreoverSection 92A conditions are left to be decided by the controller; further the 3year lock-in period under Section 84 may prove to be deterrent given any unknown epidemic to occur. Moreover post 2005; many of the drugs may fall under the patent regime). This is an area which is subject to international pressures, political considerations and varied role of civil society including NGOs and the implementation may not be an easy task. The circumstances as stated in Section 92 (Para 40 & 41) are different from those sated in Section 100 (50 & 51). Section 100 provisions appear to vest in more authority with the Central Government or its constituents for using an invention for the purpose of Government. Given the societal context and the social and public interest that the Government of India concentrates upon the provisions of Section 92 and 100 while being complimentary; albeit Section 100 would cover extreme situations under Section 92 provisions.

It is a fact that drugs patented before 2005 Indian Patent Amendment are "off" patent items; that apart after the new patent regime for India in 2005 there have been instances of highly prices patented drugs in India and therefore there is a need that price control of patented medicine should not only be brought under the mandate of NPPA which presently caters to control the price of scheduled drugs and monitors the prices of non-scheduled drugs but also the patented drugs (*supra).*

Sections 84 to 94 of the Patents Act, 1970 deals with issue of compulsory licences i.e. circumstances under which compulsory licence should be issued, procedure for dealing with applications for compulsory licences, powers of the Controller to grant compulsory licence and terms and conditions of licence (*supra)*. But the time frame within which such compulsory licence should be given, once application for licence has been submitted has not been mentioned under the Act including time frame for Controller to dispose of general applications for compulsory licences, time frame to serve copy of application on the Patentee/patentee to oppose the application, time frame to grant/revoke licence on submission of opposition statement by the patentee,time frame for issue of compulsory licence under Sec.92A for export of patented pharmaceutical products in certain exceptional circumstances and time frame for information to be given to patentee under Section 92, where compulsory licence is issued on notification by Central Government in case of national emergency, extreme urgency or public non-commercial use. Further, the meaning of national emergency, extreme urgency and public non-commercial use should be clearly defined in the Patents Act. The circumstances under which these terms can be used should also be given in detail. Under Section 84(6) (ii) and (iii), the Controller is required to satisfy himself about the ability of the applicant to work the invention to the public advantage as well as the capacity of the applicant to undertake the risk in providing capital and working the invention, if the application were granted.

Article 27(1) of TRIPS interalia states "… patents shall be available and patent rights enjoyable without discrimination as to ...whether products are imported or locally produced" implying that so long as the patented product is available in the market at an affordable cost, the use of the patent cannot be differentiated on the basis of its sourcing – whether it was manufactured within the country or imported from without (*supra)*. The bone of contention has been that the exceptions provided

in Articles 30 and 31 of TRIPS override the general stipulations in Article 27 with Articles 7 and 8 of TRIPS which recognizing transfer of technology to support provisions for local sourcing making local working stipulations valid and enforceable.

Findings: What is needed in India is robust regulations to allow for compulsory licensing at standard royalty rates so that the essential medicine are priced competitively. After the Doha Declaration over 50 countries have issued CLs prominent being USA, UK, Canada, Italy and amongst developing ones; Brazil(2007 for an anti AIDS drug); Thailand(2006 and 2007 for anti AIDS drugs), Malaysia (2003 for Anti AIDS drugs), South Africa (Anti Aids Drug) Kenya (voluntary licenses issued in 2004 after threat of CL), and most recently Ecuador (April 2010 for an anti AIDS drug) (*supra)*.It also remains a fact that in Thailand, use of CL provisions while being totally compliance with the TRIP Law was criticized by the pharmaceutical companies and the Governments of developed countries and it showed the clout of the pharmaceutical industry in their displeasure against the use of CLs. It is gathered that with such successful intervention the pricing of ARVs could be reduced by 40%. A study highlights that CLs are waning away much to detriment of bringing serenity in drug pricing and improved health governance.

While Section 84(1) of the Indian Patent Act provides that at any time after the expiration of three years from the date of the grant of a patent, any person interested may make an application to the Controller for grant of compulsory licence; lack of an objective framework for the issue and maintenance of compulsory licences has not made permeation of the likely benefits of Compulsory Licensing in India (*supra)*. Manufactured in India for working of a patent would foster domestic pharmaceutical industry aiding employment of chemists, physiologists, pharmacists, doctors thus effectively contributing to national economy by producing medication that is compatible with the average local income, because the cost of labour would be commensurate with the average income. It would be important to examine the price or availability of a drug becoming perilous through an anti competitive agreement or a combination which has an adverse effect on competition; or the abuse of dominant position and take appropriate regulatory intervention. For affirmative action to take place on SDG-3 relating Good Health and Well being; there is inherent need to revive discussions on Compulsorily License Framework to address issues of equity and reach while maintaining balance between Patent Rights and Competition framework[17].

A Study on Sociodemographic Profile and Comparison of Pattern of Facial Injuries in Victims of Two Wheeler Road Traffic Accident with and without usage of Helmet in South Chennai

P. Shruthi[1], R.Venkat[2]

[1]Associate Professor, Department of Forensic Medicine and Toxicology, Saveetha Medical College,
[2]2nd Year MBBS Student, Saveetha Medical College

Abstract

Background and Aim: Road traffic accident a cause of unnatural death is the third major preventable one amongst all death. Maxillofacial trauma is often encountered in accidents either as isolated injury or along with several injuries to the head, neck, chest and abdomen.

Materials and Method: A retrospective observational study was conducted in the Department of Forensic Medicine and Toxicology at Saveetha Medical College between January 2018 to December 2018 with an objective to analyse the Sociodemographic profile and compare the pattern of facial injuries in Road Traffic Accident cases with and without helmet usage.

Results: Out of total 2438 RTA cases analysed, 1523 were two wheeler RTAs (62.5%). Amongst 1523 cases,173 (11.36%) had facial injuries. The peak incidence of maxillofacial injuries (42.7%) was observed in the age group of 21 to 30 years, with males outnumbering females in all age groups. The maximum number of trauma cases was reported in late evening hours. Maximum RTAs occured in the months of winter usually in the semi urban areas. The injuries were sustained mostly due to frontal impact. Injuries to lip particularly laceration injuries were most frequent. Injuries occured most commonly to the riders. The injuries were seen more amongst the non helmet usage cases amounting to 68% of cases.

Conclusion: The changing trend of etiology of maxillofacial injuries due to Road traffic Accidents in Chennai necessitates strict traffic legislation and better health care facilities with respect to maxillofacial units.

Keywords: *Accident, Etiology, Demographic profile, maxillofacial trauma, helmet.*

Introduction

India accounts for about 10 percent of road accident fatalities worldwide, 85% of all road accident deaths occurring in developing countries, and nearly half in the Asia-Pacific region. [1] The human face often constitute the first point of contact in various two wheeler RTAs. Maxillofacial trauma is thus a common presentation in accident and emergency department of hospitals either as an isolated injury or as a part of multiple injuries to the head, neck, chest and abdomen. These injuries may cause serious physical, psychological and emotional distress. The etiology of maxillofacial trauma varies from one geographical region to another and event within the same region depending on the prevailing socio-economic, cultural and environmental factors. The severity of injury may vary from simple soft

tissues lacerations to more complicated fractures of maxillofacial skeleton**.** [2] Injuries due to RTA of two wheelers depend upon a number of factors such as human errors, riders fatigue, poor traffic sense, mechanical fault of vehicle, speeding and overtaking, violation of traffic rules, poor road conditions, etc. Clearer insight into etiologic, epidemiologic and demographic factors related to maxillofacial trauma would help prepare more reliable preventive and health care in such cases. [3]

Method

This study was conducted in department of forensic medicine and toxicology in Saveetha Medical Hospital after obtaining clearance from the Institutional Ethics Committee(SMC/IEC/2018/11/559). The basis of the study was data obtained from RTA case record sheets of 173 two wheeler RTA cases who reported to the hospital emergency during the period from January 1st 2018 to December 31st 2018. The case sheets were thoroughly scrutinized and various Socio-demographic profile and maxillofacial injury profile were recorded in specially designed proformas. The data were analysed and interpreted with appropriate statistical tests using SPSS software.

Results

Out of total 2438 RTA cases analysed, 1023 were two wheeler RTAs (41.96%). Amongst 1023 cases,173 (16.91%) had facial injuries . Out of 173 cases with facial injuries, 117 cases (68%) were found not to be using any helmet. More than 3/4th of maxillofacial injuries cases belonged to the riders (142, 82.08%) and pillion riders comprised (31, 17.92%) only**.(Fig 1)**

The age of patients was found to be between 4 to 79 years .Amongst these, more than half of the cases (60.12%) were in the second or third decade of their life, with peak incidence (43.36%) of maxillofacial trauma observed in the age group of 21-30 years. The least number of accident observed between 71-80 years (0.58%). A total of 107 males (61.85%) and 66 females (38.15%) were found in the study. The males outnumbered females in each age group with maximum sex ratio being in the age group of 11-20Years (2.13:1). (**Table-1)**

The greatest incidence (42.77%) of maxillofacial trauma was observed in the evening hours between 6pm to 12am followed by 12pm to 6pm (32.37%). The least number of cases (10.99%) were reported between 12am to 6am.Majority of the cases were found to be in winter (53.17%) followed by monsoon (27.75%).

Majority of RTA cases (22.0%) comprised of unemployed, followed by semi-professional, professional, semiskilled, unskilled, clerical and the least number of RTA cases (4.62%) comprised of skilled workers. 26.01% of the cases belonged to lower class followed closely by upper middle class comprising of 21.97% of the cases.

The maximum incidence (70.52%) of maxillofacial trauma was observed in semi urban areas, followed by rural and the least incidence (12.13%) observed in urban areas. (**Table-2)**

About 1/3rd of the maxillofacial injuries were reported due to skid and fall followed by the impact with an offending vehicle. (**Table-3)** In 63.58% of maxillofacial trauma reported, the collision was from the front direction followed by left and right impact.

The greatest incidence of maxillofacial trauma was observed as laceration (28.32%) followed by abrasion and the least observed injuries were facial bone fractures (21.96%)(**Table-4)**

Majority of maxillofacial injuries in both cases of helmet and non helmet users were reported in lips(62.43%),followed by nose, eye and jaw, chin and the least were reported in cheek and maxilla(2.31%). (**Table-2)**

Table-1: Age and Sex Distribution

Age	Sex		Total(%)	Sex Ratio
	Male	Female		
1-10yrs	4	2	6 (3.47%)	2:1
11-20yrs	17	8	25(14.45%)	2.13:1
21-30yrs	43	32	75(43.36%)	1.34:1
31-40yrs	19	10	29(16.76%)	1.9:1
41-50yrs	15	9	24(13.87%)	1.67:1
51-60yrs	5	3	8(4.62%)	1.67:1

Abrasion	16	31	47
Contusion	11	28	39
Laceration	17	32	49
Fracture Of Facial Bones	12	26	38

Discussion

Considerable variation has been reported in profile of facial injuries with respect to geographical location, socio economic status and cultural background.

The pattern of age distribution in maxillofacial trauma demonstrated people of all ages were affected, the peak incidence was however observed in the age group 21-30 years followed by that between 31-40Years .The second and third decade is possibly the most active period of life where people tend to remain outdoors to explore their means of livelihood and are thus more susceptible to vehicular accidents and falls. Individuals in extremes of life were found to be least affected and most of the injuries (78.61%) were observed in persons of working age group (21-60 Years).

The gender distribution revealed male preponderance in all age groups as has been reported in other studies. The lower socioeconomic group, which constitutes bulk of patients reporting to this particular hospital, men are often the primary bread winners of the family and tend to remain outdoors for a large period of time, thus making them susceptible to trauma in general and

maxillofacial trauma in particular. All so females drive less frequently and are thus less likely to be involved in vehicular accidents especially related to alcohol consumption. [4, 5]

The greatest incidence (42.77%) of maxillofacial trauma following RTA was observed in the evening hours between 6pm to 12am and it was followed by 12pm to 6pm. This finding accordance with those of Veeresha et al and may be attributed to sustainable increasing in traffic after the office hours,when people are returning home and to a tendency to consume alcohol in the evenings. [4]

The most common type of maxillofacial road traffic injury was found to be in semi urban areas (70.52%). Due to heavy congestion and traffic. This will lead to stress and lack of concentration result in accident.

Two factors have been consistently associated with facial injury namely alcohol and unemployment . Unemployment and the associated frustration and rage, particularly in youth of lower socio economic group drives them to take hasty decisions. In developing country, such as ours, RTA is generally believed to be the most common cause of facial trauma [6].This is in consistency with our findings of cases been noticed more in the lower socioeconomic strata [7,8].

The most common type of maxillofacial injury was found to be soft tissue trauma. This finding is in accordance with that of Gassner et al [9], who demonstrated a very high frequency of soft tissue injuries in the comprehensive review of Cranio-maxillofacial trauma and also with those of Le et al [10], who reported that soft tissue injuries were the most common type of injuries: Facial Laceration was the most frequent type of soft tissue injury than abrasion and contusion.

The most common type of maxillofacial trauma subsequent to vehicular accident were reported from skid and fall due to lack of control during riding fast, overtaking and also due to consumption of alcohol, followed by hit and fall by opposite vehicle and the least incidence was observed as hit and fall by dog.

The most common type of maxillofacial trauma were reported for riders as they were about likely to have been involved in a loss of control crash or a collision with another motor vehicle, in comparison with the pillion riders. Possibly, the presence of pillion riders lessen the risk of loss of control and crashes by reducing risk taking or drowsiness [10].

Even though the use of helmets has been made mandatory for the rider and the pillion rider also, the strict adherence to the law is yet to be seen. The type of helmets worn also plays a role in the etiology of trauma. Full-faced helmets protect the rider from brutal injuries when compared to open-face helmets.In our study, non helmet wearers were found to be more than twice likely to have injuries than the helmet wearers. This is in concurrence with another study done in South India that reported four times more likely chance to sustain head injuries amongst victims not wearing helmets. [11]

Conclusion

The maxillofacial injures is proved to be due to traumatic injuries, especially from Road injuries. Provision of well lit pedestrian friendly trail, roads and streets, isolation of heavy and light motor vehicles and strict governance by traffic personnel is must to minimize the physical, psychological and emotional distress associated with trauma in general and maxillofacial trauma in particular.The high incidence of maxillofacial trauma also has implication for the establishment of dedicated maxillofacial units in districts and tertiary care hospital. The effectiveness of various preventive and educational programs with respect to maxillofacial trauma may be publicized through continuing audit of pattern of such trauma in different parts of world.

[2]Asst. Professor, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, India

Abstract

Introduction: Coronary artery bypass grafting (CABG) surgery is one among the most common procedures performed in the world, and it is one of the possible treatments for coronary artery disease (CAD). Although the effectiveness of coronary artery bypass grafting (CABG) is being evaluated in terms of mortality, complications or recurrence of symptoms, empirical studies assessing the change in patients quality of life (QOL) after CABG need to be studied as findings keep changing as time progress. A systematic analysis of how well the patient is considering a multiple variable need to be studied which has greater impact in improving the overall performance of the patients after CABG.

Aim: Aim of the study is to assess the quality of life among post coronary artery bypass grafting (CABG) patients.

Method: A quantitative approach with a descriptive design using a non-probability convenience sampling technique was used to collect data from 101 post CABG patients. The setting used for the study was CVTS OPDs at AIMS, Kochi. A standardized quality of life questionnaire (SF-36) along with a semi-structured questionnaire to assess socio-demographic and clinical data.

Results: The study result showed that the majority of samples (97%) had good QOL with mean score of 69.22. PCS (96%) showed higher value than MCS (68. 3). A significant association found between QOL and socio-demographic variables like occupation (p=0.018).

Conclusion: Overall QOL improved one year after CABG.

Keywords: *Quality of life and CABG.*

Introduction

Cardio vascular diseases is one of the most common diseases seen in elderly persons and approximately 50% of persons over 65 years of age have clinical signs of the disease. Cardiovascular disease is a major cause of functional impairment and is the cause of death in elderly persons. The cardiovascular changes affect the overall functions of persons life(1)

The treatment of coronary artery disease are mainly medical therapy and surgical therapy. Failure of medical management often leads to surgical management, that is revascularization with percutaneous coronary intervention or coronary artery bypass grafting (CABG), uses arterial or venous vessels to create a new pathway for blood to reach the coronary arteries, thus "bypassing" the stenosis(2).

Coronary artery bypass grafting (CABG) is an established and highly effective therapy for coronary artery disease. CABG has been effective than the medical therapy, for the relief of angina pectoris[4]. The first coronary artery bypass operation in human being

was using a saphenous vein graft and coronary artery anastomosis was performed in November 1964 by Garrett and Debakky[3].

According to American Heart Association (AHA) 2015, health data, more than 190 countries shows coronary artery disease remains as the number one global cause of death with 17.3 million of deaths in each year. The number is expected to rise up 23.6 million by 203010[4]

The global burden of disease (GBD) study reported, it is estimated that 47 million Indians had coronary artery disease (CAD) in 2013. Cardio vascular disease has become the leading cause of morbidity and mortality in India during the last three decade[5].

CABG is associated with financial burden because of days lost from work, excess cardiology visits, diagnostic testing, and use of medications. The self-perception of the quality of life depends on the patient's own abilities to cope with the illness, usually individuals who are better able to adjust to their illness perceive the quality of life as being higher. A poor psychosocial adjustment to illness in turn reflects a more impairment of the quality of life

Preoperative risk scores are essential tools for risk assessment, cost–benefit analysis, and the study of therapy trends. Various scoring systems have been developed to predict mortality and morbidity after cardiac surgery. Risk stratification will inform patients and clinicians of the likely risk of death for a group of patients with a similar risk profile undergoing the proposed operation. This information is useful and should form part of the basis on which the patient and surgeon decide whether to proceed or not. Risk models were also applied for quality improvement programs comparing year-to-year outcomes, as well as allocation of healthcare resources through the prediction of length of stay and postoperative complication rates [11].

Although the effectiveness of coronary artery bypass grafting (CABG) is being evaluated in terms of mortality, complications or recurrence of symptoms, empirical studies assessing the change in patients quality of life (QOL) after CABG need to be studied as findings keep changing as time progress. A systematic analysis of how well the patient is considering a multiple variable need to be studied which has greater impact in improving the overall performance of the patients after CABG.

Although the effectiveness of coronary artery bypass grafting (CABG) is being evaluated in terms of mortality, complications or recurrence of symptoms, empirical studies assessing the change in patients quality of life (QOL) after CABG need to be studied as findings keep changing as time progress. A systematic analysis of how well the patient is considering a multiple variable need to be studied which has greater impact in improving the overall performance of the patients after CABG.

Method of Study

Quantitative research approach with descriptive design was used to identify the QOL among post CABG patients. The study was conducted among 101 post CABG patients after one year of surgery and coming for follow up in CVTS OPDs of Amrita Institute of Medical science, Kochi. The subjects were selected by non-probability convenience sampling technique. The data were collected using structured questionnaire. The tool developed and used for the study were tool I was a semi-structured questionnaire to assess the socio-demographic characteristics, which had two sections. Section A socio –demographic variables and section B included clinical variables. Tool II was a SF-36 standardized tool to assess the quality of life of post CABG patients. The tool developed and used for data collection was a standardized structured questionnaire. The content validity was obtained from 7 experts. The tool was found to be valid. Informed written consent was obtained from the samples after explaining the purpose of the study. Data collection was conducted in CVTS OPD. Anonymity and confidentiality of samples were maintained. A pilot study was conducted among 10 samples who met the eligibility criteria . It was found that the research design was appropriate, research tools were valid and reliable and the study was amendable to statistical analysis .The data was analyzed using descriptive and inferential statistics. The description of sample characteristics based on socio-demographic and clinical variables were computed using descriptive statistics. Association between QOL and selected socio demographic and clinical variables were assessed using inferential statistics.

Result

Table I: Distribution of sample characteristics based on demographic variables n = 101

Sl. No.	Demographic variables	Frequency (f)	Percentage (%)
1	**Marital status**		
	Single	31	30.7
	Married	58	57.4
	Widow/widower	10	9.9
	Divorced/separated	2	2
2	**Education**		
	Primary education	32	31.7
	High school	46	45.5
	Diploma	23	22.7
3	**Occupation**		
	Employed	60	59.5
	Unemployed	41	40.5
4	**Food**		
	Vegetarian	21	20.8
	Non- vegetarian	80	79.2
5	**Income**		
	2165-6430	3	3
	6431-10718	13	12.9
	10719-16077	43	42.6
	16078-21347	42	41.6
6.	**Type of family**		
	Joint family	9	8.9
	High school	92	91.1

The data presented in table I shows that the majority of sample 65(64.4%) were under the age group of 61-70 years. In gender, majority of sample were male 92 (91.1%). Most of the sample 58(57.4%) were married & 46 (45.5%) were having high school education. The data illustrated that most of the samples were unemployed retired 27(26.7%) and 25(24.8%) were private employed. The monthly income of 43(42.6%) sample were ranges from Rs. 10719-16077. When considering the food habits most of the 80(79.2%) sample were non vegetarian. The majority 92(91.1%) of the sample were belongs to nuclear family.

Table 2: Distribution of sample characteristics based on clinical variables n=101

Sl.No.	Clinical variables	Frequency (f)	Percentage (%)
1	Types of surgery		
	ON pump	16	15.8
	OFF pump	85	84.2
2	**Indications of CABG**		
	Single vessel disease	2	2
	Double vessel disease	23	22.8
	Triple vessel disease	76	75.3

Sl.No.	Clinical variables	Frequency (f)	Percentage (%)
3	**Ejection fraction**		
	Normal (52-72%)	78	77.2
	Mild (41-51%)	19	18.8
	Moderate (30-40%)	4	4
4	**Alcoholic habits**		
	Current alcoholic	3	3
	Non –alcoholic	27	26.7
	Ex-alcoholic	62	61.4
	Occasionally alcoholic	9	8.9
5	**Smoking habits**		
	Current smoker	6	5.9
	Non-smoker	30	29.7
	Ex-smoker	65	64.4
6	**Body mass index**		
	Over weight	5	4.9
	Obesity	1	1
	Normal	95	94.1
7	**Complications after CABG**		
	Without complications	60	59.4
	Wound infection	1	1
	Pain	1	1
	Others	39	38.6
8	**Hours of sleep per day**		
	More than 10 hours	7	6.9
	6-8 hours	78	77.2
	4-6 hours	10	9.9
	4 hours	6	5.9
9	**Co morbidities**		
	One co-morbidity	1	1
	Hypertension	13	12.9
	Diabetes mellitus		3
	Dyslipidaemia	3	
	Two co-morbidities	11	10.9
	Hypertension and diabetes	17	16.8
	Hypertension and dyslipidaemia		
	Dyslipidaemia and diabetes	4	4
	Three co-morbidities		
	Hypertension, diabetes mellitus and dyslipidaemia	15	14.9

Data in the table-2 depicts that among 101 samples the common types of surgery were OFF pump 85(84.2%). Consider the indications of surgery majority were having triple vessel disease 76(75.3%) and were having normal EF 78(77.2%). Regarding smoking habit majority of the samples were ex-smoker 65(64.4%) and 62(61.4%) were ex alcoholic. Among the samples 95(94.1%) had normal BMI. Considering the complications majority 60(59.4%) were had no complications after CABG. Regarding the hours of sleep per day most of them had 6-8 hours of sleep.

Section II: Description of QOL assessment of post CABG patients:

Table 3: Description of quality of life among post CABG patients n=101

	Minimum value	Maximum value	Good QOL (%)	Poor QOL (%)	Mean value	Standard deviation
Overall quality of life (QOL)	39	94	97	3	69.22	9.368

Table 3 shows that among 101 samples majority of them (97%) had good quality of life with a mean score of 69.22 and standard deviation of 9.368.

Section II: Description of samples based on components of quality of life n=101

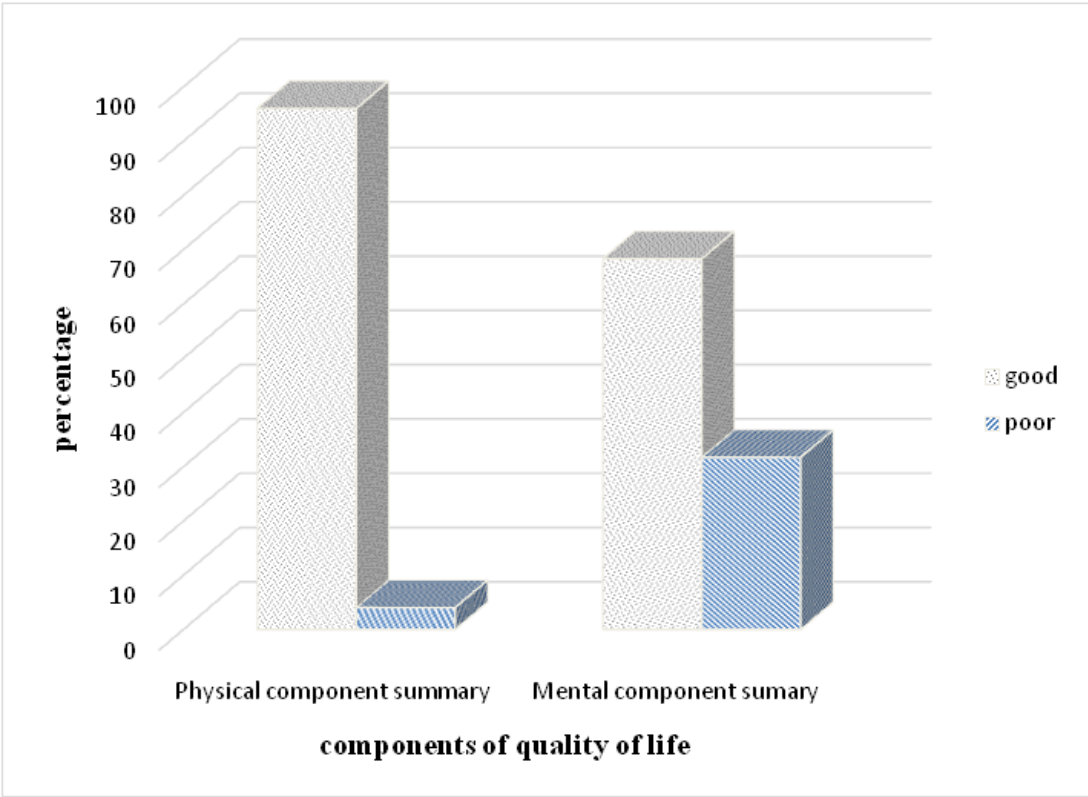

Figure 1: Bar diagram representing distribution of samples based on components of quality of life.

Figure 1 depicting the components of QOL, in the physical component summary 96% had good physical component score with mean score 77.98 and 68.3% had good mental component score with mean value of 57.07. Hence physical functioning was considered to be better than mental functioning

Section II : Description of samples based on domains of physical components summary n=101

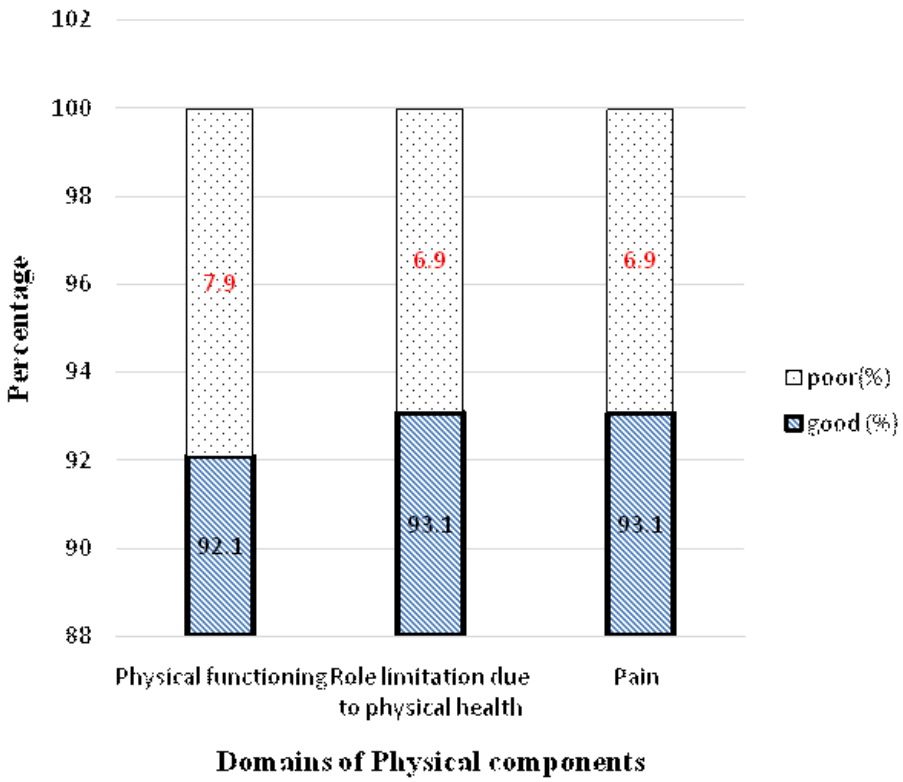

Figure 2: Bar diagram representing quality of lifebased on domains of physical components

Figure 2 depicting domains of physical component summary (PCS) of QOL. Majority (93.1%) expressed they had no role limitation due to physical health, regarding pain majority (93.1%) had no pain. Considering the physical functioning, majority (92.1%) had good physical functioning.

Section II: Description of samples based on domains of mental components summary n=101

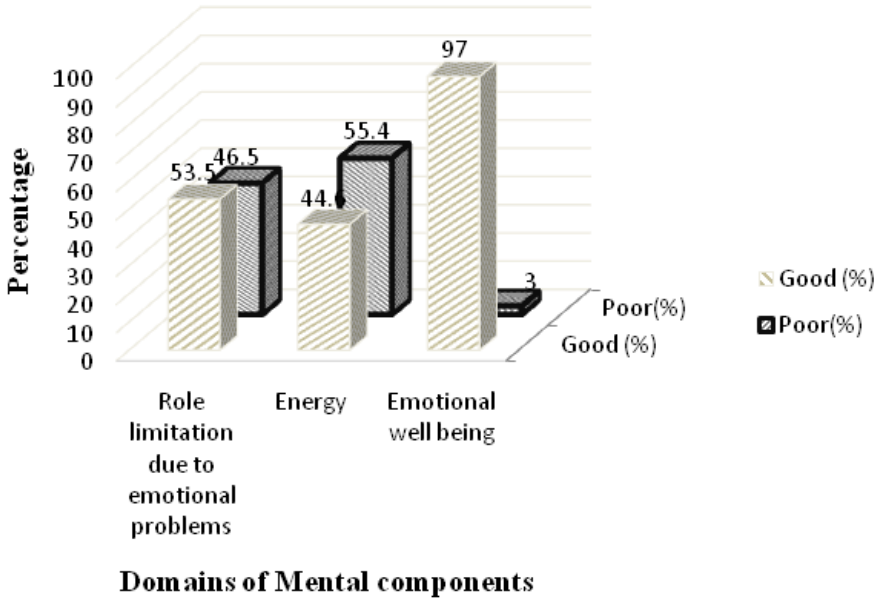

Figure 3: Diagram representing quality of lifebased on domains of mental components

Figure 3 depicting domains of mental component summary (MCS) of QOL. Majority (97%) samples experienced good emotional wellbeing and 53.5% expressed good score in role limitation due to emotional problems. Considering energy and fatigue 44.6% had good energy.

Distribution of mean and standard deviation of quality of life: Among 101 samples the highest mean score was observed in bodily pain (84.30), it means that patients had less pain and lowest mean score was observed in energy/fatigue (46.93) means that they had lack of energy.

Association between quality of sleep and selected demographic variables: The association between Quality of sleep and selected demographic variables like age, gender, marital status, education, income, diet pattern and type of family were not statistically significant with p value of 0.05 level. Whereas, occupation showed statistically significant (0.051).

Discussion

The first objective was to identify the quality of life among post coronary artery bypass grafting patients: The results from the present study showed that overall quality of life of post CABG patients 97% had good quality of life with mean score of 69.22 and standard deviation 9.368. Considering the physical component summary 96% samples had good quality of life with mean score 77.98, and mental component summary 68.3% samples had good quality of life with mean score 57.07. That means PCS higher than MCS.

In relation to physical component summary, majority of the samples (93.1%) expressed no role limitation due to physical health with a mean score of 73.64. considering the physical functioning most of them (93.1%) were having good physical functioning with a mean score of 73.79. Regarding pain 93.1% had no pain with mean score of 84.30.

In relation to mental component summary most of the sample (55.4%) were lacking energy level with mean score 46.93. Regarding role limitation due to emotional wellbeing majority of the patient (53.5%) weren't having any role limitations with a mean score of 55.78. A vast majority of sample (97%) expressed good emotional well-being with a mean score of 68.51.

The similar findings were observed in a descriptive study conducted by Anastasios Merkouris, Dimitrios Pistalos to assess the QOL after CABG patients at Greece in 2008. The findings showed that the overall QOL of patients was improved, good level of QOL with an average score of 80.4[6].

The present study findings are contradictory to a study findings done by Lee GA conducted a cohort study to assess the patients reported health related quality of life five years post CABG at Australia in the year 2008. The findings showed that good level of QOL with an average score of 66.02%. MCS (53.6) was higher than PCS (45.8). PCS had poor QOL and MCS had good QOL[7].

The second objective was to find the association between the quality of life and with selected socio demographic variables among post Coronary Artery Bypass Grafting patients

The present study showed a significant association with occupation and QOL (p=0.018), QOL was unaffected by all the other socio-demographic variables

Taghipour H.R conducted a descriptive study to assess the QOL one year after CABG at Iran in 2011. The result showed that mean age of patients was 61.4, most of them are male. On pump surgery had better general health than off pump 47.9 (p=0.024). Negatively correlated with EF r=-0.220. chi- square value is 0.19[8].

Descriptive study conducted by Elishevasimchen to assess the relation between QOL and socio demographic factors at Israel. The findings showed that female sex and low socio economic background were associated with low health related QOL.[9]

Conclusion

Overall QOL improved one year after CABG. majority of the samples expressed more physical wellbeing than of emotional wellbeing henceforth,there is an alarming need to give a holistic care for patients.

Pulpectomy: A Comprehensive Review

Akankhya Jena

Intern, Institute of Dental Science, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Several pulp therapies both vital and non-vital pulp therapies for preserving the physiologic integrity as well as the well being of the tooth have been developed as a necessity for the healthy growth of the teeth. It mainly aims at protecting the teeth from trauma, caries, or any other infections. Pulp exposures resultants to caries are the most universal in deciduous teeth due to the relatively bulky size of the pulp chamber. The pulp in deciduous teeth is capable of healing, following control of infection, and inflammation. A pulpectomy is mainly preferred in non-vital teeth (done in various vital teeth also), where the teeth can be cleaned and disinfected and preserved for more no. of coming years. Pulp rehabilitation for pulpally implicated deciduous teeth continues to be a confront to practitioners. One of the majority important areas of continued examination is in the area of discovering obturating resources to suit the precise properties of these teeth. This piece of writing aims at reviewing the objectives, types, technique, restorative materials used, indications and contraindications and conclusion.

Keywords: *Pulp, Pulpectomy, Root Canals, Resorbing Material, Obturating Material, Vital And Nonvital Pulp Therapies*

Introduction

One of the majority important services a pediatric dentist can make available for the child patient is the adequate treatment of pulp involved deciduous teeth. For many years, different principles as well as techniques for the management and conservation of deciduous teeth have been suggested by the dental profession. The pulp is an obligatory element for maintaining the healthy physiological integrity of the tooth. Conditions like irreversible pulpitis, pulp necrosis, or dentoalveolar abscess in deciduous teeth are best treated by non-vital pulp therapies. Soft tissue therapy is extensively used during the management of pediatric patients, at the same time as attempting to stop happening impulsive exfoliation of the deciduous teeth.[1] The most important purpose of endodontic supervision is the full amount of exclusion of microorganisms commencing the root canal, and the avoidance of consequent reinfection. This is achieved through cautious cleanout in addition to shaping followed via the total obturation of the canal space. The final objective of endodontic obturation has remained the same intended for the past 50 years: to generate a fluid-tight close up along the length of the root canal arrangement, commencing the coronal opening of the apical termination. A pulpectomy is one of these therapies conducted on deciduous teeth for the prevention of subsequent re-infection by the total abolition of the microbes and bacteria from the root canals.[2]

Definition: Pulpectomy is a dental procedure that involves the entire exclusion of the coronal as well as the radicular portion of the pulp cavity to get admittance to the root canals that are debrided, inflamed, distended as well as disinfected moreover resorbable substance are used to fill the canals.[3]

Types:

Partial Pulpectomy: One third to one half of the coronal segment of the radicular pulp tissue is detached from the canals.

Complete Pulpectomy: complete removal of pulp tissue from the root canal

Objectives:

- Resolving of the infectious process, following the treatment

- Overextension as well as under filling should be avoided with successful radiographic evidence.
- Resorption of the deciduous tooth structure as well as filling material should take an appropriate time
- No other pathology or internal or external root resorption should be present
- There should be no sensitivity, pain or swelling present
- No further breaking down of the supporting tissues after the treatment.

Indications:

- Patients along with their parents should be cooperative.
- A patient with good health along with no serious disease is preferred
- Indications of deciduous teeth in absence of its permanent successor
- Irreversible pulpitis
- Internal resorption
- At least two-thirds of the root length is supposed to be accessible.

Contraindication:

- Mobile tooth or reduced bone support
- A tooth that is non-resorbable
- Any dentigerous or follicular cyst present beneath
- Root length remaining less than 2/3rd
- Perforation of pulpal floor
- Children those are medically compromised

Procedure:

Single-visit Pulpectomy:

Indication: This course of action is an addition of pulpotomy. Wherever the inflammation extends further than coronal soft tissue, indicated by hemorrhage from the amputated radicular stumps with the purpose of is oozing endlessly and is unmanageable.[4]

Procedure:

- Suitably administer local anesthesia along with isolation of the tooth using the rubber dam.
- Arrange an access cavity; expose the coronal soft tissue; all the reachable pulp tissue (coronal as well as radicular) is extirpated with the assistance of barbed broaches.
- After extirpation of the pulp tissue is completed, irrigate the pulp cavity as well as a canal using saline in addition to a diagnostic radiograph that is in use for the working length of the file.
- Shaping, irrigating of canals be undertaken, dehydrated the canals with absorbent paper points.
- Position the final restoration

Multiple visit Pulpectomy:

Indication:

- A tooth with necrotic pulp in addition to periapical involvement.
- The occurrence of illness, chronic sinus, or abscess.
- Nonvital deciduous tooth.

Procedure:

Through the first appointment:

a) Correctly administer local anesthesia as well as detach tooth from surrounding oral environment using a rubber dam.

b) arrange the access cavity as well as expose the coronal soft tissue along with extirpating of all pulp tissues using barbed broaches

c) Position the cotton pellet above the pulp chamber soaked by formocresol along with temporary restoration set over it.

Following the period of 1week recall the patient.

Through the second appointment

a) Smoothly eradicate impermanent restoration; irrigate the canals as well as begin with biomechanical preparation of canals.

Note: Employ appropriate working length of files to stay away from perforation of canals.

b) Irrigate the dry canals as well as place sterilized cotton pellets in addition to position temporary restoration above it.

Through the third appointment

a) Smoothly eradicate the temporary restoration, irrigate as well as dry the canals using absorbent paper points.

b) Coat the ramparts of canals using the luting consistency of cement with the assistance of reamers along with them fill the canals by bulky consistency of cement through the help of lentiluospirals.

c) Stick down the chamber through the temporary restoration.

Following the period of 1-week call the patient.

through the fourth appointment

a) Condition tooth is asymptomatic, place the final restoration; set a stainless-steel crown.

Procedure:

Access Opening:

Anterior deciduous teeth: The best sites of access opening are the lingual surfaces of the anterior deciduous tooth along with the permanent tooth. Except that stained maxillary deciduous incisors are approached through facial surface followed through an acid etch composite restoration.[5]

Posterior deciduous teeth: Deciduous Teeth are comparable to those of the permanent teeth. The simple divergence among the deciduous and the permanent teeth are the level of the crown, the bulging form of the crown as well as the very thin dentinal ramparts of the pulpal floor and its roots.

While the top of the pulp chamber is detached distinguish the orifice of the root canals.

- Canal cleaning along with shaping: - The canals cleaning in addition to shaping is the mainly considerable step of deciduous root canal management. The foremost intention of biomechanical preparation is debridement of canals. Only NiTi files are suggested for the deciduous root canal preparations. The canals are enlarged several sizes past the 1st file to fit contentedly in the canal through a minimum size of 30 to 35 no. file.
- Working length determination: - At the beginning working length is determined using a radiograph. The working length is after that determined via a radiograph by a Ni-Ti file inside the canals (apex locator is undependable and unreliable in working length determination in deciduous teeth). It is advisable with the intention that the working length would be shortened to 2 to 3mm short of radiographic root apex for precise length determination.[6]
- Filling with the material.

Obturating Techniques: Numerous techniques have been intended for substantial filling of substance into deciduous teeth canals The deciduous teeth with the bigger canals are capable of being filled through the slim mix; coating the ramparts of the canals with the aid of reamer in an anticlockwise course at the same time as taking out slowly followed by placement of thicker mix which is then pressed manually. The paste can be filled by way of lentiluospirals mounted on the micromotor handpiece. The course of rotary motion needs to be checked for the substance to appropriately flow into the canal. The endodontic pressure syringe is as well effectual for the insertion of the materials that are used in the canals. The vitapex system besides uses the syringe with the material in it. The syringe is introduced up to 1/5th distance as of the apex of the canal along with the material which is slowly injected at the same time as the syringe is withdrawn from the canal. Despite the technique adopted to fill the canal, care is supposed to be taken to avoid extrusion of material into the periapical tissues. The sufficiency of obturation is checked using radiographs. In the occurrence, if a small amount of ZOE is by mistake enforced through the apical foramen it is left unaccompanied since the material is resorbable. While the canals are satisfactory obturated a quick set temporary cement is positioned in the pulp chamber to close over ZOE canal filling. The deciduous tooth is restored in the company of a stainless steel crown.[7]

Filling of the deciduous root canals: Developmental, anatomic, and physiologic differences stuck between deciduous and permanent teeth call for differences in the criteria designed for root canal filling materials.[8]

Ideal requirements are:

- Resorb speed of the deciduous roots as well as the resorb material be supposed to be identical.
- It is supposed to be undisruptive to the periapical tissues along with the permanent tooth germ, resorb readily if hard-pressed further than the apex.
- It is supposed to have an unwavering disinfecting influence.

- It is supposed to be inserted without difficulty into the root canal as well as removed effortlessly if required.
- It is supposed to hold fast to the walls of the canals as well as should not shrink.
- It must not be soluble in water.
- Be radiopaque as well as not stain the tooth.

Filling materials used:

- ZOE paste: most regularly worn filling material in deciduous teeth. Disadvantages are the divergence stuck between its rate of resorption as well as that of the tooth root, including overfilling and underfilling. The success rate is 65%. This is also known as zinc oxide eugenol paste.
- Iodoform paste: Also known as KRI paste (Iodoform), it absorbs speedily as well as has no enviable result on succedaneous teeth when used as a pulp canal medicament during abscessed deciduous teeth. It even has a long-lasting bactericidal effect. Its success rate is 85%.
- Calcium hydroxide: calcium hydroxide along with Iodoform mixture has been found effortless, to apply as well as resorbs imprecisely more rapidly than that of the root, with no noxious end product on the descendant tooth in addition to, it is radio-opaque. It is nearly an ideal filling material with a success rate of 100%.
- Colla cote: it is a soft, white, pliable, biocompatible sponge obtained from bovine collagen. It is an absorbable collagen barrier, which prevents or diminishes extravasations of filling material used in the root canal treatment during deciduous molar Pulpectomy.
- Endoflas: - it can be used as an alternative root canal filling material for deciduous teeth. Microleakage should be prevented to have a success rate. Any signs of inflammation, the filling being replaced with the permanent filling material. The success rate is 70%.[9,10]

Conclusion

In conclusion, I would like to say that calcium hydroxide – Iodoform mixture is the closest to the being the ultimate root canal filling substance for deciduous teeth.

Ethical Marketing in Orthodontics: A Review

Sumita Mishra[1], Ananya Panda[2], Smruti B. Nanda[3]

[1]Associate Professor, [2]Post Graduate Trainee, [3]Head of the Department, Department of Orthodontics and Dentofacial Orthopedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Due to rise in the Orthodontic treatment by general dental practitioners and pedodontists, there has been a widespread increase in the mass promotion and publicizing by the Orthodontists about their specialty and particular expertise. Earlier, treatments were advocated in the form of maintenance of good oral health, however, it is now being recommended to patients as life-enhancing. Commercialism in publicizing orthodontic care has taken up the field. Because of the elective nature of Orthodontics, highly productive marketing strategies are aimed at those with discretionary income or insurance benefits. This kind of commercialism deteriorates the name and fame of the Orthodontist and the opinion of the people by casting a picture of greed. Inappropriate advertising can make a dental practitioner look more like a business person than a professional service provider.

Keywords: *Ethical Marketing; Orthodontic treatment; Dental Practitioner.*

Introduction

Years of self-regulation in the field of medicine, dentistry, and allied health sciences ended with the change in the law by The Supreme Court acknowledging the Federal Trade Commission's proposition to legalize advertising by the health care providers in the year 1975. This change was basically due to the lack of basic and relevant information to the general public and the various options to explore while selecting a health service provider through advertisements and promotions.[1-3] However, the opponents of the ruling had the apprehension that some health care personnel would misuse the freedom of marketing, thus, reducing professionalism into mere commercialism. According to Welie et al, marketing or advertising is ethically difficult because it is more of a commercial than a practicing genuine dentistry. The client knows, he has to be aware to get the best bargain and he knows the trader will make efforts to gain maximum profits. This has always been the game of merchandising. Advertisements are used by traders or sellers to attract clients away from other traders. Similarly, advertisements by Orthodontists encourages competitions among other Orthodontists and general dentists and Pedodontists who also provide Orthodontic treatment rather than a sense of joint responsibility for providing quality dental care.[1-3]

Ethical Principles of Veracity in Marketing: Ethical marketing is a method of recognizing, foreseeing and satisfying the needs of the patients in a profitable manner which the dentists do in their regular practice such as consultation, patient examination and the required treatment, for years. This requires thorough research of the market by understanding the needs of the people, anticipating their future requirements and building a product or delivering a service that would satisfy the need, publicizing it and confirming that the whole procedure is profitable. On the other hand, Unethical marketing is influencing people and convincing them to purchase what one is intending to sell.[4]

Corresponding Author:
Dr. Sumita Mishra
Associate Professor, Department of Orthodontics and Dentofacial Orthopedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: sumita.mitali@gmail.com

Orthodontists, not anymore depend on the referrals from the general dental practitioners, but have switched to a different approach to the market and promote themselves to the likely patients directly. This method of marketing is known as "direct-to-costumer" marketing. The outcome is that some Orthodontists have become shrewd and determined marketers, to achieve freedom from the general practitioners on whom they were profoundly dependent, even if there is a violation of ethical code and professionalism. The AAO's Ethical principles and Code of Conduct, section V, mentions that the members of the association shall make sure that the announcements made by them in the public or any publicizing campaigns or activities with an intent to inform and enlighten the people and help them make informed decisions, are not bamboozling, untruthful, or fabricated. This reprimand is also mentioned in the "American Board of Orthodontics' (ABO) Guidelines for the use of the diplomate title or logo" in which the ABO prohibits diplomates to issue any statement about their reputation that renders them more proficient or competent than non-boarded Orthodontists. [5-7]

In the past, because of the FTC ruling, 1975, the commercialism has almost taken over professionalism in the field of health. Each Orthodontist must have an attitude that creates a sense of professionalism and exhibits the utmost care for the patients. This will attract patients to maintain the respect and value for our society. Being authentic and restricting one from portraying supremacy might help in preventing the degradation from Orthodontic specialty to meager trade. Furthermost, the suitable way to react to any other practitioner's inappropriate methods of advertising is to retain one's professional stance in all forms of marketing, rather than adopting methods that defame, devalue or degrade our specialty.[5,6]

Clarity in Marketing: Several patients and general dental practitioners are not aware of the scholarly importance of a specialist and the advantages of board recognition. A lot of patients are fascinated by the faster esthetic enhancement. According to the Pennsylvania Code, marketing or advertising is fabricated, untruthful, or fallacious if it is adopting any one of the following:

a) Consists of a falsification of facts or excludes a fact obligatory to make the report considered altogether and not materially deceiving.

b) Builds baseless expectations about the treatment results the dentist can accomplish

c) Evaluating the publicizing dental practitioner's facilities with the facilities of other dentists unless the evaluation can be realistically validated. [8]

If any untruthful or fallacious advertising is found, a complaint will be filed against the offender in the State board's professional compliance cell. There will be an inquiry for penalization if the complaint is found relevant. There are disparities between the ethical principles of the AAO and the specialized laws implemented by each state. Breach of any law or principle of ethics could lead to eviction from the association and board; and breach of the legitimate laws by the state could result in a way serious aftermath apart from the monetary penalty or restraint from practice. The parameters for ethical marketing are distinctly demarcated for both the general dental practitioners an Orthodontic specialist. Even if certain general practitioners facilitate Orthodontic treatment, layman should not be confused when selecting a dental health care provider. The Orthodontists should try to reduce the exposure of the prospective patients to deceptive and untruthful marketing. Along with the presence of the ethical rights of the patient, the orthodontist should make sure that the patients get the best that dental science can provide.[2]

Discretion in Marketing: The 1975 ruling was done to improve the well-being of patients by promoting free competition and information on available facilities. It was meant to be advantageous and constructive for the ones who used discretion in their marketing strategies. However, the opinion and morals vary among the people and the health care providers and there remains a fine thin line between commercialism and professionalism.[3] Many Orthodontists get involved in group discount marketing which is not only damaging to the image of the specialty but also harmful to the Orthodontists as he/she loses the skill to choose which patients to treat. While the right to autonomy gives patients their right to select different alternative options for treatment, it also permits the Orthodontist to choose his/her patients. The group discount advertisement makes the Orthodontist give up the freedom of choice as anyone who responds to the offer is mandatory to be attended by that practice. Also, the Orthodontist in the contractual agreement with the group coupon advertisement administrators, gives away the freedom to manipulate the fundamentals of the proposal as well as the percentage of the fees collected for treatment from the patients. This involves "fee-splitting" which is highly unethical as well as illegal. [9,10]

Widespread flashy and derogatory marketing makes us wonder if the future generation of Orthodontists will value the dignity and respect our forerunners have established for our specialty. It took years to uplift the field of dental sciences and Orthodontics to an eminent and notable status. Thus, we must always be cautious among us to avoid deterioration and regression of our profession to meager trade.

Acceptable Self-Promotion: Self-promotion is defined as performance shown or action taken to grab attention mainly in work or business. There was a time when self-promotion of an Orthodontist and his practice was thought to be immoral. Even there were restraints on marketing and campaigning. Even the letter size on the board outside an Orthodontist's clinic or house was strictly restricted to 8 inches. Marketing through newspapers, magazines, or on television was never heard of and would have been considered unacceptable.

Time has changed drastically. Today, marketing by Orthodontists has become common. For a few years, the AAO has expended a significant amount of time and wealth, publicizing Orthodontists to the general people through magazines. Campaigning through television targets the adults but how well they influence the people to make suitable choices whether to go for Orthodontic treatment or not and if yes then which and whose office to choose is always a matter of question. Strategies like entertaining your referral sources by giving them holiday grants or taking them for lunch, perhaps maybe advantageous but would cost a fortune and also demands a lot of time. Nevertheless, self-promotion can be done in a way that costs minimal, educates the people and publicize your practice without breaching the code of ethics. The most efficient method to publicize starts at the patient level through a satisfied patient.[12] Patients who are satisfied with the Orthodontic treatment will return and also refer their relatives and friends due to the positive experience they had with the particular Orthodontist. A way to achieve this is by surrounding yourself by pleasing staff and to behave in an amicable and friendly manner with the patients every time. Always having a follow-up session post-Orthodontic treatment creates a positive impact on the patients. There are numerous advantages of the follow-up appointments. Firstly, regularly reviewing the pre-Orthodontic treatment and post-Orthodontic treatment records of the patients provide substantial information regarding the treatments and their approaches. Secondly, for the endurance of the practice, this allows highlighting the long term functional and aesthetic improvements due to the Orthodontic treatment to the patients and their family. Thus, post-Orthodontic treatment consultation can be considered as an acceptable self- promotion.

Direct-to-Consumer Marketing: "Direct-to-consumer (DTC) marketing" provides information regarding the products directly to the consumers or buyers. But the marketing campaigns do not provide all the information about the products and which can be deceiving.[12] Invisalign adopted the marketing strategy of DTC marketing that disturbed the Orthodontic society. At present, Invisalign advertisements range from ads in magazines to commercials that air on television. However, there is a reasonable concern that these ads could be deceptive and misinforming. Invisalign advertisements portray each one of us as a probable patient, and that may not be true. It entails that treatment with bracket system and wires is painful and an obsolete technology and treatment with clear aligners is comfortable and esthetically pleasing. The advertisements obscure the line between the Orthodontists and a general dental practitioner. Perhaps, this sort of marketing has increased the need for the Orthodontists but with a negative impact on the Orthodontic specialty. Also, due to the direct marketing to the consumers, patients turn up at the clinic with an expectation of treatment with Invisalign without a complete examination to ascertain whether they are suited for it or not. General dental practitioners with incompetent diagnostic proficiencies and training consider that altering clear plastic trays can treat any malocclusion. This, in turn, puts pressure on the Orthodontists to recommend their patients for Invisalign treatment due to the distress of losing a patient to any other dentist. Such a scenario is neither in favor of the patients nor follows the ethics of marketing. With the growth in advertisements on social media, misleading claims of Orthodontic treatment in six months were advertised on various platforms of social media which is highly deceiving. It misinforms people about the differences in expertise and training of general dental practitioners and Orthodontists, as well as, the difference in the treatments provided by them. Over the years, Orthodontists have started marketing directly to their patients by adopting many external as well as internal marketing strategies.[12] Many were not in terms of marketing ethics such as branded tokens, small presents, discount coupons, etc. However, the best long-term direct marketing is always recommendations from a satisfied patient. The most influencing sort of

external marketing in today's generation is the website of Orthodontic practice. Such websites are increasingly developing into more attractive and communicative incorporating links of various platforms of social media for interacting with the designated fraternity or with the satisfied patients and their relatives.

Contemporary forms of direct internal marketing comprise several ways to attract patients such as including newer advanced technology, keeping typodonts to educate patients, a photographic book of pre and post-Orthodontic treated patients, a wall exhibiting the smile photographs of the best-finished cases. Irrespective of the various current methods of marketing, Orthodontists are trying to make use of this opportunity to educate and create awareness among people in particular. Direct mails, posters inside the clinic or even colloquiums conducted for patients, provide informative data like the appropriate age and time for the initial visit to an Orthodontist and the advantages of different types of Orthodontic treatment. Several Orthodontists also meticulously make effort to educate people regarding the difference between a general dental practitioner and an Orthodontist not with a selfish motive but with a motive to ensure the general public is getting the Orthodontic treatment from a specialist who is an expert in his field having proficient knowledge of his work.

Conclusion

Numerous circumstances have affected the kind and extent of marketing in the field of Orthodontics. This even consists of the surge in number of general dental practitioners providing amateur Orthodontic treatments, the violation of the ethical principles of marketing, the excessive advertising by "direct-to-consumer" ads, and alterations in referral patterns and sources: competition instead of collegiality. The present DTC marketing method by Orthodontists has been the major reason for the increase in such issues. Genuine referrals by general dental practitioners will always be a vital source to an Orthodontist; however, increased marketing directly to the patients targets at enormous freedom, but must be considered with sincere concern for professional code of ethics.

Abstract

Introduction: Planned nursing intervention and health education regarding exclusive breastfeeding (EBF) improved knowledge, practice and attitude of mothers and contributed to prevention of EBF discontinuation which can consequently reduce the worldwide infants' morbidity and mortality rates. **Aim of the Study:** The present study aimed to investigate the effect of nursing intervention on prevention of EBF discontinuation. **Study Design:** A quasi-experimental design was utilized. **Setting:** Obstetric Outpatient Clinic, Breast Feeding Room in NICU of Children's Hospital affiliated to Ain Shams University hospitals and MCH center in Abassia sector/Cairo/Egypt. **Subject:** A purposive sample of 100 mothers of infants aged from birth up to 6 months. **Tools of the Study:** Predesigned questionnaire to assess: mothers and infants characteristics, knowledge regarding factors affecting EBF discontinuation and its prevention, Iowa Infant Feeding Attitude Scale and observational checklists to assess mothers' breastfeeding practice. **Results:** It was clear that the majority of the studied mothers had good knowledge, positive attitude towards prevention of EBF discontinuation and improved practice of breastfeeding post implementation of nursing intervention. There was statistical significant difference between total knowledge of the studied mothers regarding factors affecting EBF discontinuation and its preventionand total practice of breastfeeding pre/post nursing intervention. **Conclusion:** Nursing intervention had a positive effect on prevention of EBF discontinuation. **Recommendation:** Developing initiatives,pre and postnatal health education programs for protecting, promoting and supporting breastfeeding which aid in the prevention of EBF discontinuation.

Keywords: *Exclusive breastfeeding, prevention, discontinuation, nursing intervention.*

Introduction

Exclusive breastfeedingis the cornerstone of child survival, nutrition, development and maternal health. Infants take EBF have higher intelligence scores, resulting in higher educational achievement. Breastfeed Mothers have a lower risk of breast and ovarian cancer, improved birth spacing and may also have a lower risk of diabetes and overweight/obesity. The world Health Organization recommends EBF, including initiation within the first hour of life and continues for up to 2 years.[1]

Discontinuation of EBF can negatively affect a child's physical and emotional development in both short and long-term achievement. Annually EBF could prevent 823,000 deaths in children under age 5 and 20,000 deaths in mothers from breast cancer. Only 42% mothers begin breastfeeding within an hour of birth, and 41% practice EBF.[2] In Egypt; breastfeeding practices are not always optimal. The EBF among infants under two months of age constitutes 71%. By age 4-6 months, only 13% are exclusively breastfed.[3]

Nurses have an important role in protecting, promoting, supporting and preventing EBF discontinuation through initiatives to improve positive attitudes and enhanced education. Mothers need antenatal

care to reduce perinatal and neonatal problems. Training community health care workers can provide support and knowledge to lactating mothers for prevention of EBF discontinuation.[4]

Material and Method

The aim was study the effect of nursing interventionon prevention of EBF discontinuation using the quasi-experimental design in the current study. It was conducted at Obstetric Outpatient Clinic, Breast Feeding room in NICU of Children's Hospital affiliated to Ain Shams University and MCH center in Abassia sector/ Cairo/Egypt. The study sample was a purposive sample that composed of 100 mothers of infants aged from birth up to 6 months regardless their characteristics.

The first tool of data collection was the pre-designed interviewing questionnaire which was prepared by the researcher in an Arabic language after reviewing the related literature. It was designed to gather the dataregarding characteristics of the studied mothers and mothers' knowledge regarding factors affecting EBF discontinuation and its prevention (pre/post nursing intervention).Items of mothers' knowledge regarding factors affecting EBF discontinuation and its prevention consisted of 30 closed ended questions. Knowledge scores were classified into good (>75%), average (65:75%) and poor knowledge (< 65%).

The second tool was Iowa Infant Feeding Attitude Scale (IIFAS) that was adapted from De la Mora, Russell, Dungy, Losch and Dusdieker (1999) to assess attitude of the studied mothers towards prevention of EBF discontinuation. The IIFAS contains 17 questions. The total score of attitude was 17 point. Score of less than 60% was disagree and the score between 60% to less than 75% was neutral and equal or more than 75% was agree (pre/post nursing intervention).

The third tool was observational checklist that was adapted from Verma et al., (2015)[5] to assess the studied mothers practice regarding breastfeeding (pre and post nursing intervention). Each step is checked either done correctly (1 score) or not done (zero). Then the total practice of breast feeding was scored competent (≥85%) and incompetent (<85 %).

The study tools was assessed and ascertained by a panel of five experts in Pediatric Nursing Department/ Ain Shams University/Cairo/Egypt to validate its consistency, accuracy and relevancy. The reliability of each tool was confirmed by using Cronbach's alpha test and it was 0.77 for knowledge questionnaire tool 1. The reliability of the attitude tool 2 and practice tool 3 were 0.80 and 0.85 respectively.

A pilot study was carried out, involving 10% (10) of mothers with their infants aged from birth up to 6 months and they were excluded from the study sample later. It helped in modification of the study tools, where some items were corrected, omitted and added as necessary.

The nursing intervention was developed based on the actual needs assessment of the studied mothers in the form of educational program. Nursing intervention appraisal was done by using study tools pre and post to determine the effect of implemented nursing intervention regarding prevention of EBF discontinuation.

The data collected were statistically analyzed by using computer program (SPSS) version20. Descriptive statistics like mean and percentage were used to analyze the data.

Findings: Table (1) revealed that $\bar{x}$±SD of mothers' age was 27.45±5.62. More than two fifths (42%) of the studied mothers had technical diploma, nearly two thirds (63%) were employed and more than half (52.4%) of the employed mothers worked six hours outside home.

Figure (1) showed that, nearly two thirds (62%) of the studied mothers had good knowledge about prevention of EBF discontinuation post nursing intervention compared to less than one third (29%) of them pre nursing intervention of prevention EBF discontinuation.

As noticed from **figure (2),**nearly two thirds(61%) of the studied mothers had positive attitude towards prevention of EBF discontinuation post compared to 23%pre nursing intervention of prevention EBF discontinuation.

Figure (3) illustrated that more than three fourths (78%) of the studied mothers performed steps of breast feeding practice correctly post compared to only two fifths (41%) of them pre nursing intervention of prevention EBF discontinuation.

Table (2) showed that there was statistical significant difference between total knowledge of the studied mothers regarding factors affecting EBF discontinuation and its prevention and total practice of breastfeeding pre/post implementation of nursing intervention about prevention of EBF discontinuation (P-value=<0.001*).

Table (1): Distribution of the studied mothers according to theircharacteristics (n=100).

Sociodemographic characteristics of mothers		No	%
Age (in years)	15- < 20	14	14
	20- < 25	40	40
	25- < 30	22	22
	30-35	24	24
X̄±SD 27.45±5.62			
Level of Education	Uneducated	4	4
	Primary school	16	16
	Preparatory school	10	10
	Technical diploma	42	42
	Highly educated	28	28
Employment status	Work	63	63
	Not work	37	37
Working hours outside home (n = 63)	6	33	52.4
	8	24	38.1
	More than 8	6	9.5

Figure (2): Distribution of the studied mothers according to attitude towards prevention of EBF discontinuation (pre/post nursing intervention) (n=100).

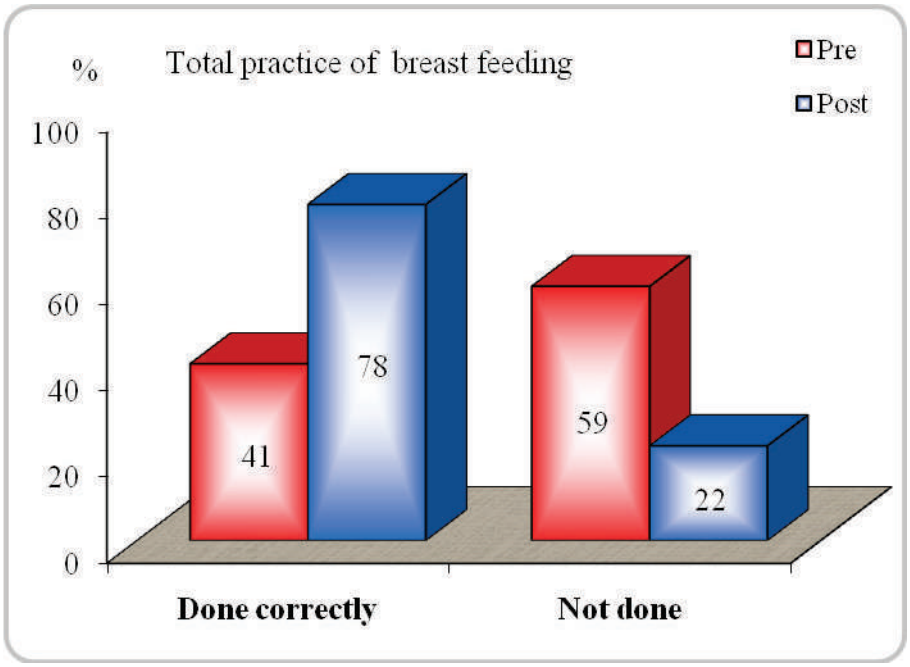

Figure (3): Distribution of the studied mothers according to total practice of breast feeding (pre/post nursing intervention) (n= 100).

Table (2): Relation between total practice of breastfeeding and total knowledge regarding factors affecting EBF discontinuation and its prevention (pre/post nursing intervention) (n=100).

Total practice of breast feeding	Total knowledge regarding factors affecting EBF discontinuation and its prevention	
	r	P-value
Pre	0.543	<0.001**
Post	0.386	<0.001**

Discussion

Every day, 4,000 infants and young children die worldwide because of not exclusively breastfeeding. Increases the rate of non-communicable diseases such as obesity, autoimmune disorders and Cardiovascular Disease (CVD) is likely associated with a decrease in the practice of the EBF. Nursing intervention and peer support is the most effective strategy for prevention of EBF discontinuation.[6]

Regarding characteristics of the studied mothers, the current study revealed that $\bar{x}$±SD of mothers' age was 27.45±5.62**.** This finding is almost in accordance with **Mélo et al. (2016)** who mentioned in a study entitled "Nurses participation in promoting exclusive breastfeeding", that regarding the age of the participants, it was varied from 18 to 42 years old ($\bar{x}$ ± SD was 26.84 ± 5.84).[7] This similarity may because the age of marriage and having children is nearly similar in different settings.

In the light of the current study findings, it was found that more than two fifths of the studied mothers had technical diploma. This result is in contrary with **Rahman et al. (2017)** who mentioned in a study entitled **"**Factors related to EBF among mothers in the city of Palu, Central Sulawesi, Indonesia", that the educational level of the most of subjects was junior high school and the most of the studied mothers were housewives. [8]

The current study revealed that nearly two thirds of the studied mothers were employed and more than half of them worked six hours outside home. This result is in contrary with **Tadesse et al. (2019)** in a study entitled "Exclusive breastfeeding and maternal employment among mothers of infants from three to five months old in the Fafan zone, Somali regional state of Ethiopia" that the most of the studied mothers were unemployed and EBF was lesscommon among employed mothers due to being engaged at work place for more time than unemployed mothers.[9]

Concerning the total knowledge about prevention of EBF discontinuation, the current study showed that two thirds of the studied mothers had good knowledge post implementation of nursing intervention about prevention of EBF discontinuation. This result is in accordance with **Abdulahi et al. (2018)** in a study entitled "Effect of breastfeeding education and support intervention versus routine care on timely initiation and exclusive breastfeeding in Southwest Ethiopia", that the majority of mothers had good knowledge in posttest. In researcher point of view, community-based health education provided prenatally and postnatal is effective in increasing mothers' knowledge which prevents EBF discontinuation. [10]

Concerning mothers' attitude towards prevention of EBF discontinuation, the current study revealed that, nearly two thirds of the studied mothers had positive attitude post compared to nearly one fourth of them pre nursing intervention of prevention EBF discontinuation. This result is similar to **Alnasser et al. (2018),** in a study of attitude impact and knowledge on intention to EBF who mentioned that the percentage of mothers with a positive attitude towards prevention of EBF discontinuation was much higher post implementation of education regarding the EBF. In researcher point of view, this change in attitude toward prevention of EBF discontinuation is due to increased awareness regarding importance of EBF for mothers, infants and society.[11]

Regarding the mothers total practice of breastfeeding, the current study illustrated that more than three fourths of the studied mothers performed breastfeeding correctly post compared to only two fifths of them pre nursing intervention of prevention EBF discontinuation. This result is in accordance with **Okyere et al. (2014)** in the study aboutthe effectiveness of health education in increasing the duration of EBFwhich stated thathealth education intervention was an effective strategy in promoting the practice of EBF and prevention of EBF discontinuation. In researcher point of view, mothers need to follow breastfeeding steps orderly through planned health education to prevent any problems may arise and subsequently prevent EBF discontinuation.[12]

The current study showed that there was statistical significant difference between total knowledge of the studied mothers regarding factors affecting EBF discontinuation and its prevention and total practice of breastfeeding pre/post nursing intervention about prevention of EBF discontinuation (P-value=<0.001*). This result is in accordance with **Wan et al. (2016)** in a study entitled "Effects of a theory- based breastfeeding promotion intervention on exclusive breastfeeding in China" which stated the statistical significant difference between total knowledge and total practice of breastfeeding. The nursing intervention program and planned health education promotes mothers' breastfeeding knowledge, practice and EBF continuation. Routine prenatal education and breastfeeding interventions after delivery at hospital and at home were needed to prevent EBF discontinuation.[13]

Conclusion

In the light of the present findings, it can be concluded that mothers had good knowledge, positive attitude towards prevention of EBF discontinuation and improved breastfeeding practiceso; nursing intervention had a positive effect on prevention of EBF discontinuation.

Conflict of Interest: Nil

Source of Funding: Nil

Ethical Clearance: The research approval was obtained from the Scientific Ethical Research Committee, Faculty of Nursing/Ain Shams University/ Egypt. An oral approval to carry out the study was taken from each mother in the study sample. Mothers were assured that all the gathered data will be treated confidentially. Mothers were also informed about their right to withdraw from the study at any time without giving any reason.

Call for Papers / Article Submission

Indian Journal of Forensic Medicine & Toxicology has commenced publication since 2007. IJFMT will be published two times in a year.

Purpose & Scope: Indian Journal of Forensic Medicine & Toxicology is a peer reviewed six monthly Journal. It deals with Forensic Medicine, Forensic Science, Toxicology, DNA fingerprinting, sexual medicine and environmental medicine. It has been assigned International standard serial No. p-0973-9122 and e-0973-9130 **website: www.ijfmt.com**. This journal is also indexed with Index Copernicus (Poland).

The journal encourages research from theoretical perspectives, research reports of evidence based practice as well as praxis research work that focuses on the interface between theory and practice and how each can support the other. In addition, the journal strongly encourages reports of research carried out within or involving countries in the Asia- Pacific region.

Invitation to submit papers:
A general invitation is extended to authors to submit journal papers for publication in IJFMT.

The following guidelines should be noted:

1. The article must be send by E-mail in word only as attachment. Hard copy need not be send.
2. The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
3. References should be in Vancouver style.
4. As a policy matter, journal encourages articles regarding new concepts and new information.

Please submit paper in following format as far as applicable

1. Title
2. Names of authors
3. Your Affiliation (designations with college address), email id
4. Corresponding author- name , designations, address,email id
5. Abstract with key words
6. Introduction or back ground
7. Material and Methods
8. Findings
9. Discussion / Conclusion
10. Conflict of Interest
11. Source of Support
12. Ethical Clearance
13. References in Vancouver style.
14. Word limit 2500-3000 words, MSWORD Format, single file
15. Please. quote references in text by superscripting
