Abstract

Methemoglobin (MetHb) is a physiological blood component that performs protective functions and neutralizes the endogenous hydrocyanic acid, hydrogen sulfide and other poisons. MetHb is slowly formed in the blood, its surplus is constantly restored while the content in blood remains low.

The spectrophotometric method has been used to measure the methemoglobin concentration in 72 traumatic subdural and epidural hematomas of various prescriptions. Based on the data obtained, the limitation of subdural and epidural hematomas has been determined by the methemoglobin concentration. The results are recommended for use in the forensic expert examinations.

Keywords: *Subdural and epidural hematomas, methemoglobin level, statute of limitations, forensic medicine, blood, hematoma, methemoglobin, intracranial.*

Introduction

Information on the methemoglobin concentration in the blood of healthy persons is very controversial. According to some researchers, MetHb is found in the blood of healthy adults in 23-25% of cases; however, its average concentration in the blood does not exceed 3 - 5%. Moreover, the concentration is higher in females than in males[1]. Many researchers believe that the MetHb content in human blood does not exceed 1%. According to others, MetHb formed in red blood cells during lifetime is reverted into hemoglobin by enzymes contained in red blood cells[2]. Moreover, the intracellular MetHb concentration is increased in corpses when the reducing enzyme substrates disappear from the red blood cells. 70% of red blood cells do not contain any methemoglobin.[3] With that, the more MetHB in cells, the less often they are found in the bloodstream.[4] Such distribution pattern indicates the active elimination of red blood cells with methemoglobin from the hematopoietic stream.

The MetHb content is increased depending on the erythrocyte aging. It is triggered by the direct changes in hemoglobin molecules. The electronic configuration of hemoglobin protein molecules is varying, therefore, the methemoglobin formation and reverse recovery are not uniform and depends on the medium pH.[5] In an acidic environment, oxidation is easier than in an alkaline one. Supposedly, it leads to the higher methemoglobin content in capillary blood than in venous blood. The MetHb increase in the blood is possible in various morbid conditions. However, under normal conditions, it is formed in the body in small quantities while quickly reverting into hemoglobin.[6]

Some researchers point out that assimilation and dissimilation in the body are not interrupted immediately and that the cadaveric red blood cells retain their gaseous metabolism for some time. As time passes after death, the MetHb content in the blood is increased both in the human cadavers and animal carcasses. An increase in ambient temperature accelerates the methemoglobin spontaneous generation in the blood of the dead, as well as the methemoglobin reduction and disintegration.

The processes of MetHb generation and reduction in the blood are directly dependent on the storage temperature requirements. Its most intense formation was recorded at a temperature of t18±24ºC.

As a result, the identification of posthumous biochemical patterns is of interest, both for determining the time of death and for assessing the recentness of brain injury in relation to the intracranial hematomas. Moreover, special emphasis was put on the temperature conditions in our Republic when studying the methemoglobin generation in the intracranial hemorrhages.[7]

In this regard, *the research objective* is to analyze the increase in MetHb concentration in the intracranial hematomas depending on the time of injury, as well as to reveal the trends in the process development based on the data obtained for determination of the injury time.[8]

The research materials and method: In order to determine the methemoglobin concentration in the blood, a spectrophotometric method was used. Spectrophotometry is based on measuring the monochromatic light flux attenuation degree as a result of selective light absorption by a dissolved substance.

The spectrophotometric method are based on the Beer-Lambert-Bouguer law of light absorption that determines the ratio between the impinging light intensity passed through the absorbed solution and monochromatic radiation. The log ratio between the light flux intensity entering the solution and the light flux intensity escaping from the solution is directly proportional to the substance concentration and the absorbing layer thickness: $D=lgIo/I=Cl\Sigma$. The lq value specifies the attenuation degree of the radiation intensity after its transmission through the solution. It is called the solution transmission density - D (A or Σ). The law indicates the linear dependence of D on the absorbing substance concentration (C), the absorbing layer thickness (I), the absorption coefficient or extinction coefficient (Σ).

The attenuation degree of the light intensity passing through the substance (solution) can describe the transmission: $T= Io/I= Io- \Sigma Cl.$ T (transmission) is the ratio of the radiation intensity transmitted through the absorbing solution to the initial radiation intensity.

Transmission can be ranged from 0 to 100%.

During the spectrophotometric analysis, the qualitative spectrophotometry is widely distributed in addition to the quantitative spectrophotometry, i.e. identification of dissolved matters by the light absorption curve shape or the so-called absorption spectrum.

In general, these curves are shown in a Cartesian coordinate system so that the optical density values (D) or extinction coefficients are plotted on the ordinate, and the length (in microns) is plotted on the abscissa. During the curve assessment, attention is brought to availability of the maximum and minimum light absorption values, its relative intensity, as well as the wavelengths that correspond to the spectrophotometric curve knees.

For this purpose, we took hematoma (subdural and epidural) and blood from the cerebral sinuses (to control the methemoglobin generation). The hematoma was ground in a glass homogenizer to a homogeneous liquid state for a hemolysate preparation. We used the cyanide method developed by M.S. Kushakovsky (19680 based on the indirect method by Evellyn and Malloy (1938).[9]

This method has a fairly high sensitivity and accuracy. It is notable for the following advantages:

1. It is simple and affordable.
2. It can also be used when, in addition to oxyhemoglobin (HbO^2) and methemoglobin (MetHb), other hemoglobin derivatives are available in the blood solution.

The repeatability of the results is very high. The single-measurement uncertainty did not exceed 0.2–0.3% methemoglobin of total hemoglobin.

The method is based on the well-known fact that the methemoglobin absorption band (acidic medium) disappears in the red region when cyanite is added. In this case, methemoglobin is turned into cyanmethogemoglobin.

If we take the total Hb (hemoglobin) concentration as 100%, then the MetHb concentration (x%) will be: $X= C\ MetHb\ x\ 100/C\ total\ Hb\%.$

In such a way, the calculation formula for the MetHb concentration is as follows: $X=(D_1-D_2)x11x100/3.6xD_3.$

The dependence of methemoglobin concentration on the time of injury was determined by the univariable linear regression analysis. According to this method, the constraint equation is as follows: $M=a_0+a_1t$, where M is the MetHb concentration, t is the time elapsed since the injury; a_0 and a_1 are the equation variables.

In order to perform quantitative methemoglobin determination in the substrates of intracranial hemorrhages, the spectrophotometric analysis for

methemoglobin concentration in the blood from the intracranial hematomas was performed in relation to 72 cadavers with the established terms of injury who were subject to a forensic medical study. The bodies were dissected according to the generally accepted method 24-36% after death. The blood from the superior sagittal cerebral sinus was used as a control.

The spectrophotometric study results, obtained as a difference in the MetHb concentration from the intracranial hemorrhages and the control blood group from the superior sagittal cerebral sinus at various times of brain injury, were subject to evaluation. The MetHb concentration between the study groups was compared in relation to 7 periods of post-traumatic hematoma development: up to 3 hours; up to 12 hours; up to 24 hours; up to 48 hours; up to 60 hours; up to 72 hours; more than 3 days.

Study Results

In the first group of the injured who suffered the brain injury and died within 3 hours after the injury (16 cases), it was found that the MetHb concentration in the studied hematomas ranged from 1.03 to 1.7, and the average value was 1.26±0.17.

The statistical processing of the results in 7 study groups revealed the statistically significant differences in concentrations at different times after the brain injury compared with the control group. Thus, in the 2nd group of injured with the period of up to 12 hours after the brain injury, the MetHb concentration was equal to 7.78±0.3% compared with the control values of 1.04±0.04% (P<0.01).

In the third group, where death after the brain injury occurred within one day, we observed the noticeable increase in the MetHb concentration up to 10.6±0.50% (P<0.01), in the fourth group, respectively, the MetHb concentration increased up to 15.21±0.7% (1.6±0.07% for the control group) (P<0.01).

The same trend is observed in other groups (V, VI, VII) where the methemoglobin concentration is gradually increased with increase in the body survivability period after the brain injury.

Table 1: Comparative values of methemoglobin concentration in the intracranial hematomas

Study groups according to the prescription of death coming	Methemoglobin concentration, %		
	Compared group	Control value	P<
1st group – death within up to 3 hours after the brain injury	1,7±0,06	0,82±0,02	0,01
2nd group – death within up to 12 hours after the brain injury	7,78±0,3	1,04±0,04	0,01
3rd group – death within up to 24 hours after the brain injury	10,6±0,50	1,5±0,06	0,01
4th group – death within up to 48 hours after the brain injury	15,21±0,7	1,6±0,07	0,01
5th group – death within up to 60 hours after the brain injury	16,7±0,63	1,8±0,12	0,01
6th group – death within up to 72 hours after the brain injury	18,2±0,74	1,8±0,14	0,01
7th group – death after 3 days	23,52±0,92	2,61±0,19	0,01

The 6th and 7th groups of post-traumatic intracranial hematoma development, indicated by a period of 3 or more days, demonstrated a slow increase in the methemoglobin concentration to an average value of 19.72%. When the injury survivability time is increased up to more than 10 days due to the organizational processes in hematomas (formed sacs and vascular neoplasms, fresh hemorrhages in the hematoma substrates), these MetHb concentrations have the quantitative variation and are not subject to adjustment.[10]

In such a way, the body survivability period after the brain injury and formation of intracranial hematomas leads to the increase in methemoglobin content in red blood cells. In part, the reasons for this is a decrease in methemoglobin reductive activity in the senescent cells. Contrarily, there are direct changes in the hemoglobin molecules. The spectrophotometric data obtained can undoubtedly serve as an additional criterion for recentness assessment of the resulting brain injury.[11]

At the next stage, we performed the recentness assessment of intracranial hematomas by the structural changes.[12]

Our observations were divided into seven periods, depending on the body survivability periods after the brain injury.[13]

The first period included 16 observations, the second period consisted of 12 observations, the third, fourth, fifth, sixth, seventh periods consisted of 8, 9, 10, 6 and 5 observations, respectively. During the first time period after the injury, the hemorrhages were represented by liquid blood with almost similar color regardless of localization and bleeding point. It should be noted that such a condition of hematomas remained unchanged during rather long-term storage of a corpse in the refrigerator.[14] The specific features of this study group were as follows: changes in the tinctorial collagen fiber properties in the form of pronounced basophilia, eosinophilia and insignificant cerebral edema, severity of vascular responses in the form of angioparesis and angiospasm. The hematoma substrates had the ratio of normal and abnormal red blood cells in favor of the former, moderate leukocytosis and lymphocytosis (Table 2).

The first post-traumatic period with the duration of up to 3 hours is represented by the pathomorphological changes typical for the inflammatory conditions: the changes in the tinctorial collagen fiber properties of the dura matter included basophilia (13.0±1.2%), eosinophilia (11.7±1.2%) and edema (6.5±0.7%) without any necrosis.

Table 2: Structural changes in the intracranial hematomas depending on the injury limitation

Morphological features of hematomas		Study groups						
		I – up to 3 hours	II – up to 12 hours	III – up to 24 hours	IV – up to 48 hours	V – up to 60 hours	VI - up to 72 hours	VII – after 3 days
Tinctorial properties of fibers (area, %)	Basophilia	13,0±1,2	12,7±1,4	8,7±1,3	0	0	0	0
	Eosinophilia	11,7±1,2	8,4±1,4	2,3±0,4	0	0	0	0
	Edema	6,5±0,7	7,6±1,5	10,2±1,3	10,4±0,6	11,1±1,2	1,5±0,4	1,6±0,3

Fascia, %		0	0	0	0	54,2±6,8	64,4±7,4	94,1±13,6

The vascular response was represented by spasms (46.5±3.4%). The hematoma substrates had the ratio of normal red blood cells (95.6±6.4%) with a small admixture of abnormal red blood cells (4.3±1.2%). The leukocytosis was noted mainly at the border with the dura mater due to the normal white blood cells (28.1±2.8%). This case is represented by the single lymphocytes (1.4±0.3%). According to the above specifications, there are statistically significant differences from the subsequent study group (Table 3).

Table 3: Changes in blood properties (in the intracranial hematoma substrates) during the first period after an injury (up to 3 hours)

Indicators of blood and hematoma properties	Degree of incidence in %
Basophilia	13,0±1,2
Eosinophilia	11,7±1,2
Edema	6,5±0,7
Spasm	46,5±3,4
Normal red blood cells	95,6±6,4
Abnormal red blood cells	4,3±1,2
Normal white blood cells	28,1±2,8
Abnormal white blood cells	0

The second injury survivability period (up to 12 hours) was described by an insignificant increase in cerebral edema (7.6±1.5%) and decrease in eosinophilia up to (8.4±1.4%) collagen fibers, decrease in the number of vessels with spasm (27.8±9.2%). The hematoma substrates adjacent to the dura mater showed an insignificant change in the ratio of normal (92.5±5.2%) and lysed red blood cells (7.4±1.5%), an increase in leukocytosis up to 30.4±1.2% cells with the leukocyte debris (6.40±1.2%).

The macrolesions (1.4±0.2%) and fibrin in the form of individual strands were detected for the first time in 83.0±6.2% of cases. The number of leukocytes is hardly varying. In the hematoma substrates on the periphery of the dura mater, the inflammatory response is increasing much more slowly (Table 4).

The survivability period after the injury (up to 24 hours) was described by the occurrence of necrosis in the collagen fibers (55.6±6.9%) in the setting of increasing cerebral edema (10.2±1.2%), decrease in basophilia (8,7±1.3%) and eosinophilia (2.3±0.4). The vascular response is represented by plasmorrhagia of the vascular walls (78.7±4.2%) and the first appeared fibrinoid necrosis. The normal red blood cells remain almost at the same level (87.0±3.8%), the number of both normal (55.8±2.6%) and destructed white blood cells (16.8±1.8%) is increased. The number of macrophages has been increased up to 15.8±1.6% of the cells, the lymphocytosis was accumulated up to 4.3±0.6% of the cells. Free hemosiderin was found with the value of up to 1.3±0.4% for the first time. Fibrin is available predominantly in the form of a mesh (76.4±4.1%).

Table 4: Changes in blood properties (in the intracranial hematoma substrates) during the death period after an injury (up to 12 hours)

Indicators	Degree of incidence in %
Basophilia	12,7±1,4
Eosinophilia	8,4±1,4
Edema	7,6±1,5
Spasm	27,8±9,2
Plasmorrhagia	30,4±3,2
Normal red blood cells	92,5±5,2
Normal white blood cells	30,4±1,2
Leukocyte debris	6,4±1,2
Macrophages	1,4±0,2
Lymphocytes	1,6±0,2
Fibrin strands	83,0±6,2
Abnormal red blood cells	7,4±1,5

The hematoma substrates located on the cerebral periphery demonstrate an insignificant increase in the number of leukocytes, as well as the first occurrence free hemosiderin (Table 5).

Table 5: Content of distinctive features in the intracranial hematoma substrates during the survivability period after injury (up to 24 hours)

Features	Degree of incidence in %
1	2
Basophilia	8,7±1,3
Eosinophilia	2,3±0,4
Edema	10,2±1,3
Necrosis	55,6±6,9
Spasm	6,5±1,6
Plasmorrhagia	78,7±4,2
Fibrinoid necrosis	20,5±1,6

Features	Degree of incidence in %
Normal red blood cells	87,0±3,8
Abnormal red blood cells	10,7±1,3
Normal white blood cells	24,0±2,6
Leukocyte debris	16,8±1,8
Macrophages	15,8±1,6
Hemosiderin	1,3±0,4
Lymphocytes	4,3±0,6
Fibrin mesh	76,4±4,1

The following survivability periods (24-72 hours) were described by a sharp increase in the collagen fiber necrosis (13.6±1.1%) on the setting of pronounced cerebral edema (11.1±1.2%). The basophilia and eosinophilia are not found. The vascular walls are subject to the fibrinoid necrosis (54.6±2.6%). The hematoma substrates adjacent to the dura mater showed a decrease in the number of normal red blood cells up to 32.6±2.6%, decrease in the number of white blood cells up to 16.7±1.8%, including 25.4±1.8% of destructed cells.

The level of macrophages (25.2±1.4%) and lymphocytes (16.4±2.1%) is increasing. Free hemosiderin reaches a maximum level of up to 7.5±0.8% of the lump. The fibrin clots are shown in 76.6±4.4% of cases. The fibroplasts are found for the first time (38.4±3.0%).

The injury survivability period of more than 3 days is described by the cerebral productive processes. The fascia formation was noted in 64.4±7.4% of cases. The number of fibroblasts, macrophages and lymphocytes reached the levels of 45.0±4.3%, 23.2±1.8%, and 14.4±6.8%, respectively.

The hematoma substrates demonstrate a sharp decrease in the normal red blood cells (up to 15.6±1.2%). The number of leukocytes is decreased up to 8.6±0.6%. Fibrins have the form of granular mass (85.5±6.4%). In the hematoma substrates on the cerebral periphery, the inflammatory response dynamics is slowed down. The macrophages (Table 6) in large numbers are found for the first time.

As a result, our studies using the spectrophotometric and pathomorphological data indicate specific changes in the methemoglobin concentration and structural parameters in the intracranial hematoma substrates, depending on the body survivability period after the severe brain injury.

Table 6: Morphological indicators in the intracranial hematoma substrates during the period after the injury (after 3 days)

Indicators	Degree of incidence in %
Edema	1,6±0,3
Normal red blood cells	25,6±1,2
Abnormal red blood cells	62,7±4,2
Normal white blood cells	15,6±0,6
Leukocyte debris	12,1±1,8
Macrophages	23,2±1,8
Hemosiderin	4,6±0,4
Lymphocytes	14,4±6,8
Fibroblasts	14,5±4,3
Fibrin grain bodies	85,5±6,4

While using the obtained data, we conducted the forensic medical studies based on the spectrophotometric and pathomorphological studies presented above.

When studying the brain injury cases with intracranial hemorrhage in the mortuaries of the Tashkent urban and Karakalpakstan branches of the Republican Scientific Center for Forensic Medical Examination, it was found that in 45.5% of studies, the injury terms were not determined. In this regard, we have attempted to determine the brain injury limitation period using the spectrophotometric and pathomorphological data obtained in relation to the people with the known injury terms.

Based on the data obtained as a result of structural and spectrophotometric studies of autopsy material of intracranial hemorrhages and the adjacent dura mater and the known brain injury terms, we have revealed the statistically significant differences between a number of time intervals that demonstrate specific manifestations of the inflammatory process.

Conclusions

1. The intracranial hematomas reach their maximum volume during the first few minutes after the injury, and one of the main factors determining the clinical implications is its generation rate.
2. The identification of post-mortem biochemical patterns is of concern, both for determining the death term and for assessing the brain injury limitation in the study of intracranial hematomas.

3. During the spectrophotometric study of the intracranial hematoma substrates, it is necessary to use the structural studies of intracranial hematomas and the adjacent dura mater according to our recommendations provided in this chapter in order to correctly interpret the results obtained and to avoid possible errors in determining the injury terms.

Abstract

Recently,the activity of preschool institutions experiencing dramatic changes, which lead to the emergence of new requirements for medical care for children. The most important element of health care system is nursery. Current model of nursing is a science and practice aimed to improve the health status of each child. The main purpose of this review is to present different approaches of development of an integrated health care system in kindergartens used in ex-Soviet countries. Systematization of accumulated experience and knowledge will help to develop the system theoretical and practical provisions, when the activities of medical staff of preschool institutions are determined.

Keywords: *Nursing; preschool institutions; nurse's role; child.*

Introduction

Nowadays there is a sharp deterioration in the health status of children, which is one of the most significant problems facing society. Among various age groups, the most vulnerable are children attending preschool educational institutions. For this reason, improvement of health of children in preschool educational institutions is the primary task for pedagogical and medical staff. Kindergartens have been the site for health programming in many countries for long years. Since public education became compulsory in the mid-nineteenth century, the strategic role that pre-school institutions could play in promoting and protecting health became recognized. Nurseries and infant schools soon became the front line in the fight against infectious disease and the hub for providing a wide range of health and social services for children. As times changed, health programs in these institutions have changed to keep pace with the changing needs of children. Definition of pre-school institutions and their purposes**.** Nurseries/kindergartens are pre-school institutions designed to accommodate children under 6 years[1]. In most countries nursery is a socio-educational institution aimed for children aged between 3 months and 3 years. Nurseries provide children with appropriate conditions for harmonious development, while collaborating with their parents throughout the whole education process[2]. The kindergarten is a pre-school institution for children aged from 3 to 5 years. It aims at promoting children's development and providing educational activities[3]. Pre-school education is the first stage of basic education that focuses on the balanced development of children's potential, giving them the opportunity to develop their autonomy and socialization skills, preparing them for a successful education path, and supporting the families in children's education[4].

In recent years,the activity of preschool institutions experienced dramatic changes. These changes include introduction of specialists in different disciplines, such as sports, arts and dance. More attention from teachers and medical staff began to attend to organization of motor activity of children using modern medical equipment complexes. Also much more time is now attended to development of skills of independence, personal qualities and higher mental functions[5].

Discussion

The essence of nursing in preschool: Usually, medical care for children in preschool institutions on the territory of countries of former Soviet Union is the competence of medical staff serving this institution. It is also controlled by the authorities of sanitary supervision and public education[6]. Means and method of solving the problems of medical support for children in preschool educational institutions are diverse, dynamic in time and changeable. They are developed by various departments and specialists. Approaches to the same problem are often interpreted from opposite positions[7].

Diagnosis of pre-nosological conditions in children, which can no longer be rated as healthy and, at the same time, are not a disease plays the leading role in health care process of preschool institutions. Active preventive intervention at this stage of possible disease gives the greatest effect and the least material costs.

The greatest amount of preventive work falls on the shoulders of pedagogical staff of preschool educational institution, and doctor with nurse act as methodologists who plan, train and supervise the implementation of this work. Unfortunately, this is not always adequately perceived by educators and their assistants, who often refuse to perform some healthcare measures[8].

Nursing in a kindergarten as part of the healthcare system is a science aimed at solving existing and potential health problems in changing environment. The purpose of nursing is to carry out a nursing process. The nurse strives to carry out her work professionally, respecting and protecting children's rights and dignity, and helping to improve their relations with society. Recent model of nursing is a science and practice aimed to improve the health status of each child. Nurse is a person who shares the philosophy of nursing and carries out nursing practice professionally and creatively. Nursing is a job performed by a nurse in accordance with her functional responsibilities[9]. These functional responsibilitiescharacterized as maintaining and strengthening of health condition, patient's care and rehabilitation assistance[10].

Clinical training in nursing is also an essential period in medical students study. It allows students of medical colleges to learn as members of a team, in direct contact with healthy and ill children, and as part of a group in the planning, implementation, and evaluation of comprehensive nursing care based on the acquired knowledge and skills. Students are expected to develop necessary skills in order to deliver comprehensive health care to children. Students clinical training in this area often takes place in nurseries/kindergartens[11].

The health condition of children in preschool institutions. The Center for Disease Control and Prevention (CDC) noted that six categories of behavior are responsible for about 70% of children mortality and morbidity. These include unintentional and intentional injuries, diseases resulting from inadequate physical activity, and health problems due to inadequate dietary patterns. A significant part of our youth is at risk for dropping out of school as a consequence of a number of health and behavioral problems; further, many children do not have access to basic preventive and primary care[10].

According to statistics, almost every child attending kindergarten has suffered from flu or other acute infectious disease. Almost every fifth child is under observation with certain chronic disease[13]. Eye diseases lead among other illnesses with 32 cases per 1000 children. Approximately the same frequency (18-22 cases per 1000 children) observed in diseases of nervous, respiratory, digestive and musculoskeletal systems. It turns out that 20% health condition depends on the genotype, 20% on the impact of environment, 50% on the lifestyle, and only 10% on condition of medical care[12].

According to definition of World Health Organization, human health is the complete physical, mental and social well-being with absence of disease. Such well-being ensured by complex of external and internal factors[14]. Internal factors characterized by the features of morphological and psychological development of the child. One of the main criteria for health is the ability of human organism to adapt to conditions of environment and the ability to carry out activities in various settings.

According toinformation of Research Institute of Hygiene of children and adolescents of Russian Federation[15], there is four basic criteria of children's health:

1. Level of physical development and its harmony;
2. Level of physiological systems of organism;
3. The absence of disease during examination;

4. The degree of resistance to effects of pathological factors.

Development of the child's body is a process of qualitative and quantitative changes leading to a new, higher level of organization of all physiological systems of the body. This process includes three main interrelated factors: differentiation of organs and tissues, growth and formation.

The child's organism differs from the adult organism with a number of factors:

- Incomplete morphological and functional development of all physiological systems;
- Continuity of growth processes, development and differentiation of organs and tissues;
- High degree of reactivity to on external influences;
- Less resistance to environmental factors;
- Uneven growth and development at different age periods;
- Heterochronism (different periods) of maturation of various functional systems[16].

With age, the pattern of the most common diseases in children varies: in age under three yearsmost often children suffer from bronchitis, diathesis, rickets, anemia, malnutrition and dental pathology. Further children more affected by adenoids, tonsillitis and otitis. From 3 to 7 years most common diseases of childhoodare diseases of digestive system that closely associated with dental caries, diseases of pulmonary system, nervous system, sensory organs and allergic diseases[16].

The number of children with varying degrees of visual impairment and disease of musculoskeletal system is increasing dramatically. In children in age of 2-4 year functional disorders with the decrease in the body's resistance to diseases, are associated mainly with imperfection of the functions of thermoregulation and immune system are quite often.

Preschool children with abnormal physical development or neuropsychological condition, are usually more vulnerable to different diseases than others. These diseases further reduce their depressed immunity and increase their susceptibility to repeated disorders. Such condition have negative impactto study process of children and their ability to assimilate knowledge due to missed classes and poor performance[17]. Studies of children 's health at different levels of health in a preschool educational institution showed that in pupils of second health group health indicators from the beginning to the end of the year, as well as during the week, decreased more significantly then in children with relatively mild forms of health disorders and healthy children (for 30–35% and 12–15% in relation to the initial level)[18].

Access to Health Care in pre-school institutions: According to National Health/Education Consortium, millions of children in developed countries have inadequate insurance plans that fail to cover even such simple preventive services as immunization. About 12 million children do not get such basic preventive care as periodic physical examinations or immunizations at the proper intervals, and only half of all infant school children routinely receive health care. Moreover, 7.5 children require mental health services, fewer than one in eight actually receives them (GAO, 1994b)[20].

Access to children health care include concerns beyond mere financial issues. Transportation, convenience, and cultural sensitivity are also factors. Additionally, parental support and encouragement, as well as understanding the importance of health care and how to approach the result, influence the process. Even with access to health care, children may not be receiving the appropriate attention they need. Even children in those families with insurance and family doctors do not receive help from health care professionals for problems of greatest importance for their high-risk behaviors. Many studies have shown that an initial visit to doctor and physical examination for a new patient in pre-school institution should require not less than 30-45 minutes. Although 25% of doctor visits are first encounters, half of all visits last 10 minutes or less, 30% percent last 10-15 minutes, and only 4% are 30 minutes or longer[19].

The comprehensive pre-school health program that developed in ex-Soviet countries is seen as a new solution needed to deal with the problems of today's children in kindergartens[15]. It became clear to social committees that, although a variety of different models exist, comprehensive programs are still essentially an unrealized ideal in most institutions[21]. Many specialists came into the study with a range of backgrounds, and they determined that it needed to establish their own working definition of the term "comprehensive health program" which would guide further work with children[22].

The mainpreventive activities: The main priority of the activities carried out in the preschool educational institution is measures to prevent diseases. Currently, a number of infectious diseases are prevented by specificimmunization[22]. The incidence of viral infections of respiratory tract constitutesa high percentage of all diseasesamong preschool age children[23]. The vaccine against flu widely advertised during pre-epidemiological period does not always give expected results, its effectiveness decreases due to variety and variability of viruses[24]. Therefore, method aimed to increase protective mechanisms of the organism itself and to improve resistance to pathogenic, environmental factors play the leading rolein the system of health-improving of preschool institution[25].

The level of child's adaptation to changing environmental conditions have great importance in assessment of health. Leading pediatricians have repeatedly pointed out that non-specific prophylaxis of diseases is based on a set of general strengthening measures that include tempering and provision of full-fledged physical education that adequate to physiological capabilities of the child's body[21].

The protective reactions of the body enhanced by the systematic and regular use of small doses of the stimulus - low or high temperatures of water or air, and influence of natural factors. As a result, this leads to training of thermoregulation mechanisms and otherphysiological systems involved in strengthening of immunity.

One of the hallmarks of the Soviet recovery system is hardening. Hardening is an active process, representing a set of method for stimulating the hidden reserves of the body's defenses, improving it's flexibility and versatility. It is the development of a conditioned reflex to a particular irritation. Therefore, this is a training process, the construction of which in order to achieve the maximum final effect must be subject to certain physiological laws that underlie the mechanism for generating a conditioned reflex. The biological basis of any training process, including hardening, is adaptation to the acting loads, mainly cumulative adaptation. It is characterized by adaptive changes that occur under the influence of regularly repeated external influences. The properties acquired as a result of cumulative adaptation are stable and persist for some time after the cessation of external influences. Adaptive changes that occur in the child's body during the hardening process go through two stages: transitional and stationary. In the first stage, the adaptation process itself (hardening) takes place, in the second stage the adaptation state (hardening) is achieved, and if the body is not exposed to new influences or the load is insufficient, the process of readaptation will begin, a gradual return of all body systems to the initial level of functioning[1]. The hardening effect is achieved by a systematic, repeated exposure to a particular hardening factor and a gradual increase in its dosage[3]. Hardening is specific, as it is determined by a gradual decrease in the body's sensitivity only to the action of the hardening factor[5].

The body of preschool children characterized by insufficient functional condition of physiological systems, the purpose of which is to maintain thermal comfort. Therefore, the children's body responds with adverse reactions even to minor deviations in the weather. It is at an early and preschool age that hardening takes on special significance.

Hardening in a preschool institution is most advisable in the first half of the day before a sleep or immediately after a walk, depending on the season, local and climatic conditions. Also, good hardening agent is the sleep process, if it takes place in a well-ventilated room, under favorable hygienic conditions[8].

Anthropometric examination and determination of the degree of physical development according to its evaluation tables (standards) are the responsibility of nurse and their interpretation is the responsibility of the institution's doctor. Today there is a paradoxical situation when the standards of the 80-90s became unusable due to the changed biogenic situation. The acceleration of the young generation was replaced by stabilization and even a return to lower indicators of physical development of modern children[27]. On the other hand, the development of new regional age-gender standards requires the allocation of absolutely healthy children. Against the backdrop of Russia's economic difficulties, it is very difficult to implement this. Under these conditions, interest in genetic growth standards reappeared, the idea of which belongs to E.A. Shaposhnikov[26].

Studies conducted by this author, allowed him to establish a number of previously unknown statistical laws of the physical development of children. They are based on the law of repeatability of equal average values of mass and average parameters of proportions with equal average body length. Children of different nationalities, various social groups living in different

territories of country have average body weight and average parameters of the length of body, legs, arms, diameter of the shoulders, pelvis, chest and other somatometric signs, reduced to the same body lengths are approximately the same and remain virtually unchanged during generations.

The lag of growth processes, if it is not associated with the somatic pathology, means inhibition of the development and differentiation of internal organs. The greater lag in physical development of child means the more pronounced changes in the immune system. The change of an anthropometric indicator in the early stages allows doctor to suspect the development of pathology. It could be the emerging growth retardation; the development of dystrophies of various origins, obesity, narrow breasts, often accompanied by various anomalies in the development of the lung, broad chest, as manifestations of an increase in lung volume, micro- and macrocephaly, partially due to hydrocephalus. The physical development of the child depends on specific environmental factors and lifestyle. To assess physical development of group, it is necessary to conduct its individual assessment and give a final assessment of specific gravity of children with good physical development. The physical development of team is considered satisfactory if at least 68% of children have normal harmonious physical development.

In the early 90s of the last century, in the Soviet Union, with a total number of about 90-100 million children, 47–48 million cases of childhood infectious diseases and 36–39 million cases of flu were noted annually. But the incidence rate of diphtheria, whooping cough, measles, and other infection diseases is not determined by the state of science, but depends solely on the setting of preventive and health-improving measures in children's institutions. Preventive work in the preschool educational institution is defined by two main areas, the content of which is clearly delineated.

1. Scheduled preventive maintenance involves a set of measures to increase the specific and nonspecific resistance of the child's organism to adverse external influences and covers all healthy children in preschool education[11], that is, 1st and 2nd A health groups.
2. Wellness activities include the improvement of children's health from risk groups, primarily children with reduced immunoresistance (children of group 2nd B) and conducting a certain amount of medical and recreational activities based on the possibilities of preschool education[14]. Therefore, this service is best implemented in specialized health-improving preschool institutions for children with reduced resistance[15].

Conclusion

Thus, distinctive feature of the system of organization of medical care in preschool institutions of ex-Soviet countries is comprehensive pre-school health program, which is still the basis of successful development of children. Similar to United States and European countries, nursing plays a significant role in the implementation of preventive measures in preschool institutions. Along with this, the system of child health protection has a number of distinctive features expressed in the application of hardening method for prevention and a special approach to assessing the physical development of children.

Development and Validation of UV-Spectrophotometric Method for Quantitative Assessment of Metronidazole in the "Metromed® Neo" Solution for Infusion

Khilola Ganieva[1], Akhmad Yunuskhodjaev[2]

[1]PhD, Docent, Department of Pharmaceutical Chemistry, Tashkent Pharmaceutical Institute, Aybek Street 45, Tashkent City, Uzbekistan, 100015, [2]Professor, DSs in Pharmaceutical Science, Scientific Consultant at "Med-Standard Scientific Centre" Pvt. Ltd., Qorasaroy Street 343, Almazar District, Tashkent City, Uzbekistan. 100034

Abstract

Introduction: Metronidazole is widely used in medicine and issues of quality control of its dosage forms are relevant. Objective - development and validation of a UV spectrophotometric method for monitoring the quality of metronidazole in the «Metromed® Neo» solution for infusion.

Materials and Method: The object of the study was a solution for infusion containing metronidazole. The method used is UV spectrophotometry.

Results: The relative error of the developed UV spectrophotometric method for the quantitative assessment of metronidazole in the solution for infusion was 1.9%. Validation characteristics of the method are within acceptable limits.

Conclusion: A UV spectrophotometric technique was developed and validated to assess the quality of the solution for infusion containing metronidazole. The results of the studies make it possible to use the developed and validated methodology in assessing the quality of metronidazole.

Keywords: *Metronidazole, UV spectrophotometry, solution for infusion, quality assurance, validation.*

Introduction

Antibacterial therapy is one of the most important components of intensive therapy of purulent-septic diseases, and its effectiveness has a significant impact on the course and outcome of the disease. Of particular interest is metronidazole. The mechanism of action of metronidazole is the biochemical reduction of the 5-nitro group of metronidazole by intracellular transport proteins of anaerobic microorganisms and protozoa [1].

In the US Pharmacopoeia, for the assessment of the authenticity and quantitative content of metronidazole in both substance and injectable dosage form[2], a method of high-performance liquid chromatography was proposed[3]. Existing method for assessing the quality of metronidazole do not always meet modern requirements. They have several disadvantages: the complexity, the duration of the implementation, the use of toxic organic solvents, expensive reagents and devices. This suggests that the problem of improving existing and developing new method for the analysis of metronidazole is relevant[4].

Spectrophotometry as a physicochemical method is characterized by high sensitivity and expressiveness. The development of simple, affordable, and highly accurate method for controlling the quality of drugs is essential for pharmaceutical manufacturers[5]. However, it should be noted that in order to confirm and ensure the quality of pharmaceutical products, the control method used must be validated. Currently, on the validation of analytical works, there are a number of regulatory documents, as well as scientific works, which describe in detail the conditions for the validation of analytical method [7].

Aim of the study was to develop and validate a UV spectrophotometric method for monitoring the quality of metronidazole in the Metromed® Neo infusion solution.

Materials and Method

Experimental Part

The infusion solution containing metronidazole has the following composition:

Composition:

Metronidazole 500 mg

(Brit. F., Heb. F,)

Sodium Chloride 800 mg

(Brit. F., Heb. F., FS 42 Uz-0129-2011)

Water for injection up to 100 ml

(FS 42 Uz-0512-2012)

Research on the development of metronidazole quality control method began with a study of the physicochemical properties of the substance.

Metronidazole or 2- (2-methyl-5-nitroimidazol-1-yl) ethanol is a white to white powder with a greenish-yellow tint, slightly soluble in water, acetone and alcohol 96%.

Results

Preparation of a working standard sample of metronidazole: 40 mg of metronidazole is placed in a 100 ml volumetric flask, a 0.1 M solution of hydrochloric acid is added, and the volume of the solution is adjusted with the same solvent. 5 ml of the resulting solution is transferred into a volumetric flask with a capacity of 100 ml, the volume of the solution is adjusted with the same solvent. The UV spectrum of the resulting solution was determined in the wavelength range from 230 nm to 350 nm in a cell with a layer thickness of 1 cm (Fig. 1).

The above spectrum indicates that metronidazole has a maximum absorption at a wavelength of 277 nm.

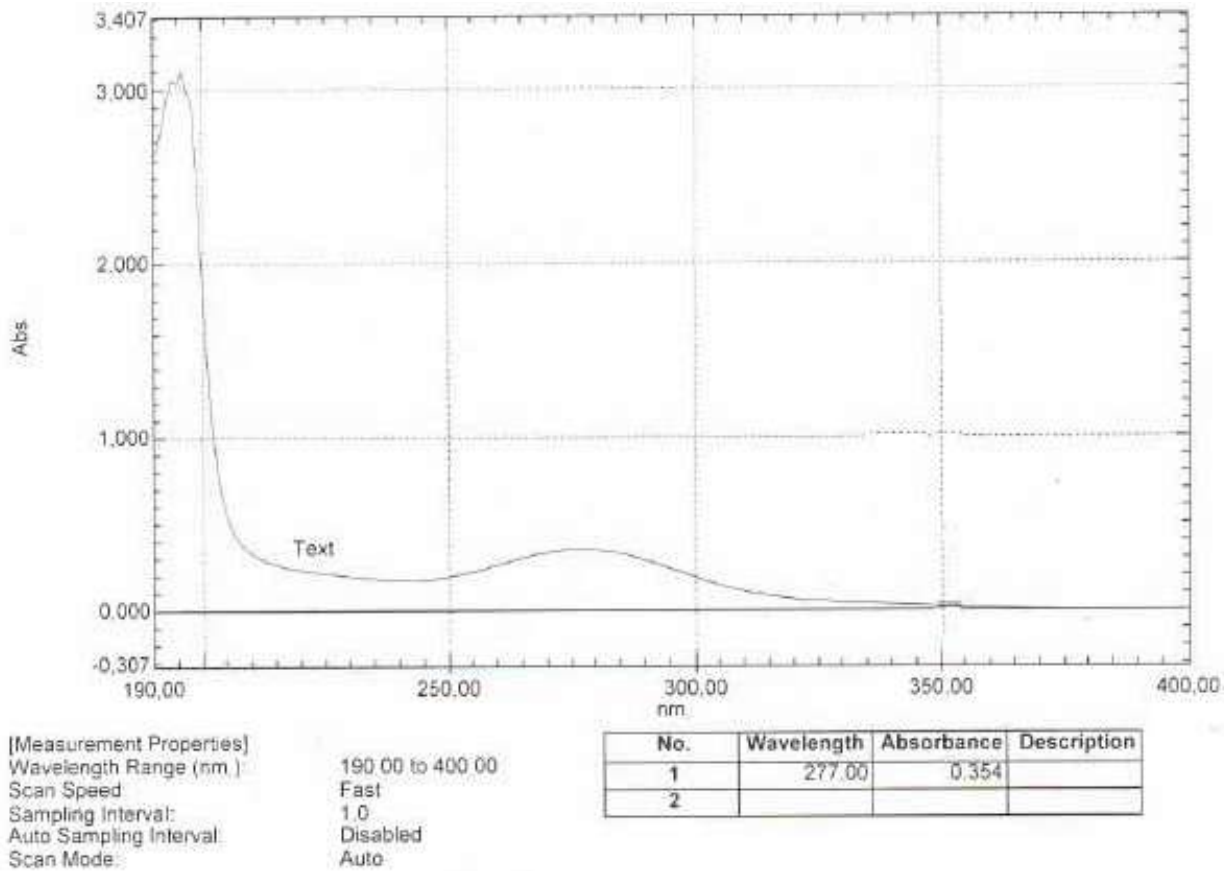

Fig. 1. UV spectrum of OCR metronidazole

To quantify metronidazole in the infusion solution, a test solution of metronidazole was previously prepared.

10 ml of the test solution of metronidazole was transferred into a volumetric flask with a capacity of 100 ml, the volume of the solution was brought to the mark with a 0.1 M hydrochloric acid solution, and stirred. 5 ml of the resulting solution was transferred into a volumetric flask with a capacity of 250 ml and the volume of the solution was adjusted to the mark with a 0.1 M hydrochloric acid solution and stirred. The optical density of the resulting solution was measured at a wavelength of 277 nm, using a 0.1 M hydrochloric acid solution as a reference solution.

The content of metronidazole in grams was calculated by the formula:

$$X = \frac{D \cdot 1 \cdot 100 \cdot 250}{375 \cdot 100 \cdot 0 \cdot 5} = \frac{D \cdot 5}{375},$$

where D is the optical density of the test solution.

375 - specific absorption rate of 1% solution of metronidazole.

The content of metronidazode (C6H9N3O3) in 1 ml of the drug should be from 0.0045 g to 0.0055 g.

Table 1: Metrological characteristics of the results of the quantitative assessment of metronidazole in the drug «Metromed® Neo», solution for infusion 500mg/100ml

The content of active substance, mg/100 ml	The limit of active substances in mg/ml	The average value of the quantity found, Xav	Sample Deviation, S	Relative Standard Deviation, RSD	Relative error, ε cf
Metronidazole					
500 mg	from 4.5 mg to 5.5 mg in 1 ml of the drug	4,720	0,1257	1,0%	1,9688
		4,759			
		4,773			

The results presented in table 1, indicate the reliability of the data.

Discussion

The next stage of the research was the validation of the developed UV spectrophotometry technique. Validation parameters were - correctness; precision (convergence, reproducibility), linearity, specificity.

1. The correctness of the analytical method characterizes the proximity of the test results obtained by this method to the true value.

Correctness was evaluated on the basis of at least 9 determination results at a minimum of 3 concentration levels in the limit of the analytical region (for example, 3 replicates of the determination for 3 analytical concentrations). Prepared solutions containing metronidazole in the amount of 80%, 100%, 120% of the declared value. The optical density of metronidazole in all mixtures was determined in three parallel determinations, and the quantitative determination of the active substance in each solution was calculated.

Acceptance criterion: the percentage of recovery when using concentrations of 80, 100 and 120%, adjusted to 100%, should be in the range from 98.0% to 102.0%.

Recovery percentage (R):

$$R = \frac{A}{B} * 100\%$$

where R (Recovery) - output, A – measured content, B-specified (actual) level.

The results of the analysis are presented in the table:

Table 2: Correctness of the UV spectrophotometric method for the quantitative determination of metronidazole in the drug «Metromed® Neo», 500mg/100ml solution for infusion

The claimed amount of metronidazole in test solutions, mg/ml	Found amount of metronidazole in test solutions, mg	Regeneration, %	Metrological characteristic
3,3	3,31	100,3	X_{av} = 99,0; S = 0,96; S^2 = 0,92; Δx = 2,22; Δx av = 0,74; E_{av} = 0,74
3,3	3,29	99,9	
3,3	3,28	99,3	
5,0	4,95	99,0	
5,0	4,88	97,6	
5,0	4,99	99,8	
6,0	5,97	99,5	
6,0	5,88	98,0	
6,0	5,88	98,0	
The average percentage of regeneration		99,0%	

From the results of the table it is seen that the average percentage of metronidazole regeneration is 99.0%, which indicates satisfactory correctness of the method.

2. The precision of the analytical method characterizes the degree of closeness of the independent results of individual tests obtained in specific specified conditions. This characteristic depends only on random factors and is not related to the true value of the measured quantity. It is expressed by the standard deviation - the coefficient of variation. Extreme precision indicators - convergence and reproducibility.

2.1. Convergence characterizes the degree of consistency of the results of measurements (tests) obtained by the same method at identical test objects, in the same laboratory, by the same operator, using the same equipment, within a short period of time.

Acceptance criterion: the coefficient of variation of parallel determinations for 6 measurements should be no more than 2%.

Table 3: The convergence of the UV spectrophotometric method for the quantitative determination of metronidazole in the drug "Metromed® Neo", solution for infusion 500mg/100ml

Solution No.	Found amount of metronidazole in test solutions, mg/ml	Arithmetic mean of all definitions, $\bar{X}$	Standard deviation, S	Coefficient of variation, CV
1	4,77	4,96	0,093	1,8
2	4,99			
3	5,00			
4	5,00			
5	5,01			
6	4,98			

The results presented in table 3 indicate a high convergence of the obtained data.

2.2. Reproducibility characterizes the measure of coincidence of the measurement results obtained by the same method on identical samples, in different laboratories, by different operators, using different equipment, a relatively long period of time between measurements, separate, presumably identical samples taken from the same batch of material.

Acceptance criterion: the coefficient of variation in each of the levels of accuracy is determined. The criterion of instrumental reproducibility is 1%, intralaboratory reproducibility is 2% for the quantitative determination of the main component.

The method for the quantitative determination of metronidazole in the analyzed medicinal product was tested in two laboratories:

1. Laboratory of expertise and standardization of medicines JV LLC Remedy Group.
2. Scientific laboratory LLC Medstandart.

The results of the analysis are presented in the table:

Table 4: Reproducibility of the UV spectrophotometric method for the quantitative determination of metronidazole in the drug «Metromed® Neo», 500mg/100ml solution for infusion

Lab Name	Solution No.	Found amount of metronidazole in test solutions, mg	Arithmetic mean of all definitions, $\bar{X}$	Standard deviation, S	Coefficient of variation, CV
Laboratory of Expertise and Standardization of Medicines JV Remedy Group LLC.	1	4,77	4,96	0,0928	1,82
	2	5,00			
	3	4,99

The calculated values of the coefficient of variation are within acceptable limits and indicate the reproducibility of the developed technique.

3. Linearity is established on the basis of test results that are proportional to the concentration of the analyte in the sample within the analytical method. The linearity of the results can be represented graphically in the form of a dependence of analytical signals on the concentration of a substance (at least 5). The following parameters are used to confirm the linearity of the analytical technique: the regression coefficient and the slope of the regression line.

The determination is usually carried out on solutions with concentrations of 80, 90, 100, 110 and 120%.

Acceptance criterion: the technique is considered linear if the correlation coefficient between a series of obtained values is not lower than 0.995.

The results of the study of linearity must be indicated in the graphic image.

Table 5: Linearity of the UV spectrophotometric method for the quantitative determination of metronidazole in the drug «Metromed® Neo», 500mg/100ml solution for infusion

№	The concentration of the solution,%	The concentration of the solution, mg/ml	Optical density value	Correlation coefficient, R
1	80	0,008	0,283	0,9993
2	90	0,009	0,315	
3	100	0,010	0,354	
4	110	0,011	0,389	
5	120	0,012	0,420	

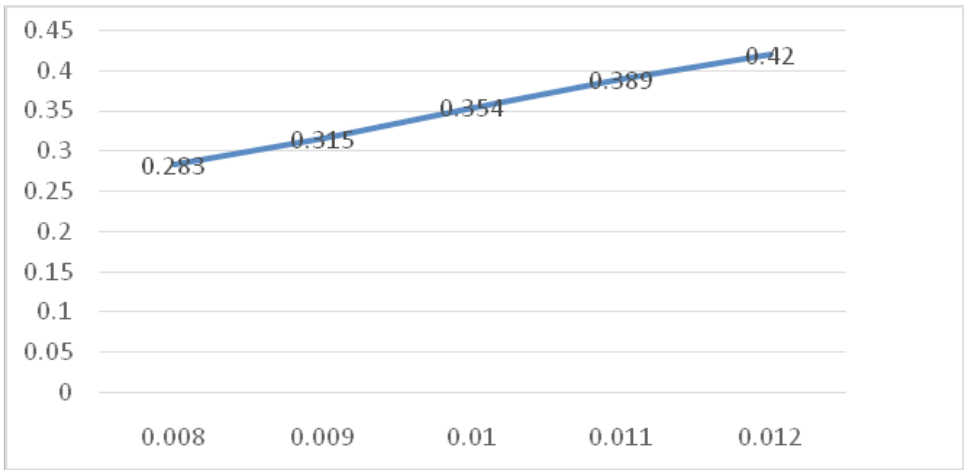

Fig. 2. The linear dependence of the optical density of metronidazole on its concentration in the test solution

From the data presented in table 5 and the graphic image, we can conclude that there is a linear dependence in a given concentration range. The value of corelation is within the acceptable range.

3. The specificity of the analytical method is determined by its ability to reliably determine the drug substance in the presence of impurity compounds, degradation products and excipients.

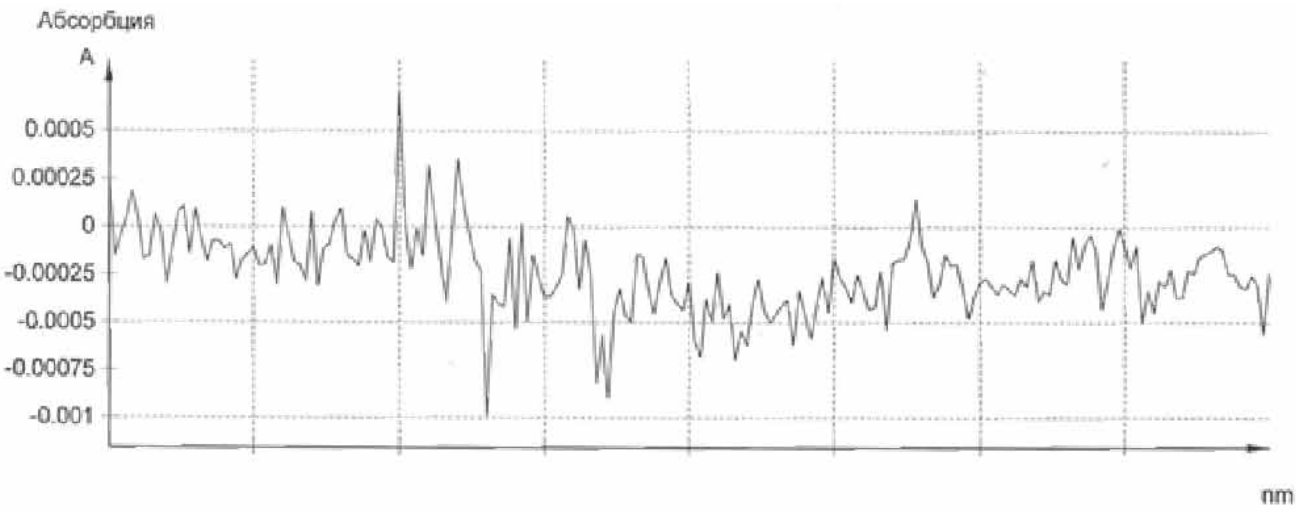

Fig. 2. The placebo absorption spectrum in the range from 250 nm to 320 nm

Preparation of a placebo solution: 800 mg of sodium chloride salt is dissolved in water for injection up to 100 ml. 10 ml of the resulting solution was transferred into a volumetric flask with a capacity of 100 ml, the volume of the solution was adjusted to the mark with a 0.1 M hydrochloric acid solution, and stirred. 5 ml of the resulting solution was transferred into a volumetric flask with a capacity of 250 ml and the volume of the solution was adjusted to the mark with a 0.1 M hydrochloric acid solution and stirred. The optical density of the resulting solution is measured at a wavelength of 277 nm, using a 0.1 M hydrochloric acid solution as a reference solution.

Acceptance criterion: impurities of the active substance, excipients and solvent for the test sample should not interfere with the quantitative determination of the basic substance.

From this spectrum it is seen that in the wavelength range from 250 nm to 320 nm, the placebo solution has no absorption in the UV light region. The maximum optical density obtained in a given wavelength range was 0.0005, which does not affect the quantification of the active substance.

Conclusion

Methodology was developed and validated for the quantitative assessment of metronidazole in the Metromed® Neo infusion solution. The obtained values of the validation characteristics are within acceptable limits, which allows using the developed technique in assessing the quality of the infusion solution.

Features of Manifestation of Optokinetic Nystagmus in Meniere'S Disease

Makhzuna Tahsinovna Nasretdinova[1], Ozod Rakhmatullaevich Nabiev[1]

[1]Associate Professor, Samarkand State Medical Institute, Republic of Uzbekistan, Samarkand

Abstract

The characteristics of optokinetic nystagmus (OKN) were studied in 20 healthy individuals and 30 individuals suffering from Meniere's disease in remission. The results recorded by the method of electronystagmography at frequency optokinetic stimulation 66,90 156 and field/min. found that in healthy people, the frequency of IPOs, the total amplitude and the speed of the slow phase(sp) nystagmus increases proportional to the increase in the frequency optokinetic stimulation; accordingly, consistently reduced the average amplitude window. In Meniere's disease, OKN indicators are generally characterized by lower values than normal, and an increase in the frequency of optokinetic stimulation is accompanied not only by a more pronounced decrease in the total amplitude indicators, but also by a decrease in the speed of the slow phase of OKN. After the glycerol load and with positive results of the glycerol test, the quantitative indicators of OKN increase in patients, approaching the physiological norm. It is concluded that it is appropriate to study the OKN in Meniere's disease to clarify the stage of the disease and predict the effectiveness of treatment.

Keywords: *Meniere,total amplitude, optokinetic nystagm, glicerol test.*

Introduction

According to the literature, the study of optokinetic nystagmus (OKN) is widely used for the differential diagnosis of hemianopsias[1], oculomotor disorders, and diseases of the Central nervous system[2].

In recent years, a number of papers have been published on the study of OKN features in disorders of both Central and peripheral parts of the vestibular analyzer [3]. It is experimentally proved that the peripheral labyrinth can give pathological optokinetic nystagmus[4]. Many authors first reported the neutralization of optokinetic nystagmus by supra-threshold post-caloric or post-dictatorial nystagmus in humans and indicated that sub-threshold vestibular stimuli increase the optokinetic response. Visual assessment of OKN disorders under the influence of stimulation in all directions in limes suffering from Meniere's disease and cochlear vestibulopathy caused by vegetative vascular dystonia[3], cervical osteochondrosis and other causes was not revealed[5]. However, when analyzing electronystagmogram was certain violations of the settings window. In this regard, it is advisable to further identify violations of the peripheral parts of the vestibular analyzer, in particular, in Meniere's disease, caused by the hydrops's of the labyrinth.

The aim of the study was to determine the features of the manifestation of optokinetic nystagmus in patients with Meniere's disease.

Materials and Method

A Total number of examined people in the clinic No. 1 of the Samarkand medical Institute were 50, including 20 healthy (control group) aged 17 to 41 years, who do not suffer from vestibular dysfunction, and 30 people with Meniere's disease aged 25 to 52 years, with a prescription of the disease from 5 months to 14 years. The examination of patients was carried out in the inter-access period.Method of work inspection, audiometric, vestibulometric study, as well as learning the OCN with the help of stat-tomographic recording. Audiometric examination was performed in a sound-attenuated chamber on an audiometer MA-30 (GDR). hearing tests included tonal threshold, supra-threshold and audiometry.

During vestibulometry, statokinetic stability was determined, and spontaneous and experimental

nystagmus obtained with caloric and rotational stimulation was recorded.

OKN was induced by observation of the examinee for optokinetic rotation of the drum, which caused the four black vertical stripes, a Rotating cylinder was carried out at three fixed angular velocities: 99, 135, 2340 in 1 second, which provides the frequency optokinetic stimulation, respectively, 66, 90 and 156 of the bands in the I min. In assessing the entry window takes into account the frequency nystagmoid movements, the amplitude and total average speed of nystagmus slow phase (sp) and efficiency bands. In addition, the severity of optosensory and opto vegetative reactions was recorded.

Based on the oral audiometry data, it was found that the examined patients had predominantly unilateral hearing loss on the side of the patient's labyrinth. The curves of the hearing thresholds were mostly horizontal, less often descending and ascending. In most cases, an interval of 10-30 dB was observed between the bone and air conduction curves. We noted low differential thresholds for the perception of sound power (0.4 0.8 dB at an over-threshold tone of 500 and 2000 Hz with an intensity of 20 dB), and a positive SISI test (80-100% of positive responses). According to vestibulometry, the predominant type of disorders was hyporeflexia, in rare cases hyperreflexia of vestibular excitability was observed.

Results

The frequency of OKN in healthy people increased linearly as the frequency of stimulation increased (from 1.2 at the frequency of stimulation of 66 bands/min to 2.64 at the frequency of 156 bands/min). There was an increase in the total amplitude (from 180 to 227.40) and SP (from 18.8 to 26.90/c). At the same time, the average amplitude tended to decrease (from 15 to 8.90) bands (the ratio of the number of nystagmal responses to the number of bands passing in the field of view per unit of time), regardless of the frequency of stimulation, was close to one. Optosensors and opto autonomic reactions were absent (table. 1).

Table 1: Characteristics of OKN in normal and Meniere's disease

Indicators	Main group			Persons suffering from Meniere's disease		
	Frequency of stimulation(number of bands per 1 minute)					
	66	90	156	66	90	156
Frequency OKN in Hz	1,2±0,1	1,6±0,1	2,64±0,02	1,18±0,01	1,55±0,015	2,43±0,06
The total amplitude (in degrees)	180±8,6	216,6±8	227,4±15,6	123,4±5,8	141,8±6,5	136,2±8,1
The average amplitude (in degrees)	15±0,72	13,7±0,65	8,9±0,55	9,9±0,48	8,3±0,48	5,2±0,29
SMF of optokinetic nystagmus (in degrees/s)	18,8±0,82	23,9±0,88	26,9±0,88	13,1±0,65	15,1±0,76	15,4±0,95
Band efficiency	1±0,1	1±0,1	0,957±0,12	0,952±0,022	0,928±0,016	0,831±0,028

When examining people suffering from Meniere's disease, the WINDOW parameters considered are of a different nature (see table. 1). The frequency of the window increases evenly (from 1.18 to 2.43 Hz). The average amplitude and performance indicators of the bands decrease linearly, and their value is significantly less than the "normal" one. The quantitative values of the total amplitude and CP of nystagmus increase to the frequency of stimulation of 90 bands/min, and with stimulation of 156 bands/min, their indicators decrease slightly, while in the control group, the characteristics under consideration increase linearly. In some patients, an increase in the speed of stimulation caused a feeling of vestibular "discomfort", manifested by dizziness and nausea.

To determine the stage of the process in the subjects, we performed a glycerol test, which is used in diagnostic practice to characterize the reversibility or irreversibility of pathological changes in the receptor formations of the labyrinth in Meniere's disease[5]. The patient was offered to take inside a mixture of pure medical glycerol in half

with sour fruit juice at the rate of 1.5 g of glycerol per 1 kg of body weight. Audiometry, vestibulometry, and optokinetic recording were performed up to h 3 hours after taking glycerol.

Discussion

According to the results of studies after taking glycerol, patients were divided into two groups. The first group included individuals who had a decrease in tone perception thresholds by 10 to 15 dB during audiometry, and with experimental vestibular samples, the nystagmal response indicators significantly increased. The second group included patients who did not have any significant changes in auditory and vestibular functions after the glycerol test.

Comparison of the results of optokinetic stimulation with the initial data showed that the subjects with a positive glycerol test showed an improvement in all the characteristics of OKN. So, for example, when stimulated 156 hollow/min, the total amplitude increased to 155.5" at the initial value of 136.2", and sp - to 17.8/s (before taking glycerol, this value was 15.49/s), in patients with a negative glycerol test, we did not note significant changes in the considered characteristics of the OKN.

Comparison of records allows us to conclude that with a positive glicerol test, there is a "revival" of the OKN in comparison with the original data.

Conclusions

Based on the results of the survey, the following conclusion can be made. In healthy people, there is a linear increase in the frequency, total amplitude, and speed of the slow phase of optokinetic nystagmus and a consistent decrease in the average amplitude with an increase in the frequency of optokinetic stimulation. In individuals suffering from Meniere's disease, OKN is characterized by lower parameters, and as the frequency of stimulation increases, the total amplitude of the CMF tends to decrease. Reduced endolymphatic labyrinth as a result of the action is accompanied by an increase in the quantitative characteristics of the WINDOW

Thus, the characteristics of OKN in Meniere's disease may be important for identifying additional criteria for diagnosing diseases of the labyrinth and predicting the effectiveness of treatment.

Some Features of the Bacteria of the Family Enterobacteriaceae Allocated from Small Cattle at Different Pathological Processes

Ruslan Gayrabekov[1], Raisa Gayrabekova[1], Luiza Molochaeva[1]

[1]*Associate Professor, Chechen State University, Grozny, Russia*

Abstract

Enterobacteria with a certain set of pathogenicity factors and capable of leading to the development of diseases of animals and humans are ubiquitous in nature, which can be recognized as the result of anthropogenic activity. Recently, they have been isolated with increasing frequency from soil, water, from fruits, vegetables, grains, plants, from representatives of various systematic groups of animals and humans. We have obtained bacteria from sheep with gastrointestinal pathologies. From sick animals, we have identified a large number of bacterial cultures belonging to species of different genera of the *Enterobacteriaceae* family. Among them, 190 cultures, species belonging to *Escherichia coli*, 124 cultures of *Enterobacter cloacae*, 74 cultures of *Morganella morganii*, 51 culture of *Citrobacter freundii*, 29 cultures of *Serratia marcescens*. For these microorganisms a large set of various pathogenicity factors was characteristic: antilysocyme, anti-complementary, anti-interferon activity, adhesive ability, hemolytic activity, multiple resistance to antibacterial drugs.

The aim of our work is to study the spread of enterobacteriosis, some features of the epizootic process in these diseases in the territory of the Chechen Republic

Keywords: *Epizoology, farm animals, enterobacteriosis, disease, small ruminants, pathogen, skin, wool.*

Introduction

Independence of the state is defined not only by the power of their military forces, but also by the capability to supply the population with food. According to the standards of UN FAO of the WHO, a person has to consume around 959.7 kg of plant and animal food products annually. In Russian Federation there are on average 701.6 kg of food per person annually[1]. Meat and milk consumption per person is 80% of the norm and fish consumption is 55% of the norm[2].

Only innovation-driven growth of APC can provide Russia with food supply security[3]. The issue of animal production intensification in Russian new economic conditions is one of the most acute, because it is directly connected with the quality of population nutrition and their life in general. Scientific approach to dealing with this acute issue is absolutely necessary, since food supply becomes a lever of economic and political pressure in international relations.[4]

At present, animal production industry is in crisis, it is considered unprofitable and has to cut the main qualitative parameters. This issue is especially acute in the present conditions of the imposed import substitution policy.

The popularity of import substitution policy in agricultural sector and on the food market is increasing. The problem of production intensification, based on innovation-driven technologies, in particular, on energy saving technologies, is very acute.

During the past years Russia has increased production rate, in particular, agricultural production rate, and, as a result, became one of the exporters. In 2014 export profit of agricultural production exceeded 20 billion dollars, which is higher by one forth than the profit from military equipment export and by one third than from gas resources export.

The concept of long-term social and economic

development of Russian Federation defined the main objective that population should be supplied with agricultural products and food by domestic industry. Thus, by 2020 Russia should reach the level of the recommended daily food norm of animal food products consumption. Meat production is expected to increase by 1.7 times and milk production is expected to increase by 27%. It is planned to provide the industry with breeding animals and increase their productivity[5] to the levels compatible with those of West European countries.

State support of establishment of the additional and modernization of the existing animal breeding genetic centers should provide the import substitution policy implementation by 80% and create conditions for parental and line breeding animals and their reproductive and productive characteristic improvement[4]. This is expected to develop animal breeding industry and increase its competitive advantages on Russian and world markets».[6]

«Successful animal production development is defined by veterinary policies that protect animal farms from infectious and parasitic diseases. Scientific research data[7] and practical experience in veterinary show that the majority of infectious diseases, as a rule, is diagnosed not as mono infection, but as associated parasite community[56]. It should be noted that parasite associations in farm animals are diverse in both taxonomic aspect (viruses, bacteria, protozoan, helminths)[8] and the pathologies caused».[9]

The diseases caused in animals and humans by different genera of the *Enterobacteriaceae* family, i.e. enterobacteriosis, are quite widespread. These diseases often lead to lethality in the infected individuals.

Enterobacteriosis pathogens are often isolated from soil, water, plant and animal products, domestic and wild animals, as well as humans. Among these microorganisms there are strains that differ significantly from each other by biological properties, ecological peculiarities, range of hosts, pathogenic factors and virulence. A number of species cause gastrointestinal problems. 12 out of 30 geniof the *Enterobacteriaceae* family–*Citrobacter*, *Escherichia*, *Enterobacter*, *Hafnia*, *Klebsiella*, *Morganella*, *Proteus*, *Providencia*, *Salmonella*, *Serratia*, *Shigella*, *Yersinia*,cause different pathologies. In the Chechen Republic these diseases were registered annually in farm animals from 2002 to 2015. The annual season dependent dynamics of morbidity was identified in young small ruminants[9].

Materials and Method

For evaluation and analysis of enterobacteriosis epizootic situation (colibacillosis, salmonellosis, serratiosis, etc.) among small ruminants in the Chechen Republic, the authors used the data from annual reports from republic and regional vet laboratories. Epizoologic screening was performed from 2002 to 2015 according to the common methodical guidelines [10].

Isolation of opportunistic and pathogenic enterobacteria, their cultivation and evaluation of pathogenicity factors were conducted according to the common method.

Cultivation of microorganisms was done on 1.5% meat and peptone nutrient agar and nutrient broth. Bacteria culture was cultivated in thermostat at 37°C within 18-24 hours. The bacteria were isolated and identified according to the "Methodical guidelines to bacteriological diagnostics of associated intestinal infections caused by pathogenic enterobacteria in animal growing stock[11].

Morphologic, tinctorial and cultural properties evaluation was performed according to the method, outlined in the reference books on microbiology[12].

Disc diffuse method was used for identification of sensitivity range of the studied bacterial culture, isolated from sheep, to antibiotics[13].

Lysozymic activityof the studied cultures was assessed by the microorganism lysozyme capacity to split β-(1-4)-glycoside bonds of mucopolysaccharide complex in cell walls of the reference strain *Micrococcus luteus var. Lysodeikticus*[13].

Assessment of antilysozymic activity was done by the method of O.V. Bukharin et al.[13].

Adhesive activity of the studied bacteria was evaluated by the reaction of hemagglutination with 3% goat erythrocyte suspension in the presence of D-mannose and without it[13].

Hemolytic activity of the studied cultures was assessed on nutrient agar in the presence of 3-5% rabbit washed erythrocytes. Thiol dependent hemolysines were identified by cultivation on trypticase soy agar in the presence of 3-5% rabbit washed erythrocytes (washed three times in Hank's solution) according to the recommendations of Albesa I. et al[13].

Anti-interferon activity in the isolated cultures was studied by O.V. Bukharin and V.Y. Sokolov in association with antibacterial effect of leucocytal human interferon drug [14].

Anticomplementary activity was evaluated by the method of O.V. Brudastovet al[15].

Results

The results of the present study showed that 80% of enterobacteriosis cases in small ruminants were diagnosed as associated diseases and epizootically appeared on a wide territory in the Republic[9]. Their role and place in the formation of nosologic profile of the infectious pathology is quite significant[16].

During the years of screening, small ruminants, morbidity rate varied from 0.01% to 7.3% at serratiosis, from 0.05% to 11.5% at colibacillosis, from 0.01% to 3.7% at enterobacteriosis. Lamb mortality rate during these years varied from 0.02% to 2.2%, from 0.2% to 6.2%, from 0.01% to 1.5%, respectively. The present study allowed the authors to identify the peculiarities of serratiosis, colibacillosis and enterobacteriosis disease development in small ruminants on the territory of the Chechen Republic.

The study of this pathology annual dynamics allowed the authors to identify significant seasonal dependence in lamb morbidity rate. Thus, in February-March enterobacteriosis morbidity rate varied from 0.055 to 0.1%, decreased during the following months and increased again in June to 0.05%. Consequently, seasonal epizootological changes in these diseases are characterized by infection rate increase in the end of summer and in autumn and infection rate increase at the end of winter and in spring.

These bacterial pathologies in small ruminants have the following symptoms: appetite decrease, fatigue, low mobility, permanent diarrhea, decrease of life mass gain in comparison with healthy animals, hyperthermia, heart rate increase and tachycardia, unfavorable outcome rate during the first days of disease reached 60%.

Flashness of animal corpses was below the average, skin and wool around anal orifice, on the tail, hips and back abdominal part were covered with liquid feces, mucous membranes had signs of anemia. Pathological study of fallen animals showed peculiar changes in the intestine and parenchymatous organs, which were primarily observed in abdominal cavity: forth stomach mucous was irritated, tremellose infiltrated with hemorrhages. Mesenterium lymphatic vessels were enlarged, often hyperemic, fleshy on section cuts. Serosal abdominal layers often contained hemorrhages.

Splinter was slightly enlarged without significant alterations in most cases. Liver and kidneys had signs of anemia, often with hemorrhages under their coats, gall-bladder was filled with dark-green bile. Bladder mucous layer did not have significant changes in rare cases it was hyperemic.

Intestine content was rare, mixed with mucus and was red because of blood presence (catarrhal hemorrhagic colitis).Mucous membranes of large and small intestine were swollen, covered with mucus, hyperemic and often with hemorrhages. Mucous intestine layer had signs of necrotic colitis and proctitis localized in different parts of intestine in different animals. In most cases blindgut was filled with hydrous content and was inflated because of gases (meteorism)[17]. Thoracic cavity contained hemorrhages under serous membranes, significant deviations from the norm were not observed[18].

Enterobacteriosis was diagnosed based on bacteriologic tests performed in bacteriologic laboratory.

A lot bacterial cultures from the *Enterobacteriaceae* family were isolated from infected animals. Among them there were 190 cultures of *Escherichia coli* species, 124 cultures of *Enterobacter cloacae*, 74 cultures of *Morganella morganii*, 51 cultures of *Citrobacter freundii* and 29 cultures of *Serratia marcescens*. These microorganisms had a wide range of pathogenic factors: antilysozymic, anticompiementary, antiinterferon, adhesive, hemolytic activity and multiple resistance to antibiotics[19].

Thus, the studied microorganisms antilysozymic activity varied from 43.5% in representatives of genus Enterobacter to 86.2% in ygenus Serratia bacteria.

Antiinterferon activity was minimum 28.4% in genus Morganella and maximum in genus Escherichia representatives. Minimal number of cultures with anticomplementary activity was among representatives of genus Enterobacter and maximum number of strains with this feature was in genus Enterobacter.[17]

The study of goat erythrocytes agglutinative capability in the presence of D-mannose showed that

this feature was present in all the species of the studied enterobacteria. However, in different species this feature was present at different rate. Hemagglutinating capability was quite expressed in 94.7% of Escherichia strains. The identified hemagglutinins in the studied Escherichia strains had different sensitivity to mannose. Mannose resistant hemagglutinins to goat erythrocytes were identified in 73 Escherichia strains (39.2%). 24 out of 29 Serratia strains had hemagglutinating capability in the absence of D-mannose among Serratia, which is 82.75%. D-mannose resistant hemagglutinating activity was observed in 24 of the studied Serratia strains. The lowest number of strains with hemagglutinating activity (42 out of 124 (33.84%)) was identified among Enterobacter cloacae cultures. Among the studied Morganellastrains hemagglutinating activity was observed in 58.9% of cultures. The studied Morganella cultures produced mannose resistant hemagglutinins more often (63.64%) than mannose sensitive ones (36.4%). Goat erythrocyte agglutinating activity was identified in 180 out of 190 (94.7%) Escherichia strains. Hemagglutinins, identified in Escherichia strains, had different sensitivity to mannose. Thus, human erythrocyte agglutination was inhibited by mannose in 84 cultures (44.7%), and mannose resistant hemagglutinins were identified in 68 strains of the studied bacteria. Goat erythrocyte mannose resistant hemagglutinins were observed in 73 strains (39.2%).[18]

Among the studied cultures of microorganisms, the lowest amount of hemolytically active strains (16.1%) were found in genus Enterobacter and the highest amount of representatives with this feature was found in genus Citrobacter (58.8%).

All the studied cultures had sensitivity to 9 groups of antibiotics: group I – β-lactam antibiotics of penicillin group, group II – β-lactam antibiotics of cephalosporin group, group III – tetracyclines, group IV – aminoglycosides, group V –macrolides, group VI – rifamycins, group VII– glycopeptides, group VIII– nitrobenzenes (laevomycetin group), group IX – polypeptides (polymyxins).

The studied Escherichia strains showed higher resistance to β-lactams, tetracyclines, macrolides, rifamycinsandglycopeptides. The highest sensitivity in these cultures was to polymyxin and laevomycetin. Among Escherichia strains half of the studied cultures (47.7%) were the strains with multiply resistance to the used antibacterial drugs.[20]

Evaluation of Enterobacter cloacae cultures sensitivity to antibiotics showed that there was a number of strains with multiply resistance to drugs (45.16%). The studied Enterobacter cloacaestrains were mostly sensitive tomonomycin (81%), carbenicillin (29.0%), laevomycetin (17.8%) andneomycin (8.1%), to other antibiotics they were highly resistant.[21]

High ratio of the strains with multiple antibiotic resistance was identified among Serratia marcescens strains (68.96%).[22]

The studied Morganella cultures had absolute resistance to methicillin, streptomycin, ampicillin, benzylpenicillin, rifampicin, ristomycin, neomycin and erythromycin. Morganellas were sensitive togentamicin, kanamycin and laevomycetin. 82% of the studied Morganella cultures were multiple antibiotic resistance.

Among the studied *Citrobacter freundii*cultures, there were many strains with multiple antibiotic resistance(49.7%).

Discussion

The results of the present study allowed the authors to conclude that the disease outbreak and development in lambs was associated with both environmental factors (sharp temperature fluctuations in winter-spring seasons, traditionally high air humidity, high level of solar activity, etc. in the Republic) and uncontrolled indication of antibiotics to animals as food additives for growth stimulation, that led to appearance of strains with multiple resistance to antibiotics and high range of pathogenic features. Environmental factors are accompanied by the conditions of sheep barn housing in the Republic. This period coincides with high lamb birth rate, which leads to sheep concentration increase on the limited barn area. This, in its turn, leads to worsening of sanitary conditions in sheep farms. Feed supply and feed quality reduction (feed with insufficient amount of nutrients, vitamins, microelements, etc.) in the end of winter-spring season leads to animal immune system weakening.

Often, water and food, contaminated with pathogenic or opportunistic pathogenic bacteria, can become a source of infection because of sanitation and hygiene standards of animal keeping violation.

The obtained data indicates on widespread and unfavorable conditions of animal farm keeping in the

Republic, which makes sick and recovered animals the main source of pathologic infection.

During the analysis of epidemiologic situation in Chechen Republic, it was important not only to isolate bacteria cultures and identify their species, but also to confirm the fact that those particular cultures were the etiological agents that caused the diseases, because they had a number of pathogenic features defining their virulence. Development of labelling method, as well as identification of the isolated bacteria sensitivity to antibiotics, has great practical significance for establishing antibiotic therapy regimen for the sick animals on the territory of the Chechen republic.[13]

Conclusion

1. The results of the studies showed that enterobacteriosis of small cattle in 80% of cases occurs as associative diseases and have wide territorial boundaries of epizootic manifestations in the republic, and their role and place in the formation of the nosological profile of the infectious pathology of sheep is very significant.
2. From sick animals, we isolated a large number of bacterial cultures belonging to species of different genera of the *Enterobacteriaceae* family. Among them 190 cultures belonging to the species *Escherichia coli*, 124 cultures of *Enterobacter cloacae*, 74 cultures of *Morganella morganii*, 51 cultures of *Citrobacter freundii*, 29 cultures of *Serratia marcescens*. These microorganisms were characterized by a large set of various pathogenicity factors: antilysocyme, anticomplementary, anti-interferon activity, adhesive ability, hemolytic activity, multiple resistance to antibacterial drugs.

The Communicative Skills Correction Technology of Children with Autistic Spectrum Disorder in the Crimea

Svetlana Motornaya[1], Margarita Belenkova[1]

[1]*Associate Professor, Sevastopol State University, Sevastopol, Russia*

Abstract

The communicative skills correction technology in children with autism spectrum disorder is considered. In the Crimea centers and funds which provide support and assistance to families raising children with special developmental features, in particular autism, are being analyzed. The results of a communicative skills correction study in children with autism spectrum disorder are presented.

Keywords: *Technology, autism spectrum disorder (ASD), preschool age, communicative skills correction, health camp, Crimea.*

Introduction

In recent decades, the number of children with impaired mental development, particularly with autism spectrum disorder (ASD), has increased significantly at the national and regional levels.

«Several decades ago, there was one resident with autism spectrum disorder per 10,000 inhabitants. In 1995, there was already one person with autism per 5,000 people. In 2017, there was one person with autism spectrum disorder... the autistic spectrum is already prominent among 50 people» [1]. The earlier such people are assisted by specialists, the more likely their socialization will be. The growth dynamics of people with ASD and the need to correct their communication skills from early childhood predetermined the relevance of our study.

Among the scientists who studied the phenomenon of ASD, we can mention the works of E. S. Ivanov, E. R. Baenskaya, M. M. Liling, O. S. Nikolskaya, V. Bettelheim, U. Frith, L. Wing, who note that one of the "main violations preventing successful adaptation and socialization of an ASD child is its underdevelopment"[5]. Nevertheless, it is important to consider the technology of corrective actions and the creation of conditions for the development of communication abilities of children with ASD for their successful socialization. At the same time, the scientific literature reveals a lack of research on this problem, especially at the regional level. In this regard, the purpose of our study is to examine the correction of communication skills of children with ASD in the Crimean region and Sevastopol.

Research Methodology. Nowadays, according to children's neurologist of the Ministry of Health and Social Development, Professor A. Petrukhin, autism is among the most common disorders in Russia. The first works on the need for specially organized assistance to children with this type of dysontogenesis in Russian psychology can be considered the work by G.E. Sukhareva in 1955, which examined autism disorders in childhood schizoidia. In 2010, the main provisions of the "Special Federal State Standard for Primary Education and School System for Children with Developmental Disabilities of the Autistic Spectrum" were published. The document appeared due to the activity of O.S. Nikolskaya[9] and was prompted by the requirements of the reform of the education system in Russia.

According to Maureen Durkin, PhD in epidemiology, Professor of Public Health and Pediatrics (USA), «recent studies of the prevalence [in Russia] of eight-year-old children show that the number of cases of ASD can be 1.5% or even 2%» [4]. Among other facets of the problem in this area, apart from revealing the fact of autism in the Russian population, it should be noted that 92% of 100% of people with ASD in the US are adapted, while in Russia only 10% are adapted[3]. The third facet of the problem is that autism in adults is not recognized in Russia. Without knowing how many children in Russia

have autism spectrum disorders, it is impossible to build a literate system of state assistance to these children in health care, education, and social protection.

Modern scientists believe that ASD does not depend on a person's ethnopsychological peculiarities, social conditions of his life, his material well-being. At the heart of a child's adaptation in the process of socialization to the requirements of life in society is the degree of development of his or her communication abilities. «The main characteristic of the disorder is the permanent deficiency in social communication and social interaction. The main deficit in people with autism spectrum disorder is the skills of divided attention and reciprocity in contact»[2].

Due to the lack of social contacts in children with ASD, the emergence of difficulties in communicating with their loved ones and the world around them, an increase in primary lack of communication skills is formed due to the effect of «snowball». The speech function, the holistic picture of the world, and the sense of meaning are formed in a distorted way. «Echolalia, blurred speech, chanting pronunciation, speech with shorthand, a peculiar voice intonation with a predominance of high tonality, long naming of oneself in the second and third persons, absence of words in expressive speech that designate people close to the child, autostimulations realized in citing poems, songs, quotations, etc.».[6].

T. Grandin and M. Scariano note that such a child is limited by the fact that he can only build his relationship with the world around him through an adult. «Having lost contact with their emotional donor, translator, and arranger of meanings around them, such a child stops developing and can regress»[8]. By the period of enrollment in school, children with ASD show "a pronounced cognitive deficit, non-formation of arbitrary forms of activity, specificity of perception, thinking, and speech"[7], "in expressive speech, there is a predominance of a nominal vocabulary over the predicative one" [3].

The most competent assistance can be provided to the child in special centers for correction of communication skills disorders. In Russia, the First Federal Resource Center for Supporting Children with ASD and their Families was opened in 2016. Its main goal is to develop a system of comprehensive assistance to children with autism spectrum disorders.

On the other hand, there is the Regional Center for Autism, a unique school in St. Petersburg, where parents from all over Russia bring their children. The peculiarity of this Center is that it already works with speaking, adult children, who are prepared for the stage of self-determination. However, ASD children from preschool age who are not yet speaking cannot determine their interaction with the surrounding reality, and are not given due attention.

There are no specialized centers for developing communication skills for children with ASD in remote towns. All this creates a need to open new centers to improve the current situation. When searching for a location for a specialized center for developing communication skills for children with ASD, in our opinion, it is necessary to take into account whether there is a need for such a center in the region or whether the center already exists. On the other hand, it is important to take into account the climatic conditions, which should be aimed at creating favorable conditions that would enhance the possibilities of the corrective programs used.

Research results and Discussion. In this regard, let us consider the opportunities that the Crimean peninsula offers to solve the problem. Here, thanks to climatic conditions are enriched both physical and mental, and social health, which for a child with ASD, primarily manifested in the mastery of speech skills and basic communication. Crimea as a natural object provides the possibility of using complex therapy, parts of which are climatotherapy, landscape therapy, and aromatherapy. In a combination of mountain and sea air, phytoncides of medicinal plants and herbs: aromas of juniper, pine, arborvitae, lavender, sage, lemon wormwood, health improvement of spirit and body of the child, its hardening, which in turn leads to the strengthening of all components of health. Healing air, warm sea, the unique beauty of nature has a beneficial effect on the emerging body of the child: the child feels comfortable and has positive emotions; the result is a successful consolidation of skills learned by a specially designed program.

Now in Sevastopol, just over 100 people with ASD have been identified. But, according to the head of the organization «Special Children» A. Menanova, they «do not receive the quality assistance they need»[10].

Starting from 2017, Crimea began to open centers to work with children with various developmental features: the M. Lynskayacenter[11] and the centers of

"Territory of Speech" in Simferopol and Sevastopol. The latter's work is based on the method of T. Gruzinova and E. Gurina and is aimed at children with communicative disorders ranging from lack of speech to speech delays of various genesis (sensomotoralalia, autism spectrum disorders, dysarthric disorders), and includes three areas: ABA-therapy (Applied Behavioral Analysis), individual work with a neuropsychologist (neurogymnastics), game speech therapy. A distinctive feature of the centers is the use of author's innovative technologies contributing to the development of communication in children with ASD.

Our research was carried out on the basis of a speech therapy center «Territory of Speech» in the Crimea at the summer health camp «We're together». During the life of the student in the camp is communicative intensity (14 days). Group sessions are held in groups of up to 6 people with children 5-6 years old, the purpose of which is to acquire and develop skills to interact with peers in a safe environment. In individual sessions, a complex interaction with the following specialists is used: a speech therapist to practice speech skills; a neuropsychologist who performs neurogymnastics to restore normal brain function in a child; and an ABA-therapist.

During the two weeks of stay in the camp, the whole range of activities allowed to intensify mental processes, contributing to the development of communication skills of children of preschool age. Specially organized «parenting» events were held daily for parents.

Meetings» under the guidance of a psychologist consultant, as well as «Family Soft School» for parents and children by the method of E. Glushkova. The basis of the school's technology was the use of game exercises that develop flexibility, plasticity of the child, his or her ability to master his or her body and be active, perceptive, and adequate in any situation.

The peculiarities of the site where the psychocorrection was carried out required its creative improvement, as a result of which we developed and implemented the author's technological elements of the psychocorrection program for the development of communicative skills of preschool children with PAC. The first block of the program consisted of individual lessons with a game speech therapist according to the method of T. Gruzinova; the second block consisted of creative elements of the psychologically corrective program developed by us:

– Group lessons to develop communicative interaction;

It took two weeks, two hours a day. The following materials were used: pyramid, peg top, bubbles, balloons, chalk board, cards, napkins, grains, water. The sequence of corrective actions in the lessons is given below.

1. Children sit in a circle. Behind each child sits a tutor. The whole process is managed by the leader of the communication group.
2. The leader of the group gives the following instructions: "Who should I give the bubbles to?" (or any other kind of material).
3. The leader looks carefully at which of the children took the initiative in the form of a gesture request, a vocal request. If the children cannot ask for it themselves, the tutor does it for the child with a physical prompt.
4. The child who has asked the presenter is given an object for manipulation.
5. All children command the child by name (for example: the presenter gave N bubbles): N, "blow". Execution of the command is based on the capabilities of the child: if the child can not address the N by name and does not look at him, the tutor helps the child by turning his head and pointing to the N.

If the child does not speak or imitate a gesture, the tutor helps him with a physical clue. This happens in the following way: the tutor takes the child's hand, puts it on his lips and makes a verbal gesture "blow". As time goes by, the hint becomes weakened and, as a result, the child can give instructions to the participant on how to communicate. Each child has the opportunity to manipulate any presented leading object.

At the end of the communication group training, each participant is trained to give instructions to the other and perform them independently;

- Yard games - bodily, visual, audio communication with the purpose of

"See me, notice me." Children in individual games learned to see each other, notice each other and interact with each other through different channels of perception. This is the direction of psychocorrective work combined and developed all aspects of communication. An example of author's yard games is presented in Table 1.

Table 1: Examples of copyright pickup games

Game Title	Accompaniment	Game participants	Actions of the game participants
Playhouses and cards	The active melody in major tone is switched on.	1. Group Leader 2. Tutors 3. Kids.	The presenter places the playhouses of four basic colors (green, yellow, and red, blue) in any part of the room. While the music is playing, the children run in a chaotic direction. When the music stops, the presenter raises a card of any color and gives instructions: find a playhouse like this. Each participant independently or with the help of a tutor finds a playhouse of the corresponding color.
Flower Bees	The active melody in major tone is switched on.	1. Group Leader 2. Tutors 3. Kids.	The presenter distributes hats with the image of bees to all children, and then spreads flowers sewn from fabric on the lawn (fabric of green color). Flowers have the same appearance and are equal to the number of children. While the music is playing, children run in a chaotic direction. When the music stops, each child finds a free flower for himself or herself or with the help of a tutor and becomes on it. Then the game can become more complicated depending on the possibilities of the group as a whole. The instruction is added: Remember, where your flower is, and when the music is over, find it.

- Creative workshop.

The creative workshop implied the development of small and large motors, the development of skills for independent creative activity. Creative workshops based on the elements of ART-therapy were conducted as follows. Every day the theme was chosen from what the children saw with their own eyes in the correctional camp: mountains, rocks, sea, plants. Then the trainees took seats at the table next to the tutor and tried to display what they saw with a brush on canvas or a plastic on a board.

Each learner gave out materials to others. For example, if he gave out child N, he would go with a piece of paper, and all the other students, according to their abilities, would ask for a piece of paper for themselves. Someone would do it vocally, someone would gesture, bending their palm. If the child did not have speech skills at all and could not ask with a gesture, the tutor gave a physical clue. Thus, the trainees gave out all the materials to each other, and they communicated based on their communication skills: vocally or by gestures, independently or with a physical clue. An important element of this communication was eye to eye contact. «Eyes» followed by the presenter and tutor. After all the materials had been distributed to the student, the presenter gave the instruction: «cut» and showed the verb with a gesture (he collected his index and middle finger, depicting scissors). During the instruction, the tutors from time to time reminded the child to 'cut' vocally and with a gesture to reinforce the skill and automate it.

Every day the creative workshop ended with a finished work, which was hung in a special room for creativity. All children had an opportunity to come to the hall, find their drawing and show their parents the element of their creativity. An opportunity was provided to consolidate the learning process with positive emotions: a manifestation of joy from the results of their creative activity and the creative work done.

In general, children from families that participated in the work of the «We are together» remedial camp received positive results, as shown in table 2.

Table 2: Results of children with ASD who underwent «intensive» summer camp in Crimea

Name	Age	Diagnosis	Pre-intensive course performance	After-intensive course performance (new elements)
1	5 years 2 months	ASD	Requests:0 Indicative gesture:- Sounds arbitrary:- Sounds involuntary: P,B. Words:-	Requests:1 (give - gesture) Indicative gesture:+
2	5 years 9 months	ASD	Requests:0 Indicative gesture:- Sounds arbitrary:- Sounds involuntary: P,B. Words:-	Requests:1 (give, open - gesture) Indicative gesture: +
3	6 years	ASD	Requests: 1 (give – vocally) Indicative gesture:- Sounds arbitrary: “Papa” (Dad) Sounds involuntary: B,D. Words:-	Requests: 3 (open, close, blow - with gestures).
4	6 years 2 months	ASD	Requests:0 Indicative gesture:- Sounds arbitrary:- Sounds involuntary: P,B. Words:-	Requests:2 (give, water - in gestures). Indicative gesture:+
5	5 years 7 months	ASD	Requests: 1 (give – gesture) Indicative gesture: + Sounds arbitrary:- Sounds involuntary: H,P. Words:-	Requests: 1 (give - vocally)
6	5 years 10 months	ASD	Requests:0 Indicative gesture:- Sounds arbitrary: Ba Sounds involuntary: P. Words:-	Requests:1 (give - gesture) Indicative gesture:+ Sounds arbitrary: P
7	5 years 6 months	ASD	Requests:0 Indicative gesture:- Sounds arbitrary: Vi Sounds involuntary: Di. Words:-	Requests:1 (give - gesture + vocal) Indicative gesture: + Sounds arbitrary: D.
8	5 years 4 months	ASD	Requests: 2 (give, open – gesture) Indicative gesture: + Sounds arbitrary: - Sounds involuntary: Pa. Words:-	Requests: 2 (give, open -vocally)
9	5 years 8 months	ASD	Requests: 0 Indicative gesture: + Sounds arbitrary: Ma Sounds involuntary: P,D. Words: Mama (Mother)	Requests:1 (give - gesture + vocal) Sounds arbitrary: P, D

Name	Age	Diagnosis	Pre-intensive course performance	After-intensive course performance (new elements)
10	6 years 2 months	ASD	Requests: 0 Indicative gesture:- Sounds arbitrary: P Sounds involuntary: B. Words:-	Requests:1 (give – gesture) Indicative gesture: +
11	5 years 9 months	ASD	Requests: 1 (open – vocally "aka") Indicative gesture: + Sounds arbitrary: M Sounds involuntary: D. Words:-	Requests: 1 (open vocally "aka + gesture")
12	6 years	ASD	Requests: 0 Indicative gesture: + Sounds arbitrary: Mi Sounds involuntary: Ti. Words:-	Requests: 2 (open, give - gesture)
13	5 years 11 months	ASD	Requests: 1 (give – vocally) Indicative gesture: + Sounds arbitrary: Give Sounds involuntary: P,B. Words:-	Requests:1 (give - vocal + gesture) Sounds arbitrary: P, B
14	5 years 10 months	ASD	Requests: 0 Indicative gesture:- Sounds arbitrary:- Sounds involuntary: M,P. Words:-	Requests:2 (give, water - gesture) Sounds arbitrary: M, P
15	5 years 6 months	ASD	Requests: 1 Vkluchi (Turn on) Indicative gesture: + Sounds arbitrary: Ku, Chi, Chu Sounds involuntary: P,B. Words:-	Requests:2 (give - vocal, blow - gesture) Sounds arbitrary: P,B

The data in Table 2 are the result of a comprehensive impact on communication skills development for children with ASD.

Conclusion

Due to a properly organized and implemented program, each child has received positive results, which will later be consolidated to automatism and applied in life. So, as a result of the educational development program in the summer camp all its participants, children with ASD who came with their families from different regions of Russia, achieved results. Let us cite the parents' opinion about the summer camp program: "We are happy: the impossible has turned out to be real". Of course, it is necessary to have more such centers so that all families with children with ASD could, with the help of the correctional programs of these centers, develop their children and improve their worldview, peace and harmony of families.

It is envisaged to continue further research in order to improve the technology considered and to create conditions for children with ASD to achieve results for everyone.

The research was supported by the grants #Est#Kontakt (#Contact #made) 01.08.2019 - 28.12.2019 of the Federal Agency for Youth Affairs (All-Russian competition of youth projects among individuals) and "Methodology for the use of information technology in the education and professional activities support of facilitator educators" reg. Abstract

Introduction: The aim of study was to research hemodynamic shifts in conditions of carry out combined anesthesia on the base of isoflurane with preservation of spontaneous breathing at small surgical operations in children.

Materials and Method: The research was carried out at 44 sick children at the age from 3 to 14 years with inguinal and inguinal hernias (41,7 %), hydrocele was (19,4 %) section of abscesses and suppurations were (38,9%). The duration of anesthesia benefit at 58,3 % patients was from 30 to 40 minutes, at 40,66 % it was about 60 minutes.

Results: The clinical monitoring was performed with study AP, HR and oxygen. For objective evaluation of cardiovascular functional condition, the echocardiography way was use. The first group patients were introduced intravenously the ketamine solution in doze 3 mgr/kg of body weight, propofole in dose 2 mgr/kg of body weight and izoflurane up to 3 ob % in 30-40 minutes after premedication. The second group patients were introduced intravenously the ketamine solution in dose 4-5 mgr/body weight and sibazone in dose 0,4 mgr/kg.

Conclusion: Complex clinical study and taken results of hemodynamic parameters showed the efficiency of carried out anesthesia with safety of independent breathing at small surgical operations at children.

Keywords: *Combined ànesthesia, small surgical operations, propofole, ketamine, sibazone, izoflurane.*

Introduction

Any operation, even small surgical intervention[2] or diagnostic manipulations are multicomponent stress which may be incompatible[3] with the life of many people[5].

The small surgical operations are more often performed in conditions of general anesthesia at children. The given necessity was proved by physiological peculiarities of child's organism, keeping safety of psychoemotial sphere, age features and severity of trauma. But these drugs in recommended doses often give the series negative effects including: suppression of independent breathing, and, the reducing amount of dose leads to non-adequate anesthesia[6]. The choice of anesthetics or their combinations depended on patient's

state, presence severe accompanied diseases, mainly, from the side of cardiovascular system, and also from pharmacodynamics and pharmacokinetic properties of drugs[7].

For solving the given problems some authors[1] offer to use several drugs of different action direction which allow to reduce their doses, and, at the same time to save the demanded level[4] of anesthesia[6].

Nowadays at carry out series small surgical operations in children the special place takes anesthetics, they are propofole and ketamine, which in combination with inhalation anesthesia isoflurane are matching with their pharmacological actions. These combinations of drugs have definite advantages of safe independent breathing[2].

In child's anesthesiology the increase dose and concentration of using drugs lead to depression contractive ability of myocardium[3], considerable changes in hemodynamic indices, which may lead to severe, and, in some cases to irreversible complications at patients with sharply reduced reserves of adaptation[8]. All the above mentioned have the definite actuality of searches more secure ways of anesthesia with safe independent breathing at children.

The aim of study is to research hemodynamic shifts in conditions of taking combined anesthesia on the base of izoflurane with keeping spontaneous breathing at small surgical operations at children.

Materials and Method

The study was carried out in 44 sick children at the age from 3 to 14 years with inguinal and scrotum hernias (41,7 %), hydrocele (19,4%) and at section of abscesses and suppurations.

The premedication was directed to remove vagal reflexes, anxiety, prevention of nausea and vomiting. The duration of anesthetic benefit at 58,3 % patients was to 30 minutes, at 40,66% persons to 60 minutes. Complex clinical study and taken physiological indices such as statistic parameters of cardiac rhythm allowed to evaluate objectively the level of functional shifts in child's organism at presence pain syndrome, which was necessary condition for choice adequate and effective anesthesia.

The patients' examinations were carried out at the following stages: before operation (outcome), after premedication, at introducing narcosis, at maintain period, at waking up time.

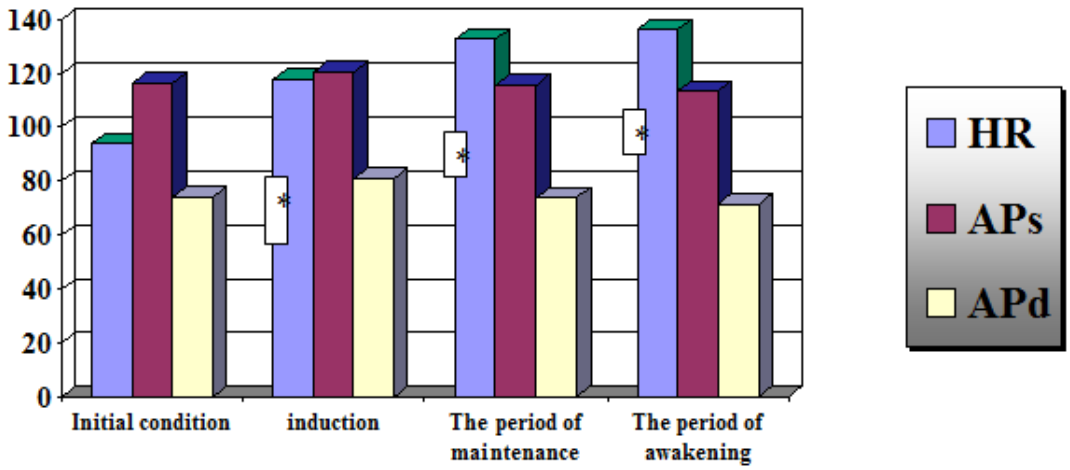
For objective evaluation of functional state for cardiovascular system the complex of bloodless electrophysiological ways of blood flow study were used. With this purpose the echocardiography way with analysis of final-diastolic size(FDS), final-systolic size(FSS) of left ventricle, R-R interval and expulsion time were used. The study was carried out on echocardiograph "Interscan 250" (Germany) with sensor 3,5 MHz. The systolic, diastolic and middle arterial pressures were measured by oscillographic method. With the purpose of more detailed and exact estimation the functions of left parts in heart with the help of computer analysis EchoCG the next indices of myocardium contraction ability and diastolic function of left ventricle: cardiac index (CI), beat index (BI), fraction of expulsion (FE), fraction of shortening (FS), specific peripheral resistance (SPR) were carried out.

The control after HR (heart rate) and AP (arterial pressure) were constantly carried out with monitor "Life Scope" (Japan). The index of oxygen saturation was determined with the method of pulse oxymetry.

During premedication the atropine sulfate 0,1 % - 0,01 mgr/kg body weight, dimedrol 1 % solution 0,1 mgr/kg body weight were prescribed, at open repositions for premedication enhancement: 0,5% solution of sibazone in dose 0,25 mgr/kg body weight and 5% ketamine solution in dose 2,5 mgr/kg body weight were additionally administered.

The patients of the first (main) group in 30 – 40 minutes after premedication ketamine solution in dose 3 mgr/kg body weight and propofole in dose 2 mgr/kg body weight and iziflurane inhalation to 3 ob% were introduced. The patients of the second group the ketamine solution in dose 4 – 5 mgr/kg body weight and sibazone in dose 0,4 mgr/kg were intravenously introduced. The maintain doses of drugs composed ½ part from the main ones.

Statistic processing of quantity indices, being taken at the result of special electrophysiological researches was carried out with the help of mathematical statistics. For statistically true results differences were taken only those meanings of "P" which were found in Student table and were less than 0,05. The factual material was given in relative meanings for leveling of age differences for homeostasis on the stage of study (initial data were



taken for 100%). The authenticity was calculated on the ratio to initial and previous stage of study.

Results

On the stage of introduction narcosis, the loss of consciousness became on the background of intravenous propofole introduction in dose 3 mgr/kg intravenously. After introduction ketamine the insignificant AP (arterial pressure) increase was marked on 5,5% from the level of initial one. RRM (respiration rate movement) was 22 – 36 times per minute. At performing operation more than 30 minutes the patients were intravenously introduced the second dose of ketamine and propofole composing 2/3 part of the main dose. Inhalation with izoflurane was to 1,5 ob%. In 40-50 minutes after carry out operation the patients answered questions in adequate way, orientated themselves in time and space, they recover consciousness in 1,5 hours after performing operation.

The indices of HR (heart rate), AP (arterial pressure) and oxygen saturation ($sP0_2$) at introduction period of anesthesia with use ketamine and propofole were characterized with stability. Smooth falling asleep was marked during 30-40 seconds after bolus introduction propofole, moreover, the disorder of breathing wasn't marked, skin coverings were warm and had usual color. The cornea was moist and shining, cornea reflex was moderately reduced, the eyeballs made swimming movements and they were fixed centrally. The pupils were moderately constricted with safe the reaction to light. The HR (heart rate) increased on 6,36%, there was tendency to increase APc on 3,2% and APd on 2,9% in comparison with their initial data. At introduction propopole in dose 3 mgr/kg the hypotension was observed to 5% from initial index only in 10% cases of observations. In other cases, AP wasn't changed, may be, in connection with ketamine action to increase AP. Thus, ketamine corrected propofole action and reduced hypotensive effect of propofole.

The waking up period was not long and continued 30-40 minutes it was depended on general dose, time of introduction the last sodium oxibutirate dose and individual features of patients. The extubation of trachea was performed at appearance adequate spontaneous breathing. The skin coverings were rose and warm, the vision, larynx, pharynx, coughing reflexes and moving activity were fast restored. APc reduced to 2,86%, APd to 3,49% in comparison with initial data.

* Authenticity of indices differences in comparison with primary ones (P<0,05)

Figure 1. Changes of indices APc, APd и HR at carry out combined anesthesia with ketamine and propofole

At use ketamine in combination with sibazone at children the fast and smooth induction was observed, moreover, depending on dose in that or another level the cardio-respiratory effect as decrease of arterial pressure and reducing breathing, sometimes apnea at fast introduction of drugs, were present. Together with it the sibazone doses for induction anesthesia and its maintain are various depending on age and way of induction (induction dose is from 3 to 5 mgr/kg weight).

Discussion

At combined anesthesia with use ketamine and sibazone the smooth falling asleep of patients was marked during 30 – 60 seconds after bolus introduction of ketamine in dose 5 mgr/kg and sibazone in dose from 3 – 5 mgr/kg body weight, moreover, the disorder of breathing wasn't marked, the skin coverings were warm and had usual color. It was marked the increasing HR on 8,24%, decreasing APc on 6,68% и APd on 4,76% in comparison with initial data (tabl.2).

After introduction calculated dose of ketamine and sibazone the sedative effect was observed. Children began falling asleep and didn't react upon external sounds. The eyeballs made slow swimming movements, the pupils were constricted, their alive reaction to light was saved, the cornea was moist and shining, corneal reflexes were saved. The relaxation of muscular tonus was marked. The respiration rate decreased to 2-3 cycles per minute, moreover, its depth wasn't changed. The tendon and skin reflexes, warm, tactile and pain sensitivity were decreased. In 2-3 minutes was the loss of consciousness. The expressed changes of AP weren't marked either. After introduction ketamine in dose 4-5 mgr/kg body weight, the pupils were sharply constricted with preservation weak reaction to light. The reflexes were depressed. The breathing was smooth and deep. At introduction period of anesthesia, the increase APc index was marked on 7,98% and HR on 32,68% (P<0,05) in comparison with their initial data. At the period of maintain anesthesia the clinical displays were characterized with stability of general symptoms, being marked at the period of introducing narcosis. At the most traumatic moments of operation the researching indices were unauthentic measured.

The results of hemodynamic researches at children at carry out combined ahesthesia with ketamine and propofole are given in table 1. In comparison with initial data on premedication background the increase HR was on 25,27% and specific peripheral resistance (SPR) was on 24,52%. Other indices were little changed. At introduction period of anesthesia, the decrease of CI was on 10,64%, increase of HR was on 15,46% and SPR was on 25,58%. The indices BI, SAP, CI were changed a little in comparison with previous period. During the anesthesia maintain the definite indices changes of central hemodynamics were also observed. Thus, at the most traumatic operation stages in comparison with previous period the tendency to decrease indices CI on 2,38%, BI on 2,97% and SPR on 7,55%, moreover, HR increased on 12,52%.

Table 1. Indices of central hemodynamics in children at carry out combined anesthesia with ketamine, propofole and izoflurane

Indices	Outcome	Premedication	Introduction period	Traumatic stage of operation	Final stage of operation
BI ml/m^2	41,54±1,22	40,49±3,15	41,74±2,01	40,5±3,68	39,63±4,19
SAP mm.m.c.	88,85±1,21	91,2±2,93	94,22±3,75	87,81±4,0	85,44±2,56
HR min^{-1}	94,0±2,38	117,75±2,87*	117,93±3,93*	132,7±8,41*	136,01±8,45*
CI l/min x m^2	4,7±0,4	5,0±0,5	4,2±0,2	4,1±0,4	4,0±0,4
SPR con.un.	40,42±5,31	50,33±7,74	50,76±5,85	46,93±5,17	48,16±7,56

Note: * Authenticity of different indices in comparison with initial meaning (P<0,05).

The data on analogical researches of central hemodynamics at carry out combined anesthesia with ketamine and sibazone are given in table 2.

Table 2. Indices of central hemodynamics in children at carry out anesthesia with ketamine and sibazone

Indices	Outcome	Premedication	Introduction period	Traumatic stage of operation	Final stage of operation
BI ml/m^2	44,86±0,79	51,12±2,14*	49,08±1,91	50,34±2,15*	53,54±6,91
SAP mm. m.c	72,42±2,27	77,03±2,29	77,03±2,4	75,97±2,78	73,03±2,06

HR min^{-1}	92,14±2,09	125,26±3,07*	122,25±2,13*	130,52±5,23*	143,75±7,93*
CI l/min. x m^2	4,83±0,35	5,11±0,21	4,91±0,19	6,63±0,48***	8,03±1,39*
SPR con.un.	71,18±4,74	88,1±10,6	82,24±8,69	83,72±10,6	72,88±4,87

Note: *Authenticity of different indices in comparison with initial meaning (P<0,05). ** authenticity of different indices in comparison with previous stage of study (P<0,05). *** authenticity of different indices in comparison with initial and previous stages of study (P<0,05)

At introduction period of anesthesia, the increase of HR on 32,68% (P<0,05), SPR on 23,77%, BI on 9,41% in relation to their initial meanings were observed. At the most traumatic stages of operation the increase of CI, HR, SI accordingly to 37,27%, 41,65% and 12,22% (P<0,05), and, in comparison with previous stage of study these indices were changed unauthentically. At the end of operation in comparison with the stage of traumatic moment for operation the indices of central hemodynamics were changed a little., which had unauthentical character.

At all main stages in two groups of combined anesthesia the increase SpO_2 index was marked.

Thus, the study clinical symptomatology and noninvasive hemodynamic indices allowed to state that the course of given kinds of anesthesia was accompanied minimum hemodynamic shifts that witnessed on adequacy of anesthesia course.

Conclusion

1. Combined anesthesia with use little doses of ketamine, propofole in combination with inhalation izoflurane at small surgical operations at children was characterized with smooth clinical course, fast waking up from narcosis.
2. In condition of carry out anesthetic benefit with use ketamine, propofole and isoflurane the moderate changes of main indices in central hemodynamics without decrease of the heart performance were marked in children.
3. Use combined anesthesia with ketamine, propofole in combination with izoflurane is optimum method of anesthesia and safe independent breathing at carry out small surgical operation in children.

Abstract

Coronavirus infection COVID-19 (acronym for *Corona Virus Disease 2019*), formerly Coronavirus infection 2019-nCoV is a potentially severe acute respiratory infection caused by SARS-CoV-2. It is a dangerous disease that can take the form of an acute respiratory viral infection of the lung or a severe form, the specific complications of which may include viral pneumonia leading to acute respiratory distress syndrome or respiratory failure with a risk of death.

Keywords: *Melatonin, cell, production, infection, treatment*

Introduction

The disease is caused by a new virus, people have no acquired immunity to it, people of all age categories are susceptible to infection[1]. The virus is spread by airborne droplets through inhalation of sprayed droplets with the virus by coughing or sneezing, as well as through the virus getting on the surface and then getting into the eyes, nose or mouth. Effective preventive measures include frequent hand washing and observance of respiratory hygiene rules[2].

In about 15% of cases, the disease is severe with the need for oxygen therapy, and in 5% more patients are critical. Globally, as of 01 April, the mortality rate is estimated at around 5%. According to the analysis of data for 1099 patients as of February 28, 2020, 91.1% of patients with COVID-19 were diagnosed with pneumonia[3]. Figures may change over time.

On 11 March, the spread of the virus was declared a pandemic[4]. The epidemic is the first ever verifiable pandemic in human history[5]. It makes sense for Governments to prepare lists of trained personnel who can take control of the situation, as well as lists of medicines[6], personal protective equipment, supplies and equipment needed for treatment[7]. World Health Organization (WHO) encourages countries to train hospitals, protect health workers and decide whether some form of social distancing is necessary[8].

In response to the epidemic, the World Health Organization (WHO) has declared a public health emergency of international concern, and risks at the global level are assessed as very high[9]. The situation is developing rapidly, with a daily increase in the number of cases and deaths. Various scientific and clinical studies are being conducted[10].

The 2019-nCoV strain was first detected in December 2019 as a result of nucleic acid analysis in a patient with pneumonia[11].

Since the nucleic acid content is highest in the cell nucleus, it was named after the Latin word “nucleus” (“cell nucleus”, Latin).[12] However, nucleic acids are not only found in the nucleus, where they are definitely the most, but also in chloroplastics and mitochondria[13]. DNA and RNA nucleic acids are present in cells of all living organisms and perform the most important functions for storage, transfer and realization of hereditary information[14].

The coronavirus infection COVID-19 enters deeply into the cells to the level of the nucleus[15]. Once the virus (or its nucleic acid) penetrates the cell, the cell resources are switched to the synthesis of viral nucleic acid and proteins[16]. The genes are expressed. Gene expression is the process by which genetic information from a gene (DNA nucleotide sequence) is transformed into a functional product - RNA or protein.[17]

Some stages of gene expression can be regulated: transcription, translation, RNA splicing and the stage of posttranslational modification of proteins.[18] The process of activating gene expression in short double-stranded RNA is called RNA activation.[19]

When the cellular resources are exhausted, its shell is torn and ready viral particles are poured out of it.[20] This way, other cells are affected. Fibrous tissue is formed in the place of the bloated cell.[21]

Expression of genes is a substrate for evolutionary changes, as control over time; place and quantitative characteristics of the expression of one gene may have an impact on the functions of other genes in the body as a whole.[22] This is called a gene mutation. [22,23]

There are no specific antiviral treatments or prophylaxis against the disease yet. Since, to the level of the nucleus is not yet reached any antiviral drug.[24]

In most cases (about 80%), no specific treatment is required and recovery takes place on its own.[25] Severe forms of disease are more likely to develop in older people and in people with certain diseases, including asthma, diabetes and heart disease. In severe cases, means are used to maintain the functions of vital organs[26].

Today we want to tell you about melatonin, the "sleep hormone".

Melatonin is a hormone that is naturally secreted by our body and whose functions are crucial for our physical and mental well-being.[27] It is closely linked to the control of circadian rhythms, our biological clock, and thus helps us sleep better.[28]

Among other things, this substance is involved in neuroendocrine, neurophysiological and immune processes, which are necessary for many vital tasks of the body.[29] However, its production takes place only at night and, if something prevents it, a person has trouble sleeping and a good rest.[30]

Melatonin hormone was discovered in 1958 by A.B.Lerner. It is the main hormone of epiphysis - the organ that transmits information about the light regime of the environment into the internal environment of the body.[31] Changes in melatonin concentration have a noticeable daily rhythm - usually a high level of the hormone during the night and low levels during the day.[32] Maximum concentrations of melatonin in human blood are observed between midnight and 5 am local sunshine time. Melatonin is produced by the main secretory cells of epiphysis - pinealocytes.[33]

The biological half-life time of melatonin is 45 minutes. This means that for research purposes, blood samples must be collected at short intervals in order to determine the period of melatonin production.[34] In addition, a patient's sleep disturbance during the night in order to collect samples may affect the blood melatonin levels. These problems can be avoided by determining melatonin metabolite levels: melatonin sulfate (6-sulfatoxymelatonin) and 6-hydroxyglucuronide in urine. 80-90% of melatonin is secreted to the urine as melatonin sulfate. The concentration of melatonin sulfate in the urine correlates well with the total level of melatonin in the blood during the collection period. [35]

Melatonin synthesized in epiphysis enters the blood and cerebrospinal fluid, the liquor, through which it accumulates in the hypothalamus. In addition to blood and cerebrospinal fluid, melatonin is found in urine, saliva and amniotic fluid[36].

Melatonin is a rare example of a hormone that has both membrane and nuclear receptors[4].

In the human body melatonin is synthesized from the amino acid tryptophan, which is involved in the synthesis of neurotransmitter (neurotransmitter) serotonin, and it in turn turns into melatonin under the influence of the enzyme N-acetyltransferase.[38] Melatonin has been shown to be an indole derivative of serotonin and to be synthesized at night by the enzymes N-acetyltransferase and hydroxyindol-O-methyltransferase. About 30 μg of melatonin is synthesized in an adult during the day, its concentration in serum at night is 30 times higher than during the day, and the maximum concentration is about 2 hours of the night local sun time, on average for many observations.[39] Melatonin is transported by serum albumin, after liberation from albumin it binds to specific receptors on the membrane of target cells penetrates into the nucleus and there performs its action. Melatonin is quickly hydrolyzed in the liver and excreted with urine; the main metabolite is 6-hydroxymelatonin sulfate, the content of which allows to indirectly judging the production of melatonin epiphysis.[40]

The body also contains melatonin, which is formed outside the epiphysis. This discovery was made in 1974 by Russian scientists N.T. Reichlin and I.M. Kvetnoy, who discovered that melatonin is synthesized in cells of the worm-like intestinal process.[6] Then it turned

out that melatonin is also formed in other parts of the gastrointestinal tract, as well as in many other organs.

The secretion of melatonin is subject to the daily rhythm, which in turn determines the rhythmicity of gonadotropic effects and sexual function. Synthesis and secretion of melatonin depend on the illumination - excess light reduces its formation, and a decrease in illumination increases the synthesis and secretion of the hormone. In a person with a normal daily routine (sleep at night), melatonin accounts for approximately 70% of the daily production of melatonin. In clinical conditions, it has been established that sleep deprivation during night hours leads to a disturbance in the daily rhythm of melatonin production - production at night is reduced and approaches the daily level.[2,13]

Melatonin secretion rhythm shift also occurs when flying to other time zones.

Melatonin is also known as N-acetyl-5-methoxytryptamine and N-[2-(5-Methoxy-1H-indol-3-yl) ethyl] acetamide.

Melatonin production depends entirely on the biological clock of the human body and the change of the natural day-night cycle. Since melatonin production depends on the length of the daylight, many animals use it as a «seasonal clock». People, like animals, have *less melatonin in summer than in winter*.

So, melatonin can regulate the functions that depend on the photoperiod - reproduction, migration behavior, seasonal molting. In bird and mammal species that breed at long bottoms, melatonin suppresses gonadotropin secretion and reduces sexual activity. In animals that breed at a short light day, melatonin stimulates sexual activity. The effect of melatonin on reproductive function in humans has not been sufficiently studied. During puberty the peak (night) concentration of melatonin decreases sharply. In winter the number of menstrual cycles not ending in ovulation is on average higher than in summer. In women with pituitary amenorrhea the concentration of melatonin is reliably higher than in healthy women. These data suggest that melatonin suppresses reproductive functions in women.

Melatonin is a solid, absorbing or dissolving fat, a water-soluble substance that is a powerful *natural antioxidant*. By synthesizing it, the body is protected from the excessive formation of free radicals - metabolic products that cause rapid aging and cancer.

Melatonin has a unique ability, unlike other antioxidants, to penetrate into any cell in any part of the body and have a specific protective effect on the nucleus - the central structure of the cell containing DNA, i.e. the structure that *allows the damaged cell to recover*. Melatonin is known to have a stimulating effect on the enzyme glutathionoperoxidase, which has antioxidant properties. Melatonin may also exist in a synthetic form, which is used as an additive with sleeping pills and antioxidant properties. This becomes relevant with age when the activity of the body's internal secretion glands dies out.

Antioxidant Effect: Melatonin neutralizes the damaging effects of oxidation processes, which are the main cause of skin aging and ageing. The most important function of melatonin is its antioxidant activity, which manifests itself everywhere in the body, as melatonin penetrates all organs and tissues. The mechanism of antioxidant action is manifested in the fact that melatonin has a pronounced ability to bind free radicals, including those formed by the lipid peroxidation of hydroxyl radicals, and exogenous carcinogens, and it activates glutathione peroxidase - a factor in protecting the body from free-radical damage. The main functions of melatonin's antioxidant action are aimed at *protecting DNA*. To a lesser extent, it protects proteins and lipids.

Melatonin is the strongest known endogenous free radical absorbers. In recent years, there has been evidence that melatonin can be found not only in plasma, but also in the nuclei of cells and protect the nucleus macromolecules from oxidative damage in all subcellular structures.

Immune stimulating effect: An important consequence of long-term stress is stress immunodeficiency. Melatonin helps to normalize immunological indicators.

Melatonin and other epiphyseal hormones may be classified as geroprotective. A connection has been established between the degree of age-related epiphysis involution and tissue shriveling. It is known that in aging the degree of immunological protection decreases, and melatonin, as has been repeatedly stated, has immunomodulatory activity. With age, the concentration of melatonin in human blood decreases. When its level decreases below 20% of the norm, the leukocytes stop recognizing parasites in the blood and viruses, the infection of the organism starts.

Melatonin stimulates the immune system (immunostimulant) as it participates in the regulation of thymus and thyroid function, increasing the activity of T-cells and phagocytes, which is a warning for a number of diseases and, as laboratory studies show, slows down the growth of seven types of cancer cells, including breast and prostate cancer cells.

Lack of melatonin in the body: Experiments on laboratory animals showed that with melatonin deficiency caused by the removal of receptors, animals began to age faster: earlier menopause began, free radical cell damage accumulated, insulin sensitivity decreased, obesity and cancer developed.

Melatonin extrapine synthesis: The amount of hormone that is produced in the pineal gland is not enough to provide so many biological effects of melatonin. Studies have shown that significant amounts of melatonin are found in the blood of experimental animals after pineal gland removal. It is now firmly established that the pineal gland is not a monopolistic organ of melatonin production. Extrapineal sources of melatonin synthesis are enterochromaffin cells of gastrointestinal tract (EC-cells), main serotonin depot cells (contain up to 95% of all endogenous serotonin) - melatonin precursor. This hormone has been synthesized in a large number of neuroendocrine cells of airways, lungs, in the cortical layer of kidneys and along the border between the cortical and cerebral adrenal layer, under the hepatic capsule, in paraganglia, ovaries, endometrium, prostate, placenta, gallbladder and inner ear. Melatonin synthesis has also been found in non-endocrine cells such as fat cells, lymphocytes, platelets, eosinophilic leukocytes, in the thymus, pancreas, cerebellum, eye retina and in some endothelial cells.

Functionally, many cells producing melatonin belong to the so-called diffuse neuroendocrine system - a universal system of adaptation and maintenance of homeostasis in the body.

Within this system there are two melatonin links in the producing cells:

- Central (includes the pineal gland and visual system cells), where the rhythm of melatonin secretion coincides with the rhythm of "light-dark";
- Peripheral - all other cells where the secretion of the hormone does not depend on light.

With age, the activity of epiphysis decreases, so the amount of melatonin decreases, sleep becomes superficial and restless, sleeplessness is possible.

Symptoms of melatonin deficiency

- Insomnia and other sleep disorders
- Violation of sleep and waking cycles
- Weakening the immune system
- Fluctuations in blood pressure
- Disorders of mental adjustment
- Anxiety and depression conditions

The main causes of disturbance of natural melatonin production:

- Disturbances in sleep and waking,
- Regular consumption of alcohol and nicotine
- Unbalanced nutrition
- Natural decrease in melatonin production with age
- Shift schedule, night shifts
- Sleeping in an illuminated room

Aspirin, beta-blockers can reduce melatonin levels in the body. Sedative antidepressants, tranquilizers and other sedatives may reduce the expected effect.

Returning to the beginning, almost all bats (as well as winged bats in general) lead nightlife and sleep during the day. In addition, bats often take shelter in cracks in trees, rocks or cracks in buildings. Sanctuaries can be caverns in trees, caves, grottoes and various artificial structures, both aboveground and underground. Bats are able to fall into a daze, accompanied by reduced metabolic rate, breathing intensity and heart rate; many can fall into prolonged seasonal hibernation (up to 8 months). Retinol and tocopherol levels in bats have been found to be high enough to withstand the absence of bonded antioxidants for a long time while maintaining the reserves required for reproduction.

Bats are a natural reservoir of rabies and, according to the WHO, Marburg, Ebola and coronavirus viruses are among the most dangerous infections, a list of the most dangerous known pathogens for humans that cause fatal diseases. There is evidence of the involvement of bats in transmission.

Conclusions

1. Melatonin production decreases with age, which may adversely affect the clinical course of coronavirus infection COVID-19.
2. Unhealthy lifestyle reduces melatonin production.
3. Medicines reduce melatonin levels.
4. Melatonin makes bats not die, but become carriers of infection.
5. The number of coronavirus infected during the summer months may increase by lengthening the daylight hours. Excess light reduces melatonin formation.

Recommendations: The usage of Melatonin in the treatment of patients with coronavirus COVID19 may have a beneficial effect on the outcome and outcome of treatment. Thus, Exogenous Melatonin activates killer cells and monocytes in both bone marrow and spleen with a latency period of 7-14 days. These are components of nonspecific immune protection; some authors believe that melatonin can block tumor growth and destroy infected cells. Melatonin has been found to stimulate the synthesis and release of opioid peptides and thus participate in the regulation of cell hemopoiesis and humoral immunity. The introduction of melatonin in vaccination potentiates the production of specific antibodies. It is known that under stressful and significant physical activity there is an activation of pro-inflammatory factors (cytokines and eicosanoids), the level of alpha tumor necrosis factor (TNF-α) increases, and the level of lymphocytes in blood increases. Lipopolysaccharides (LPS) potentiate these effects - a situation that can occur under inadequate, draining the body's defenses physical activity. At the same time, there are increasing manifestations of oxidative stress, which leads to the violation of the integrity of the hemato-intestinal barrier and LPS in the blood. The fact that melatonin suppresses the inflammatory reaction in response to physical activity should be taken into account in the preparation of athletes and recovery activities in people engaged in hard physical work. Due to its antioxidant and anti-inflammatory properties, melatonin can reduce stomach mucosa damage caused by many damaging factors: stress, alcohol, bile and non-steroidal anti-inflammatory drugs.

Activation of macrophages in pathological conditions leads to an increase in nitric oxide (NO) production. This process is not indifferent to the body and can lead to the development of degenerative diseases. Melatonin inhibits these changes by inhibiting the expression of inducible macrophage NO-synthesis. The introduction of pharmacological doses of melatonin prevented the development of damage in vivo, and inhibited peroxidation and induction of NO in cell culture of the large intestine.

Thanks to intensive research in recent years, there have been reports of the successful use of melatonin in bacterial meningitis as a protection for brain neurons from damage, to normalize sleep and general condition in attention and hyperactivity disorder, in sleep phase disorders syndrome, migraine and headache attacks, in complex therapy of multiple sclerosis, chronic fatigue syndrome, bronchial asthma night attacks, fibromyalgia, irritable colon syndrome, respiratory distress of newborn syndrome.

Nevertheless, the research of the chemical and biological properties of melatonin allows its wide application in medical practice, as experimental data confirm its positive effect on the course of both physiological processes and leveling of many pathological conditions.

Abstract

Diabetes mellitus and its complications are considered far from unresolved problems of modern medicine. An important aspect in solving fundamental problems is experimental research aimed at assessing the state of change of pathogenetic important key positions in the development of such a formidable complication of diabetes as angiopathy. On the other hand, surgeons' great interest in bariatric and metabolic surgery, as method of surgical treatment of type 2 diabetes mellitus, requires in-depth studies to assess the state of angiogenic changes in the organs of the gastrointestinal tract, namely in the intestine. The article describes the morphological changes in the vascular capillary bed in the dynamics of the development of a new experimental model of diabetes mellitus, namely the chemical method of diabetic angiopathy. The development of an experimental model of diabetic angiopathy showed the staged nature of the changes in the form of the initial signs of angiopathy, with perivascular infiltration and edema in the form of congestive plethora in the flesh until the development of vascular hyalinosis, which indicates the irreversibility of the processes of pathological transformation. Thus, the results of morphological studies in the dynamics of modeling of diabetic angiopathy indicate the development of diabetes mellitus with its complication in the form of microangiopathy.

Keywords: *Diabetes mellitustype 2, microangiopathy, vascular morphology, diabetic angiopathy, bariatric surgery, obesity.*

Introduction

One of the important world problems of drug therapy for type 2 diabetes, along with the prevalence of this disease, is its lack of effectiveness. It is known, that compensation of type 2 diabetes mellitus, through its traditional treatment, reaches only 30% of patients, and remission in a minimal proportion of patients [1]. Nowadays, it has been proven, that a clinically significant alternative in the treatment of type 2 diabetes is bariatric surgery, which is used in patients with obesity[2], i.e. with a BMI (body mass index) above 35 kg/m2 and providing attainment of diabetes compensation in 76.8% of cases[14].

The great clinical interest are the possibilities of surgical treatment[3] of type 2 diabetes mellitus in patients with normal or reduced body mass index[15]. However, the effectiveness of such operations[4] requires fundamental research in the experiment, proving the safety and effectiveness of this procedure, including taking into account the existing pathomorphological transformations as a form of diabetic gastropathies and enteropathies[5]. The basis of their pathogenesis[7], of course, is the development of diabetic angiopathy[8].

The literature presents the results of experimental studies of the effect of bariatric and metabolic operations on the condition of the mucous membrane of the stomach and intestines, in particular, changes in its cellular balance[9]. Nevertheless, there is no information regarding the characteristics of angiogenic changes in the intestinal walls and stomach in the background of progression of type 2 diabetes. In turn, this would make possible to evaluate objectively the positive and negative aspects of the effect of these operations in the treatment of type 2 diabetes with a normal body mass index, but with the presence of diabetic angiopathy.

Materials and Method

In the experiment were used laboratory Wistar rats weighing 150-250 g on a normal laboratory diet. By the beginning of the experiment, each group consisted of 10-12 rats. 112 animals were used overall.

Diabetic microangiopathy in animals was modeled according to original technique developed by us ("A method of modeling diabetic angiopathy" Patent No. IAP 03642 PV RUz of 2006). The simulation was carried out as follows: laboratory rats weighing 150-250 grams on an empty stomach under ether anesthesia were injected 100-110 mg/kg of doxorubicin with 0.9% sodium chloride solution intraperitoneally, and 48 hours later, they were once daily injected intraperitoneally for 3 days 0.2-0.4 ml of a 70% sorbitol solution. In dynamics, starting from the first day after the injection of the last dose of sorbitol, we observed the development of diabetes mellitus and the manifestations of its angiogenic complications. The main criterion in the reproducibility of the disease was the presence of a stable level of glycemia (at least 9 mmol/l on an empty stomach) starting from the 3rd day after doxorubicin injection. Over the next 30 days, the animals developed diabetic microangiopathy. Animals with normal glycemia level were removed from further researches, and the results obtained during the studies were canceled. Carbohydrate metabolism: blood glucose (mmol/l) was determined on a VitrosDT-60 automatic biochemical analyzer (Austria) using reagents express medical chemistry.

For histological examination, Pieces of the studied intestinal zone were fixed in neutral formalin, Carnoy fluids and embedded in paraffin. Cross-sections were stained with hemotoxylin-eosin according to Van Gieson. Light microscopy and morphometry were carried out on a XSZ-20 trinocular microscope (China) with an optical resolution of 4x to 400x with a direct electronic nozzle in digital format.

Results

With a 5-day period of the experimental model, there were noted mild manifestations of diabetic microangiopathy.

They were manifested a certain increase in proliferation and swelling of arteriole endothelial cells, and areas of plasma impregnation of their walls, mainly in subendothelial zones with plasma proteins, detected in the form of small foci.

Swelling of endotheliocytes in some places was accompanied by destructive changes in some of them. Sometimes perivascular edema and weak lymphohistiocytic infiltration around individual arterioles were detected.

On the 10th day of observation in the capillaries and venules, were noted along with the phenomena of stagnant flushing, with a tendency to hemolysis, thinning of the walls of vessels containing, in addition to red blood cells, a lot of neutrophils.

On the 20th day of the reproduction of diabetic microangiopathy morphologically, more significant disorders of most capillaries and arterioles were observed, compared with those of the previous observation period. They manifested themselves in a marked swelling of endotheliocytes, flattening of the nuclei with a thickening of their basement membrane, and in some cases, their desquamation into the lumen of the vessels. Plasma impregnation with fixation of plasma components in the subendothelium was observed in the vessel wall. In addition to thickening of the basement membranes in arterioles, thickening of their layers and the presence of pericytes in small vessels were observed. Around the blood vessels revealed edema and perivascular infiltration.

On the 30th day of the reproduction of diabetic microangiopathy, the lumen of the capillaries looked wide with the phenomena of stagnant flushing. Some of them were in a state of thrombosis (Fig. 3). Arterial capillaries were characterized by changes in blood cells in the form of adhesion of red blood cells to the surface of endotheliocytes, and in some places, to the basement membrane. In addition to narrowing the lumen of some arterioles, due to thickening of the walls, as a result of plasma soaking, swelling and desquamation of endothelial cells in their lumen, sections of thinning of the walls were found (Fig. 4) with the release of red blood cells.

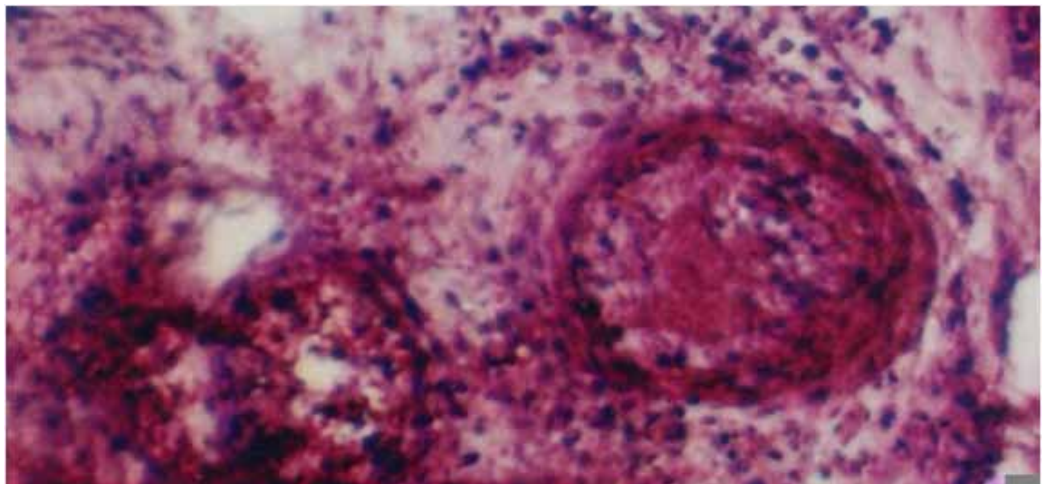

Figure 1. 30 days of modeling diabetic microangiopathy. Flushing of capillaries with signs of thrombosis and adhesion of red blood cells to the basement membrane. Hemotoxylin and eosin. Enlarged 400x.

Venules were characterized by widened lumen and severe perivascular infiltration.

40 days of modeling diabetic microangiopathy were manifested pronounced swelling of endothelial cells, its hypertrophy, destruction, detachment from the basement membrane, and their rejection into the lumen of the vessel.

Discussion

Sometimes, processes of pericytes or smooth muscle cells were immersed in the formed cracks. The marked thickening of the walls of most arterioles was accompanied by hyalinosis of their walls, which was both segmental and circulatory nature. A more significant, compared with the early observation period, plasma impregnation of the vessel walls was revealed, moreover, it was observed in all layers. A significant thickening of the walls of the arterioles occurred, mainly due to an increase in the thickness of the endotheliocytes' basement membrane. In some cases, it's profusion into the lumen of the vessel was determined, leading, together with the above changes, to a significant narrowing of it or complete obliteration (Fig. 6). In separate observations, on the 50th day of modeling, re-calibration was detected in arterioles, leading to occurence of "vasa vasorum". (fig 3).

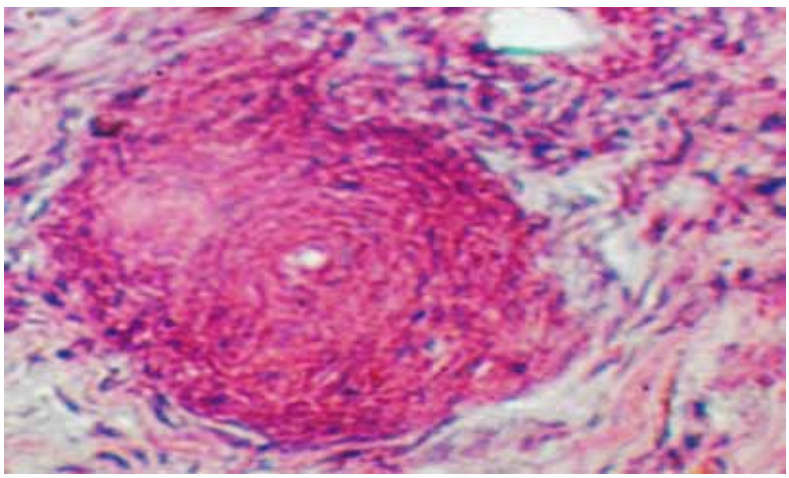

Figure 2. 40th day of modeling diabetic microangiopathy. Hyalinosis, thickening of the arteriole wall with a sharp narrowing of the lumen (obliteration). Hemotoxylin and eosin. Enlarged 400x.

In the later stages of the experiment (60-80th day), maintaining all of the above morphological signs of microangiopathy, the phenomena of complete loss of the endothelial lining by the hyalinized vessels are noted. In view of this, they were represented by acellular tubules which lumen was filled with nests of red blood cells, with the occurrence of thrombosis. These terms were characterized by significant problems of blood cells, in particular, the phenomena of hemolysis, and areas of thrombosis. As a result of this, erythrocytes redistributed to the surface of endotheliocytes (Fig. 4).In addition to the accumulation of erythrocyte aggregates resembling the shape of mulberries, swollen and torn away from the basement membrane endotheliocytes clogged the lumen of the vessels. Moreover, in some cases, perivascular pronounced proliferation of connective tissue, forming a kind of connective tissue "couplings", was observed.

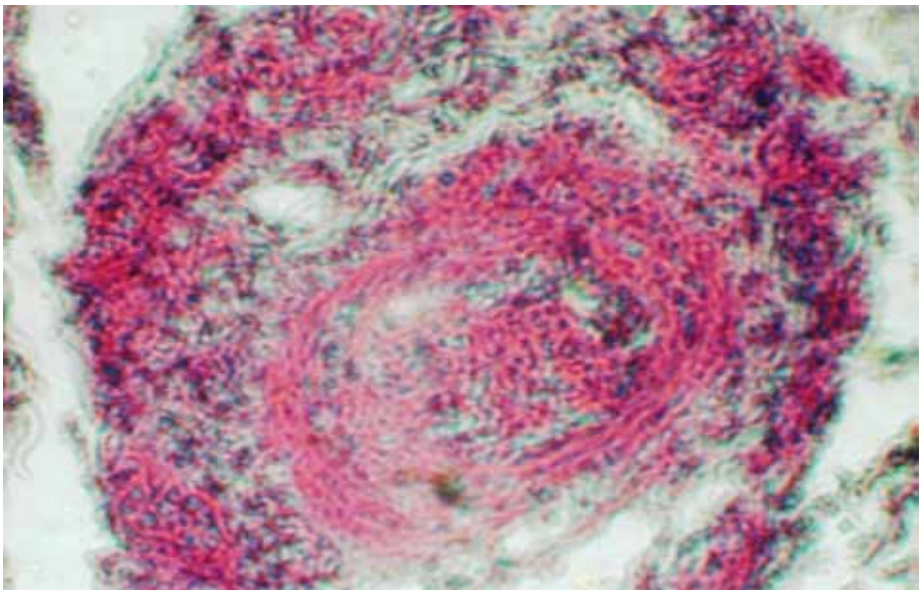

Figure 3. 50th day of diabetic microangiopathy. The phenomenon of percolibration with the advent of "vasa vasorum". Hemotoxylin and eosin. Enlarged 400x

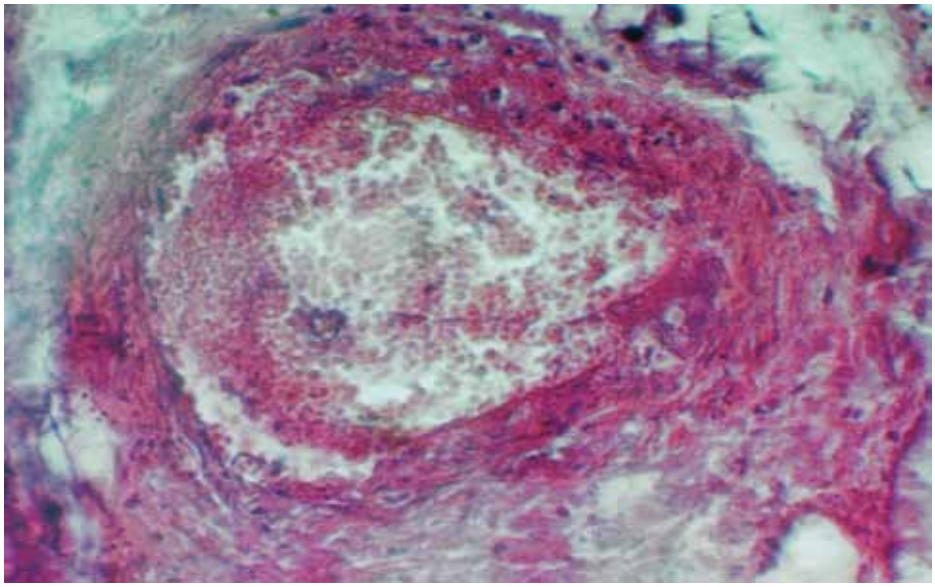

Figure 4. 60th day of modeling diabetic microangiopathy. Hyalinosis of the wall of the arterioles with a complete absence of the endothelial layer, the phenomenon of hemolysis of red blood cells with their location at the basement membrane. Hemotoxylin and eosin. Enlarged 400x

Conclusion

Thus, the results of our morphological studies in dynamics from 5 to 80 hours show that diabetic microangiopathy leads to the diabetes mellitus with its complications, which indicates the presence of damaged vessels when a distinct degree of microangiopathy is seen. This is due to pathomorphological changes in blood vessels. It is characteristically, that changes in experimental diabetes mellitus were exposed to all structural components of the vascular wall.

According to a number of authors, diabetes mellitus is a metabolic disease, called diabetic microangiopathy [10]. For this, the most characteristic morphological sign is the presence of a pronounced degree of severity of thickening of the basement membranes, plasma impregnation[11], hyalinosis of the walls of capillaries and arterioles, narrowing of lumen of blood vessels, proliferation of endothelial cells, perithelium, their destruction and rejection, changes in the rheological characteristics of blood [12].

You know, that diabetes mellitus with diabetic microangiopathy for 80 years is the result of all pathogenetic changes:

I period up to 10 hours: the allocation of mild signs of angiopathy with swelling of the endothelium, arterioles, soaking their walls, plasma protein, perivascular infiltration and edema in the form of stagnant congestion. Thinning of the walls of the capillaries was observed.

In the II period of experimental modeling (days 20-30), progressive processes are observed, which manifest themselves in deeper structural changes in the main vessels. In addition to plasma impregnation of the subendothelial departments of arterioles, proliferation of endothelial and perithelial cells, as well as their desquamation, enlightenment due to leakage of the walls was observed. It was also noted the expansion of the lumen of small vessels, their stagnant congestion, infiltration of adventitia layers.

III period (40-80th day) was characterized by a more significant development of morphological signs of diabetic microangiopathy. Along with morphological changes identified in the early stages, the phenomenon of hyalinosis of the majority of the walls of the arterioles, as well as their marked plasma soaking, were noted. Swelling and detachment of endotheliocytes with intercalation of smooth muscle cells into the vessel wall with their perical calibration and the formation of vasa vasorum, as well as a significant narrowing of the lumen of arterioles. At the same time, perivascular edema, infiltration and proliferation of connective tissue were observed. Changes in blood cells were manifested in their tendency to hemolysis, adhesion on the lumenal surface, the appearance of red blood cell aggregates with the development of thrombosis. Moreover, a pronounced lesion of endotheliocytes, their detachment from the basement membrane led to an increase in the clearance of arterioles, and the reaction of smooth muscle cells and pericytes contributed to the thickening of the basement membranes. Prolonged plasma impregnation causes the development of hyalinosis in microvessels.

Abstract

Habitual miscarriage is currently one of the most frequent complications of the gestational process, which is diagnosed in 10-25% of pregnant women. (IuA, 2017) Habitual abortion (miscarriage) - spontaneous interruption of pregnancy two or more times in a row.

So, high expression of miR133a may mediate a decrease in HLA-G expression at the protein level and may be implicated in the pathogenesis of habitual miscarriage, since HLA-G provides immune tolerance in pregnancy[49]. So, the literature data suggest that microRNA dysregulation may be related to the pathogenesis of various obstetric complications, but accurate methodological approaches to the diagnosis and prediction of pregnancy complications using microRNA require further study.

Keywords: *Microrna, pregnancy, placenta, gene.*

Introduction

In some countries, three or more abortions are considered habitual, but examination for the cause of the abortion is recommended after two abortions[2]. The frequency of Habitual miscarriage in the population is up to 5% of pregnancies. In the structure of miscarriage, the frequency of miscarriage is up to 20%. Habitual miscarriage is a polyethological complication of pregnancy based on reproductive disorders[1] The causes of miscarriage, both episodic (single or repeated) and recurrent (loss of three or more consecutive pregnancies), are similar. They can be combined into the following groups: genetic, infectious, endocrine, anatomical, immunological, and idiopathic[3] Biomarkers, which are present in the mother's serum, will be the most valuable, as obtaining the mother's blood is a safe and affordable method, and blood can be obtained in sufficient quantities.[4] The exchange of information between the functional systems of the mother and fetus is important for normal pregnancy, fetal development and growth. This connection reduces the risk of rhesus conflict and coordinates biological resources for the benefit of both organisms. Previously, the mother-fetal link was thought to provide hormones and growth factors that are soluble in the blood or bound protein carriers and serve as paracrine or endocrine signals to control healthy pregnancy. It is now clear that nucleic acids, and especially small RNA molecules, circulate between tissues and affect them at the cellular level.

The main class of non-coding RNA and one of the most well studied is the family of small regulatory RNA called micro-RNA. The term micro-RNA was first introduced in the early 2000s. Micro-RNA were originally described in the Caenorhabditis Elegans nematode in 1993 and later were found in the genome of many organisms, including humans. The human genome encodes more than 1000 micro-RNA species and about 60% of the human and other mammalian genes are targeted[5]

Micro-RNA's (miRNA's) are endogenous RNA's ranging in size from 20-22 nucliotides that can play

an important regulatory role in animals and plants by targeting mRNA's for cleavage or translational repression. Oligonucleotide micromatrixes have shown that microRNAs are highly enriched in the placenta. (Wu et al., 2012) RNA-induced jamming complex to the RNA target, with subsequent weakening of gene expression by inhibiting matrix RNA (mRNA) translation and/or RNA degradation. This is accomplished by complementary binding their «seed sequence» to the target in the 3'-nontransmitted mRNA region either by detaching the Cap 5'-structure (decapitation) or deadenylating the poly(A)tail. Consequently, they participate in transcription and posttranscriptional regulation of gene expression and play an important role in various biological processes[6].

Cells transcribe microRNA precursors (primary transcripts) (PRI-microRNA), which undergoes multistage biogenesis with the formation of mature microRNA 18-25 nucleotides in length. The synthesis of microRNA begins in the nucleus, with RNA polymerase II-mediated transcription, using genomic DNA as a matrix. A long primary microRNA (known as PRI-microRNA) is then formed, which forms a complex secondary structure by folding loops and studs.) The dual-chain structure of RNA can be easily recognized by the nuclear protein DGCR8, which functions in combination with Drosha, the protein that cuts through RNA, due to the catalytic domain of RNAase III, forming a precursor microRNA molecule in the form of a stud. PRE-microRNA can bind to the nuclear transport factor, the exporter-5, and is exported to the cytoplasm by the energy of guanosine triphosphate. In cytoplasm, PRE-microRNA is broken down by endonucleases specific to double-stranded RNA, resulting in the formation of microRNA: duplex of ~22 nucleotides in length. As a rule, only a few can bind to Argonaute proteins in the RNA-induced Gene Jamming Complex (RISC) and participate in the RNA interference process. The remainder is destroyed by the gene jamming complex. miRNA's specifically expressed in human placenta were found in the sera of pregnant women and were found to be significantly elevated in comparison with those of non-pregnant women; their levels increased with gestational age and decreased after delivery, providing a new group of molecular markers for monitoring pregnancy[7].It should be noted that the expression profile of tissue-specific and disease-associated microRNA's is more selective and stable than the general mRNA profile. The biological efficacy of specific mRNA's is in their subsequent conversion into specific proteins as compared to microRNA's, which act as key regulators of polymer genes. So, microRNA more accurately reflects physiological changes in the body. After long researches it was proved that microRNA is everywhere present in body fluids and the mechanism of genetic exchange between cells in horizontal order takes place. Circulating or extracellular microRNA's are more stable and protected against RNAase degradation. This protection is achieved either by complexes with different proteins or by inclusion in different types of extracellular vesicles. MicroRNA's have been shown to be ten times more stable than mRNA's, which have a half-life expectancy of ~10 hours. The average half-life of microRNA, according to a mathematical model, is 119 h and some microRNA's, such as 125b microRNA (half-life, 225 h), are more stable than others. This is probably due to their inherent structural features[8]. The use of single-primer real-time PCR or real-time PCR using high-capacity platforms ensures that quantitative analysis of microRNA from tissue or plasma/serum will be easier and more accurate. This highlights the ease of using microRNA as a biomarker for the development of practical method to detect obstetric pathology. MicroRNA analysis shows that tissue diversity is reflected in the microRNA expression profile. In addition, the expression profile of pathological tissue differs significantly from that of normal tissue, which can be useful for clinical diagnostics. So, aberrant microRNA expression is associated with cellular dysfunction and a number of pathological conditions such as cancer, inflammatory and immune diseases, cardiovascular disorders[9]. Abnormal expression of miRNA's has been observed in multiple diseases of the human reproductive tract, including preeclampsia, endometrial endometrial adenocarcinoma, leiomyoma, and ovarian cancer, endometriosis, and pregnancy recurrence. The following review provides an update on the role of microRNA and gynaecological diseases, covering not only the impact of microRNA regulatory violations on the origin of each disease, but also shows the potential useful diagnostic and therapeutic tool that miRNA can play in these gynecological pathologies[10]

The increased expression of specific microRNA's causes a repressive transmission from the mRNA target, while the decreased expression of these microRNAs has the opposite effect. These changes in mRNA translation define a distinct protein expression profile, affecting multiple molecular pathways, and induce many different

cell and tissue changes. Thus, the cumulative effect of multiple microRNAs can affect human health as well as determine the outcome of a particular disease. These data may allow for a better understanding of changes associated with genital tract diseases and may be useful for developing newer therapeutic approaches as well as less invasive and more effective diagnostic tools[11]. MicroRNAs play an important role in regulating many events, such as inflammatory and immune responses, cellular cycle, differentiation, apoptosis and tissue remodeling. The precise regulation of the expression of these genes is fundamental to the normal functioning of the endometrium. Thus, dysregulation of microRNA expression is associated with certain gynecological pathological processes such as endometriosis, leiomyoma and habitual miscarriage[12]. The microRNA expression profile has been shown to be more important than the mRNA expression profile for discriminating normal and pathological tissues. As a result, microRNA may have a significant impact on the development of new and more accurate diagnostic method as well as more effective therapeutic approaches. A number of microRNAs specific to the human placenta have been detected using the Real Time Polymerase Chain Reaction (PCR-RT) method, each of which has an individual expression level[12]. Some specific microRNA (microRNA516-5p, 517*, 518b, 520a*, 520h, 525 and 526a) are considered pregnancy-specific microRNAs. The importance of mRNA in early embryo development has been identified in a number of species, from Caenorhabditis elegans to mammals.[13-18]It has been shown that in these organisms miRNA-supplied gene regulation is necessary for normal embryogenesis, as evidenced by the reduced survival of embryos in mutant embryos.

The importance of microRNA is confirmed by the fact that deletion of Dicer1 gene (Dcr-1) in mice leads to stopping embryo development on 7.5 days due to differentiation defects[19]. Jan et al.[20] reported similar effects between 12.5 and 14.5 days of pregnancy due to altered embryonic angiogenesis, which also appears to be regulated by microRNA. These researchers have demonstrated that, since miRNAs act as posttranscriptional suppressors of target genes, a defect in Dicer leads to defects in miRNAs. This, in turn, causes the over-expression of target genes such as Ang-1 and PTEN in embryos. In the same way, Medeiros et al [21]. have demonstrated that miRNA Mir-290-295 deficiency leads to partial embryo death and germ cell defects. Micro-RNAs are also highly expressed in human embryonic stem cells. [23]. Rehn and Co. found that miR-520 may be closely involved in human embryonic cell function. Other miRNAs, such as miR-302 and miR-200 families, were similarly observed in human [30] and mouse embryonic stem cells[31]. Rosenbluth et al.[34] studied 754 microRNAs, were expressed in 14 blastocysts (five females, four males and five aneuploid embryos) with matrix screening. They confirmed using real-time quantitative PCR (RTR) the most expressed microRNAs including miR-372, miR-720 and miR-302c in 27 blastocysts (seven males, eleven females and nine aneuploids). These researchers observed that human blastocysts express a large number of microRNAs, which are necessary for the survival and development of embryos, as well as to preserve pluripotency of stem cells. Most of them have already been registered in human embryonic stem cells[29] mammalian embryos[35] or primate placenta[37]. Moreover, when comparing male and female embryos, these researchers found that one miRNA, miR-518d-5p, was expressed 5.6 times in male embryos, indicating some degree of sexual differentiation even at the blastocyst stage. Interestingly, Mir-518d-5p mRNA belongs to C19MC cluster, the largest human cluster where miRNA genes are organized. In these clusters, miRNA genes are expressed only in the placenta and can participate in the development and implantation of the placenta. Similarly, miRNA expression was found to be higher in mouse embryos than in mature tissues, confirming their role in embryo development [38]. More recently, Rosenbluth et al.[39] have demonstrated that miRNA can be detected in In Vitro Fertilization (IVF) culture media where they are differentially expressed according to the fertilization method, chromosome status and pregnancy outcome. These results show that miRNAs are potential markers for predicting success after IVF[40].

Concentrations of some other microRNAs are significantly higher in plasma in pregnant women than in non-pregnant women. Moreover, the concentration of some microRNAs (e.g. microRNA 141) increases with increasing gestation period[41]. The highest intensity of expression in the placenta is typical for microRNA 517a, 517b, 516b, 525 -5p, 512-3p, 515-3p[42]. It is also noted that microRNA 517a-3r, 519 a-3r, 520 s-3r are determined in mesenchymal stromal cells of the placenta, being an indicator that the specific functions of the placenta are not limited only to the trophblast. At the same time, the intensity of microRNA expression of 125b5p in the trofooblast is much higher in the third trimester compared to I. The different expression of microRNA patterns in the nap tree of the placenta in

the first and third trimesters of pregnancy highlights the individual profiling of microRNA and ensures normal development of the placenta. Therefore, the level of microRNA expression can be an indicator of placenta changes during pregnancy depending on the period of gestation and development of the choroid branches[8]. The search for microRNAs that could serve as biomarkers of complications during pregnancy was initiated by Chim and colleagues in 2008. At the time, about 100 microRNAs were known to be expressed primarily in the placenta, but it was not known whether microRNAs obtained from the placenta would be detected in the mother's blood and useful in diagnosis. In a landmark study, Chim and his colleagues suggested that most plasma microRNAs, which are not pregnancy-related, originate in the hematopoietic compartments, and therefore they compared 157 microRNA profiles isolated from the placental tissue in the third trimester of pregnancy with microRNA isolated from the mother's blood cells. They identified 34 microRNAs that were present in the placenta at concentrations tens of times greater than those in the maternal blood cells. Importantly, the researchers additionally showed that the four most common of these placental microRNAs (microRNA-141, microRNA-149, microRNA-299-5p, and microRNA-135b) were found in the mother's plasma during pregnancy but were not found in postpartum plasma, another confirmation that they were of placental origin. Placental specific microRNAs were subsequently detected in plasma and serum and in a number of other studies. These data clearly show that placental microRNAs are present in the maternal bloodstream[8]. It was originally thought that nucleic acids (DNA and RNA) of placental origin enter the maternal bloodstream as apoptosis cells. Lo et al. have shown that microRNAs are exported from the human placental syncytial trophoblast to the maternal bloodstream through exosomes, and suggested that circulating microRNAs derived from the trophoblast reflect the physiological state of pregnancy and can be used for diagnostic purposes. Because their concentrations probably reflect tissue-specific physiological or pathological conditions, many recent studies have focused on identifying microRNAs that correlate with them and thus allow predicting complications of pregnancy. As for the normal human placenta, the expression of microRNA belonging to the C19MC, C14MC and miR-371-3 clusters depends on the gestational period. C14MC, the largest microRNA cluster containing 52 microRNA genes, is preserved without significant structural changes and is unequivocally determined in placental mammals. This suggests the important role of C14MC microRNA in controlling neurogenesis, embryonic development, transcription regulation and RNA metabolism. The C19MC cluster of 46 microRNA genes plays an important role in human embryonic development in the same way as the insulin-like growth factor-2 (IGF-2). It should be noted that some of the C19MC cluster microRNAs were found in the maternal bloodstream during pregnancy, including microRNA-515-3p, microRNA-516-5p, microRNA-517A, microRNA-517c, microRNA-518B, microRNA-520a *, microRNA-520h, microRNA-526a and microRNA-526b. Thus, maternal, circulating microRNAs may have the potential to become a new diagnostic tool for pregnancy pathology[47]. The cluster of microRNA-371-3 consists mainly of three microRNAs, HSA-Mir-371- 5p, HSA-microRNA-372 and HSA-Mir-373-5p and is located on chromosome 19. The cluster mainly expresses itself in the placenta, and the amount of its microRNA decreases in the process of development, therefore it seems to be important for the maintenance and regulation of proliferation and apoptosis. In addition, it was found that microRNA's from the cluster microRNA-17-92 are expressed in the normal motensive placenta. These microRNA's are important for angiogenesis and affect the expression of many genes, namely HIF1A, interleukin-8, tissue inhibitor metalloproteinase-2, metallopeptidase-2 matrix, VEGFA, efrin-B, and efrin receptor B4. The abundant expression of microRNA in amniotic fluid has been confirmed; it contains mainly those microRNA's that are involved in supporting embryonic development and immunity, thus protecting the fetus from external pathogens and the mother's immune response[44]. Some microRNAs with oncogenic and immunologic suppressor characteristics, such as cluster microRNA-17-92, microRNA-371, C14MC, and C19MC, mentioned above, have been found to express themselves more strongly in the first trimester of pregnancy, a microRNA of oncosupressors and those microRNAs that promote differentiation and have hematopoietic activity, including LET-7 family microRNA and cluster microRNA-29 and microRNA-34, are more strongly expressed in the third trimester of pregnancy. In addition, aberrant expression of some microRNA's has been recorded in placenta or lint in women with pathological pregnancy. Expression of HSA-MIR-184, HSA-MIR-187 and HSA-MIR-125b-2 in the lint of patients with normal pregnancy loss has been found to be significantly increased, while expression of HSA-MIR-520F, HSA-MIR-3175 and

HSA-Mir-4672 has been significantly reduced compared to that of women with normal pregnancy.

Studies in the laboratory have shown that microRNA is involved in the regulation of proliferation, migration, invasion, apoptosis and angiogenesis of trophoblast cells. Thus, it is quite probable that microRNA is necessary for normal development of the placenta and that pathological expression of microRNA may lead to defective placenta and abnormal pregnancy, resulting in miscarriage[46]. It has been shown that seven specific placental microRNAs present in maternal plasma (microRNA-516-5p, microRNA-517, microRNA-518b, microRNA-520a, microRNA-520H, microRNA-525 and microRNA-526a) are associated with pregnancy and may have diagnostic potential. There is a direct correlation between the level in maternal plasma of extracellular pregnancy-associated placenta-specific microRNA-515-3p, MIR-517A, MIR-517c and microRNA-518B and placental mass. The relationship between placental preposition and extracellular pregnancy-associated placental-specific microRNAs in the mother's plasma has been identified. They found significantly higher concentrations in plasma of extracellular MIR-517A and significantly lower concentrations in plasma of extracellular MIR-518B in the placenta predestination group in comparison with the control group and suggested that the level of circulating extracellular MIR-517A can be a prognostic marker of the risk of bleeding at late stages of pregnancy and massive bleeding at delivery. Other studies have provided evidence that functional oligonucleotide polymorphisms (OP) of microRNA-125 may increase susceptibility to habitual miscarriage. Two variants of the allele in primal-microRNA-125 have been identified, namely rs41275794 and rs12976445, which lead to changes in microRNA-125 production. Genes of inhibitory factor leukemia receptor (LIFR) and ERBB2 are targets of microRNA-125. LIF is a gene involved in the growth of the trophoblast and differentiation of the human placenta, which, like ERBB2, regulates the proliferation of stroma cells and differentiation of the trophoblast cells in the placenta in the period after implantation. In addition, ERBB2 can stimulate angiogenesis and invasion by increasing the concentration of vascular endothelial growth factors (VEGF). All these data suggest that these genes may play an important role at early gestational ages and their disruption may lead to PPB in some patients.

Expression of microRNA-125 A-T haplotype decreases in microRNA-125, which leads to increased expression of LIFR and ERBB2. Apparently, ectopic expression of LIFR may partially block LIF activity and cause disturbances of trophoblast growth and differentiation during the post implantation period, which leads to the usual loss of pregnancy. Finally, further studies have investigated associations of microRNA polymorphisms including MIR-146aC> G, MIR-149T> C, MIR-196a2T> C and MIR-499A> G in women with habitual miscarriage. Patients suffering from miscarriage showed a higher frequency of microRNA-196a2CC and microRNA-499AGþG genotypes compared to the control group of healthy patients. The combination of both mutations showed synergistic effects; all these polymorphisms are largely related to idiopathic loss of pregnancy.

Functional genomics has been widely studied, and recently endometrial gene expression signature has been used for implant window screening. Endometrial microRNA has been identified in recent years, during the middle secretory phase, and it is assumed that it regulates cell proliferation and differentiation, which may affect embryo implantation, but their exact role is not yet understood.

In order to study microRNA (miRNA), a prospective cohort study including 12 good female infertility predictions and endometrial gene expression tests during natural cycles before IVF treatment, ERA analysis revealed 5 receptive and 7 post-receptive endometrial samples. No depressed miRNA's were found comparing receptive and post-receptive endometrium. However, eight miRNA's were found to be activated with a multiple of more than 3.0 changes in susceptible samples. Among them, two positively regulated miRNA's were statistically significant: has-miR-374a-5p (multiple: 8.9, $p = 0.03$) and has-miR-17-5p (multiple: 8.9, $p = 0.03$). Despite their insignificance, the other two miRNAs had high multiples of has-miR-30a-5p (multiples of 9.7, $p = 0.116$) and has-miR-103a-3p (multiples of 10.5, $p = 0.125$). Eight microRNAs have been identified as being differently compressed in the receptive endometria by ERA analysis and may be considered as new potential candidate biomarkers for endometrial susceptibility.

Researches show that miR-374a and miR-103 family members are miRNA's associated with cell proliferation, mainly in cancer, while miR-17 and miR-30 family members were identified in the uterine cavity during the implantation window and may be associated with endometrial susceptibility[48].

Recent studies have evaluated the effect of microRNA on the regulation of the HLA-G gene in habitual miscarriage. HLA-G is a non-classical antigen of the main Histocompatibility Complex (MNS) and is expressed almost exclusively on the surface of trophoblast lint in the transplacental barrier during pregnancy, playing a crucial role in the immune tolerance of the mother to the fetus. After microRNA microchipping in habitual miscarriage patients and a control group of patients undergoing planned abortions, it was found that excess expression of microRNA-133a was found in abortions with abnormal karyotype. Further analysis showed that HLA-G is the target of miR133a. It is regulated by binding to a 3'' untranslatable area of HLA-G.

So, high expression of miR133a may mediate a decrease in HLA-G expression at the protein level and may be implicated in the pathogenesis of habitual miscarriage, since HLA-G provides immune tolerance in pregnancy[49]. So, the literature data suggest that microRNA dysregulation may be related to the pathogenesis of various obstetric complications, but accurate methodological approaches to the diagnosis and prediction of pregnancy complications using microRNA require further study.

Abstract

This article describes the clinical picture of multiple sclerosis (MS) depending on indices of the neurospecific protein s-100β and low-density lipoproteins. In patients with MS in the phase of activity, high levels of s-100β protein and LDL were found. It means that in patients with MS, demyelination and degeneration process continues, and as a result, patients are more likely to develop new symptoms. Thus, the study results of s-100β protein and LDL can be used to predict possible development of adverse symptoms in multiple sclerosis.

Keywords: *Multiple sclerosisneurospecific protein lipoproteins central nervous systemdemyelinating diseases.*

Introduction

Multiple sclerosis (MS) is a fairly widespread dysimmune neurodegenerative disease of the central nervous system, affecting mainly young people and almost inevitably causes disability at a certain stage of its development. Early diagnosis of multiple sclerosis is considered one of the most significant tasks of modern neurology. The etiology, pathogenesis and factors, affecting demyelination in multiple sclerosis, are still not clearly understood.

Demyelinating diseases belong to the group of autoimmune diseases, develop with destruction of the myelin sheaths in the central and peripheral nervous system. According to scientific literature, this process is caused by imbalance of 1,2,3-group cytokines of T-lymphocytes. An increase in the activity of T-1 lymphocytes leads to an increase in pro-inflammatory cytokines: IL-2, TNF-alpha, IFN-gamma, IL-12, causing a loss of tolerance to autopeptides and enhancement of autoimmune processes[5]. Synthesized “anti-myelinic” “antibodies” leading to central nervous system demyelination, dramatically reduce impulse conduction along nerve fibres. In patients’ blood, in relation to antigens of brain structural elements, that is, oligodendrocytes - to myelin basic protein (MBP), S-100 glial protein, antibodies are formed and detected[3]. The detected S-100 glial protein is considered to be an inducer of glial cell destruction. Sensitivity to this immunocyte protein in 70% of cases is determined in the blood; it is explained by destruction of glia and neurons. Also, in 50% of cases, the integrity of neuronal membranes is broken. The following types of s-100 protein are present: s-100 άά (specific to skeletal muscles, heart muscles, kidneys, liver); s-100 άβ (specific to glial cells, melanocytes); s-100 ββ (specific to Schwann cells). An increase in the concentration of s-100 άβ and s-100 ββ in cerebrospinal fluid and plasma is a brain damage marker. The results of s-100 study can be used to predict possible development of adverse symptoms in multiple sclerosis. In humans, elevated S100B levels have been detected in various clinical conditions. Brain injury and ischemia are associated with an increase in S100B concentration, probably, due to destruction of astrocytes. In neurodegenerative, inflammatory and mental diseases, elevated S100B levels may be caused by secreted S100Bs or release from damaged astrocytes. This review summarizes published S100B data regarding human brain damage and neurodegeneration[6]

An increase in the level of this protein is detected in the cerebrospinal fluid and blood plasma of patients with MS with exacerbation[4].

In MS pathogenesis, lipid storage disease is also

present. Lipids comprise 70% of the myelin sheath dry weight. They are structurally and functionally significant, their composition under demyelinating diseases undergoes great changes. The lipids involvement in all 4 development stages of the demyelinating process is demonstrated. In animal models, encephalithogenicity of myelin glycolipids was shown[7]. Thus, lipids may act as ligands of innate immunity receptors or pro-inflammatory agents that potentiate activity of innate immunity receptors and affect the inflammatory process with demyelinating diseases.

Despite great successes in documenting cellular and molecular mechanisms, underlying multiple sclerosis pathophysiology, the autoimmunity structure also cannot provide an exhaustive explanation of the disease etiology. I propose a new framework for MS as a lipid metabolism dysfunction. In particular, lipid metabolism homeostasis is destructed during the acute phase of inflammatory response, induced by a pathogen, trauma or stress, starting a feedback loop of increased oxidative stress, inflammatory response and proliferation of cytotoxic foam cells, crossing the blood-brain barrier, catalysing myelin and preventing remyelination. Understanding MS as a chronic metabolic disorder, makes it possible to single out four aspects of the disease onset and progression: 1) its pathophysiology; 2) genetic susceptibility; 3) environmental and pathogenic triggers; and 4) asymmetric sex ratio in patients. It also provides new treatment options.[2].

Cholesterol is an important component of mammalian cell and myelin membranes. In this systematic review we studied the relationship between cholesterol levels and cholesterol turnover markers in blood circulation and/or cerebrospinal fluid (CSF) and disease outcomes in adults with clinically isolated syndrome (CIS) or confirmed MS. Studies show that elevated levels of circulating cholesterol of low density lipoproteins (LDL), total cholesterol, and,in particular, apolipoprotein B and oxidized LDL, are associated with adverse clinical and MRI outcomes in MS. These relationships were observed back in the CIS. Studies also show that oxysterols, cholesterol precursors and apolipoprotein E may be a marker of specific disease processes in MS, but further research is required to clarify these processes and relationships. When analysed together, these data mean that cholesterol and cholesterol turnover markers are potentially suitable for clinical use as biomarkers of disease activity and may even be involved in MS pathogenesis. [1]

Purpose of our Study: to study the role and importance of neurospecific protein s-100β and lipid profile indices in the pathogenesis of multiple sclerosis development.

Material and Research Method

40 patients with multiple sclerosis (MS), aged from 21 to 45 years (mean age 33±1.5) were examined. Of these, 14 (35%) were men and 26 (65%) were women. All patients underwent clinical and neurological examinations and head MRI. Patients were divided according to MS course: with remitting MS - 18 (45%), primary progressive MS - 7 (10%) and secondary progressive MS - (15) 37.5%. The study of MS duration from the disease onset showed that patients with duration of "1-5 years" were 58%, "5-10 years" - 22%, "over 10 years" - 20%. There were 26 patients with MS in the active phase (65%), and 14 (35%) in the remission phase. A neurospecific s-100β protein (s-100β protein) (normal < 0.11 μg/L) and low-density lipoproteins (LDL) (normal < 2.5 mmol/L) were studied in blood plasma.

Study Results

The study results showed that in patients with MS, s-100β protein values vary from 0.06 to 0.22 μg/L (mean 0.17±0.09 μg/L). In 70% of cases, this index is higher than normal (28 patients). A study of neurospecific protein indices depending on the disease course showed, that in patients with a remitting course, s-100β protein was 0.14±0.1 μg/L, and, accordingly, in a primary progressive course - 0.21±0.0 μg/L, secondary progressive course - 0.18±0.06 μg/L, that is, in all types of course, s-100β index is increased, but the highest index is registered in the primary progressive course. In MS active phase, s-100β protein index was increased 0.13±0.01 μg/L, and during remission, within the normal range, - 0.08±0.2 μg/L.

The s-100β protein index did not differ by sex. Thus, in men it was 0.12±0.01 μg/L and in women - 0.14±0.02 μg/L.

It was determined that the longer the disease lasts, the more s-100β protein index is increased, regardless of the activity phase. With duration of the disease for "1-5 years" s-100β was 0.16±0.1 μg/L, "5-10 years" - 0.21±0.05 μg/L and "more than 10 years" - 0.2±0.1 μg/L.

Studies showed that in patients with MS, LDL levels ranged from 2.2 mmol/L to 4.65 mmol/L, mean of 3.6±0.1 mmol/L.

In all MS forms, mean LDL value is increased, especially with a secondary progressive course (3.6±0.1 mmol/L), remitting course (3.4±0 mmol/L) and primary progressive course (3.1±0.02 mmol/L).LDL in the active phase (3.5±1.3 mmol/L) differs sharply from that during remission phase (3.0±1.1 mmol/L). There were no gender differences in LDL indices (male - 3.4±0.03 mmol/L and female - 3.4±0.15 mmol/L).

The longer MS duration is, the higher LDL index is. So, with duration of "1-5 years", this index was 3.4±0.01 mmol/L, "5-10 years" - 3.6±0.1 mmol/L, "more than 10 years" - 3.7±0.2 mmol/L.

When protein indices s-100β and LDL were compared, it showed a negative correlation (r = - 0.12).

Conclusions

Evaluation of study results showed, that in all MS forms, the mean index of neurospecific protein s-100β and LDL was increased. It means, that our patients have a demyelinating and neurodegenerative process. A study of the disease duration showed, that the longer the disease lasts, the more intensive demyelination (degeneration) process is. A comparative study, depending on the disease course showed, that in a primary progressive course, the protein index s-100β is permanently high, LDL index is high in a secondary progressive course. Both analysed parameters are higher in the active than in the remission phase. Based on study results, in MS patients, high s-100β protein and LDL indices demonstrate, that in patients with MS the demyelination (degeneration) process continues; as a result, patients are more likely to develop new symptoms.Based on the analysis of studied parameters, depending on MS activation and remission, it can be observed that s-100β protein index in the active phase is increased, whereas in the remission phase it is within the normal range; LDL index is increased in all phases. Logically, patients in active phase of the disease re treated for demyelination (degeneration) processes (hormone therapy, interferons, immune adjuvants). As a result, s-100β protein index in the remission phase is within normal range. However, as a rule, patients with MS do not receive lipid-improving drugs. On the other hand, it takes a long time, on average, 3-6 months to normalize the lipid profile. But, by this time, either the disease exacerbation or the disease progression occurs.

Thus, in MS treatment, the disease phase shall be transferred from the active to remission phase, patients shall also be treated against risk factors, contributing to emergence of demyelination (degeneration) processes. This is a very important tactic for secondary prevention of the disease.

Thus, the study results of s-100β protein and LDL can be used to predict possible development of adverse symptoms in multiple sclerosis.

Epidemic Process of Salmonellosis in Tashkent

Nargiza S. Saidkasimova[1], Omon M. Mirtazaev[2]

1MD, Assistant Professor, Department of Epidemiology, Tashkent Medical Academy, Tashkent, Uzbekistan,
[2]MD, Department of Epidemiology, Tashkent Medical Academy, Tashkent, Uzbekistan

Abstract

In the latest decade, epidemiological features of salmonellosis morbidity have changed, in particular, the fraction of humans and animals, caused by S. enteritidis, has increased. It was caused by social changes in the population life: widespread development of private property, increased population migration, rapid development of the public catering system, etc. The features of salmonellosis epidemic process were analysed in Tashkent. S. enteritidis has also dominated in the causal structure of salmonellosis, registered in food products and other environmental objects over the past twenty years in Tashkent.

In the long-term dynamics of salmonellosis morbidity in Tashkent, there is a downward trend: in 1991 - 92.85 cases per 100 thousand people, in 2017 - 13.2, that is, over a 26-year period, the morbidity decreased by 6.7 times.

Keywords: *Salmonellosis, epidemiology, prevention.*

Introduction

Salmonellosis, called the “disease of civilization” is so widespread that at present it cannot be eliminated in any country, the morbidity rate can only be decreased[7]. Salmonellosis occupies a special place among acute intestinal infections. Unlike dysentery, typhoid fever, colibacillosis and cholera, they are caused by microorganisms being pathogenic for animals and humans in natural conditions[9]. There are two salmonella reservoirs in nature - animals and humans. There are two salmonella reservoirs in nature - animals and humans[10]. The expansion of international trade in animals and animal products, feed, a high concentration of livestock in a limited area, environmental changes, leading to the emergence of new Salmonella properties[3], introduction of modern mass technologies for slaughter and processing of animals, expansion of the catering network, are the main factors, contributing to salmonellosis spread[5].

In the latest decade, epidemiological characteristics of salmonella morbidity in Uzbekistan have changed, in particular, the fraction of people, suffering from S. enteritidis, the incidence of Salmonella infection in farm animals, birds, and the environment has increased[2]. It was caused by social changes in the population life: widespread development of private property, increased population migration, rapid development of the public catering system, etc[1].

In the 90-ies, in Uzbekistan, as a result of political and economic reforms, significant changes took place in the system of food production and sale, including poultry products. Most catering and trade enterprises became privately owned. At the same time, a sanitary-epidemiological service reform was introduced, accompanied by a sharp limitation of the frequency of inspections of controlled objects and the volume of microbiological studies of environmental samples. These social changes had a serious impact on salmonellosis epidemic and epizootic processes[6].

In this situation, there is a need for a theoretical justification of measures to control and prevent salmonella infection, considering current features of not only epidemiology, but also epizootology of salmonellosis enteritis. Meanwhile, the epizootic process of salmonellosis enteritis among farm animals and birds and its effect on intensity, dynamics and structure of the population morbidity in Uzbekistan have not been studied. Currently, the prevalence of bacterial diseases in animal husbandry worldwide is 16.2%, of them 10.9% are mixed bacterial diseases. In the development and increase of livestock yield, being the agricultural

main sector, it is important to increase livestock on state farms, farms and private farms, increase their yield, get healthy livestock, provide good care and protect it from various diseases[10]. The increasing epidemiological role of livestock and poultry, industrial poultry products, relationship of epizootic and epidemic processes call for restructuring of the existing system of salmonellosis epidemiological surveillance according to epizootological and epidemiological surveillance principles[7].

The purpose of this study was to research the prevalence of salmonellosis morbidity in Tashkent and determine epidemic process features of this infection.

Materials and Method

The study was based on official data of the State Sanitary and Epidemiological Surveillance Department on salmonellosis causal structure and retrospective epidemiological analysis results of salmonellosis morbidity in 1992-2017 in Tashkent. The epidemiological survey results of 114 salmonellosis foci, registered in Tashkent, were studied. The method of epidemiological survey of foci and epidemiological analysis were applied: descriptive research method (observation technique, study method of spatial spread of diseases, method for temporal distribution cases in time, method for cases distribution among different population groups, statistical method), analytical research method (formal logic, statistical, cohort and retrospective study method).

Results and Discussion

The spatial distribution of salmonellosis diseases was contrasting, with Tashkent being extremely unfavourable in terms of salmonellosis, high morbidity was also registered in Tashkent, Ferghana and Andijan regions (Fig. 1).

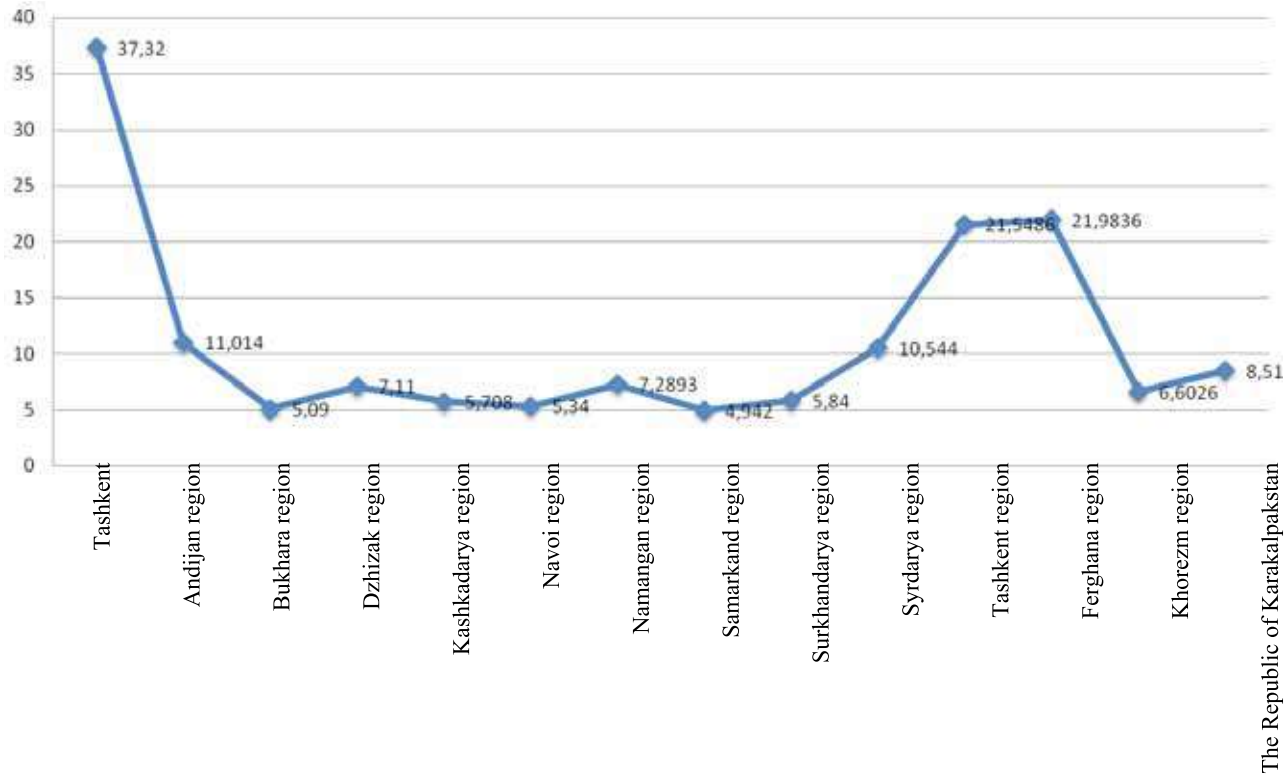

Fig. 1. Spatial distribution of salmonellosis morbidity in the Republic of Uzbekistan over 26 years (1991-2017)

One of the most important epidemiological determinants, defining the nature of salmonellosis epidemic process is attributed to serovar, prevailing in the causal profile. S. enteritidis has dominated in the causal structure of salmonellosis, registered in food products and other environmental objects over the past twenty years in Tashkent. The proportion of diseases caused by S. enteritidis in the general structure of salmonellosis

was s follows (1992 - 17.1*%,* 2008 - 35*%).* Another serovar, S. infantis, rarely registered in humans until the 1990s, subsequently occupied sufficient proportion in the causal structure of salmonellosis (1992 -6 6% 2008 r.-14.6%).

The causal structure ofsalmonellosis in humans and the serotypic profile of salmonella, registered in food products and environmental objects, often were the same. Common serovars, dominating in humans and food products were as follows: S, typhimurium, S. enteritidis, and S. infantis. Moreover, these salmonella were polyresistant to antibiotics.

The study results of animal salmonellosis showed significant infection of birds, pigs and cattle to a lesser extent. Salmonella, registered in animals, were distributed in 13 serological variants. Adapted Salmonella serovars were mostly registered. In the long-term dynamics of salmonellosis morbidity in Tashkent, there is a downward trend: in 1991 - 92.85 cases per 100 thousand people, in 2017 - 13.2, that is, over a 26-year period, the morbidity decreased by 6.7 times (Fig. 2).

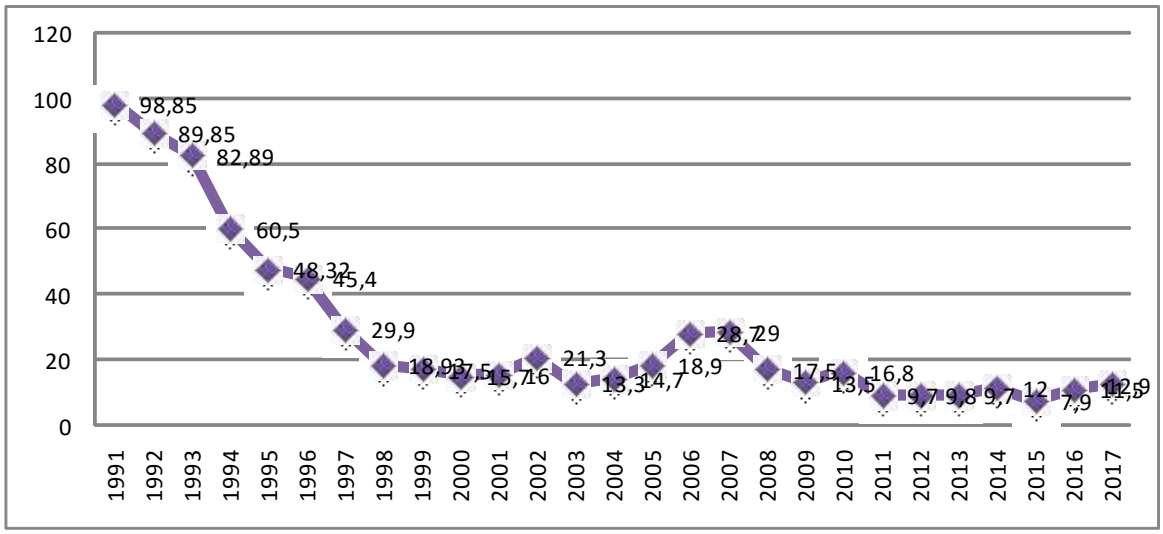

Fig. 2. The dynamics of salmonellosis morbidity in Tashkent during 26 years (1991-2017) in int. indices

The salmonellosis incidence is registered in all age groups. Social factors had the greatest effect on morbidity formation in children under the age of 14. We determined that children under the age of 14 are more likely to suffer from salmonellosis, and a significant number of patients are observed among adolescents of 15 years of age and older. The salmonella mostly enters the human body orally by consumption of meat and dairy products that do not meet hygiene requirements. Considering a great number of private catering facilities are organized, they often sell food, very popular among children and adolescents (fast food, pizza, grilled chicken, etc.), the control over food preparation and storage is not always proper, which is so it may be the cause of salmonellosis. All these factors present mass transmission pathogens in the period of a seasonal increase in the morbidity among older people[4].

The monthly distribution of salmonellosis morbidity was quite regular, with the highest rates in Tashkent recorded during hot months: up to 60% of cases were diagnosed during June-September. Such seasonal distribution is related to activation of nutritional transmission factor (meat, dairy products, vegetables, fruit). The role of open water as an additional factor in the transmission of infection is not excluded, since salmonella of the same serovars are detected in water as in humans. According to Kh.B. Magzumov's data (1975), in the conditions of

Uzbekistan, developed horticulture, vegetable growing, and picking vegetables and fruit in summer also contribute to salmonella infection, the special experimental studies have shown significant salmonella contamination of vegetables and fruit.

The epidemiological survey of the foci showed sporadic morbidity (92%). Multiple foci amounted to 8%. Most of the multiple foci were registered in children's hospitals, child care facilities and apartments. The foci were different by nature: food or household episodes; the causative agent was transmitted among children, especially in hospitals, in households and among adults with food products

Conclusions

1. In recent years, in the causal structure of salmonellosis, a decrease in proportion of S. typhimurium has been observed, S. enteritidis and S. infantis became more significant.
2. A long-term study (26 years) of the dynamics of of salmonellosis morbidity in Tashkent showed a downward trend.
3. In regions of the republic, cases of morbidity are distributed unevenly due to social changes: widespread development of private property, increased population migration, rapid development of the public catering system, etc.
4. The salmonellosis morbidity is registered in all age groups.
5. The morbidity is predominantly sporadic by nature, there are minor multiple foci related to food and domestic transmission.

Effectiveness of Integrated Treatment Strategy for Diabetic Retinopathy in Patients with Diabetes Mellitus: A Case Report

Nargiza Normatova

PhD, MD, Docent, Department of Ophtalmology, Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan

Abstract

Vascular pathologies are considered as severe complications of diabetes mellitus, which occur very frequently in patients. Namely, diabetic retinopathy, being one clinical form of diabetic angiopathy, may lead to distressing socioeconomic burden like decreasing visual acuity and blindness. In the literature, many treatment method have been described and used in many centres.

We present a case of 60-year-old diabetes sufferer, who underwent combined treatment strategy including panretinal laser coagulation, enzyme therapy, vitreoretinal surgery and intravitreal administration of an inhibitor of angiogenesis, which was highly effective in terms of restoring visual acuity with minimal periprocedural complications.

Keywords: *Diabetes mellitus, diabetic retinopathy, panretinal laser coagulation, vitreoretinal surgery, intravitreal administration of inhibitor of angiogenesis.*

Introduction

Diabetes mellitus is associated with vascular complications very frequently, which clinically presents with micro- and macrocircular disturbances. The basis of these disorders are hyperglycemia, metabolic disorders and insulin resistance due to the insulin deficiency and/or dysfunctions of its working mechanisms (Gurieva et al, 2019)[1].

Diabetic retinopathy (DR) is considered to be the fifth leading cause of visual impairment worldwide, and is a huge social and economic burden to the healthcare system[2]. Taking in account the escalating prevalence of DR in the world, WHO identified a variety of approaches to screening for the blindness prophylaxis, early diagnosis and treatment of the population in different conditions[4].

In the treatment of DR and diabetic maculopathy (DM), laser coagulation of the retina is remaining as the gold standard of the therapy due to its accessibility and long-lasting propitious effects after the treatment.[5]

Today, there are three main strategies in the treatment of patients with proliferative diabetic retinopathy (PDR) and diabetic macular edema (DME): pharmacological (compensation of glycemia, control of blood pressure, metabolism correction)[6], laser and surgical (intravitreal administration (IVA) of anti-VEGF medicines and vitrectomy) (Fayzrakhmanov et al, 2017; Bhat et al, 2017; Figueira et al, 2018; Rong et al 2017)[7]. The combination of these treatment strategies often provides a more pronounced positive effect (Mitchell et al, 2011 and Nguyen et al, 2012)[8].

According to some researchers, anti-VEGF drugs are an important addition to the arsenal of treatment for PDR (Zhao et al, 2018)[9]. Efficiency and safety of local anti-VEGF therapy in DME was proved by a largeinternational multicenter studies undertaken in accordance with all rules of evidence based medicine (EBM) (Cheung et al, 2014 and Do et al, 2016)[10].

The complexity of the treatment of the PDR, in many cases, is defined by the absence of a unique opinion on the pathogenetic mechanisms of development of pathological processes in the posterior part of the eyeball, although for this issue is devoted a large number of studies (Yuldasheva, 2014).[11]

The purpose of the studywas to present a clinical case, demonstrating the efficiency of complex treatment of PDR and DME in a patient with second type diabetes mellitus.

Case Presentation: Patient S., was born in 1959, suffering from second type diabetes mellitus during 18 years. He admitted to the Clinical Ophthalmic Hospital of the Ministry of Health of the Republic of Uzbekistan in January 2015 with complaints of decreased vision, fog in front of both eyes. Vis OD = 0.04 sph - 3.0 D = 0.6-0.7. Vis OS = 0.05 sph - 4.0 D = Vis 0.8. The intraocular pressure of both eyes was normal. The front section is not changed. Local opacities of the lens. There are separate floating opacities, which is not fixed to the retina in the vitreous body.

In the fundus of eye: fibrovascular tissue along the temporal vascular arcades, neovascularization of the optic disc, cystic macular edema (up to 480 μm in height in the right eye, 420 μm in the left one). The level of glycemia ranges from 6.8 to 8.9 mmol/L. Microalbuminuria up to 0.086 g/l. Blood pressure was 130/80 mm.Hg. Diagnosis: Proliferative diabetic retinopathy, cystic macular edema, complicated with catarrh bilateral cataract. Second type diabetes mellitus, severe course, subcompensated stage.

In February 2015, to patient was performed panretinal laser photocoagulation in full volume (OD - 2350 coagulates, OS - 1693 coagulates). All stages of laser interventions went without complications. Visual acuity with correction OD - 0.2, OS - 0.7. On the left eye,we could manage to stabilize the pathologic process. In November of 2015, the patient admitted to our clinic with the presence of hemophthalmus in OD and a decrease in vision up to 0.06. Considering the freshness of the pathological process, the patient underwent resorption therapy with 0.5 ml Gemaza enzyme in combination with a solution of dexamethasone 0.5 in the same syringe. 5 parabulbar injection were performed. Wobenzym tablets were administrated orally (3 tablets three times per day), as systemic enzyme therapy. This drug is proved as absorbable agent in hemophthalmia. In the dynamics of observation, visual acuity improved to 0.2 with correction and it became possible to examine the eye fundus, where the growth of fibroglial tissue on the retina was observed ophthalmoscopically. At the control examination after 1 month in the right eye, the growth of the phenomenon of cystic macular edema and proliferation intensified with the development of traction retinal detachment. According to the results of OCT, the height of detachment of neuroepithelium in the macula increased to 759 microns on the right eye, epiretinal fibrosis proceeded in the central region. In February of 2016, patient was admitting with recurrent hemophthalmus and tractional retinaldetachment detected on the “B” scan, which were an indication for two-step vitreoretinal surgery on the right eye. The patient performed a subtotal vitrectomy 25 G with a temporary tamponade vitreal cavity perfluoroorganic compound substituting the silicon oil, removing epiretinal fibrosis and endolasercoagulation. During the postoperative period arterial hypertension was observed in the patient up to 180/100 mm Hg, which was cut off with medicines. Arterial blood pressure was steadily normalized by the use of ACE inhibitors at the level of 110/70 - 130/80 mm Hg. The glycemic range was between 5.7 and 7.2 mmol/L. Proteinuria up to 0.072 g/l. At the end of the surgical treatment, Vis OD = 0.1 n/corr. Vis OS = 0.05 sph - 4.0 D = 0.6. We detected a partial regression in fibrovascular proliferation. Three months later, on the right eye silicone oil was replaced with saline.

However, in May 2016, relapsed partial gemoftalms in the right eye first, and from July 2016 - in the left eye as well with decreased visual acuity to hand movement of a person, and 0.1, respectively. In the “B” scan,opacification was noted with the presence of cell suspension in the eye vitreous haze. Taking in account the previous experience that conservative therapy may not be effective due to the larger volume of hemorrhage in the vitreous body and the presence of neovascularization of disc of optic nerve, it was decided to intravitreal administration of an inhibitor of angiogenesis (IVAIA). From May to November 2016, patient had 4 injections of IVAIA on avitreal right eye, then from July to December 2016 4 injections were performed in the left eye. Injections were performed in the operating room under local anesthesia through the flat part of the ciliary body 27 G needle through tunnel access with dose of 1.25 mg. Postoperative examinations were carried out on the next day and after 7 days. During and after intravitreal injection of IVAIA we did not note any ophthalmic and somatic complications. During the treatment, active resorption of hemophthalmus, regression and obliteration of neovascularization, especially on the optic disc and in the vascular arcades, a decrease in fibrovascular proliferation, and a decrease in neuroepithelial edema in the macula were observed. As of March 2017, Vis OD = 0.1 sph - 3.5 D=0.3-0.4. Vis OS=0.08 sph - 3.75 D=0.5-0.6. Thickness of neuroepitheliumaccording to OCT OD

- 360 microns on OS - 257 microns. In October 2017, during the next subsequent examination noted the rapid progression of cataract in the right eye. Therefore, to the patient was performed facoemulsification of complicated cataract with IOL of Acrysof implantation on the right eye. The operation went without any complications. As of February 21, 2018. Vis OD = 0.3 sph - 1.5 D = 0.4-0.5. Vis OS = 0.1 sph - 4.5 D = 0.7-0.8. Objectively: OD - IOL in a capsule bag. In the lower parts of the vitreous cavity, fibrotic changes. Fundus of the eye: all parts of the retina adjoined, no fresh bleedings. Remains of glial tissue on the optic nerve disc and preretinal fibrosis in the lower segments are detected. Dystrophic changes in the macula, focal atrophy of the pigment epithelium. The thickness of the neuroepithelium on the OCT is 255 microns. OS - initial clouding of the lens. In ophthalmoscopy: optic disc is pale pink, borders are clear. In the course of the temporal vascular arcade, fibrovascular proliferation was reduced, there were no fresh hemorrhages. Architectonics of central part of macula is saved. The thickness of the neuroepithelium is 247 microns. The patient was under observation of an ophthalmologist at the place of residence, follow-up examinations are every three months, with the additional anti-angiogenic therapy if needed.

Discussion

In our opinion, this case report is very interesting for several reasons. During the entire period of observation, we used all method of treatment, ranging from conservative therapy with enzymes and hormones, further laser-coagulation of retina, vitrectomy with silicone oil tamponade, followed by its removal and intravitreal administration of an inhibitor of angiogenesis.

According to the standards of treatment of diabetic retinopathy, with complicated hemorrhagic changes, conservative enzyme therapy was proved and is effective in early treatment of the patient with partial hemophthalmia with relative visualization eye fundus.

The rest of the treatment method we used affect the level of VEGF-factor in the eye cavity: panretinal laser coagulation by blocking the production of neovascular factor in zones of poor perfusion, subtotal vitrectomy - by mechanically removed the VEGF from the cavity vitreous body, the introduction of an angiogenesis inhibitor by binding its molecules to a specific antigen. However, combined use of several anti-VEGF techniques demonstrates high efficacy in cases of advanced PDR.

In this clinical case, our IVA anti- VEGF technique once in every first 6 weeks (1 time in 1.5 months) 4 times, and then 1 time in 2-3 months for 2 years was enough effective. Intravitreal administering of VEGF inhibitors in standard dosage, not only inhibit the progression of neovascularization, epiretinal gliosis and cystoid macular edema development, but also ensured the preservation of the productive central vision. Our studies prove that stopping the processes of proliferation and neovascularization on timely prolonged, massive intravitreal administration of angiogenesis inhibitors is fully proved. Taking into account that with increasing duration of diabetes mellitus, pathophysiological processes in the retina cannot be improved independently, refractory edema of the macular zone does not spontaneously resolved, especially patients with the background of increasing arterial blood pressure are not guaranteed from relapse of hemophthalmus. So, we recommend to conduct IVAIA throughout the whole life for patients with indications.

Our 5-year observation period for patients with PDR who received intravitreal angiogenesis inhibitors showed that most of them managed to achieve improved functional results during the entire observation period and with a minimum number of IA injections after 3 years. During the observation period, no systemic adverse events were observed in the patient. Exceptions group consisted of patients who had undergone acute cerebrovascular accident or myocardial infaction during the last 6 months.

In the literature the potential risk of systemic side effects of intravitreal administration of VEGF-factor inhibitors are clearly described, namely - arterial hypertension, proteinuria, gastrointestinal bleeding, impaired wound healing process, which is particularly unfavorable in diabetic patients.

Conclusion

The case study shows that combined use of several anti-VEGF techniques guaranteesthe effectiveness of treatment for advanced proliferative diabetic retinopathy, complicated with DME and recurrent hemophthalmus. In planning vitrectomy after applying the anti- VEGF drugs, it is reachable to decrease fibrovascular tissue hemorrhages, therefore there is less intraoperative bleedingand, in many cases, it is fully avoidable this kind of complications.

Patient Consent: Written informed consent was obtained from the patientfor publication of this case report and any accompanying information related to this study. A copy of the written consent is available for review by the authors of the paper.

Authors' Contributions: The first author drafted the manuscript. All authors read and approved the final article.

Abstract

In recent decades, in many countries of the world there has been an increase in the incidence of colorectal cancer (CRC). The annual occurrence of 50 new cases of colorectal cancer per 100,000 population determines a 5% population risk of developing the disease throughout life 1. An alarming fact is that for the 100 newly diagnosed patients with CRC, more than 70 deaths occur, of which, in the 1st year from the moment of diagnosis, about 40%. This circumstance is due to the fact that when patients first go to the doctor, advanced forms of CRC (stage III-IV) are diagnosed in 62.4% of patients. In 25-30% of patients, distant metastases are detected at the time of surgery. In recent years, there has been a tendency to expand indications for organ-preserving operations in the CRC.At the same time, it is necessary to formulate clear criteria for their implementation on the basis of a comparative analysis of long-term treatment results, the frequency of local regional relapses, the development and implementation of techniques using staplers, as well as the justification of indications for the use of combined and complex treatment programs that increase the radicalism and ablasticity of surgical interventions.

Keywords: *Colorectal cancer, radiation therapy, ampullar colorectal cancer, perineal extirpation of the rectum.*

Introduction

The main and most effective method of treating CRC is the surgical method, in compliance with the principles of oncological radicalism. However, the use of only the surgical method of treating CRC demonstrates low efficiency - over the past 20-25 years, 5-year survival rates, which average 52%, have remained stably low. In this case, the cause of death of approximately 68% of patients is relapse of cancer after surgery, and the incidence of loco-regional metastases ranges from 20-40% 3. These failures determine the feasibility of finding ways to increase an acceptable and effective method of treatment through the use of combined and complex treatment method for CRC.

Recent decades have been characterized by the search for optimal regimens for combined and complex treatment of CRC by combining the surgical method with radiatiotherapy or chemotherapy in order to improve the treatment outcomes of a severe category of patients with a locally advanced process and the presence of metastases [4].

In modern clinical oncology, the search for the most effective method for combining surgical intervention with various options for radiation therapy (preoperative, intra- or postoperative), as well as large-fraction ones 5. At the same time, to date, there are no clear indications on the timing, doses and method of exposure to radiation therapy in PKK, which indicates the need to find ways to improve and increase the effectiveness of this method of exposure [6].

Practical significance of the research results: Developed indications for organ-preserving surgical interventions for lower ampullar colorectal cancer, the most effective variants of chemoradiation method have been proposed in the practical health care system of Uzbekistan.

The developed variants of the schemes and method of combined and complex therapy, improvement of the surgical technique, method of correction and prevention of complications help to reduce the incidence of early postoperative complications, mortality rate, as well as the occurrence of relapses and metastases, which will increase the effectiveness of treatment, improve the quality of life of patients and reduce terms of their rehabilitation.

Based on the studies, the basic scientific provisions that are made are substantiated and formulated:

1. An analysis of the dependence of the number of postoperative complications in patients with colorectal cancer associated with performing surgical intervention showed that after organ-sparing surgeries, complications were observed in 14 (11.2%) patients, and after performing peritoneal perineal extirpation of the rectum (PPER) - in 14 (9.5%) patients. Analysis of postoperative complications of a general nature showed that their number did not depend on the type of surgical intervention.
2. On the example of 120 patients with rectal cancer with T3-4N0-1M0 stages of the disease, the possibility of performing organ-saving operations in this category of patients is shown. The presence of severe concomitant pathology along with the individual characteristics of tumor growth may serve as a contraindication to performing such operations.
3. New method have been developed for the complex treatment of patients with colorectal cancer, including various schemes of preoperative high-dose radiation therapy, as well as method of preoperative lymphatic polychemotherapy with subsequent organ-preserving operations.
4. The five-year survival rate for patients with colorectal cancer after complex treatment with organ-preserving surgeries was 75.2%, and in patients in the control group after complex treatment with PPER, 74.8%. Moreover, in the group of patients with organ-sparing surgeries after carrying out the method of lymphatic polychemotherapy, this indicator amounted to 76.1%, and after various schemes of high-dose radiation therapy - 73.0%.
5. Organ-saving operations in the complex treatment of patients with rectal cancer with T3-4N0-1M0 stages of the disease significantly increase the quality of life of this category of patients, their social and labor rehabilitation, without compromising overall and relapse-free survival rates, which makes it possible to recommend the use of these techniques in complex treatment of this category of patients.

Diagnosis and treatment of locally advanced colorectal cancer: The five-year survival of patients with CRC in the T1N0M0 stage after surgical treatment is 90%; T2N0M0 after combined treatment - 70-80%; T3N0M0 after combined treatment - 60-65%, and after only surgical treatment 50-55%. T1-3N1-3M0 after combined treatment is 50-55%, and after only surgical treatment - 25-30%. In the T4N0-1M0 stage, 10-15% .[8].

The situation when the neoplasm has exceeded not only the intestinal wall, but also the periintestinal tissue and has spread to nearby organs, or to the pelvic peritoneum, perivesical tissue, etc. commonly called locally distributed RC.9. More broadly, the concept of locally distributed RC may include the following definition: an immobile or limitedly mobile tumor, circularly covering all the walls of the intestine, 5 cm long, narrowing the lumen of the intestine with the involvement of neighboring organs and tissues and possible formation of fistulas or purulent cavities, and not having distant metastases [10].

The most adverse forms are mucous adenocarcinoma, cricoid-cell, undifferentiated cancer, and unclassified tumors. With a relatively small damage to the intestinal mucosa, they metastasize faster and more often spread not only to the entire intestinal wall, but also to surrounding tissues and organs. PKK can germinate in any adjacent organs or tissues. The bladder, small intestine, pelvic bones, ovaries, uterus, posterior wall of the vagina, prostate and seminal vesicles are most commonly affected. However, such germination is not always accompanied by distant metastasis, therefore, in such cases, it is advisable to conduct combined resections.

Local tumor growth and lymphogenous metastasis in RC are interrelated, but not always parallel. So, 15% of tumors limited by the muscle layer of the intestinal

wall are accompanied by lymphogenous metastasis. When germinating in all layers of the intestinal wall, the lymph nodes are affected in more than 50% of cases. At the same time, even when the tumor invades the neighboring organs (locally advanced forms of cancer), lymphogenous metastasis is often (30%) absent.

According to many authors, 70-80% of patients with RC enter clinics with stage III-IV disease. Among the reasons for the late diagnosis of RC, it should be noted the absence of a mandatory standard examination scheme for a patient who suspects this disease, the inadequate use of previously developed diagnostic method, and the limited use of new examination method [11].

The primary RC is characterized by the fact that the tumor remains localized for a long time and grows relatively slowly compared to other tumors of the digestive tract. Localized and slow growth is also characteristic of metastases to the lymph nodes. Given this biological feature of RC, it was suggested that by increasing the number of lymphadenectomies, a reduction in the number of relapses can be achieved. At the same time, according to many researchers, the average five-year survival of patients, even when the operation is expanded to total pelvioabdominal lymphadenectomy, ranges from 45 to 60% .[12].

In this regard, increasing the effectiveness of treatment for RC, today remains an urgent problem of modern oncology. In recent decades, there has been a tendency to expand indications for organ-preserving operations in the RC. Many authors note that even with a pronounced spread of the cancer process, distant metastases may be absent, and it is possible to perform extended surgical interventions 13. At the same time, it is necessary to formulate clear criteria for their implementation on the basis of a comparative analysis of the long-term results of treatment, the frequency of local regional relapses; the introduction of combined and comprehensive treatment programs that increase the flexibility of surgical interventions [14].

Modern directions of organ-preserving surgical treatment of colorectal cancer: Modern method of surgery for colorectal cancer are numerous. To choose one of them is directly dependent on the location of the tumor, its type of growth, degree of spread, its anatomical features, the patient's condition and the surgeon's qualifications. When choosing surgical tactics in patients with colorectal cancer with sprouting into neighboring organs, one should be guided not only by such criteria as the size of the tumor, its location, growth form and histological structure, which always determine the technical capabilities of radical surgery, but such the most important prognostic factor, as the depth of tumor invasion [15]. An operation can be considered radical only if, along with a sufficiently wide resection of the area of the intestine affected by the tumor, the zone of possible regional metastasis is also removed.

The main and most effective method of treating RC is the surgical method, in compliance with the principles of oncological radicalism. However, the use of only the surgical method of treating RC demonstrates low efficiency - for 20–25 years, 5-year survival rates after radical surgeries remain at 46–62%, which is an average of 52%. Many authors attribute the main causes of failures in the surgical method of treatment to the occurrence of relapses and distant metastases that occur at different times after surgery. The cause of death in approximately 68% of patients is cancer recurrence after surgery, and the incidence of locoregional metastases ranges from 20-40% .16. These failures determine the feasibility of finding ways to increase an acceptable and effective method of treatment through the use of combined and complex treatment method for RC.

Among the many factors that determine the nature and extent of surgical interventions, and first of all organ-preserving ones, the fundamental role belongs to the degree of local spread of the tumor process and the level of tumor localization in the rectum. In RPK, typical operations depending on the height of the primary tumor are: anterior resection, abdominal-anal resection of the rectum with sigmoid reduction, obstructive resection (Hartmann's surgery) and abdominal-perineal extirpation (BPE) of the rectum [17].

Common forms of RC are often the main reason for abandoning active surgical tactics. Often, patients in this group perform symptomatic palliative surgery, in which there are a large number of postoperative complications and high rates of postoperative mortality. At the same time, the quality of life of these patients is significantly deteriorating, which is due to the increasing effect on their body of the not removed primary tumor and the progression of metastatic growth. The average life expectancy of these patients does not exceed 3–7 months.[18]

The main argument of opponents of superradical

interventions is the high technical complexity and invasiveness of the latter. However, many surgeons do not agree with this judgment, since long-term world practice of performing combined and advanced operations not only allows us to hope for good long-term results, but also opens up great prospects for improving the quality of life of patients by performing simultaneous or delayed plastic surgeries [19].

The current trend in locally advanced RC can be attributed to the tendency to perform saving interventions in the form of trans-abdominal resection and abdominal-anal resection of the rectum, naturally, in the absence of oncologicalcontraindications. The postoperative mortality in these interventions is not much higher than that in conventional operations - for example, 30-40% of patients undergoing combined operations survive a 5-year period. One of the important contraindications for performing combined operations is the presence of concomitant diseases that cannot be corrected in the preoperative period, especially in elderly patients .[20].

Materials and Method

In our work, a retrospective analysis of the clinical data of 120 patients with colorectal cancer (CRC) with a T3-4N0-1M0 stage of the disease, who were treated in the Department of Oncoproctology, Republican Cancer Research Centre, Ministry of Health, Republic of Uzbekistan in the period from 2005 to 2015, was carried out.

Patients were divided into the main and control clinical groups. The main group included 60 patients with RC who underwent various types of operations during complex treatment: abdominal-anal resection of the rectum (AARR), anterior resection of the rectum (ARR), Hartmann's operation. The control group included 60 patients with RC who underwent abdominal-perineal extirpation of the rectum (APER).

In this case, the main and control groups of patients with RC were additionally divided into 3 subgroups depending on the nature of chemo- and radiatiotherapy (tables 1,2). Thus, patients in 1 subgroup received surgical treatment with endolymphaticpolychemotherapy (ELPCH) and regional lymphatic polychemotherapy (RLPCH) and hypoxiradiotherapy (HRT), in 2 subgroups received surgical treatment in combination with radiatiotherapy (RT), in 3 subgroups received surgical treatment in combined with ELPCH and RLPCH.

We did not include in the observation of patients with acute intestinal obstruction, requiring emergency surgery, with a generalization of the process in the abdominal organs, ascites, lymphostasis, the presence of distant metastases, as well as with severe concomitant diseases requiring specialized treatment.

Table 1: Distribution of patients with colorectal cancer depending on the type of treatment in the main group, n=60

Sub-Group	Type of operation	Combinationtherapy	Number of patients	
			Abs.	%
1	PRR, Hartmann's operation	ELPCHT	21	35,0
2	PARR	ELPCHT	23	38,3
3		LT	16	26,7
Total			**60**	**100**

Table 2: Distribution of patients with colorectal cancer depending on the type of treatment in the control group, n=60

Subgroup	Type of operation	Combination therapy	Number of patients	
			Abs.	%
1	PPER	ELPCHT+RLPCHT+HRT	19	31,7
2		ELPCHT+RLPCHT	24	40,0
3		LT	17	28,3
Total			**60**	**100**

A study of the distribution of patients by gender and age showed that in the main group of patients with RC there were 34 men (56.7%) and 26 women (43.3%), in the control group these figures were 36 (60%) and 24 (40%) respectively. The average age of patients in the main group was 49.1±0.8 years, in the control group - 48.9±0.7 years.

Table 3: Distribution of patients with colorectal cancer by gender and age in the control group, n=60

Age	Gender				Total	
	Men		Women			
	Abs.	%	Abs.	%	Abs.	%
18-45	18	30,0	9	15,0	27	45,0
46-60	11	18,3	8	13,3	19	31,6
60 and upper	7	11,7	7	11,7	14	23,4
Total	**36**	**60**	**24**	**40**	**60**	**100**

A study of the anamnesis of patients with PKK showed that in 17 (14.2%) of them, the duration of the disease was up to 3 months, in 42 (35%) - up to 6 months, in 36 (30%) - up to 1 year, in 13 (10.8%) - up to 2 years and 12 (10.0%) - up to 3 years (table 5).

Table 4: Description of anamnesis of patients with colorectal cancer, n=120

Anamnesis of disease	Patients groups				Total	
	Main		Control			
	Abs.	%	Abs.	%	Abs.	%
Up to 3 months	3	5,0	6	10,0	17	14,2
Up to 6 months	14	23,3	12	20,0	42	35,0
Up to 1 year	19	31,7	26	43,3	36	30,0
Up to 2 year	17	28,3	14	23,4	13	10,8
Up to 3 year	7	11,7	2	3,3	12	10,0
Total	**60**	**100**	**60**	**100**	**120**	**100**

This subjective indicator shows the presence of an erased RC clinic, as evidenced by a three- and six-month history in less than half of patients (44.1%).

When conducting a rectoscopic examination, the exact localization of the tumor process and its extent was established (table 6). As follows from the table, in the patients examined by us, the distal location of the tumor was mainly determined. So, during proctoscopy in 58 (48.3%) patients with CRC, the tumor was limited to localization in the anal canal. In rectoscopy in 50 (41.7%) patients, the tumor process was determined at a distance of 5–9 cm from the anus and in 12 (10%) patients at a distance of 10 cm or more from the anus level.

Table 5: Localization of the tumor process in relation to its location from the anus, n=120

Tumor localization	Patients groups				Total	
	Main		Control			
	Abs.	%	Abs.	%	Abs.	%
In the anal canal (up to 3-4 cm)	28	46,7	30	50,0	58	48,3
At a distance of 5-9 cm from the anus	26	43,3	24	40,0	50	41,7
At a distance of 10cm from the anus	6	10,0	6	10,0	12	10,0
Total:	**60**	**100**	**60**	**100**	**120**	**100**

In assessing the prevalence of the disease, the TNM system was used (8th edition, 2008) (table 7). As follows from the table, stage IIa of the disease occurred in 18 (30.9%) patients, IIb in 32 (19.1%) and stage IIIb in 70 (50.0%) patients. Moreover, in 32 (26.7%) patients there was a local spread of the tumor process (T4N0-1M0).

The study of the histological structure of tumors showed that adenocarcinoma was predominantly found in 106 (88.3%) patients. At the same time, moderately differentiated adenocarcinoma was found in 39 (32.5%) patients, low-differentiated adenocarcinoma in 31 (25.8%) and highly differentiated adenocarcinomas in 36 (30.0%) patients with RC. Cricoid cell adenocarcinoma was diagnosed in 5 (4.2%) patients. Other histological forms of tumors were found in 9 (7.5%) patients.

Endolymphatic and regional lymphatic administration of chemotherapydrugs.

Preoperative endolymphatic polychemotherapy (ELPCH) and regional lymphatic chemotherapy (RLPCH) were performed in 47 (39.2%) patients with CRC, of which 23 (19.2%) were patients in the main group and 24 (20.07%) were in the control group.

At the same time, 21 (17.5%) patients of the main group underwent ELPCHT and RLPT in combination with hypoxiradiotherapy (HRT); in the control group, this type of treatment was used in 19 (15.8%) patients. Other 23 (19.2%) patients of the main group and 24 (20.0%) patients of the control group received only ELPCH and RLPCH.

Thin polyethylene catheters (PE10) were used for cannulation of the lymphatic vessels (Fig. 1).

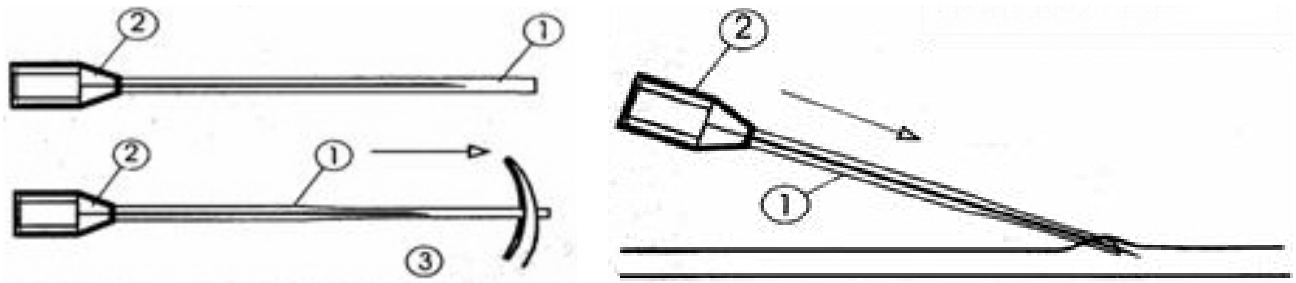

Fig. 1 Method of catheterization of the peripheral lymphatic vessel of the lower limb. 1 - mandrin of an epidural catheter; 2 - polyethylene catheter PE 10; 3 - clamp.

Direct introduction of the cytostatic agent into the lymphatic channel provides a direct supply of the drug to the tumor and to metastases in the regional lymph nodes. This leads to an increase in the antitumor effect of chemotherapy with a decrease in the general and local toxicity of chemotherapy.

The duration of ELCHT was 96 hours continuously:

1. Methotrexate (Mtx) - 50 mg/m2 for 24 hours in 24 hours, 1 day;
2. 5-fluorouracil (5-Fu) - 1000 mg/m2 for 24 hours, 2, 3 days - 48 hours.

RLPCH (with the preliminary introduction of a cocktail of lymphostimulants, consisting of: novocaine - 0.25% - 4 ml, heparin - 2500 U, furosemide - 0.5 ml):

1. Mtx - 50 mg/m2 1 time, 4 days;
2. 5-Fu - 1000 mg/m2 1 time, 5.6 days.

The catheter is cut 2-3 mm longer than the mandrel. The protruding end of the catheter is fixed with a clamp and stretched until the catheter becomes thin (0.25-0.45 mm), while it should fit snugly against the mandrel. Then the catheter is cut 1-2 mm shorter than the mandrel.

Lymphatic catheterization for long-term administration of drugs was carried out as follows. The site of the procedure was chosen large interdigital gap on the rear foot. After treating the skin with 5% iodine solution and 96% alcohol, 1 ml of 1% methylene blue or 0.4% indigo carmine diluted in 0.25% 1.0 ml novocaine solution is introduced into the first interdigital space to stain the lymphatic vessel; retreating 5-6 cm upwards, a longitudinal skin incision of 2-3 cm was performed, a stained lymphatic vessel was found, it was isolated from adipose tissue and a dental spatula was placed under it. Previously, two ligatures were performed under the vessel, which were fixed with clamps directed to the proximal part of the wound.

To enlarge the vessel in diameter, it was pinched, pressing it above the incision with fingers. A cotton swab produced massage below the incision. After filling the vessel and increasing its size in diameter, a dental spatula was brought to the distal part of the wound. The lymphatic vessel became inactive. The vessel was punctured in its lower part by a specially prepared catheter, which was fixed with ligatures in two places above the entry into the lymphatic vessel. Then the mandrinwas removed, the lymphatic vessel was checked for leaks by introducing a solution of novocaine through a catheter. 2-3 nodal sutures were applied to the skin. The free edge of the catheter was fixed with a band-aid to the skin. A needle was inserted into the free end and a chemotherapeutic system was connected. The drugs were injected with an electronic dispenser (ДЛВ-1) at a rate of 1.0 ml/h. within 72 hours. In this case, Mtx was administered continuously - 50 mg/day x m2 for 24 hours, on days 2 and 3 of 5-Fu - 1000 mg/day x m2 for 48 hours. Then the lymphatic catheter was removed, and after treating the wound with 5% iodine, an aseptic dressing was applied.

After 6 days, a peripheral lymphatic vessel was catheterized on the back of the other foot, and the remaining half of the course dose of chemotherapy was slowly introduced into the catheter.

On the 4th day, RLPCHT was performed by injecting drugs into pararectal fiber, taking into account the localization of the tumor (Fig.).

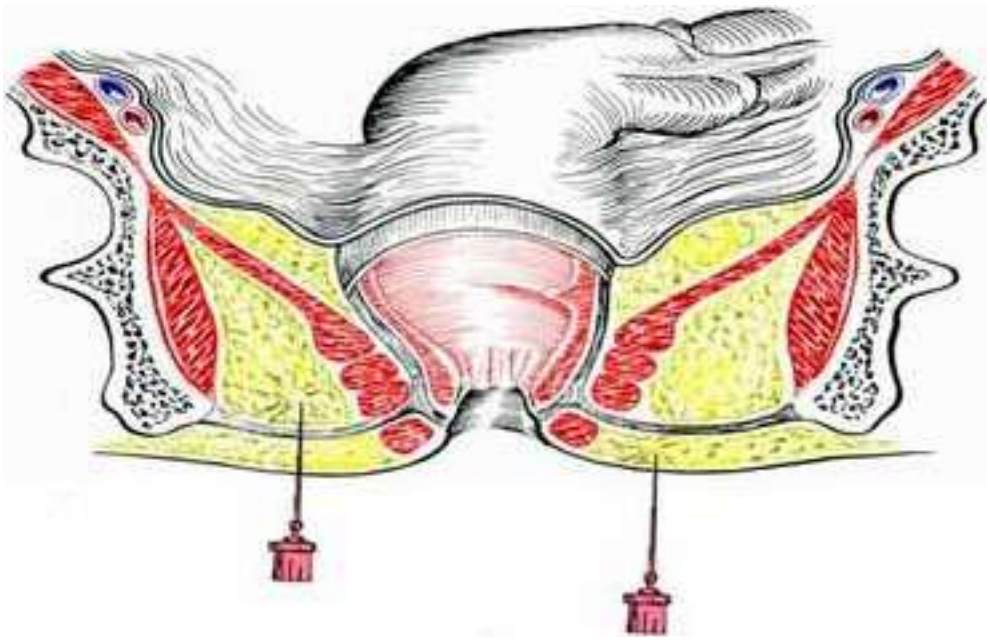

Fig. 2. Conducting regional lymphatic chemotherapy for colorectal cancer.

So, in case of a lesion of the anal canal by a tumor, the preparations were injected into the perianal tissue, and in case of a tumor of the middle and upper ampullar parts of the rectum, it was injected into the pararectal tissue closer to the tumor (i.e., to a depth of 8-10 cm from the skin).

To perform RLPCHT after thoroughly treating the perianal skin with 5% iodine solution and 76% alcohol, departing from the transition line 2 cm laterally, under the control of the finger inserted into the rectum, a needle was inserted into the pararectal tissue, leading its end towards the tumor.

For lymphostimulation, a cocktail of 0.25% 4.0 ml novocaine solution, 0.5 ml furosemide solution and 2500 IU heparin solution was administered. Then, without removing the needle, 3-5 minutes after complete lymphostimulation, the chemotherapy was administered through the same needle. Having removed the needle, a warming 40% alcohol compress was applied to this area for 5-6 hours. RLPCHT was performed on days 4 and 5, on day 4, Mtx was administered - 50 mg, then on day 5 5-Fu - 1000 mg of chemotherapy.

Along with the lymphotropic administration of water-soluble chemotherapy drugs, detralex was used 2 tablets 3 times a day during the course of chemotherapy in order to stimulate lymph drainage and lymphosorption in the lower extremities, to improve the penetration of chemotherapy drugs into the peripheral lymphatic channel and increase the concentration of these drugs in the lymph.

To prevent thrombosis in the lymphatic and venous bloodstream, a low molecular weight anticoagulant, fraxiparin, was administered at a dose of 0.3 ml subcutaneously 1 time per day during the administration of chemotherapy, under the control of PTI and VSK. In order to reduce the local cytotoxic effect by additional dilution of the residual amount of chemotherapy drugs in the tissues and at the same time to re-stimulate their lymphosorption, a 0.5% novocaine solution up to 50 ml was injected subcutaneously at the site of the previous chemotherapy injection, immediately after removing the cuff from the hip. At the end of the procedure for the lymphotropic administration of water-soluble chemotherapy drugs to improve venous outflow and prevent venous thrombosis of the lower extremities, elastic bandaging of the lower extremities was performed after subcutaneous administration of novocaine.

Surgery was performed 7-14 days after the last lymphatic administration of drugs, during the period of the most pronounced decrease in the biological activity of the tumor due to PCHT.

Effectiveness of treatment of patients with colorectal cancer depending from prognostic factors: The results of organ-preserving operations in the complex treatment of CRC were tracked for three and five years. Cases of relapses and metastases were analyzed, and the survival of patients over a three- and five-year period was assessed, depending on prognostic factors.

During the three-year follow-up, local relapses in the main group occurred in 10 (16.6%) patients with RC and in the control group in 13 (21.7%) patients. Relapses developed at follow-up from 6 to 27 months. The average relapse rate was 11,8±2,4 months.

Table 6: The frequency of relapse over a three-year period in patients with colorectal cancer, depending on the type of surgical treatment

Type of operation	The number of patients in groups	Patients groups			
		Main, n=60		Control, n=60	
		Abs.	%	Abs.	%
PRR with the anastomosis	Main, n=12	1	8,3	–	–
PARR with the relegation proximal colon in the anal canal	Main, n=14	2	14,2	–	–
PARR with there legation Sigma in anal canal	Main, n=25	5	20,0	–	–
PARR with colostomy	Main, n=6	1	16,6	–	–
Hartmann's operation	Main, n=3	1	33,3	–	–
PPER with sigmostomy	Control, n=60	–	–	13	21,7
Total		**10**	**16,6**	**13**	**21,7**

The results of a univariate analysis showed that the frequency of relapse over a three-year period in patients with RR was higher after the PPER in 13 (21.7%) patients than in organ-preserving operations in 10 (16.6%) patients.

The frequency of relapse over a three-year period in patients with colorectal cancer, depending on the type of preoperative lymphatic chemotherapy:

An analysis of the dependence of the recurrence rate on the lymphatic chemotherapy regimen revealed that, in the ELPCHT + RLPCHT + HRT regimen, a smaller number of tumor relapses was observed compared to the regimen without HRT. In the main group of patients, in the first case, relapses were observed in 3 (14.2%) patients, while in the case of PCHT without HRT, in 4 (17.3%) patients.

The number of relapses in the case of a single GRT of 13 Gray turned out to be slightly lower compared with the ROD of 5 Gy to SOD 25 Gy. So, in the main group of patients with RC, with a 13 GyGRT regimen, relapses were detected in 3 (14.2%) patients, and with a 5 Gy ROD regimen up to 25 Gy SOD, in 3 (18.7%) patients.

In stage IIa of the disease, the number of relapses was minimal and was observed in the main group in 1 (10.0%) patients with PKK, in stage IIb in 2 (12.5%), and in stage IIIb, the maximum number of relapses was found in 7 (20.6%) of patients.

The histological structure of the tumor also influenced the development of relapses in the distant postoperative period. The maximum number of tumor relapses in patients of the main group was found in undifferentiated form of cancer in 1 (33.3%) patients, in moderately differentiated adenocarcinoma in 5 (20.0%), and in low-grade adenocarcinoma in 3 (20.0%)) The least relapses were observed with highly differentiated adenocarcinoma - in 1 (7.1%) patients with CRC.

The macroscopic form of tumor growth also significantly affected the number of recurrences of RC. In the endophytic form of growth in the main group, we observed the highest number of relapses - in 4 (25.0%) patients, in the exophytic form - the smallest number of relapses - in 1 (7.1%), and in the mixed form of tumor growth, relapses were found in 5 (16.7%) patients.

Over a three-year period, tumor metastases to distant organs (liver and lungs) occurred in the main group in 5 (8.3%) patients with RC and in the control group in 4 (6.7%) patients. Metastases developed in the period from 6 to 18 months, which averaged 11,3±2,5months.

Moreover, the type of surgical intervention significantly influenced the development of metastases in the distant postoperative period, which is associated with various morbidity and volume of resected tissues of various surgical techniques. So, after Hartmann's operation, distant metastases occurred in 2 (66.7%) patients, after PARR with the relegation of the colon into the anal canal - in 1 (7.1%), after PPER with sigmostomy - in 4 (6.7%) and after PARR with the relegation of tyesygma into the anal canal - in 2 (8.0%) patients.

As a result of ELPCHT + RLPCHT in combination with HRT, distant metastases developed in 1 (4.8%) patients with major group RC, while metastases were detected in 2 (8.7%) patients with the same chemotherapeutic effect, but without HRT.

At the same time, we did not observe significant differences in the incidence of metastases over a three-year period in patients with colorectal cancer depending on the type of preoperative radiation therapy. So, after a single GDT at a dose of 13 Gy in the main group, metastases developed in 1 (4.8%) patients, and after an irradiation regimen of ROD of 5 Gy to SOD of 25 Gy - in 1 (6.2%) patients.

The incidence of metastases in the distant postoperative period also depended on the stage of the tumor process. So, in stage III b, metastases were detected in 4 (11.7%) patients of the main group, in stage II b - in 1 (6.2%) and metastases were not observed in stage II a.

The histological structure of the tumor also influenced the development of distant metastases. In the main group of patients with cricoid-cell form of cancer, metastases were found in 1 (100%) patients, with low differentiated adenocarcinoma - in 1 (6.7%), and with moderately differentiated adenocarcinoma - in 3 (12.0%). With highly differentiated adenocarcinoma, metastases were not observed.

In the endophytic form of tumor growth, metastases in the long-term postoperative period were determined in 2 (12.5%) patients of the main group, in the exophytic form of growth in 1 (7.1%), and in the mixed form of tumor growth in 3 (10.0 %) patients with RC.

An analysis of the three-year survival of patients with RC, depending on the type of surgical treatment performed, showed that the highest rate was observed after RC with anastomosis, where it was 91.7%. 3-year survival of patients after PARR with relegation of the colon was 85.7%, after PARR with relegation of sigma into the anal canal - 84.0%, after PPER with sigmostomy - 81.6%, after PARR with colostomy - 83.3%, and after Hartmann's operation - 66.7%.

A study of the three-year survival of patients with RC depending on the type of preoperative lymphatic chemotherapy showed that after the treatment regimen ELPCHT + RLPCHT + HRT, this indicator in the main group was 86.4%, and after ELPCHT + RLPCHT without HRT - 83.7%.

At the same time, the three-year survival rates after preoperative radiation therapy were almost identical and amounted to 83.8% after a single HRT at a dose of 13 Gy in the main group, and 80.6% after an ROD of 5 Gy to an SOD of 25 Gy.

The stage of the disease significantly affected the indicators of three-year survival of patients with RC. So, in the main group of patients, this indicator in stage IIa was 90.0%, in stage IIb - 87.5%, in stage IIIb - 79.4%.

The histological form of the tumor also significantly affected the three-year survival of patients with RC. In the main group of patients with cricoid adenocarcinoma and with undifferentiated cancer, mortality of patients for this period of time was not observed. With highly differentiated adenocarcinoma, this indicator was 92.8%, with moderately differentiated adenocarcinoma - 88.0%, with low-grade adenocarcinoma - 80.0%. Three-year survival rates for low-grade cancer were 33.3%.

Three-year survival with the exophytic form of tumor growth in the main group of patients with RC was 92.8%, with the endophytic form - 75.0% and with the mixed form of tumor growth - 83.3%.

An analysis of the five-year survival of patients with PKK, depending on the type of surgical treatment performed, showed that the highest rate was observed after PRR with anastomosis, where it was 83.3%. the five-year survival rate of patients after PARR with relegation of the colon was 71.4%, after PPER with sigmostomy - 81.6%, after PARR with sigma relegation in the anal canal - 68.0%, after PARR with colostomy - 50.0%, and after Hartmann's operation - 66.7%.

A study of the five-year survival of patients with RC depending on the type of preoperative lymphatic chemotherapy showed that after the treatment regimen ELPCHT + RLPCHT + HRT, this indicator in the main group was 76.1%, and after ELPCHT + RLPCHT without HRT - 69.6%.

At the same time, the five-year survival rates in the main group of patients after preoperative radiation therapy were slightly lower and amounted to 76.2% after a single HDT at a dose of 13 Gy in the main group, and 62.5% after the radiation treatment regimen of 5 Gy to SOD 25 Gy.

The stage of the disease significantly affected the five-year survival of patients with RC. So, in the main group of patients, this indicator in stage IIa was 80.0%, in stage IIb - 81.2%, in stage IIIb - 61.8%. The histological form of the tumor also significantly affected the five-year survival rate of RC patients.

In the main group of patients with undifferentiated cancer, with cricoid adenocarcinoma, with mucous cancer, with squamous cancer, five-year survival was not observed. With highly differentiated adenocarcinoma, this indicator was 78.6%, - 80.0%, with moderately differentiated adenocarcinoma - 88.0%, with low-grade adenocarcinoma - 60.0%.

Five-year survival with an exophytic form of tumor growth in the main group of patients with RC was 78.6%, with an endophytic form - 56.2% and with a mixed form of tumor growth - 73.3%.

Conclusions

1. An analysis of postoperative complications of a general nature showed that their number did not depend on the type of surgical intervention. The rather large clinical material shows the possibility of performing organ-preserving operations in patients with lower ampullar cancer of the rectum.
2. A new method has been developed for the complex treatment of patients with colorectal cancer, including preoperative high-dose hypoxiradiotherapy according to schemes with a single exposure at a dose of 13 Gy (in 37 patients) and irradiation with medium fractions of 5 Gy up to SOD 25 Gy (in 36 patients), followed by organ-conserving operations. The five-year survival rate for patients with colorectal cancer after endolymphaticpolychemotherapy and regional lymphatic chemotherapy with subsequent

organ-preserving surgeries was 69.6%, with the addition of preoperative hypoxiradiotherapy to 76.1%. The five-year survival rate after a single hypoxiradiotherapy at a dose of 13 Gy with subsequent organ-preserving surgeries was 76.1%, and after an irradiation regimen of ROD of 5 Gy to SOD of 25 Gy - 62.5%.

3. A new approach has been developed for the complex treatment of patients with colorectal cancer, including preoperative endolymphatic polychemotherapy and regional lymphatic polychemotherapy (in 47 patients), as well as in combination with hypoxiradiotherapy (in 40 patients), followed by organ-preserving operations.

4. An analysis of the five-year survival of patients with RC, depending on the type of surgical treatment, showed that the highest rate was observed after PRR with anastomosis, where it was 83.3%. the five-year survival rate of patients after PARR with relegation of the colon was 71.4%, after PPER with sigmostomy - 81.6%, after PARR with sigma relegation in the anal canal - 68.0%, after PARR with colostomy - 50.0%, and after Hartmann's operation - 66.7%. In patients of the control group, the five-year survival rate after performing PPER with sigmostomy was 68.3%.

Microhemodynamic Parameters of Cortical Substance of Kidneys at Experimental Hydronephrosis

Bakhtiyar Iriskulov[1], Ra'no Tadjibayeva[2]

[1]MD, Professor, Head of the Department of Normal and Pathological Physiology, Tashkent Medical Academy, Farobiy Street 2, Tashkent, Uzbekistan, [2]PhD, Senior Teacher, Department of Normal and Pathological Physiology, Tashkent Medical Academy, Farobiy Street 2, Tashkent, Uzbekistan

Abstract

Under conditions of unilateral occlusion of the ureter, the development of microhemodynamic disorders of the cortical substance of the kidneys was studied both on the damage side and on the contralateral (opposite) side. It has been established that disorders on the side of occlusion depend on the duration of obstruction of the lumen of the ureter, which determines the development of tissue hypoxia and violates trophic renal parenchyma. Dynamically functional disorders of the microvasculature occur at the early (on the 1st, 3rd, and 5th day), and irreversible changes in the renal parenchyma at the later (on the 14th and 30th day) stages of the experiment. The contralateral one responds to turning off the function of one kidney by adaptive restructuring of the microhemocirculatory system, which is manifested by dilatation of microvessels and an increase in the linear velocity of blood flow in them, which ensures its hyperfunction.

Keywords: *Microcirculation, rheology, hydronephrosis.*

Introduction

Hydronephrotic transformation of the kidneys as a result of impaired passage of urine is one of the most common forms of pathology, leading, as a rule, to the destruction of the affected kidney, a complete loss of its function[5]. Most studies on the activity of the kidneys in obstruction of the urinary tract reveal various aspects of the pathogenesis of hydronephrosis[7], structural changes in the renal parenchyma[6], and mechanisms of sanogenesis during restoration of urinary tract patency[9]. Recently, researchers have been paying close attention to the pathogenesis of microhemodynamic tissue disorders[1]. Changes in microhemodynamics lead to a decrease in adequate tissue perfusion, which naturally causes deep metabolic disturbances[4]. Disorders in the microcirculation system are the central link in the chain of disorders leading to the development of dysfunction and irreversible structural changes[7]. In the kidney, which performs the function of fluid filtration and absorption and is a well-vascularized organ with two capillary networks, pathological changes in microcirculation become extremely important. However, until now, insufficient attention has been paid to the study of the role of microhemodynamic disorders in the dynamics of the development of hydro-nephrotic transformation, which is largely due to the unsatisfactory state of the methodological base for obtaining reliable results. The current level of development of television technology allows you to plan and conduct intravital studies of internal organs in the dynamics of the development of various pathological conditions. The purpose of the study was to study the dynamics of microhemodynamic disorders of the cortical section of the renal parenchyma with unilateral full ureteral occlusion.

Materials and Method

Under the conditions of the experiment, we studied the state of microhemodynamics of the cortical region of both kidneys during the development of unilateral hydronephrosis. The experiments were conducted on 90 (48 experimental, 36 false-operated, 6 intact) outbred adult males. Occlusion of the right ureter was carried out by its complete ligation. Microcirculation of the renal cortex was examined on the 1st, 3rd, 5th, 7th, 14th and 30th days after ureter ligation. Kidney bio microscopy was performed under general anesthesia with etaminal at a dose of 8 mg/100 g of body weight of the animal.

The control was animals that underwent a laparotomy with revision of the retroperitoneal space without ureter ligation. In order to optimize research and improve the quality of the results obtained, we used a system of television analogs of the digital conversion of microstructures with morphometry of the microcirculation parameters. The results of the study were recorded on digital media.

Results

Normally, under the microscope, single efferent arterioles and peritubular capillaries are visible. The diameter of arterioles varies between 18.7–25.8 μm. The bloodstream in them is jet, in a continuous flow. The linear velocity of blood flow in arterioles was (0.557±0.073) m. Peritubular capillaries extending from the efferent arteriole, widely anastomosing each other, form a network with polygonal cells, extend along the tubules. The boundary between the tubules and capillaries differed by: due to whitish crimped stripes that appear when light is refracted by the epithelium of the tubules. It is noteworthy that almost all capillaries visible in the field of vision function. The diameter of the capillaries is - (9.70±0.38) μm of blood flow in them in a continuous flow, jet, blood flow speed –(0.446±0.044) ms.

Discussion

During studying the microvasculature, after the first day, the angioarchitectonics of the vessels were preserved on the obturated side, the individual capillaries were turned off and filled with blood plasma. They alternated with dilated capillaries in which blood flow was slowed down by 61.2% compared with the values of intact animals (table). The contours of the capillaries are even, clear. During this period, on the contralateral side, all the vessels visible in the field of view functioned, which were somewhat dilated. In individual PICs, the colloidal contents of the blood stream are fine-grained. In the control group of animals, the microvasculature was characterized by a distinct contour of the vascular bed, an insignificant (by 19.1%) decrease in the linear velocity of blood flow.

Table 1: Morphometric parameters of microhemocirculatory channel of animal kidneys with occlusion of the right ureter

Term of the experiment, day	Diameter of the capillaries of PICs, μm		Blood flow speed, ms	
	Right kidney	Left kidney	Right kidney	Left kidney
Intact animals	9.70±0.38		0.446±0.044	
1st	$\frac{10.60 \pm 0.84}{9.20 \pm 0.66}$	$\frac{9.60 \pm 0.51}{9.10 \pm 0.72}$	$\frac{0.173 \pm 0.034*}{0.381 \pm 0.043}$	$\frac{0.361 \pm 0.023}{0.389 \pm 0.057}$
3rd	$\frac{10.12 \pm 1.09}{9.50 \pm 0.71}$	$\frac{9.80 \pm 0.34}{9.70 \pm 0.82}$	$\frac{0.195 \pm 0.045*}{0.397 \pm 0.093}$	$\frac{0.339 \pm 0.022}{0.410 \pm 0.062}$
5th	$\frac{11.20 \pm 0.33*}{9.60 \pm 0.59}$	$\frac{10.20 \pm 0.48}{9.90 \pm 0.76}$	$\frac{0.142 \pm 0.036*}{0.431 \pm 0.063}$	$\frac{0.427 \pm 0.039}{0.410 \pm 0.055}$
7th	$\frac{12.30 \pm 0.68*}{9.80 \pm 0.55}$	$\frac{10.70 \pm 1.37}{9.50 \pm 0.63}$	$\frac{0.126 \pm 0.031*}{0.428 \pm 0.026}$	$\frac{0.461 \pm 0.067}{0.425 \pm 0.055}$
14th	$\frac{13.70 \pm 0.92*}{9.30 \pm 0.72}$	$\frac{11.20 \pm 0.64}{9.40 \pm 0.66}$	$\frac{0.090 \pm 0.013*}{0.415 \pm 0.041}$	$\frac{0.526 \pm 0.028*}{0.427 \pm 0.034}$
30th	$\frac{}{9.80 \pm 0.65}$	$\frac{12.60 \pm 0.71*}{9.6 \pm 0.8}$	$\frac{}{0.435 \pm 0.059}$	$\frac{0.533 \pm 0.032*}{0.423 \pm 0.021}$

Note: Numerator - values of experimental group, denominator - false-operated.
*The results are reliable in relation to control (P<0.05)

Three days later the ligation of the ureter on the obturated side, the areas of dilated capillaries alternate with the areas that function normally: without signs of stagnation. The blood flow velocity in the capillaries is - (0.195±0.045) mm/s continuous, even flow. The contours of the vessels are clear, correct, without pathological changes. Observed separate sections of blood vessels, clogged stagnant blood, as well as the foci of the capillary network that are emptied, are erased in these sections of the boundary between the individual PIC loops. On the 3rd day of the experiment, in the opposite kidney, there was an expansion of blood vessels with streaming continuous blood flow and some homogenization and the disappearance of the characteristic glow of the PIC epithelium. On the 5th day of the experiment, the angioarchitectonics were disrupted on the obturated side, only a few sharply expanded capillaries function, the blood flow in them is grainy, the boundaries are somewhat blurred. Most of the capillaries are turned off from the bloodstream. The boundary between the capillaries and the PIC is blurred. The renal parenchyma in these areas is homogenized. From the side of the opposite kidney, total abrasion of the vessels was observed. The blood flow velocity in them exceeded the corresponding indicator at the previous study period by 25.9% (see table). Plots of diapedesis are marked in places, which indicates o increased permeability of capillaries PIC. In these areas, the PIC is filled with dense contents.

On the 7th day of the experiment, the angioarchitectonics of the kidneys was disrupted due to the disappearance of the microvessels and PIC circuits, which are homogenized in most areas. Along with this, there are areas of functioning capillaries, which are sharply expanded, the blood flow in them is slow, granular, sometimes segmented. Identified areas of clogging of capillaries of stagnant bloodstream. The boundaries between the PIC loops are erased. In contrast to the obstructed, contralateral night was characterized by areas of vasodilation.

The borders of vessels are clear, without turning off. The blood flow is-(0.461±0.067) mm/s, which is slightly higher values of the intact group of animals.

On the 14th day, the renal antioarchitectonics was preserved, the contours of the vessels were smooth and clear, alternation of half-blood capillaries with plasmatized, collapsed, non-functioning ones was noted. blood flow continuous, trickle, fast. Individual PIC capillaries are sharply expanded, overflows with stagnant blood. The contours of the non-functioning vessels are blurred. There are separate sections of perivascular hemorrhages. On the opposite side, the angio-architectonics of the kidney is preserved, all vessels visible in the field of vision are functional. The contours of the vessels are even, clear. Perivascular space without inclusions. The bloodstream is fast, stream, continuous its speed is 11.8% lower than the values of the intact group of animals.

On the 30th day of the experiment, almost complete destruction of the kidney parenchyma was observed at the occlusion side. The vascular bed of the cortical crown of the affected kidney was practically undetectable. A lot of scraps of starting plasmatized and hyalinized capillaries appeared in separate thrombus capillaries. In the opposite kidney, previously detected compensatory manifestations in the microhemocirculatory system were noted: the vessels were dilated, their circuits were clear continuous; a small tortuosity of the vessels due to an increase in pressure in them.

Thus, in animals experiment a progressive decrease in renal blood flow on the side of the obstruction was established, due to an increase in the resistance of the renal microvessels associated with thrombosis and the removal of most peritubular from the bloodstream, their destruction due to a sharp increase in hydrostatic pressure. These changes, in turn, lead initially to focal, and later dates (on the 14th and 30th days of the experiment) - to diffuse necrosis and atrophy of the kidney parenchyma. No disturbances were detected in the false-operated animals. During the entire study period, the vascular architectonics were preserved, the boundary between them and the loops of the proximal convoluted tubules was clear. The blood flow in the components of the microcirculatory system accessible for microscopy was jet, in a continuous flow. The mental blood flow indices in microvessels practically did not differ from those of intact animals.

Thus, a comparative analysis of the results of the study in the experimental group and the group of false-operated animals allows us to conclude that the characteristic dynamics of unidirectional changes in the early stages is really associated with the activation of the sympathetic-adrenal system. The absence of any changes in the microcirculatory system of the kidneys in the later stages of the experiment, when the influence of stress factors associated with operating trauma is completely

excluded, once again confirms the significance of stress factors in the occurrence of microcirculatory disorders.

Conclusion

Disorders of the microvasculature of the kidneys on the side of occlusion depend on the duration of obstruction, which contributes to impaired trophism of the renal parenchyma, the development of tissue hypoxia and the emergence of dynamic functional disorders in the early days (on days 1, 3, 5) and irreversible changes in the renal parenchyma at a later date (on the 14th and 30th day) of the experiment. 2. To turn off the function of one kidney, the other responds by adaptive restructuring of the microhemocirculatory system, manifested by dilatation of microvessels and an increase in the linear velocity of blood flow in them, which ensures its hyperfunction.

Health Quality Assessment of Patients with Toxic-Diffuse Goiter

Saydiganikhodja I. Ismailov[1], Komila Kh. Khayitboeva[2], Rashid Yu. Ruzibaev[3], Duschan Sh. Sapaev[4]

[1]MD, Professor, Head of the Department of Endocrinology and Pediatric Endocrinology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [2]MD, PhD, Department of Surgical Diseases, Urgench Branch of Tashkent Medical Academy, Urgench, Uzbekistan, [3]MD, Professor, Department of Surgical Diseases, Urgench Branch of Tashkent Medical Academy, Urgench, Uzbekistan, [4]MD, PhD, Department of Surgical Diseases, Urgench Branch of Tashkent Medical Academy, Urgench, Uzbekistan

Abstract

In recent decades, there has been a significant increase in the number of patients with thyroid disorders[1,4]. The widespread introduction of highly informative diagnostics method (ultrasound, fine-needle aspiration biopsy, tests on hormones and levels of antibody) and screening studies into medical practice led to an increase in detection rate of thyroid disorders[4,5,8]. Among patients with thyroid pathology, the thyrotoxicosis syndrome significantly complicates the course of thyroid disorders, which makes it difficult to choose a rational treatment strategy, affects the long-term result of treatment, and significantly worsens the disease prognosis[8,10].

Keywords: *Thyroid disorders, Graves' disease, goiter, patient, grave.*

Introduction

In clinical practice, it is appropriate to distinguish 3 main diseases that occur with thyrotoxicosis syndrome: toxic diffuse goiter (Graves' disease), multinodular toxic goiter (MTG), and toxic adenoma (TA) of the thyroid gland. The surgeons most often face such disorders. In more rare cases, the cause of thyrotoxicosis development is iodine-induced thyrotoxicosis and inflammatory thyroid disorders - thyroiditis[8]. The thyroid disorders with thyrotoxicosis syndrome have characteristics of serious thyrotoxicosis complications that significantly worsen the course of the disease and its prognosis and influence the quality of life, such as endocrine ophthalmopathy, cardiomyopathy, arrhythmia, heart failure, weight loss, heat intolerance, insomnia, muscle weakness, pretibial myxedema, women often have menstrual disorders, men – gynecomastia, decreased libido, erectile dysfunction [1]. In case of Graves' disease, the endocrine ophthalmopathy (EOP) develops in 25-70% of cases[3], pretibial myxedema – in 2%[1]. In 5-22% of all cases the thyrotoxicosis syndrome occurs with cardiomyopathy, especially among elderly people that suffer from MTG[8]. The toxic diffuse goiter is a disease with such characteristics as increased production of thyroid hormones and diffuse growth of the thyroid gland (TG) of various degrees. The Graves' disease incidence varies from 30 to 200 per 100 thousand people within the course of one year. In regions with normal iodine supply, Graves' disease is the most common cause of persistent thyrotoxic condition, and in iodine-deficient regions, Graves' disease competes with the functional autonomy of the thyroid gland (nodular and multinodular toxic goiter) within the etiological structure of Graves' disease toxic goiter [4]. Graves' disease is one of the main causes of the endocrinological help request among population, it includes 80% of all thyroid hyperfunction cases and is most common in the age of 20 to 40 years; the disorders rate among women is in 10-20 times larger. The presence of symptoms that complicate the course of the disease undoubtedly negatively influence the health, performance and quality of life of patients [11]. In accordance with the evidence-based medicine, the study of the quality of life (QOL) among patients is mandatory in order to determine the efficiency of the treatment method [2]. The key treatment method of thyroid disorders with thyrotoxicosis syndrome ca n be combined into three groups: complex medicamentous therapy, radiotherapy (RT) and surgical treatment, used

separately and in various combinations. Each method has both advantages and disadvantages, which is a wide topic for discussion in the literature[12]. The standards of patients management with thyrotoxicosis (in accordance with the Russian, American, European, Chinese, Korean, Japanese, Australian, Latin American thyroid associations) differ significantly [13]. QOL (quality of life) is an indicator of a patient's physical, psychological, emotional and social functioning on the basis of their subjective condition perception[14].

The purpose of the research: To study the degree of toxic diffuse goiter incidence among thyroid pathologies and assess the quality of life among urban population of Urgench (Khorezm region, Uzbekistan) on the basis of the received therapy.

Materials and Method

The study included patients with thyroid pathology who sought medical service of endocrinological dispensary in Urgench from 2014 to 2019. We analyzed the medical history of 697 patients with thyroid pathology retrospectively. All patients passed the complete physical examination: General Clinical researches; hormones level detection (total T3, SV. T4, TSH); immunological indicators examination (Ab-r TSH,Ab-TPO). In addition to hormonal research, there was an ultrasound examination of the thyroid gland. There were scintigraphy and fine-needle biopsy of the thyroid gland among patients with nodules (by indications). We examined the timely visits of patients to endocrinologists, assigned standard therapy of toxic diffuse goiter. In order to study the quality of life among patients with Graves' disease, we used the SF-36 quality of life questionnaire, which reflects patients 'satisfaction with their physical and mental condition, social functioning, and self-assessment of the pain syndrom severity. We determined the sum of total score by 8 parameters: physical functioning, role functioning, pain intensity, general medical condition, vitality, social functioning, emotional functioning, and psychological health. The questionnaire has such design that a higher score reflects a higher level of quality of life. In addition, 20 healthy volunteers also completed a questionnaire to obtain benchmark indicators specific to healthy individuals. This questionnaire has Uzbek translation, and the patients managed to answer all the questions by themselves.

We used the quantitative assessment in regard to the following indicators: PF – physical functioning which reflects the extent to which the health state limits the performance of physical loads such as self-care, walking, stair climbing, heavy loads handling, body bending, and significant effort tolerance; RP is the influence of physical state on the role functioning (work, daily activities); BP – bodily pain and its impact on the ability to engage in daily activities like household duties inside and outside of the house; GH – general medical condition – health condition assessment by the patient at the moment and the prospects of a cure, resistance to disease; VT – vitality, a rise of vitality means feeling full of energy or, on the contrary, weakened; SF – social functioning, determined by the degree to which physical or emotional condition restricts social activities (communication); RE – influence of emotional state on role functioning, seeks to assess the extent to which emotional state interfere with work or other regular daily activities, as well as a heavy timetable, descrease of workload and its quality; MH – characteristics of mental health (depression, anxiety, general indicator of positive emotions).

The research materials were subject to statistical processing by means of statistics software packages Excel 2003, STATISTICA 6.0 (Stat-Soft, 2001).

Research Results and their Discussion

Table 1: The number of patients with thyroid cancer who applied to the endocrinological dispensary in the city of Urgench.

№	Nosology	Quantity
1.	Toxic diffuse goiter	109
2.	Diffuse-nodular goiter	24
3.	Toxic adenoma	45
4.	Diffuse goiter with euthyroidism	136
5.	Nodular goiter with euthyroidism	98
6.	Diffuse-nodular goiter with euthyroidism	72
7.	Autoimmune tireodit of thyrotoxic phase	23
8.	Autoimmune thyroidit with euthyroidism	79
9.	Condition after strumectomy	66
10.	Cysts of the thyroid gland	44
11.	Thyroid cancer	1

We examined the medical history of 697 patients with thyroid pathology. Among them there were 453 women and 244 men within the age range from 18 and

65. The duration of the disease with thyrotoxicosis was on the average of 8.3±2.1 years. The analysis of the patient's medical history revealed 109 (15.63%)patients with (Graves' disease), diffuse-nodular goiter among 24 (3.4%), toxic adenoma among 45 (6.48%), diffuse goiter with euthyroidism among 136 (19.51%), nodular goiter with euthyroidism among 98 (14.1%), diffuse-nodular goiter with euthyroidism among 72 (10.3%), autoimmune thyroiditis (AT) thyrotoxic phase among 23 (3.3%), AT euthyroidism among 79 (11.33%), condition after strumectomy among 66 (9.5%), thyroid cysts among 44 (6.31%), thyroid cancer in case of 1 (0.14%) patient (table 1).

The examination of the patient's medical history revealed that 178 (25.5%) patients within the group of the examined patients had thyrotoxicosis syndrome. We verified the thyrotoxicosis syndrome by the determination of thyroid hormones. The patients with Graves' disease had the average level of TSH around 0.1±0.02 MED/l, SV. T3-7,8±1.1 PG/ml, SV. T4-22.6±2.4 PG/ml, antibodies in relation to TSH receptors 2.3±1.2 IU/l, antibodies in relation to thyroperoxidase (TPO) - 58.7±3.1 IU/l (table.2.) Whereby, the reference values for TSH were 0.3-4.5 MED/l,for SV. T3 2.0-4.2 PG/ml, for ESV.T4-8,9-17,2 PG/ml, antibodies in relation to TPO-0-30ME/l, antibodies in relation to TSH receptors 0-1,49 IU/l.

Table 2: Changes in thyroid hormones in accordance with the pathology

Nosology of TG pathology	Control group, n=20	Graves ' disease, n= 109	Diffuse-nodular goiter, n= 24	Toxic adenoma, n=45
TSH, mU/l	2,2±0,7	0,1±0,02*	0,1±0,05*	0,1±0,02*
SV. T3, pg/ml	0,8±0,3	7,8±1,1*	6,2±1,3*	6,5±1,6*
Sv. T4, pg/ml	14,2±0,9	26,7±0,3*	29,4±0,4*	23,4±0,3*
Antibodies to TSH receptors, IU/l	0,3±0,02	3,4±0,5*	2,5±0,1*	2,9±0,5*
Antibodies to thyreoperoxidase, IU/l	20,6±3,4	58,7±3,1*	24,3±2,1*	27,7±2,7*

Note: Statistical significance to CG: * P<0.05 in relation to CG.

In case of endocrine profile interpretation, we found indications among 109 patients with Graves' disease, among them there were 72 (66 %) of female patients, and 37 (34 %) of male patients.

We diagnosed diffuse enlargement of the thyroid gland (TG) with palpation among each patient with Graves' disease in accordance with O. V. Nikolayev. We used the ultrasound examination in order to determine the volume and structure of the thyroid gland. We observed an TG increase of the 1st degree among 23 (21.1%) patients, of the 2 degree among 54 (49.5%), of the 3 degrees among 27 (24.8 %), of the 4 and 5 degrees among 5 (4.6%) patients. The ultrasound examination determined the volume of TG, with an average volume of 24.8±7.3 cm^3 among women and 32.3±9.3 cm^3among men.

By utilisation of services, we divided all patients with Graves' disease into 4 groups in accordance with the duration of the disease. The group 1 included patients with duration of the disease of up to 6 months, the group 2 up to 12 months and more than a year, the group 3 –3-5 years and the group 4 more than 5 years.

Table. 3: The complications development among patients with Graves' disease in accordance with the disease duration

Groups	Goiter heart	Endocrine ophthalmopathy	Toxic hepatitis	TSH, mU/l
1 group, n= 62	2 (3,2%)	24 (38,7%)	-	0,3±0,01
2 group, n=74	5 (6,8%)	32 (43,2%)	1(1,4%)	0,2±0,02
3 group, n=41	6 (14,6%)	26(63,4%)	2 (4,8%)	0,3±0,01
4 group, n=28	5 (18%)	19 (67,8%)	2 (7,1%)	0,4±0,01

In group 1, there were 62 patients who received thyrostatics with a daily dose of 25.4±2.1 mg/day (average TSH level of 0.3±0.01 Med/l), in group 2, 74 patients (thyrostatics with a dose of 20.3±2.4 mg/day and an average TSH level of 0.2±0.01 Med/l), in group 3, 41 patients that use of thyrostatics with a daily dose of 15.1±1.6 mg/day (average TSH level of 0.3±0.01 Med/l), in group 4, 28 patients that used thyrostatics with a daily dose of 12.2±1.1 mg on average (average TSH level 0.4±0.01 MED/l).As you can see, with the duration of the disease, there is a decrease in the dose of thyrostatics, but whereby there is no clinical improvement. The patients with Graves' disease with a duration of up to 6 months: we observed clinical and biochemical remission among 23 (37%) patients. The patients with Graves' disease with a duration of up to the 1st year: we observed clinical and biochemical remission among 34 (46 %) patients, in group 3 among 8 (19.5 %) patients and in group 4 - among 9 (32.1%) patients. The average TSH level was 1.2±0.05 med/l. we observed such complications as goiter heart among 2 (3.2%) patients, endocrine ophthalmopathy among 24 (38.7%) patients in the group 1, in group 2 among 5 (6.8%) patients, among 32 (43.2 %); in group 3 among 6 (14.6%), among 26 (63.4%);in group 4 among 5 (18%) and 19 (67.8%) patients, respectively. (table 3.). We did not detect any toxic hepatitis within the first group, there was 1.4% in group 2, 4.8% in group 3, and 7.1% in group 4 (table 3.) Within the examination of patients in these groups in relation to the treatment of Graves' disease, we observed that in group 1, 28 (45.1%) of patients showed improvement in their condition, 34 (54.9%) patients continued treatment with thyrostatics, despite the fact that there were indications for surgical treatment. In group 2, 24 (32.4%) patients recovered, 37 (50.0%) continued medication, and 13(17.6%) patients passed surgical treatment - total thyroidectomy. Among 24 recovered patients, the indicator of antibodies in relation to TSH receptors was on the average of 0.76±0.03 IU/l, respectively, these patients did not have clinical implications of thyrotoxicosis. In case of group 3 analysis, we observed recovery among 2 (4.9%) patients, respectively, the average level of antibody in relation to TSH receptors was 0.96±0.07 IU/l, 29 (70.7%) then the patients continued medication,since they had a high indicator of 2.3±0.05 IU/l that refer to the disorder persistence, and 12 (24.4%) passed operations. In group 4, 2 of patients (7.2 %) there was a health improvement (the average TSH level of 1.6±0.02 Med/l and TSH receptor in relation to antibodies by 0.72±0.02 IU/l), and 22 (78.6%) continued treatment with thyrostatics (average TSH level of 0.2±0.04 Med/l and TSH receptor in relation to antibodies by 2.5±0.09 IU/l) and 4 (14.3%) of patients passed medical operations(table.4.) The patients who had complaints with characteristics of the clinical thyrotoxicosis and the value of antibodies in relation to TSH receptors higher than the reference values, continued to take antithyroid medicines.

We should note that not all patients within the dynamics of treatment passed the examination on antibodies in relation to TSH receptors, since we indicated the start of disorder remission by the absence of thyrotoxicosis symptoms and normalization of antibodies in relation to TSH receptors and hormone indicators within the scope of thyroostatic therapy.

Table. 4: Dynamic observation of patients with toxic diffuse goiter

Group of patients	Recovered, n (%)	Prolonged medical treatment, n (%)	Surgical management, n(%)
1 group, n= 62	28 (45,1%)	34 (50%)	-
2 group, n= 74	24 (32,4%)	37 (50,0%)	13 (17,6%)
3 group, n= 41	2 (4,9%)	29 (70,7%)	12 (24,4%)
4 group, n= 28	2 (7,2 %)	22 (78,6 %)	4 (14,3 %)

The diffuse-nodular goiter within the TG pathology constituted 24 (3.4%) patients, and toxic adenoma 45 (6.45%) patients. During palpation and ultrasound examination, we found nodes up to 1 cm among 26 (37.7%) patients, and more than 1 cm among 43 (62.3%) patients. We made the diagnosis by means of hormone testing and TG scintigraphy. We performed the scintigraphy in the RSPC of the endocrinology. We found inflammation spots by scintigraphy. All patients received the medicamentous therapy with thyrostatics

until subclinical hypothyroidism progress within 3-6 months and passed surgery operations.

In case of the conducted thyroostatic therapy analysis among patients with Graves' disease, we found that among them 28 (25.6%) patients received long-term medication for up to 10 years with inappropriate medicamentous therapy within the latest medicine doses in regard to the severity of thyrotoxicosis and it caused various complications of Graves' disease. Subsequently, in case of ineffective medicamentous therapy for more than 5 years, 20 (71.4%) patients had a thyroidectomy, among them 9 (45.0%) patients had subtotal thyroidectomy and 11(55.0%) had total thyroidectomy. We performed the thyroidectomy in the department of surgery in the city endocrinological dispensary of Urgench. Within the treatment period from 3 to 5 years, 6 patients with cardiovascular complications did not referred for surgical treatment service and continued thyrostatics treatment. In case of operated patients observation within 3 and 6 months, we observed a decrease in the functional activity of the TG among 8 (27.6%) patients, since there was no prescription for timely hormone replacement therapy (HRT) with thyroid medications. Among the operated patients, only 5 patients (17.2%) in the early postoperative period received HRT with levothyroxine at a dose of 1.2±0.5 mcg/kg per day without full compensation. In the study of TSH and SV. T4 patients we diagnosed subclinical hypothyroidism among these, with an average TSH level of 5.4±0.7 MED/l. In order to correct these disorders, we increased the dose of levothyroxine to 1.6 mcg/kg. Whereby, the average TSH level was 5.4±0.7 MED/l. 15 patients after thyroidectomy did not come for reexaminations. In accordance with the indications, if the patient refuses surgical treatment, there were recommendations in regard to 2 patients to pass treatment with radioactive iodine in the radiological Department in the RSPC of the endocrinology.

In addition, we diagnosed T3 toxicosis among 2 women, whereby both had a common fraction. In the medical history analysis of these women, we found that they used HRT for a long time together with sex hormones. On ultrasound examination of the thyroid gland, we diagnosed a diffuse goiter of 1-2 degrees without any structural changes of TG. It is known that the medication intake leads to an increase in total T3, whereby the content of total and SV. T4, as well as TSH stay within the norm[7]. Clinically, these women did not have any complaints. These women stopped HRT by sex hormones and they got a prescription to use other non-hormonal method of pregnancy prevention.

We used a QOL questionnaire SF-36 in order to study the quality of life among patients with Graves' disease on the basis of the received therapy. We divided all patients with Graves' disease into 2 groups. The first group included 30 patients with Graves' disease who had received medicamentous therapy for more than three years and the second group 24 patients after thyroidectomy in case of Graves' disease. Among 29 patients under surgery, 3 (10.3%) had hypoparathyroidism as postoperative complication, and 2 (6.9%) had recurrent nerve paresis. These patients visited an endocrinologist and an otorhinolaryngologist in order to pass rehabilitation. We did not include these patients into this group. Among the patients of both groups, all parameters of quality of life present with examination were significantly lower than among healthy individuals ($P<0.001$) by all scales of vitality within group 1: $P<0.01$ for the vitality scale in group 2 and $P<0.001$ for all other parameters in group 2. (table 5.). Between the patients of two groups there were the following differences: the parameters physical functioning, vitality, social, emotional functioning and mental health were significantly higher in the group of patients after total and subtotal thyroidectomy ($P<0.001$),the role functioning was not significantly different in both groups of patients, and indicators of social functioning were significantly higher (30.7%) in the group of patients under medicamentous therapy by thyreostatics($P<0.001$), as endocrine ophthalmopathy was more large in this group. Within the comparison of the QOL among patients with Graves' disease within both groups, we found that the average values of physical functioning, role-based physical functioning, social functioning , role- based emotional functioning and mental health after surgery significantly exceed similar indicators among patients who received medications with thyrostatics, although the average level of TSH in both groups did not significantly differ. In the first group, the average TSH level was 2.3±0.02 Med/l, in the second group 3.1±0.05 MED/l. The emotional functioning and psychological health in the 2 group of patients are higher by 40.7% and 22.5%, respectively.

Table 5: Parameters of QOL assesment among patients with Graves' disease in accordance with the treatment

Parameters	CG, n=20	1 group, n=30	2 group, n=24
Physical functioning	60,35±2,21	17,43±3,08***	22,33±5,38***^
Role functioning	64,52±3,28	24,10±3,24***	28,14±3,62***
Pain	12,16±3,74	20,13±1,41***	15,32±6,72***
General medical condition	58,17±3,26	45,23±2,33***	47,02±3,14
Vitality	78,06±2,76	30,50±2,11***	46,25±4,22**^
Social functioning	52,13±1,84	27,33±2,59***	39,95±3,02***
Emotional functioning	81,57±2,41	29,53±1,70***	49,81±2,97***^
Psychological health	74,65±2,57	48,27±1,95***	61,28±2,64^

Note: Statistical significance with CG: * * P<0.01, ***P<0.001; statistical significance between groups 1 and 2: ^P<0.05 CG-control group

Thus, the timely appointment for thyroidectomy in cases of Graves' disease in real time leads to patients health improvement. After thyroidectomy, all patients should pass a hormone examination in order to fulfill timely hormonal replacement therapy. Timely appointment for hormonal replacement therapy with thyroid medications improves the quality of life and prevents the development of complications within various organs and systems.

Conclusions

1. Among the examined patients of the Urgench endocrinological dispensary that suffered the thyroid pathology in 2014 - 2019,we observed:15.6% of toxic diffuse goiter, 3.4% of diffuse-nodular goiter, toxic adenoma in 6.4% cases, diffuse goiter with euthyroidism in 19.5% cases, nodular goiter with euthyroidism in 14% cases, mixed goiter with euthyroidism in 10.3% cases, autoimmune thyroiditis, thyrotoxic phase in 3.3% cases, autoimmune thyroiditis with hypothyroidism in 11.3% cases, condition after strumectomy in 9.5% cases, thyroid cysts in 6.31% cases, thyroid cancer in 0.14% cases.
2. The quantity of patients with toxic diffuse goiter and goiter heart was 3.2%, endocrine ophthalmopathy 38.7% of patients within the first group, within group 2 6.8% and 43.2 %; within group 3 in 4.6% and 63.4%; within group 4 in 18% and 67.8%, respectively. There was no diagnosis of toxic hepatitis within the first group, 1.4% within group 2, 4.8% within group 3, and 7.1% within group 4, respectively. We should note that with an increase in the duration of inadequate thyrostatic therapy, the percentage of these complications increases, which confirms the need for correct medicine management and a timely transition to radical method of treatment.
3. In case of ineffective medication, only 26.6% of patients had a thyroidectomy. After surgery, only 17.2% received HRT with levothyroxine at a dose of 1.2±0.5 mcg/wt per day without full compensation. The remaining 55.1% of patients did not come to reexaminations. In order to improve the diagnosis and treatment of thyrotoxicosis syndrome in the Khorezm region, we recommend to conduct a number of seminars for doctors.
4. In comparison between the QOL among patients with Graves' disease after timely thyroidectomy, the average values of physical functioning exceed by 23% in relation to medicamentous therapy, the indicators of emotional functioning and mental health, as well as social functioning significantly exceed by 40.7%, 22.5% and 30.7%, respectively, similar indicators of patients under medicamentous therapy with thyrostatics.
5. We observed hypoparathyroidism among 0.3% of patients with toxic diffuse goiter after total thyroidectomy and among 6.9% of patients with recurrent nerve paresis, which indicates the need for training of operating surgeons in Urgench at the workplace of experienced surgeons.

Abstract

In modern cardio surgery, it has become possible to predict not only the outcome of surgical interference in order to save life, but also its effectiveness in terms of the quality of life improvement. It is proved that coronaro correcting technologies can not only soften the clinical picture of chronic coronary insufficiency, but also increase the contractility of the ischemic myocardium, as well as significantly improve the patient's quality of life, if the myocardial ischemia has the character of hibernation, and not stanning. The ability to determine which variant of the ischemic syndrome occurs in the patient before surgery helps to predict the interference effectiveness. The method used for this purpose (radioisotope scintigraphy, positron emission tomography, MRI, pharmacological stress echotests) are technically or economically inaccessible, difficult to apply in the perioperative period, and sometimes dangerous.

The purpose of the research: to offer an informative, accessible and safe method of preoperative identification of the hibernating myocardium among patients with IHD for successful prediction of the interference effectiveness.

Materials and Method: 83 patients with acute and chronic forms of IHD were under study. In the first group (49 people), there was a coronary stenting (CS). In the second group (34 patients), there was a heart bypass surgery (HB). There was the comparative assessment analysis in regard to variant of ischemic syndrome and the effectiveness of both operations by means of precardial ECG mapping and stress echotest with dipyridamole.

Results: In case of IHD acute forms (acute coronary syndrome, acute myocardial infarction) CS and HB operations had significant positive dynamics in regard to indicators of coronary blood flow within the course of ischemia and myocardial contractility in accordance with precordial mapping (area reduction of ischemia - AST and the decrease of the ischemia degree - ΣST) and stress echotest with dipyridamole (increased contractility of EF indicator and a reduction of ESV, increase in the number of eukinetic segments of the myocardium and decrease of hypokinetic segments). We observed the same dynamics, but much less pronounced, in accordance with ECG mapping and stress echotest data after both operations within the group with chronic forms of ischemia.

Conclusion: The precardial ECG mapping is informative and available for use in regional cardiosurgical clinics as a method of the hibernating myocardium identification, which is a more perspective variant of ischemia in case of IHD in terms of left ventricular contractility increase.

Keywords: *Coronary stenting, coronary bypass, prognosis, stress echocardiography, ECG mapping.*

Introduction

Currently, the prognosis of outcomes and complications in surgical treatment has gone far from the primitive principle of the patient's chances comparison in regard to a favorable outcome within conservative and surgical treatment. We consider currently performed high-tech operations as the most complex and effective (but at the same time with risk possibility) among all known coronarocorrecting operations. The new data on the pathogenesis of coronary insufficiency and variants of ischemic syndrome have created a demand for such prognosis method that allow us to calculate not only the patient's chances of survival after surgery, but also the improvement possibility degree in regard to the pumping heart function. Whereby it makes available not only as "prognosis quo ad vitam ", that is, the prognosis for survival after surgery, but also as" prognosis quo ad valetudinem", that is, the prognosis in regard to the patient's quality of life after surgery. And one can determine it by which of the ischemic syndrome variants occurs in case of this patient.

Thus, in order to calculate the patient's chances to pass coronarocorrecting interferences with high positive result, it is important that the preoperative examination helps to detect the presence of a hibernating myocardium. Whereby in this variant of ischemic syndrome (unlike stanning) the improvement of coronary blood supply restores (or at least significantly improves) their contractile function. In case of coronary syndrome promising variant includes hibernating myocardium, and effective revascularization as a result coronarocorrecting operation, one can expect a significant increment of the left ventricle contractile ability with reduction of heart failure signs, a positive clinical dynamics and improvement in quality of life.

Currently, the most widely used in coronary surgery, that is, relatively accessible, simple and informative is the indirect method of the hibernating myocardium identification – the method of stress echocardiography with dobutamine (dipyridamole or nitroglycerin). However, this method is technically quite complex, in addition, during the perioperative period, it is dangerous for patients with acute forms of IHD. We have proposed a method of precardial ECG mapping for this purpose. The origins of this method refer to the 70s of the last century in order to estimate the size of the necrosis focus in case of myocardial infarction, the area of the so-called "peri-infarction zone", or the ischemic myocardial necrosis focus around it. We consider this zone as a zone of "critical blood supply" and, as practice confirms, when the coronary blood flow improves, it completely recovers and returns to the normally functioning myocardium. If the treatment was not quite effective, this zone increases the area of the necrosis focus with complete elimination from the heartbeat[1].

Materials and Method

In order to assess the prognosis reliability in relation to complications, outcome and effectiveness of surgery operation, we examined the status of the ischemic myocardium (a form of ischaemic syndrome) and its dynamics as a result of coronary correction by CS method, and also CABG method, in two groups of patients – with acute (acute coronary syndrome, acute myocardial infarction) and chronic (angina FC II-IV) forms of IHD with initial signs of heart failure. There was an integral assessment of the heart pumping function recovery based on the results of stress echotest with dipyridamole.

The study included 83 patients of both sexes (62 men and 21 women) in the age from 38 to 65 years (average age 54.3+1.21) with acute and chronic forms of IHD. There was randomization, in which the criteria of non-inclusion were: age≥65 years; acute myocardial infarction or acute stroke, a medical history of HB or CS operations; multifocal (more than 3 vessels) demages of the coronary bed; the presence of resistant arterial hypertension, chronic bronchopulmonary conditions, thrombophilic and anaemic syndromes, heart failure above grade II in accordance with NYHA. We established such criteria because the assessment did not refered to the effectiveness of any medical or surgical interference, but to the reliability of prognosis technology.

We divided the patients under study into 2 groups. The patients of the first group (49 people) passed coronary stenting. This group included 17 patients with acute and 32 patients with chronic forms of IHD.

The second group consisted of 34 patients with acute (11 people) and chronic (23 people) forms of IHD, who passed HB. A retrospective analysis showed that the age-sex structure of all subgroups differed slightly from each other.

We performed the precardial ECG mapping five times for all patients of both groups: before the interference, 30 minutes after the operation, and 1, 3, and 6 days after the operation.

We performed the pharmacological EchoCG test with dipyridamole twice-before the interference (for one day) and before the discharge.

Results and Discussion

The research results are in tables and diagrams.

Table 1: The dynamics of area (AST) and degree of myocardial ischemia (ΣST) among patients with acute and chronic forms of IHD during treatment with the CS method

№	Time of study	ACS, AMI		CCI		P_{1-3}	P_{2-4}
		AST (M±m)	ΣST (M±m)	AST (M±m)	ΣST (M±m)		
1	Before surgery	27,84±1,66	88,42±6,67	8,13±2,81	10,81±3,11	p<0,02	p<0,001
2	After 30 ‘ p/operation	27,17±1,04***	63,19±4,48***	6,47±1,12	7,46±2,88	p<0,01	p<0,001
3	1 day	25,34±2,11***	52,68±6,64***	6,15±0,92	6,93±1,27	p<0,02	p<0,001
4	3 day	23,76±0,86***	48,46±6,40***	5,44±0,86	5,12±1,88	p<0,01	p<0,001
5	6 day	17,32±1,08***	54,17±6,18***	4,78±0,46	4,64±1,26	p<0,01	p<0,001

***High degree of statistical significance (p<0.02) between 1-2, 1-3, 1-4, 1-5.

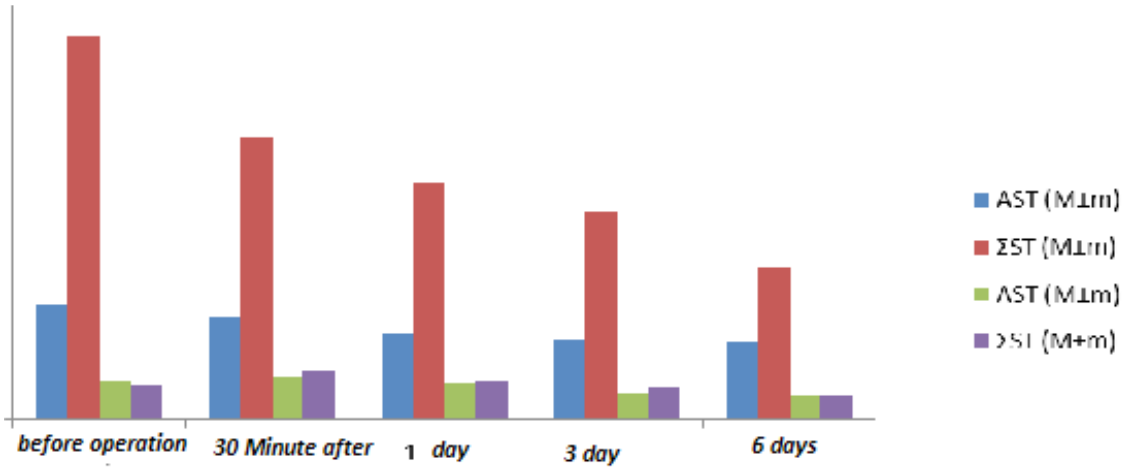

Diagram 2: The dynamics of area (AST) and degree of myocardial ischemia (ΣST) among patients with acute and chronic forms of IHD during treatment with the CABG method

As can be seen from the data provided in tables 1 and 2, we selected patients with clinically pronounced forms of the disease, with demonstrative laboratory and instrumental shifts, for both CS and CABG surgery operations. It is evident from the high initial indicators of affected area filed (AST) and degree of ischemization (ΣST) in both groups (conservative and surgical treatment). Almost all of them are active, working, highly educated people with a fairly high social status, "advanced" in the achievements of modern medicine, who value this status and their work. That is why, in contrast to conservative patients, within the choice between the proposed medication and surgical method of treatment, they preferred surgical interference. The main motivator of this choice was that the operation, even if there is a certain risk, provides a higher quality of life, gives more prospects to save the ability to work.

Both among patients treated with the CS method and in the group who passed HB, from the 1st day to the end of observation (day 6), there was a rapid and statistically significant ($p<0.02$) positive dynamics both in terms of area reduction (AST c 27.84±1.66 in the CS group, as well as from 27.50±1.93 in the HB group before surgery to 17.32±1.08 and 18.83±1.30 by day 6, respectively), and in aspect of the myocardial ischemia degree (ΣST c C 88.42±6.67 and 92.34±4.93 before treatment, up to 54.17±6.18 and 36.67±8.89 by day 6 in both groups, respectively).

In the groups with chronic IHD, treated by method of CS and HB, the results of ECG-mapping were less clear, however, quite convincing. Here, however, the elevation is not typical, but depression of the ST segment (which is specific for CCI) and this shift is less obvious than in acute forms of IHD – usually within 1-2 mm of the isoelectric line.

As can be seen from tables 1 and 2, the initial (pre-operation) indicators of the area and degree of myocardial ischemia in both groups were almost identical – AST, both in the CS group, and CABG, respectively, 8.13±2.81 and 9.25±1.67, and ΣST, respectively, 10.81±3.11 and 11.27+2.64. The dynamic control within the specified time period also demonstrated positive, but significantly slower changes of the ST segment than among patients with acute forms of IHD: by day 6, the AST indicator decreased within both groups to 5.81±1.12 and 6.19+2.03 (P0,05), respectively.

In our opinion, this difference in the extent and severity of myocardial ischemia among patients with acute and chronic forms of IHD reflects the difference in the state of the myocardium in two different variants of ischemic syndrome. It means that in acute forms, the hibernating state prevails, and in chronic forms – stanning. In order to confirm (or exclude) our assumption, we performed a pharmacological EchoCG test with dipyridamole.

We performed this functional test in accordance with the recommendations of the European Echocardiographic Association[2]. We performed the test twice-before the operation and on the 6th day after operation.

we performed the pharmacological stress echotest with dipyridamole among 28 patients from a sample in which there was ECG mapping in order to assess the effect of HB or CS surgery. In each of 4 groups, we

selected 7 patients by method of random sampling (group 1-ACS, who passed HB; group 2-with chronic IHD, who passed HB; group 3 – ACS, who passed CS; group 4 – with chronic IHD, CS). The criteria of non-inclusion: 1) severe conduction abnormality; 2) patients with chronic bronchopulmonary diseases with bronchoobstructive syndrome (bronchoconstrictor effect of dipyridamole); 3) hypotension with systolic A/D<100 mmHg.

The data on changes in cardiodynamic parameters (ejection fraction-EF and final systolic volume - ESV) among patients with ACS before and after CS and CABG operations in accordance with the echo test with dipyridamole are in table 3 and diagram 3.

Table 3: The changes in cardiodynamic parameters and local contractility among patients with acute forms of IHD during CS and HB surgery operations in accordance with the EchoCG test with dipyridamole

The indicators of cardiodynamics and local contractility	CS		HB	
	Before the CS surgery operation	6th day after CS	Before the HB surgery operation	6th day after HB
ESV, ml	114,6±4,3	77,3±3,1	109,6±4,3	74,3±3,4
EF, %	45,8±6,4	55,4±8,3	47,5±7,1	56,3±6,6
The LV segments:				
Eukinetic	168,4±7,0	232,8±6,2	192,6±5,7	236,7±8,4
Hypokinetic	62,2±4,1	24,5±2,2	62,3±4,4	32,5±2,4
Akinetic	58,3±5,6	32,4±3,5	34,5±3,1	20,1±1,7

As can be seen from table 3, before surgical interference of both types, patients showed a slight increase in ESV, which we associate with the area of the ischemic zone and indicates the latent heart failure. The degree of ESV increase in both groups was approximately the same, and the difference between them was statistically unreliable (p>0,1), which indicates the comparability of patients in both groups.

We confirmed the presence of left ventricular contractility disorders among patients of both groups by a decrease in the EF index. Moreover, these indicators among the patients of both groups did not differ significantly (p>0,2), which indicates a qualitative randomization.

By the 6th day after surgery (both in the HB group and in the CS group), myocardial contractility increased statistically in a valid way (p<0,02).

Moreover, there was a solid confirmation of such dynamics by both EchoCG indicators – both a decrease in ESV and an increase in EF (p <0.02).

Such character of changes in cardiodynamic is quite consistent with the dynamics of precordial ECG mapping indicators that showed in both groups statistically significant (p>0,02) improvement of coronary circulation within the ischemic area, both in terms of its vastness (by AST, p<0.05), and in terms of reducing the extent of ischemia (by ΣST, p<0,02).

The pronounced and rapid (in less than a week after surgery, recovery of coronary blood flow) improvement of the ischemic myocardium state and its contractility in accordance with the EchoCG test with dipyridamole helps us to explain the achieved positive effect of both surgery types by the fact that in ACS there is a hibernating version of the ischemic syndrome. While in the case of stanning, it would be impossible to count on such a rapid and pronounced positive effect of surgery. To confirm this assumption, we conducted a pharmacological EchoCG test with dipyridamole within a group of patients with chronic IHD.

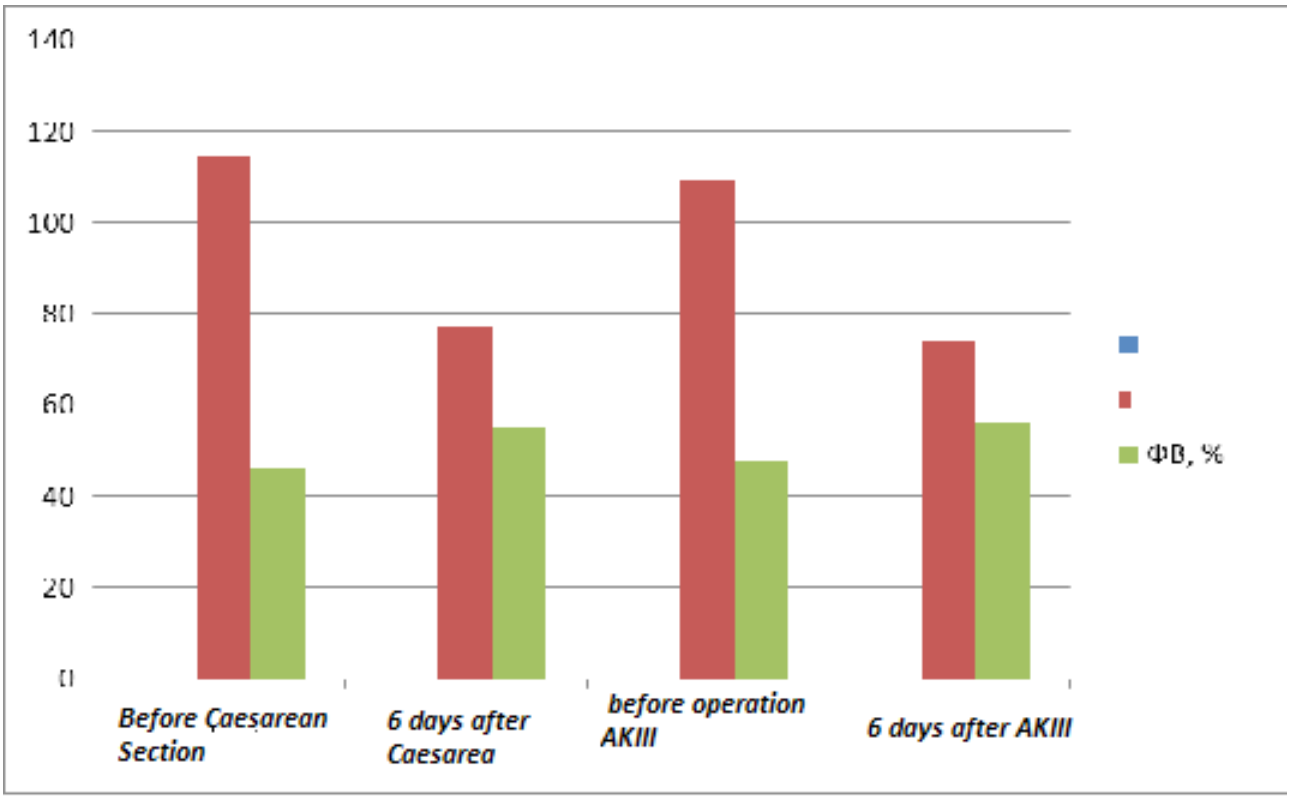

Diagram 3: The dynamics of ECHOCG parameters (ESV, EF) during CS and HB operations before and after the interference

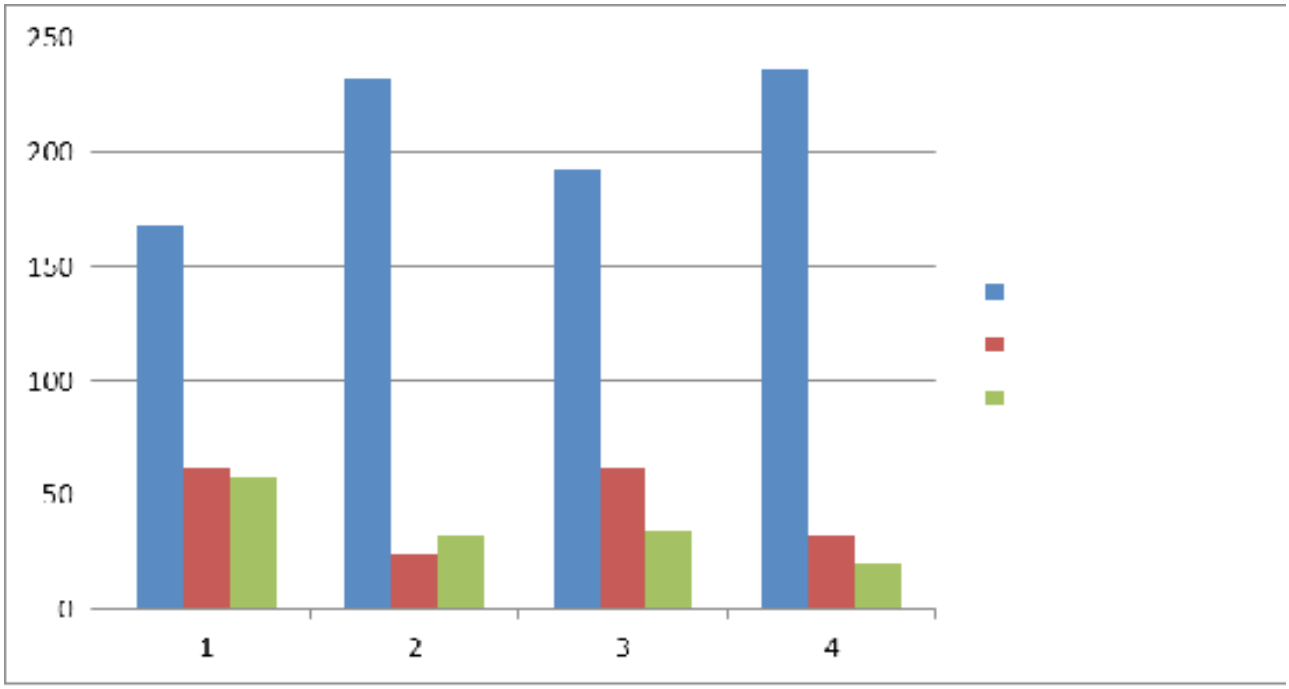

Diagram 4: The dynamics of the myocardial segments kinetics during CS and HB operations before and after the interference

Table 4: The changes in cardiodynamic parameters and local contractility among patients with chronic forms of IHD during CS and HB surgery operations in accordance with the EchoCG test with dipyridamole

The indicators of cardiodynamics and local contractility	CS		p	HB	
	Before the CS surgery operation	6th day after CS		Before the HB surgery operation	6th day after HB
ESV, ml	101,4±2,6	93,4±6.3	>0,05	113,1±3,7	69,3±6,1
EF, %	49,9±6,8	55,4±5,6	>0,05	42,2±5,1	53,3±4,8
The LV segments:					
Eukinetic	196,3±0,1	212,6±1,5	<0.05	188,4±1,1	202,9±0,6
Hypokinetic	43,0±3,3	28,3±4,1	>0,05	58,3±2,9	43,1±2,2
Akinetic	36.6±1,7.	29,5±5,0	>0,05	36,7±2,2	28,9±1,4

As can be seen from the table, among patients of both groups, in accordance with EchoCG data, there was initially a significant decrease in myocardial contractility, manifested by an increase in left ventricular of ESV and decrease of LV. It is natural, since it is known that the main markers of blood supply deterioration are chest pain (optional symptom) and segmental decrease in left ventricular pumping function (obligate symptom), usually without clinical indication and with identification by instrumental method.

The analysis of changes in cardiodynamic parameters (in accordance with the EchoCG test with dipyridamole) within two groups of patients with chronic IHD (treated with CS and HB) revealed the absence of significant improvement in left ventricular contractility after surgery to improve coronary blood flow, both by this and another method. Both indicators under study, both ESV and EF, showed some improvement, which became statistically unreliable (p>0,05). It would be groundless by definition to expect more significant changes – as is known, the term "stoned myocardium" refers to an ischemic area of the heart muscle, in which the maximum possible recovery of coronary blood supply has already occurred within these conditions (+at the expense of a decrease in coronary spasm, neoangiogenesis, recanalization of the thrombus; - at the expense of akinesia and hypokinesia). Such conclusion bases on the EchoCG research results of local myocardial contractility-in both groups of patients within the postoperative period,there was a statistically significant p<0,05 increase in the number of eukinetically shrinking segments,while the reduction in the number of hypo – and akinetic segments was statistically insignificant (p>0,05). Consequently, this suggests that in acute variants of IHD, there is hibernation of myocardium (reduction of heart function to a level adequate to reduce coronary perfusion in order to save persistent cardiomyocytes), when the restoration of blood flow leads to the restoration of full ischemic cardiomyocytes functioning. In contrast to stanning, in which chronic coronary hypoperfusion within chronic variants of IHD leads to an irreversible decrease in the contractile function of the LV myocardium (complete absence of persistent cardiomyocytes in the presence of Hypo - and akinetic sections of the myocardium).

As an illustration, we present extracts from the medical histories of operated patients.

Conclusion

The precardial ECG mapping is informative and available for use in regional cardiosurgical clinics as a method of the hibernating myocardium identification, which is a more perspective variant of ischemia among patients with IHD in aspect of left ventricular contractility increase.

Abstract

The damage features of the cerebral hemodynamics disorders and decreased responsiveness of brain vessels among the patients with HIV are the pathogenetic basis for the formation of HIV encephalopathy development. We observed patterns of changes in cerebral blood flow and immunological reactivity among patients at preclinical stages of HIV. It indicates that the vascular system of the brain is highly sensitive to the action of treponemous toxin and is responsive to damages at the early stages of the disease.

Keywords: *HIV, diagnostics, cerebral hemodynamics.*

Introduction

The HIV infection under course of slow progression influences not only the body's immune system[6]. The virus spreads throughout all the vital organs of the human body. In nine cases out of ten, the virus damages the patient's nervous system, and the HIV encephalopathy develops[4].

Although the pathomorphological studies show that one can detect the damage to nervous system in 90% of AIDS patients, clinically neurological complications in 50-70% of patients, and in 10% of cases they are the first clinical implications of the disease. Neurological complications are one of the main causes of disability and death in case of HIV infection[11].

HIV enters the CNS at early stage (macrophages and monocytes act as a" Trojan horse", within which HIV penetrates through GERD, but apparently does not directly infect neurons, and numerous neurological complications connect with the neurotoxic action of substances produced by HIV, or factors released by infected macrophages or microglial cells [8](for example, cytokines that release amino acids, etc.).[10] One can assume that some viral proteins, within the connection with neurons, can disrupt the functioning of calcium or other ion channels or affect neurotransmitter processes, which can eventually cause the death of neurons[5].

The most common neurological complication of HIV infection is HIV encephalopathy (HIV-associated dementia). One can detect it among the half of patients within the end-stage. The HIV encephalopathy develops within the scope of severe immunosuppression and systsystemic symptoms of the disease (weight loss, lymphadenopathy, alopecia), but in 3-5% of patients with HIV encephalopathy is the initial or even the only symptom of AIDS12. Pathomorphologically, we found the diffuse changes in the periventricular and deep parts of the white matter, which refer to demyelination or extravasation of plasma proteins as a result of damage to the hematoencephalic barrier, multinucleated giant cells in the cerebral cortex and white matter, astrocytic gliosis, microglial nodules,[7] perivascular lymphocytic infiltration, and a decrease in the number of neurons [9].

The first symptoms are of non-specific character: headache, rapid fatigue, decreased libido, loss of interest to work, inattention, memory loss.[12] The HIV-associated dementia combines with emotional and behavioral disorders, and may include depression[2], dysphoria, apathy, limited motivation, and lethargy. Gradually there is a development of subcortical-frontal type dementia. There often are indications of sleep disorders. About half of the patients suffer motor disorders developments: akinetic-rigid syndrome, postural instability and gait disorders, pyramidal insufficiency, generalized

hyperreflexia, cerebellar ataxia[6]. The condition progressively worsens from month to month [9]. As there is a progression of disorder, loss of orientation, confusion, epileptic attacks, and akinetic mutism develop. After the development of dementia, average death occurs after 6 months[11].

However, there are only a small number of studies in the Russian literature which refers to the early symptoms of HIV encephalopathy. There is no clear information on the issue of cerebral hemodynamics and vascular responsiveness of the brain arteries, which allows a practical doctor to get an idea of the current state within the scope of the actual problem.

The purpose of the research: To evaluate cerebral hemodynamics and vascular responsiveness of brain arteries among HIV-infected patients.

Materials and Method

We examined 56 HIV-infected patients with a verified serological and clinical diagnosis, whose average age was 35.7±1.3 years, among them there were 31 (55.4%) men and 25 (44.6%) women.

Under a detailed survey of patients, we found that the majority of patients (58.9%; 33/56) had a history of injectable narcotic substances usage, 12.5% of patients reported sexual HIV infection (7/56), and 28.6% did not know the route of HIV infection.

We divided all the patients into 4 groups. The 1st and 2nd groups included 12 and 14 people, respectively, who differ by the level of CD4 lymphocytes in the blood plasma (by the threshold level of 500 CL/ml). The patients of these groups did not have clinical implications of HIV infection in accordance with experts at the time of the study, and did not receive antiretroviral therapy.

Group 3 included 12 HIV-infected patients who had no clinical complaints or symptoms at the time of the study, but under antiretroviral therapy.

A special place belongs to the 4th group, which included 16 HIV-infected patients who were not active recipients of narcotic substances for at least 6 months before the study, as well as those infected with hepatitis C. All patients received highly active antiretroviral therapy (HAART).

The clinical observations underline that within the early stages of HIV infection, the most frequent are reactive neurotic states and symptoms of as the no vegetative syndrome.

The physical examination of patients revealed a disorientation by place, time and personality from 26.8% (15/56) to 43.9% (24/56), we noted the disorders of higher integrative functions in the form of memory and attention loss - in 19.6% of cases (11/56).

In case of the neurologic examination assessment, the majority of patients in the first three groups did not complain about difficulties in memorizing, focusing, although some had headaches, dizziness and light coordination disorders.

At the same time, the psychological examination of patients, as well as those within the first two groups, i.e. at the subclinical stage of the HIV-infection course, showed process disorders of the memorizing and information reproduction. In the fourth group, we noted focal neurological symptoms, while motor disorders, hypertension syndrome, and pronounced memory disorders prevailed. All the patients with an infection period of more than 120 months complained about difficulties in memorizing the current events, memory impairment for long-ago events, poor concentration within their daily duties at the workplace, which interfered with routine work and required active concentration and great effort.

We put the state of cerebral hemodynamics and vascular reactivity of brain arteries undr study by standard method with sensors under frequency of 2, 4, 8 MHz on the Spectromed-300 device (Russia). The research algorithm in regard to the state of cerebral hemodynamics and vasomotor reactivity included:

– Study of the main arteries within the head and intracranial arteries by method of extra - and intracranial dopplerography in order to determine the speed characteristics of blood flow, pulsation indices and circulatory resistance;

– Study of vasomotor reactivity on the basis of the compression test results. It is known that short-term finger compression of the common carotid artery (CCA) on the neck leads to a decrease in perfusion pressure and the development of a transient hyperemic response after compression stops, which allows us to calculate a number of indicators that characterize the autoregulation reserves. The patients (without constrictive lesion of arteria carotis) passed 5-6-second CCA compression with the termination

of compression in the diastole phase. We recorder the average linear blood flow rate (LBFR) within the middle cerebral artery (MCA) before compression of the ipsilateral CCA-V1, during compression-V2, after termination of compression-V3, as well as the recovery time of the original LBFR-T. With the obtained data, we calculated the coefficient of overshoot (CO) by the formula: CO = V3/V1[15].

The obtained data were subject to statistical processing by the means of statistical analysis applications package with the calculation of the arithmetic mean (M), mean square deviation (σ), standard error (m), and relative values (frequency, %). We used the confidence level P<0.05 in relation to statistically significant changes.

Results and Discussion

We characterized the cerebral hemodynamics disorder among the patients in accordance with the dopplerographic test output by a decrease in blood flow velocity within the ICA, 24.5 and 33.9 % in the MCA - 25.4 and 34.5 % in VA - 24.3 and 44.7% in LCX - 21.7-32.6% (1 and 4 groups, respectively) relative to values of the control group (table 1).

There were also signs of increased vascular tone among all the vessels under study in accordance with the increase in the pulsation index (Pi) and circulatory resistance (Ri) by an average of 1.5 and 2.3 times within group 1 and 1.8 and 2.75 times within group 4 (table 2).

There was no any hemodynamic significant stenosis of the head main arteries among the examined patients in any of cases (their presence was a criterion for exclusion from the study due to the compression tests risk).

Table 1: Hemodynamic indicators of blood flow within the main arteries of the head and intracranial arteries at rest

Vessels	LBFR (cm/s)		
	1 Group	4 Group	Control
ICA, right	40,2±5,8*	25,1±3,8*^	53,2±6,4
ICA, left	41,4±5,9*	29,9±4,1*^	51,9±5,9
MCA, right	48,7±6,2*	30,2±4,5*	62,4±11,3
MCA, left.	47,1±6,8*	32,1±3,1*^	65,2±10,7
VA, right	27,2±4,7*	20,4±3,6*	37,6±7,8
VA, left	29,1±3,7*	19,8±2,6*^	38,0±8,7
LCX	36,6±4,8*	21,3±4,3*^	46,0±5,6

Note: * - the output reliability by control indicators (P<0.05); ^ - the output reliability by group 1 indicators (P<0.05)

There was confirmation of the possibilities decrease for collateral blood flow (anatomical link of the cerebral vascular reserve) among the patients under examination by the depression relative to the control parameters of the residual blood flow rate in the MCA(V2) at the time of compression of the ipsilateral CCA by 19.3 and 28.1%, respectively, in groups 1 and 4 (table 3).

A decrease in the coefficient of overshoot among patients with respect to control by 11.6 and 16.9%, respectively, indicated a pressure within the functional link of cerebrovascular reactivity, in particular, its myogenic component due to a structure disorder of the vascular wall and its tone. The revealed 1.7-and 2.3-fold increase in the recovery time of the blood flow rate to the initial one reflected a disorder of the vascular reactivity metabolic circuit as a symptom of general dysmetabolic processes which develop within the body of HIV-infected patient.

Thus, the hypersthenia of vessels suggests a lack of dilatatory mechanisms functioning at the level of the capillary bed, which indicates a pressure within the mechanisms of brain vessels adaptation. Such condition iwithout correction can lead to the vessels failure and the development of dyscirculatory processes in the CNS among the HIV-infected patients already at the preclinical stages of the disease.

We conducted analysis of dopplerographic test output within groups 2 and 3 patients (Fig. 1) in order to determine the effect of HAART on cerebral hemodynamics and vascular reactivity of brain arteries among HIV-infected patients.

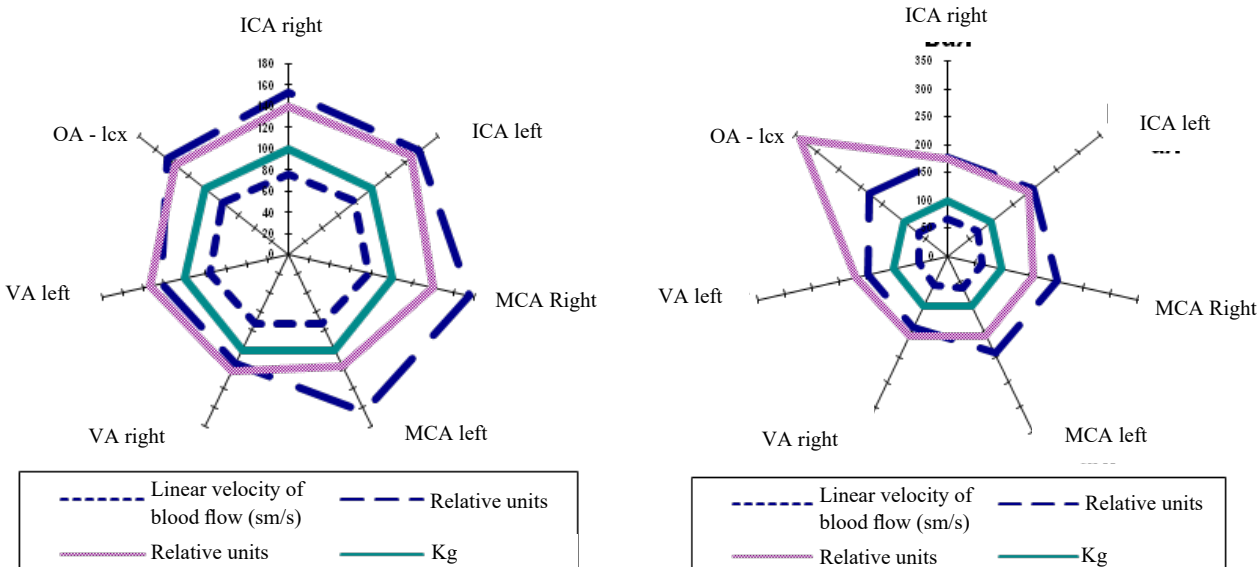

Fig. 1. Hemodynamic indicators of blood flow within the main arteries of the head and intracranial arteries at rest

There has been no proof in regard to the HAART effect on the state of the brain vessels, but the patients of group 3 had a tendency to the blood flow rate disorder in relation to the indicators of patients from group 2.

The observed patterns of changes in cerebral blood flow and immunological reactivity among patients of the 1 and group indicate that the vascular system of the brain is highly responsive to the action of treponemous toxin and is responsive to damages at the early stages of the disease (tables 4, 5).

The patients without pathological changes in hemodynamics and vascular responsiveness of the brain arteries, had the average duration of infection around 5.8 years, and the average content of CD4 + lymphocytes was higher than 500/mcl.

Conclusion

Thus, the cerebral hemodynamics disorders and decreased responsiveness of brain vessels among the patients with HIV are the pathogenetic basis for the formation of HIV encephalopathy development. With concern to the hemodynamic and metabolic disorders in case of AIDS, as well as their complex role in the pathogenesis of cerebrovascular and neurological complications, it is neccessary to include a combined medication in therapy design among the patients at preclinical stages of HIV in order to improve the state of cerebrovascular responsiveness, reduce the phenomenon of vasospasm in the cerebral vessels and normalize metabolic processes within the body, which will improve the condition of patients with HIV and their quality of life.

All the above-mentioned statements highlight the need for further study in regard to the complex of hemato-encephalic disorders among HIV patients. The authors recommend the method of transcranial stress-dopplerography to evaluate the parameters of cerebral hemodynamics among these patients.

Cardiovascular Development Abnormalities in Young Athletes

Adiba Usmankhodjaeva[1], Fotima Rakhmatova[2], T.A. Taraleva[3]

[1]MD, PhD, Associate Professor, Head of the Department of Traditional Medicine, Rehabilitation and Physical Culture, Tashkent Medical Academy, 2 Farobiy Street, Tashkent, Uzbekistan, [2]MD, PhD student, Department of Traditional Medicine, Rehabilitation and Physical culture, Tashkent Medical Academy, 2 Farobiy Street, Tashkent, Uzbekistan, [3]MD, PhD, Department of Traditional Medicine, Rehabilitation and Physical Culture, Tashkent Medical Academy, 2 Farobiy Street, Tashkent, Uzbekistan

Abstract

The article discusses the issues of small anomalies of heart development in young athletes. The question of the admission of young athletes with small anomalies of heart to sports and their impact on the state of the cardiovascular system during exercise is still an open question. To avoid subjectivity and the subsequent over diagnosis of small anomalies of heart, their objectification is necessary, through a quantitative assessment.

Keywords: *Small abnormalities of the development of the heart, additional chord, mitral valve prolapse, young athletes, sports, ventricular fibrillation.*

Introduction

Physical education and sports require increased functional capabilities of all body systems, including CVS. In this regard, any deviations, especially from the CVS, can negatively affect both the health and success rate of athletes. The term CDMA is usually used to denote inherited or congenital structural changes in the valvular apparatus and/or its connective tissue framework, including the main vessels, in the form of various anatomical abnormalities that are not accompanied by hemodynamically 'gross' disorders [1]. False ('supplemental', 'abnormally located') chords (tendons) are manifested by the presence in the ventricular cavity of additional formations in the form of connective tissue cords. Unlike normally located chords, these formations have an ectopic attachment not to the valves of the atrioventricular valves, but to the free walls of the ventricles and interventricular septum [3]. The term 'tendon' reflects the position of the abnormal cord as a geometric body which crosses the cardiac chamber. True chords are fibrous strands consisting of collagen fibers. They receive blood and innervation from the heads of papillary muscles, supply and innervation of which provided by muscle trabeculae located at their base [4]. Some clinical data and numerous morphological studies suggest that transverse, diagonal and longitudinal false tendons of basal and median localization, as well as multiple left ventricular false tendons (LVFTs) have an independent clinical significance, as it often acts as an independent cause of ventricular extrasystole. With that, single apical LVFTs are usually considered as normal variant [2]. In recent years, an active study of intracardiac structures has clearly demonstrated not only the independent clinical significance of CDMA, but also their close relationship with heritable connective tissue disorders (HCTD)[3]. The development of HCTD is based on disruption of the genes responsible for the synthesis or decay of the extracellular matrix components. A large group of HCTD is caused by mutations in the genes of extracellular matrix proteins (collagens, fibrillin, tenascin, etc.). These genes mutations lead to the development of many mendelating HCTD, the number of which exceeds 250, and most of them are very rare. Connective tissue dysplasia (CTD) is a pathological condition of organs and tissues. It is manifested in a decrease in the content of certain types of collagen or a violation of their ratio, and leads to a decrease in the strength of connective tissue of various organs and systems. In the development of CTD, gene mutations are of primary importance, since they encode the synthesis and spatial organization of collagen. They are also responsible for the formation of the structural components of the matrix and enzymes involved in fibrillogenesis. In addition, there is a complex of exogenous factors that cause a violation of

collagen synthesis. Dysplastic changes can be due to the impact of adverse environmental conditions, inadequate nutrition or stress. The severity of these changes can be affected by polymorphic variants of the genes of the renin-angiotensin system associated with the activity of antioxidant enzymes [5].

As a result, connective tissue dysplasia syndrome (CTDS) forms a pathology of a multifactorial nature with a wide range of clinical signs and a fairly high prevalence. Its further study will contribute to the development of method for identifying patients who respond positively to additional physical exertion, and those for whom such exertion may be undesirable or even harmful [7, 1].

Single false tendons don not form a contraindication to sports. With multiple false tendons, exercise is also not contraindicated, in the absence of cardiac arrhythmias. Located in the pathways of the inflow or outflow of the left ventricle, the false tendons can contribute to the emergence of a local phenomenon of ultrahigh speeds (aliasing phenomenon) and, as a result, lead to injury or the fibrosis development. Being an abnormal way of conducting an exciting impulse, false tendons can cause ventricular arrhythmias, including ventricular fibrillation. Patients with supplementary chords of the heterogeneous structure ('beam' type) are recommended for more frequent and thorough medical supervision, in order to identify early signs of aCVS arrhythmic overstrain [9].

The aim of this study is to do research of the frequency of CDMA occurrence in young athletes.

Materials and Method

The research was conducted in the Department of Sports Medicine of the City Adolescent Dispensary (Tashkent). The main group consisted of 305 athletes involved in various sports in children and youth sports schools (CYSS), aged 6-18 years - 113 females and 182 males. The control group consisted of 305 children of the same age who were not involved in sports. All children were permanent residents in Tashkent. All athletes underwent an echocardiographic examination. Statistical processing of the obtained data has been performed using the Student's t-test for the significance level $P<0.05$.

Results and Discussion

As a result of the analysis of echocardiographic examination of children, a number of CDMA have been identified. The frequency of their occurrence in comparative groups is presented in Table 1.

Table 1: Frequency of occurrence of CDMA in examined children

CDMA types	Frequency of occurrence of CDMA (%)			
	Main group (n=305)		Control group (n=305)	
	Abs.	M±m	Abs.	M±m
False tendons of the left ventricle (FTLVs)	72	23,6±2,4*	52	17,0±2,15*
Mitral valve prolapse (MVP)	3	0,98±0,56	4	1,31±0,65
Open foramen ovale (OFO)	2	0,65±0,46	1	0,33±0,33
Tricuspid valve prolapse (TVP)	2	0,65±0,46	2	0,65±0,46
Left ventricular abnormal trabeculae (LVAT)	1	0,33±0,33	0	

* - $P<0.05$ relative to the main group of the control group

As Table 1 shows, the most common CDMA (23%) in both groups - especially in athletes - is asupplementary chord. The second most frequent mitral valve prolapse is 0.98% in the main group, and the dependence of CDMA frequency on physical activity has not been observed.

Table 2: The frequency of occurrence of CDMA in the examined children, depending on gender

CDMA	Number of children with this CDMA (frequency of occurrence (%)							
	Main group-72				Control group-52			
	Females		Males		Females		Males	
	Abs, %		Abs, %		Abs, %		Abs, %	
False tendons of the left ventricle (FTLVs)	31	43±5,8*	41	56,9±5,8*	29	55,7±6,8	23	44,3±6,8
Mitral valve prolapse (MVP)	2	66,6±6,1	1	33,4±5,5	1	25±6,0	3	75±6,0
Open foramen ovale (OFO)	1	50±5,9	1	50±5,9	-		1	100
Tricuspid valve prolapse (TVP)	1	50±5,9	1	50±5,9	-		2	100
Left ventricular abnormal trabeculae (LVAT)	1	100	-		-		-	

Note: * - P<0.05 confidence of differences compared to the main and control groups

According to Table 2, it is clear that FTLVs in the main group is 1.3 times more common in males than in females (56.9% and 43%; respectively, P <0.05). By contrast, mitral valve prolapses (MVP) in the main group in females are 2 times more often than males (66.6% and 33.4%, respectively). In other cases, the frequency of CDMA occurrence depending on gender in the main group has not been detected. The following table presents data on the quantitative ratio of FTLVs in the main and control groups (Table 3)**:**

Table 3: The number and frequency of LVFTs in the experimental and control groups

FTLVs	Number of children from this CDMA (Frequency of occurrence%) n=305			
	Main group n=72		Control group n=52	
	Abs, %		Abs, %	
Single	69	95,8±2,3*	50	96,1±2,6*
Double	2	2,7±1,91	1	1,92±1,9
Multiple	1	1,38±1,35	1	1,92±1,9

Note: * - P<0.05 confidence of differences compared to the main and control groups

As Table 3 shows, the frequency of occurrence of single FTLVs is the same in children involved and not involved in sports activities. Double FTLVs are more common in children involved in sports.

In such a way, single FTLVs predominate in both groups. Duplicate FTLVs have been found to a lesser extent, and the rarest in frequency are multiple FTLVs, that are 1-2% of all FTLVs cases.

Conclusions

As a result of the research performed, it can be concluded that the most common CDMA is a supplementary chord. False tendons can cause ventricular arrhythmias, including ventricular fibrillation, which should be taken into account when admitting children to sports and planning their training regime. No gender differences in the studies have beennoted. However, it has been found that the frequency of occurrence of single chords in athletes is higher than double and multiple ones, which affects CVS in a positive way. Although a single supplementary chord does not affect the cardiac hemodynamics as often as other CDMA do, it is necessary to carry out mandatory regular supervision of transverse chords through electrocardiographic examination.

The Form of Erythrocytes and Laser Doppler Flowmetry of Skin with ACNE and Use of Medication FarGALS in its Comprehensive Treatment

Khashimov F.F.[1], Baibekov I.M.[1]

[1]Associate Professor, Tashkent Medical Academy, Department of Dermatovenereology, RSSC Named After V. Vakhidovof MHRUz

Abstract

Using the express method of a thick smear and morphometry, the state of erythrocytes obtained from the acne and finger region has been studied. Using laser Doppler flowmetry, the state of microcirculation of the skin of the finger and the acne location area has been studied.

It has been found out that comprehensive treatment with the use of FarGALS promotes the reduction in blood of pathological forms of erythrocytes and the restoration of microcirculation parameters.

Keywords: *Erythrocyte, blood, acne, pathological, microcirculation.*

Introduction

Dermatoses and infectious skin lesions are accompanied not only by significant structural changes, but also by pronounced abnormalities in the ratio of discocytes - normal erythrocytes and their pathological forms. These abnormalities are noted both in peripheral blood obtained from the finger, and, especially, in blood obtained from areas of pathologically altered skin [2].

Shifts in the ratio of discocytes and pathological[3] forms of erythrocytes cause pronounced microcirculation abnormalities[6].

However, studies of changes in the shape of erythrocytes and microcirculation with acne[7], which is one of the most common skin pathologies, especially in adolescents and young adults [4]. have not been conducted.

The medication FarGALS is registered by the Pharmaceutical Committee of the Ministry of Health of the Republic of Uzbekistan and is approved for clinical use.

It is included in the pharmacotherapeutic group - “antiseptic and wound healing agent”, has a pronounced antioxidant effect, has the property to enhance metabolism in tissues, increases oxygen consumption by them, accelerates the regeneration of damaged tissues, promotes neovasculogenesis [1]. These properties of FarGALS make in possible to suggest that it has a positive effect on erythrocyte membranes, normalization of the ratio of discocytes and their pathological forms, and contribute to the activation of microcirculation.

In this regard, the purpose of this study is defined: to study the effect of FarGALS with its complex use in the treatment of acne on erythrocytes and the state of microcirculation.

Materials and Research Method

Before and after the course of treatment, all patients’ blood obtained from the finger and acne area has been studied. Blood for light microscopy has been studied with the use of the express method of a thick smear (EMTS) - Patent Office of Uzbekistan - “Method for the Determination of RBC Forms” No. MKI 6 A 61 B 10/00, Program “Express Diagnosis of RBC Forms” No. ED-5-05.

For this, 2 drops of blood have been fixed for 3-4 minutes in 1 ml of a 2.5% solution of glutaraldehyde. Then a drop of fixed blood has been placed on a glass slide. A cover glass has been horizontally lowered onto it. A layer formed underneath is a “thick smear” - suitable for studying using a light microscope equipped with a digital camera.

Erythrocyte form ratio has been calculated at a magnification of 10x40 with a sample of at least 1000 erythrocytes for each stage and series of studies. Erythrocyte studies have been performed using Biolam-I2 and Axioscop 40 - ZEISS microscopes. Light-optical micrographs have been obtained on an Axioscop 40 - ZEISS microscope coupled to a digital camera with a data storage in a computer using the Microsoft-Windows XP-Professional application programs.

Laser Doppler flowmetry has been performed using LAKK-01 devices with a single-channel analyzer (LAZMA, Russia) coupled to a Pentium-Sh personal computer and ALT - Vostok LDF-01 device developed by domestic manufacturers ("Naf" company). A comparative assessment of the data obtained using LAKK-01 and ALT - Vostok LDF-01 has been carried out. These studies have shown the full authenticity of the devices.

LDF has been used to assess microcirculation of the skin of the finger (control) and of the face of 8 patients with normal skin (control) and in patients aged 14-24 with acne on the face. The standard conditions for registering LDF have been observed [2].

Conventional treatment included standard therapy. FarGALS has been used as a local application.

Results of the Research and Discussion

With acne, the proportion of pathological forms of erythrocytes is slightly less than half of all red blood cells (pic. 1 tab. 1).

Morphometry of blood erythrocytes obtained from the gums and from the finger (in presence of acne) has shown that pathological forms dominate among erythrocytes. This is especially pronounced in blood obtained from the area of acne.

The conventional treatment of this pathology leads to a significant reduction in the pathological forms of erythrocytes, both in the blood from the acne area and in the peripheral blood obtained from the finger (pic. 1 tab. 1).

The use of FarGALS in the comprehensive treatment of acne leads to a significant increase in the proportion of discocytes and a decrease in the proportion of pathological forms of erythrocytes. This tendency appears both in the blood from the acne area and in the peripheral blood from the finger.

A characteristic feature of blood from the finger, and especially from the acne area, is a sharp increase in the proportion of erythrocytes with a crest (pic. 1 tab. 1). Comprehensive treatment and, especially, treatment using FarGALS significantly reduces the number of pathological forms of erythrocytes, but their share remains much higher than the control level (pic. 1 table. 1) Laser Doppler flowmetry has shown that acne causes microcirculation abnormalities as in the skin of finger, and especially in the area of localization of acne. AmaxCF/AmaxLF, which reflects the measurements of arterial blood flow, decreases in the acne area by more than 3 times. AmaxHF/AmaxLF, which reflects the measurements of venous blood flow, decreases by more than 2 times. MEI - the microcirculation efficiency index reduces by 2 times.

Medication therapy leads to a tendency to normalize the studied parameters. When using FarGALS, all the studied parameters are close to the control level (tab.2).

Pathological forms of erythrocytes such as stomatocytes, echinocytes and erythrocytes with a crest are found in peripheral blood and are in the norm. However, their total share does not exceed 11-12%. Erythrocyte is the most differentiated cell in the body of mammalian animals and humans and does not have either organelles or nuclei. This determines their sensitivity to various changes in blood parameters in various pathological conditions. The shifts in the ratio of discocytes (normal red blood cells in the form of a biconcave disc and their pathological forms) are determined, first of all, by changes in the properties of their plasma membrane [2]. An increase in the proportion of pathological forms of erythrocytes leads to the abnormality of microcirculation, since discocytes have the ability to change their shape when passing through narrow capillaries with its subsequent restoration[2].

The shifts we have found in the ratio of discocytes and pathological forms of erythrocytes regarding the presence of acne are especially pronounced in the blood obtained from the skin of the acne location area. This is accompanied by shifts in all studied microcirculation parameters. Changes in blood from the finger accompanied by impaired microcirculation parameters confirm the systemic nature of microcirculation disorders in acne, where erythrocytes play a leading role.

FarGALS contributes to the restoration of the ratio of discocytes and pathological forms of erythrocytes and improves microcirculation of the skin.

Conclusions

1. With acne, there is an abnormality of the ratio of discocytes and pathological forms of erythrocytes in blood obtained from the finger and especially from the area where acne is located.
2. FarGALS contributes to the restoration of the ratio of discocytes and pathological forms of erythrocytes in blood obtained from the finger and from the area where acne is located.
3. The use of FarGALS in the comprehensive therapy of acne, along with a reduction in the proportion of pathological forms of erythrocytes, leads to an improvement in microcirculation.

Table 1: The ratio of discocytes and pathological forms of erythrocytes regarding the presence of acne and after treatment with FarGALS

Erythrocytes form	Control 1gr.	Blood from finger before treatment 2 gr.	Blood from acne area before treatment 2 gr.	Blood from acne area, treatment without FarGALS,.	Blood from finger, treatment with FarGALS,
Discocytes	89±1,7%.	65± 1,4%*	54± 1,6%*	70± 1,6%**	81±1,2%**
Echinocytes	4±0,6%.	6± 1%*	7± 1%*	5± 1%**	4±0,2%**

* Statistically significant (P <0.05) compared with control 1

The devices used make it possible to obtain over 20 parameters characterizing the state of microcirculation. An indicator of microcirculation - MI, characterizes the total microvascular blood flow. It can be represented by the following expression: MI (t) = M + .δMI (t). "M" reflects the level of perfusion (in relative units) and its value is the total reflection of the average speed of movement of erythrocytes.

In the control, M indicators are higher than in patients with periodontitis and are respectively 16.6 and 11.5 in the alveolar ridge. The earlobe is 8.5 and 5.7 respectively. In the crest δ is 4, in the earlobe is 2, while the microcirculation efficiency index (MEI), which reflects the ratio of passive and active processes in the microcirculation system, is more than 2 times higher in control compared with that in patients with periodontitis. The latter have shown a more than 1.5 times decrease in the coefficient of variation (CV), which reflects the vasomotor activity of microvessels (tab.1).

A pronounced decrease in the parameter of the amplitude coefficient (arteries/vasomotors) reflecting the relative parameter of the arterial (arteriolar) component of microcirculation has been noted. With periodontitis, the amplitude coefficient of the venous (venular) component (veins/vasomotors) reflecting the venous component of microcirculation has been especially sharply reduced (tab.1).

Conventional treatment leads to a pronounced tendency to normalize the studied parameters.

With a comprehensive treatment using ILBI, the normalization of all the studied microcirculation parameters has been observed (tab. 1).

The study of erythrocytes of the blood from the gums and from the finger has shown that with periodontitis there is a pronounced shift in the ratio of discocytes and pathological forms of erythrocytes. This is especially true for echinocytes and erythrocytes with a crest (tab. 2).

Conventional treatment leads to a pronounced tendency to normalize the ratio of discocytes and pathlogical forms of erythrocytes (tab. 2).

When using ILBI in combination with conventional treatment, there is a restoration of the proportion of discocytes to almost normal levels, especially in the blood from the finger. The content of stomatocytes and erythrocytes with a crest remains quite high (tab. 2).

Table 2: Indicators of laser Doppler flowmetry in periodontitis and its treatment using ILBI

Abstract

Background: Elderly people have a variety of medical problems and functional limitations. Most older people experience multiple chronic illnesses as they age, which is one of the reasons for reducing of their physical activity. Undoubtedly, one of the ways to prevent the occurrence and exacerbation of chronicdiseasesis to maintain a healthy lifestyle, which increases the period of active life and helps support physical activity.

Method: We used a random selection method to obtain reliable and representative data: cluster and stratified selection. In Tashkent city, we selected 2 clusters out of 11 clusters, where the proportion of elderly and senile people was the highest and 674 elderly were included into the research; in the Tashkent region 3 clusters were selected, and 473 elderly were included to our sample. Our sample was divided into 3 social categories: the first category included lonely elderly people living alone in their apartments in the amount of 310 people, the second one included lonely elderly people living in nursing homes for the elderly, in the amount of 240, and the 3rd category included elderly people living with their families, in the amount of 597 people. In order to assess the respondents' lifestyle, we studied their daily routine, dietary regimen and nature, leisure, bad habits and physical activity.

Results: Married respondents were 2.1 times more among elderly living with their families, and 5.7 times more amongelderly living alone in their apartments compared to elderly living in nursing homes. Lonely elderly of "middle-old" age are in more difficult state due to significant proportion of this age-category suffer with various disabilities. It is find out that most respondents of the research do not pay proper attention to a balanced diet. Every second elderly person in our study suffered with obesity and had an increased body mass index (BMI: 25.1<). More than half of the respondents (54.6 + 3.2%) from nursing homes smoked tobacco products 3 times more than those living with their families. Alcohol consumption among older people living in nursing homes was 6 times higher compared to older people living with their families. With an increase of the age, the number of elderly engaged in any kind of physical exercise decreased sharply.

Conclusions: The study and analysis of the socio-demographic characteristics and lifestyle of elderly in Uzbekistan revealed that divorce and loss of spouse are negative factors, whereas the presence of a family and the residence of elderlywith relatives have a positive impact on their lifestyle and, accordingly, on their health status.

Keywords: *Loneliness, elderly people, nursing homes, lifestyle, living conditions, bad habits.*

Introduction

The group of elderly patients with multiple chronic diseases is growing around the world[13]. On average, there are 2 or more chronic diseases for one elderly patient[7], while elderly patients experiencing the mostsense of loneliness might have 5-6 chronicdiseases[12]. Polymorbidity, defined as the presence of two or more long-term health conditions, tends to increase with age[1]. These health conditions are currently not treatable, but can be controlled with medicines or other treatments[3].

Numerous studies indicate that smoking increases the risk of coronary disease and death from cardiovascular diseases in people over 60 [9]. In another hand, the alcoholism of the elderly is frequently observed phenomenon that causes significant harm to the health of this category of population. According to research, factors associated with excessive drinking in older people are male gender, social isolation, loneliness, and divorce[10]. Some studies have shown a correlation between alcohol abuse and serious somatic diseases, a decrease in self-esteem of one's health, a large number of visits to the doctor[2], a greater frequency of depressive symptoms, a decrease in social contacts and, as a consequence, a decrease in the quality of life [11].

Malnutrition and dehydration in older people leads to an increase the number of falls, the vulnerability to infections, the loss of energy and mobility, the poorhealing of wounds, and the confusion. In nursing homes, the low body mass index (BMI) of dwellers is associated with a lower quality of life[4].

This study helps to understand the social and demographic characteristics of older people in Uzbekistan and their lifestyle, and could be useful in designing measures to protect and strengthen health of elderly in the other low- and middle-income countries.

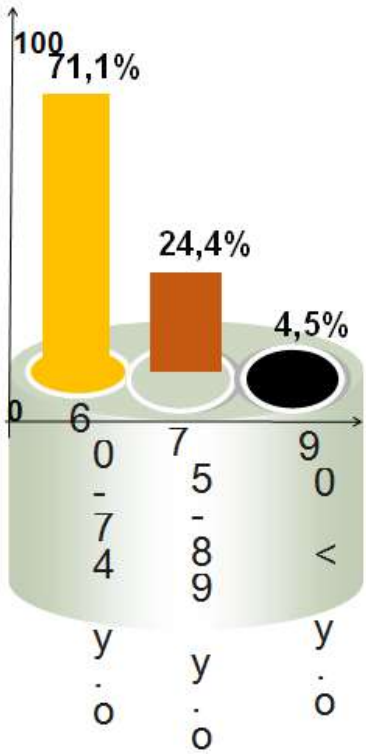
Method

The objects of the study were people of retired age living in the Tashkent city and the Tashkent region: elder people living alone in their apartments (310), were considered as a 1st social category, elder people living in nursing homes (240), were considered as a 2nd social category, and elderly people living with their families (597), were considered as a 3rd social category. Atotalof 1147 elderly people composed ours ample.

The subjects of the study were the social and demographic characteristics of elderly people and their lifestyle.

The lifestyle of elderly was studied by using a sociological research method through the conduction of a survey-interview. All data was entered in the "Elderly Lifestyle Study Questionnaire".

According to the WHO age classification, people aged 60-74 years old are elderly, 75-89 years old are senile, and over 90 years old are centenarians. We took these age periods into account when dividing our research object into the age groups.

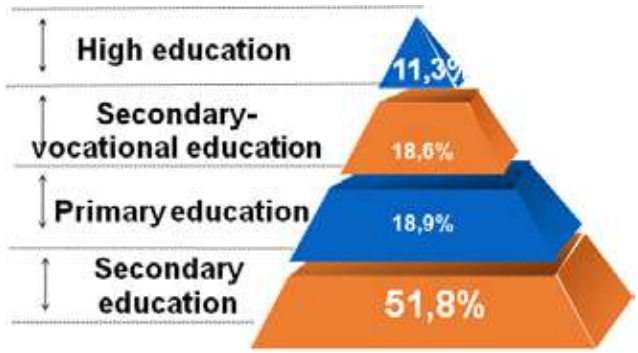


We studied living conditions, daily routine, dietary regimen and nature, leisure, bad habits and physical education along with assessment lifestyle of respondents. Elderly people were asked also about the amount of hot food consumption per day and its character to assess the regimen and nature of nutrition. A special place was given to determining the BMI of the elderly, the amount of consumed meat per week, the number of raw vegetables and fruits servedon average per week. During the study the smoking status of respondent (smoker, former smoker, did not smoke at all), the frequency and types of smoked tobaccowas clarified. Moreover, the alcohol consumption, its frequency and the amount of a standard dose of consumed alcohol over the past month was also specified to assesstheir bad habits. All respondents were asked about the performing physical training, its nature (high-intensity, medium-intensity, and low-intensity), frequency and duration of each leisure activity.

The interview data and medical records were transformed into an electronic database - MS Office Access 2018, which was then exported to the IBM SPSS Statistics version 20 statistical package. Relative and average values were calculated with the calculation of mean error (m), confidence coefficient (t) and error probability (R). To conduct the study, the approval from the National Ethics Committee of the Ministry of Health of the Republic of Uzbekistanwas obtained. After familiarizing the respondents with the goals and objectives of our study, they filledout the consent to participate in this scientific work.

Results

Analysis of the social and demographic data of our sample showed that the average age of the examined individuals was 72.5 +1.6 years. The distribution of our sample by age groups was carried out according to WHO criteria, the group of elderly, from 60 to 74 years old, the group of senile, from 75-89 years old and the group of centenarians, from 90 years and above. A large



proportion of the respondent was in the age group of the elderly (71.1%) and a smaller proportion was in the age group of centenarians (4.5%) (Fig. 1)

Picture 1. Age structure of respondents

The interesting data was observed in general distribution of the sample according to their social categories; in the category of lonely elderly people living alone in their apartments, 3.4 women corresponded to one man, and in the category of elderly people, living with their families, 2.4 women, whereas in the category of elderly living in nursing homes, this ratio was reversedwith almost 2 times more men corresponding to one woman.

Most of the respondents had a secondary education, however, it should be noted that the largest proportion of elderly people living in nursing homes were people with primary education (31.7%). (Fig. 2)

Picture 2. Distribution of respondent's education level

In the structure of marital status elderly people who interpreted their condition as "widowhood" (40.5%) were dominated. Married respondents, among elderly living with their families, were 2.1 times more than elderly living in nursing homes and 5.7 times more than lonely elderly living alone in their apartments (table 1)

Table 1: Distribution of family status of respondents according to their social categories (in %)

Marital status	Social categories			Total
	1st Category	2nd Category	3rd Category	
Married	9,7±1,6	25,8±2,8	55,1±2,0	35,7±1,4
Divorced	10,6±1,7	31,2±2,9	11,1±1,2	15,2±1,06
Never married	23,2±2,3	7,9±1,7	1,2±0,3	8,6±0,8
Widows/widowers	56,5±2,8	35,1±3,0	32,6±1,9	40,5±1,4
Total	100,0	100,0	100,0	100,0

It is noteworthy that there were almost 3 times more divorced elderly in nursing homes than among the 3rd social category, i.e. elderly living with their families[11]. This, which may be due to two reasons: firstly, in older generations, divorce and widowhood are an unpleasant and negative factor that lead to loneliness; secondly, according to various studies, the presence of a family is one of the factors that have a positive effect on the residence of the elderly in around of relatives and, naturally, on life expectancy[10].

It should be noted that lonely elderly are in the most

difficult situation, because a significant large proportion of these people have various disabilities. Unfortunately, the largest proportion of elderly is in the senile age group, which amounted to 63.8%.

The study of the composition of the social status of the participants in our sociological survey showed that 2/3 of them (65.0% + 1.4%) were non-working pensioners, disabled people of the groups I, II and III, composed respectively, 0.53%, 13.5% and 3.8%. Working retirees accounted for only 3.7%.

The social position in the context of social categories is significantly varies. It is important to note that in the 1st social category, people with disabilities of the groups I and II were mostly observed, whereas, in the 3rd social category elderly people had II and III disability groups. There were no persons with disabilities of the group III in the 1st and 2nd social categories (table 2).

Table 2: Distribution of social status of respondents according to their social categories (in %)

Social status	Social categories			Total
	1st Category	2nd Category	3rd Category	
Disabled of the I group	12,9±1,9	0,84±0,5	-	0,53±0,2
Disabled of the II group	20,0±2,2	14,2±2,2	9,9±1,2	13,5±1,0
Disabled of the III group	-	-	7,4±1,1	3,8±0,5
Working retirees	2,3±0,7	5,8±1,5	3,7±0,7	3,7±0,5
Non-working retirees	67,2±2,6	51,7±3,0	69,0±1,8	65,1±1,9
Others	9,0±1,6	27,5±2,8	10,0±1,2	13,4±1,0

Every second elderly person in our study was suffered with obesity and had an increased BMI (25.1<). Respondents with a BMI of 18.1-25.0 accounted for almost 1/3 of all social categories. The data shows the presence of obesity in the studied individuals, which may be associated with the peculiar nutrition and physical activity of the respondents (table 3).

Table 3: Comparative analysis of BMI among elderly people according to their social categories (in %)

Social categories	Average age	BMI		
		<18,5	18,6-25,0	25,1<
1st category	72,4±1,5	10,6±1,8	28,4±2,6	61,0±2,8
2nd category	73,4±1,6	20,0±2,6	29,2±2,9	50,8±3,2
3rd category	71,8±1,6	13,9±1,0	28,5±1,3	57,6±1,5

Note: (p≤0,05) in comparison with the respective groups

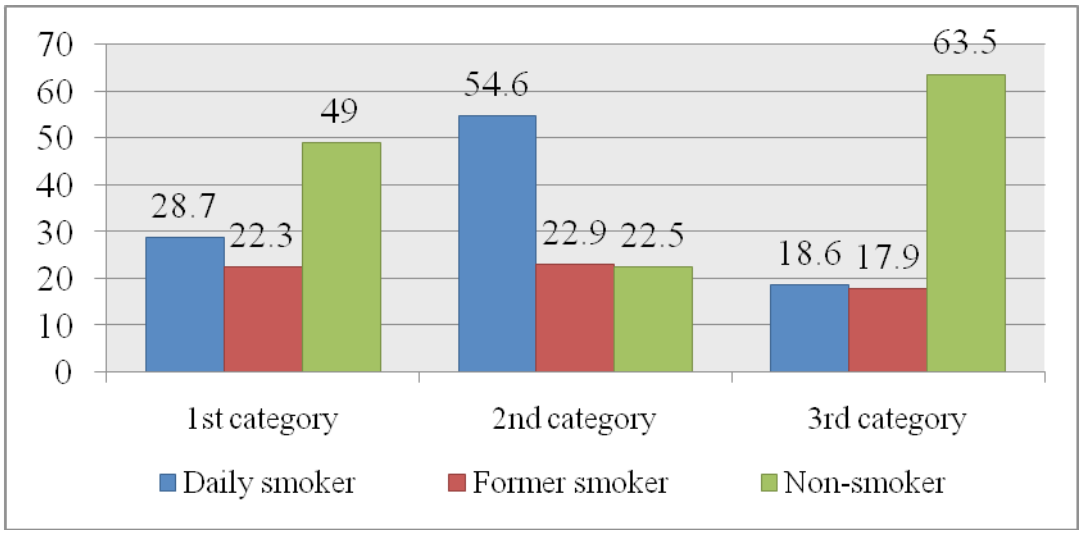
With the increasing of age, performing physical exercises is reducing. A small amount of elderly people (24.9%) is engaged only in low-intensity physical exercises.

The needs of elderly people for medical and social assistance significantly depend not only on their health status and disability degree, but also on such important factors as living conditions, organization of leisure, nutrition regimen, bad habits, and on physical activity.

Considering the human health as a harmonious development of the bodily and spiritual abilities of a person, it is important to bear in mind that human health is formed in connection with environmental conditions, in general, and in particular with his lifestyle.

One of the important indicators characterizing the living standard of the family and having a significant impact on the state of human health is living conditions, i.e. the conditions where a person lives and spends most

of his time; this applies, first of all, to lonely elderly people. An analysis and a comprehensive assessment of the living conditions of the elderly people indicate that 36.5+2.7% of lonely elderly living in their apartments lived in a one-room apartment, 36.8+2.7% in a two-room apartment, 16.1+2.9% in a three-room apartment and 10.6+1.8% in a four or more room apartment. These indicators among elderly people living with their family, respectively, amounted to 11.2+1.3%, 23.3+1.7%, 22.1+1.7%, 43.4+2.0%. Among elderly people living in nursing homes, 92.9+1.7% of them live in one-room ward, and 7.1+1.7% in two-room ward. The study showed that in all the studied social groups in Tashkent, almost 100% lonely elderly had more than 9 m^2 area per person, and had a centralized provision of hot and cold water, heating, sewage. Elderly from the 1st social category who live in the Tashkent region, 67.1+2.7% did not have central heating system, half (50.0+2.8%) were not provided with centralized hot water and 21.0+2.3% were not provided with centralized sewage system. Almost the same situation is observed in elderly people living with their family. In general, 23.7+2.3% of the 1stsocial category, 38.3+2.1% of the 2ndsocial category and 51.2+2.7% of the 3rdsocial category are living in good living conditions. The rest have quite satisfactory living conditions.



Almost all lonely elderly have a TV, newspapers and magazines in their house. However, it should be noted that 31.6+2.6% of elderly people living alone in their apartment do not have a TV, 51.3+2.8% did not have a radio and telephone, and 52.3+2.8% are not provided with newspapers and magazines, 85.5+2.0% do not have a computer. Whereas, people living in nursing homes much better provided with the necessary conditions for their leisure and cultural recreation. So, of those living in nursing homes, 97.9+0.9% responded that they have access to a TV, more than half (64.2+3.1%) replied that they have access to a radio, 49.2+3.2 % indicated the availability of updated newspapers, 60.0+3.0% indicated the presence of magazines in the place where they live.

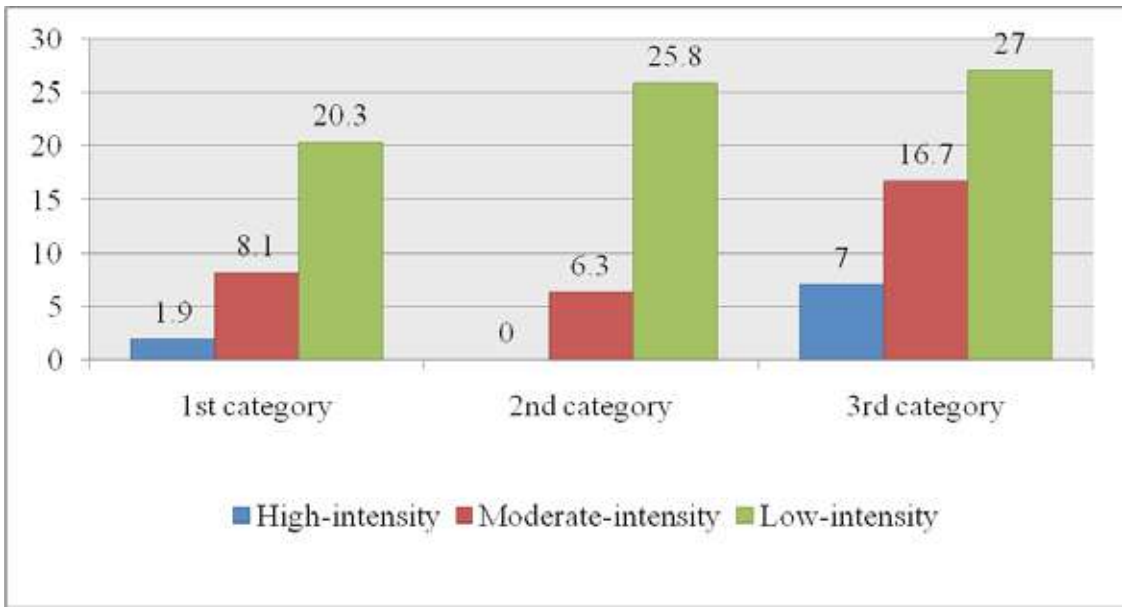
As a factor affecting human health also can be included factors such as daily routine, nutrition, recreation, and others.

During interview of the studied groups, a total of 4.6+0.6% noted that they have a monotonous food, 66.4+1.4% - a varied food, 8.3+0.8% - diet food, and 11.8+1.0% prefer to eat fatty food.

Most respondents do not pay proper attention to a balanced diet. Most of the respondents from the 1st social category noted that they consuming insufficient amount of meat, dairy products, vegetables and fruits.

The problem of smoking and alcohol consumption among the elderly deserves a separate attention. More than half of the respondents (54.6+3.2%) from nursing homes smoked tobacco products 2.0 times frequently compared to lonely elderly people living alone in their apartments (28.7+2.6%) and 3 times more than elderly people living with their families (18.6+1.6%) (Fig. 3).

Picture 3. Distribution of respondents according to their smoking status by social categories (in %)



The same trend was observed in assessing alcohol consumption. The data presented in Table 4 show that alcohol consumption is 6 times frequent among elderly people living in nursing homes compared with elderly people living with their families, and 3 times more than elderly people living alone in their flats.

Table 4: Alcohol consumption of elderly people according to their social categories (in %)

Frequency of alcohol consumption	Social categories		
	I	II	III
Daily	4,5+1,2	14,2+2,3	2,0+0,6
Weekly	6,5+1,4	25,0+2,8	2,7+0,7
Monthly	5,8+1,3	12,7+2,1	4,0+0,8
Non-drinking	83,2+2,1	48,1+3,2	91,3+1,2

It has been established that a small number of lonely elderly people regularly engaged in moderate-intensity physical exercises. So, in the first social category, their specific weight was 8.1+1.5%, in the third social category - 16.7+1.5%, and among people living in nursing homes, the second social category, their amount was significantly low (6.3+1.5%), compared with social categories I and III. Lonely elderly engaged in low-intensity physical exercises in all comparative groups were close to each other, but nevertheless their amount was much lower (Fig. 4).

With an increase the age, the number of elderly people who are engaged in any physical exercise began to decline sharply. So, if for lonely elderly people aged 60-74 years, the proportion of persons regularly engaged in physical exercises was equal to 25.4+2.7%, while in the age group of centenarians(90 years and above) its specific weight was equal only to 3.2+0.5%. Apparently, this is due to the fact that with the increase in the age, the number of chronic diseases increases as well as anatomical and physiological characteristics of the body changes which in turn influence to frequency of performance physical activity.

Picture 4. Assessment of performance physical activity among elderly people according to their social categories (in %)

Discussions

Conducted comprehensive studies of the elderly people revealed specific socio-demographic characteristics and lifestyle features for this category of population.

The average age of all examined individuals was 72.5+1.6 years. 65.1% of the surveyed individuals were non-working pensioners, 17.9% were disabled and 3.7% were working retirees. Every second elderly person living in nursing homes, or separately, in their

apartments, was widows and never married. At the same time, the proportion of people who have never been married, among elderly people living in nursing homes and lonely elderly living alone in their apartments, was 19.3 times (23.2%) and 6.6 times (7.9%) more than elderly people living with their families (1.2%). Most of all, nursing homes in Uzbekistan were crowded with men (64.6%) than women (35.4%), as well as with elderly people with primary education level (31.7%).

Anthropometric indicators of individuals did not practically differ among elderly from different social categories ($p > 0.05$).

Among elderly persons living alone in their apartments, more than 1/3 did not have access to the media compared with elderly people living in nursing homes. A small proportion of elderly people (24.9%) are engaged in low-intensive physical exercises. Elderly people engaged in physical exercises are significantly higher among those who live with their families.

The problem of loneliness in old age gives rise to a whole series of medical and social problems. It was found that 48.0% of the respondents, at the time of survey, lived outside of their families. In older age groups, divorce and widows (widowers) are negative factors that lead to loneliness. The presence of a family, the residence of the elderly in around of relatives has a positive effect on their health status and on their life expectancy. The needs of elderly people for medical and social assistance largely depend not only on their state of health, but also on the degree of limitation of their life activity.

Conclusion

It can be concluded that lonely elderly men are highly dependent on the help of others, and widowers and people with primary education are most likely to be in nursing homes. On a person who is distant from his family, the factor of loneliness affects sharply negatively.

Most of the elderly people live in good and quite satisfactory living conditions and have the necessary leisure facilities for recreation, which should be considered as a favorable factor in the socio-hygienic characteristics of the studied groups.

Along with the development of physiological and biochemical foundations for rationing the nutrition of different population groups, it should be paid special attention on the necessity of consuming vegetables, fruits, dairy and meat products for the people above the working age to maintain and strengthen their health status.

Efficient Means of Development of Speed Abilities Based on Analysis between Morphofunctional Indicators with Speed Qualities for Footballers on the Stage of Advanced Specialization

Shoxrux Erkinov

2nd Year PhD Student, Uzbekistan State University of Physical Education and Sport

Abstract

The article revised analyzes of indicators of morphofunctional parameters in the interconnections between speed indicators of football players at the stage of in-depth specialization. The experiment was conducted during the competitive period, using the method of Bioimpedansometry and the computer mathematical-statistical program SPSS for parametric non-parametric correlation.

Keywords: *Pearson-Brave correlation, Kendal and Spearman correlation, SPSS computer program, Bioimpedancemetry method, standard "8" ("eight"), physique, metabolic rate, bone mass density index.*

Introduction

Optimal change of the functional state of players by the intensity of the game is a requirement of modern football[2]. The increased functional state of football players over 15 km per match is evidenced by the rate of qualitative growth of players physical endurance in overcoming long distances during a single game, as well as the players performance of technical tricks at high speed and for a long time[1].

Relevance: The research of dependencies by method of mathematical statistics and the theory of probability, in particular by correlation analysis, helps researchers establish regularities that previously unknown to them[3]. Obtaining accurate and operational information in the analysis of sports parameters that are complex and difficult[4]. At the same time, for optimal planning of training loads, it is necessary to process the measured data during the training sessions, to assess the state of a football player after stress training is an invaluable tool in the researcher's arsenal, and especially at the stage of in-depth specialization.[5].

Object and Subject of Research

Eight football students of the RSHIOR (The Republican Olympic Reserve Boarding School) at the aged of 14 to 15 years were selected as **the object** of research. **The subject** of the research is to study of the correlation between morphofunctional and speed qualities, such as the percentage of total fat, the percentage of water in body weight, muscle mass in kg., physique, metabolic rate, bone mass density index, high start running at 10 and 30 meters, shuttle run 5 * 30m and the test "eight".

The Purpose of the Research: The purpose of this work was to research the interconnections of four speed characteristics such as the run of footballers at 10 m, 30 m, shuttle running 5*30 m and the test "eight" with physiological indicators and as a result to obtain quantitative measures of these interconnections in the form of coefficients of paired correlations to reveal effective means of developing speed qualities [6].

Method of Research

The SPSS package of computer programs for mathematical statistics, including a software procedure that implements parametric and nonparametric method of correlation analysis were used to achieve this purpose.

The physiological indicators of athletes were eight signs: body length, body weight, percent of total fat and water in the body, muscle mass, physique, metabolic

rate and bone density index. The indicators were taken using Tanita MC-980 equipment (Japanese - made) and the Bioimpedansometry method (Fig. 1).

Fig. 1. Tanita Bioimpedance Meter MS-980.

Bioimpedansometry method. The study of the component composition of the body by the method.

Assessment of body composition of athletes using bioimpedansometry method. Bioimpedansometry (BIR) or bioimpedance analysis of the diagnostics of an athlete's body composition by measuring impedance - the electrical resistance of body parts. An apparatus designed for bioimpedance measurement is called a bioimpedance meter (Tanita company, Japan). The method is based on measuring the resistance of the bioelectric resistance of body tissues (in particular, the following parameters were recorded: body length (cm), body weight (kg), relative fat mass (%), relative water mass (%), TBW (%), type of addition, level of metabolism, bone density index. (Fig. 2.2.3.)

Fig. 2.2.3. Tanita Bioimpedance Meter MS-980.

Information on the effect of physical exercises on length of body weight in young athletes is scarce. This is due to the difficulty of organizing lengthy experiments with subjects who regularly engage in physical exercises for several years. In addition, it is extremely difficult to take into account the effects of changing factors such as diet and heredity that significantly affect body size in a long study on a young man.

There is a bioimpedance method for determining body weight and percentage of fat in an athlete's body. With regular measurement of body weight and the percentage of body fat, one can accurately determine how the structural composition of the body is measured in favor of active muscle tissue. The normal fat content in young men for 18 year olds is 14-20%.

It is important to note that the composition of the body in young athletes varies, and as in adults, adipose tissue increases (Table No. 2.2.3.)

Bioimpedanceometry (BIR) or bioimpedance analysis is a method of diagnosing human body composition by measuring impedance - the electrical resistance of body parts - in different parts of the body. The device used to perform bioimpedance measurement is called a bioimpedance meter (Tanita). The method is based on measuring the bioelectric resistance of body tissues ("impedance" - resistance, "bioimpedance" - resistance of biological tissues). On the basis of the received data the conclusion about normative broken hydration of tissues, lipid and water-salt exchange is made and the results are monitored during the whole period of training work. According to the data in Table 2 translated, it should be noted that the average result of boys' body weight was 59.9 kg, their physique is large. Since the normal percentage of water $\bar{X} = 67.5\%$. The physique of trained, but observed lack of fat body weight (6.4%). Table 2.2.3.

Discussion

Correlation analysis is used to determine the degree of closeness of the interconnection between two random variables X and Y. The coefficient/correlation is used as a measure of bonding. The correlation coefficient is estimated by sampling the volume of n related observation pairs (x, y) from the joint general population X and Y. There are several types of correlation coefficients, the application of which depends on assumptions about the joint distribution of X and Y values.

Based on the above-mentioned speed and physiological indices of the athletes, we have created a sample in Excel file format consisting of eight observations (rows) and twelve indices (columns), a copy of which was then used as the source data for the correlation analysis program. Because the processed file has fewer observations, in addition to the parametric method (calculation of correlation coefficient by Pearson-Brave method) non-parametric method (method of rank correlations of Kendal and Spearman) of calculation of correlation coefficients are used.

The Results of the Research

Before starting the calculations, descriptive statistics and exploratory analysis programs were performed to determine the basic statistical characteristics and check the distribution of the initial data for normality (Table 1).

The table shows the name, average, standard deviations, and the number of all the studied indicators.

Table 3: Descriptive Statistics Table

An analysis of the data in the table showed that, out of the speed characteristics of athletes, the 10-meter run correlates not with all physiological indicators, except for the growth indicator, has no correlation, and growth correlates with an average degree of tightness with a correlation coefficient equal to r = 0.454.

The indicator of running 30 m also does not correlate with all, even with growth, physiological indicators, except for the "eight" test r = 0.8.

The shuttle running indicator 5 * 30 m showed a completely different picture concerning the physiological characteristics of athletes. This indicator correlates with physiological indicators of body length and the percentage of total fat in a weak degree, and with the latter in the opposite direction, with coefficients equal to r = 0.245 and r = -0.259, respectively. And with indicators, body weight, percentage of water, muscle mass, metabolic rate and bone density index, with an average degree of bond strength with the corresponding correlation coefficients r = 0.538, r = -0.407, r = 0.615, r = 0.603, r = 0.628. Only the type addition indicator did not correlate with the shuttle run indicator.

The "eight" test indicator with three physiological indicators (growth, percentage of total fat, and type of addition) had no correlation and correlated with other physiological indicators to an average degree of tightness with a correlation coefficient in the side-chapel r = 0,300.

Due to the smaller number of observations, in addition to the parametric method, we had to use nonparametric method for calculating pair correlation coefficients based on the Kendal rank method of correlation (Table 3) and Spearman (Table 4).

According to the Kendal ranking method (Table 3), the 10-meter running correlates on average with the growth indicator (r = 0.556) and with the percentage of total fat and water in the body, to a weak degree, respectively r = - 0.327 and r = 0.266.

Running on 30 m by this method had a correlation connection only with the index of the percentage of fat of the total in the opposite direction with the value of correlation coefficient, equal to r = - 0,327, and with other physiological indexes of running on 30 m did not correlate.

The shuttle running 5 * 30 m according to the Kendal rank correlation method had the same weak tightness of connections with two physiological indicators: muscle mass and metabolic rate (r = 0.286). This indicator also weakly correlated with bone mass index (r = 0.355), and shuttle running did not correlate with other physiological indicators.

The «eight» test only correlated with three indicators, but weakly. These indicators are growth, body weight, and the percentage of water in the body with the corresponding correlation coefficients r = 0.327, r = 0.367, and r = -0.286.

The correlation of the «eight» test with other physiological indicators was very weak.

Table 5: Kendal pair correlation table

Correlation by Kendal	10m running	30m running	Shuttle running 5*30м	Test «8» «eight»	Hight (cm)	Body mass	% total fat	% water	Muscle mass (кg) (кг)	Physiqueия	Metabolic rate
30m running	,667*										
Shuttle running 5*30m	,473	,618*									
Test «8» «eight»	,327	,473	,571*								
Hight (cm)	,556	,222	,182	,327							
Body mass (кg)	-,182	-,036	,214	,357	,255						
% total fat	-,327	-,327	-,214	-,071	-,036	,429					
% water	,255	,109	-,143	-,286	-,182	-,929**	-,500				
Muscle mass (кg)	-,109	-,109	,286	,143	,327	,786**	,357	-,857**			
Physique	,252	,168	,041	-,206	-,084	-,536	-,866**	,536	-,371		
Metabolic rate	-,109	-,109	,286	,143	,327	,786**	,357	-,857**	1,000**	-,371	
Bone mass density index	,000	,000	,355	,197	,401	,749*	,197	-,749*	,906**	-,273	,906**

According to the Spearman ranking method (Table 4), the 10-meter run correlates on average with the growth indicator (r = 0.590) and with the percentage of total fat in the body in the opposite direction and with the type of addition, lower than the average degree, respectively r = - 0.443 and r = 0.285.

Table 6: Spearman pair correlation table

Correlation by Sperman	10m running	30m running	Shuttle running 5*30м	Test «8» «eight»	Hight (cm)	Body mass	% total fat	% water	Muscle mass (кg)	Physique	Metabolic rate
30m running	,777*										
Shuttle running 5*30m	,587	,766*									
Test «8» «eight»	,407	,611	,690								
Hight (cm)	,590	,271	,299	,503

% water	,228	,168	-,262	-,333	-,275	-,976**	-,667				
Muscle mass (кg)	-,144	-,132	,333	,214	,359	,905**	,429	-,929**			
Physique	,285	,158	,126	-,252	-,095	-,693	-,945**	,693	-,441		
Metabolic rate	-,144	-,132	,333	,214	,359	,905**	,429	-,929**	1,000**	-,441	
Bone mass density index	,037	,037	,408	,284	,510	,840**	,259	-,840**	,964**	-,327	,964**

Conclusions

Running 30 m above the mentioned method very weakly correlates with the physical index of growth (r = 0.271) but with the index of the percentage of total fat in the body in the average degree and the opposite direction with the value of the correlation coefficient, equal to r = - 0.419, and with other physiological indicators correlation was not observed.

The shuttle running 5 * 30 m according to Spearman's rank correlation method had lower average connections

with the following physiological indicators: height, body weight, total fat percentage, muscle mass, metabolic rate and bone density index with corresponding correlation coefficients 0.299, 0.405, -0.310, 0.333, 0.333, 0.408.

Test «eight» to an average degree correlated with two physiological indicators. These indicators - growth (r = 0.503) and body weight (r = 0.476), and with two indicators - the percentage of water in the body and bone density index, weakly correlated with the corresponding correlation coefficients r = -0.333 and r = 0.284.

To develop the speed abilities of the players at the stage of advanced training to use the means of special physical training using a situational method. It is necessary to assess the data during the preparation.

Modern Trends in the Prevention of Liver Echinococcosis

M.M. Akbarov[1], R.Yu. Ruzibaev[2], D.Sh. Sapaev[3], P. Yu. Ruzmatov[4], F.R. Yakubov[5]

[1]MD, Doctor of Medical Sciences, Head of the Department of Liver Surgery, Republican Specialized Scientific-Practical Medical Center of Surgery Named After Academician V. Vakhidov, Tashkent, Uzbekistan, [2]MD, Professor, Department of Surgical Diseases, Urgench branch of Tashkent Medical Academy, Urgench, Uzbekistan, [3]MD, PhD, Department of Surgical Diseases, Urgench branch of Tashkent Medical Academy, Urgench, Uzbekistan, [4]MD, PhD, Head of the Department of General Surgery, Traumatology and Orthopedics, Urgench branch of Tashkent Medical Academy, Urgench, Uzbekistan, [5]MD, PhD, Associate Professor, Department of General Surgery, Traumatology and Orthopedics, Urgench branch of Tashkent Medical Academy, Urgench, Uzbekistan

Abstract

The results of diagnostics and treatment of patients with liver echinococcosis were analyzed for the period from 2010 to 2018. The follow-up amounted to 59 patients with recurrent liver echinococcosis. The acid-forming function of the stomach was analyzed in 34 patients who were on inpatient treatment for liver echinococcosis. Indicators of secretion were reliably biased towards hypoacidity. We examined 31 families of patients. The total number of examined was 93. In 66,7% of family members who had previously been operated on for echinococcosis, reduced acidity was found. This indicates that the risk of infection with echinococcosis is much higher in a hypoacid state than in normoacidic or hyperacidic gastric juice. A method of using drugs based on albendazole in the preoperative period, as well as to prevent relapses in the postoperative period, has been developed and proposed. The analysis of the incidence of liver echinococcosis in all districts of the Khorezm region was carried out. In all areas, especially in the most endemic ones, sanitary and educational activities are carried out both among the population and among the medical staff of regional clinics. Conducted interconnection with the veterinary service of the region, as well as with the sanitary and epidemiological bodies. The proposed method for applying Decasan residual cavity treatment and ultrasonic cavitation has shown impressive efficiency due to the lower number of relapses.

Keywords: *Liver echinococcosis; hypoacidity; prevention of echinococcosis with hypoacidity; perioperative prevention of recurrence of liver echinococcosis; method of echinococcectomy.*

Introduction

The relevance of the problem. In the Republic of Uzbekistan, more than 4.5 thousand operations per year are performed for liver echinococcosis[5], and more than a quarter of them suffer from complications[13].

In recent years, there has been a significant increase in the incidence of echinococcosis, with the number of patients with complicated forms reaching 5–40% [15]. Most often the liver is affected, in about 31 - 92% of cases, less often - the lungs, rarely - other organs. Mortality reaches 1.7 - 4.4%, the number of postoperative complications - 5.4 - 57.8% [14].

The difference between echinococcosis and other diseases is the difficulty of preventive measures, difficulties in early diagnosis, the use of only surgical method of treatment[5].

The increasing number of cases of echinococcosis, and many medical and social problems associated with it[7], make it necessary to further search for the causes of infection and method of prevention of this common and severe disease.

Analysis of the literature has shown that many issues of intraoperative and postoperative prevention of echinococcosis remain unresolved and contradictory. Most of the research, including fundamental monographs, scientific articles, as well as PhD and doctoral dissertations, is devoted to the technical features of performing echinococcectomies, using the latest

developments in the field of medical equipment, tools, including "Ultracision", "CUZA Exel+", "LigaSure", cystpericystectomy using an ultrasonic dissector, cystpericystectomy using an ultrasonic destructor-aspirator [8]. Of course, these method are progressive and should be implemented. However, the vast majority of clinics do not have such equipment[9].

Recurrent echinococcosis of the liver, strictly associated with the area of primary localization of the parasitic cyst, accounted for 26.6% of all recurrent forms. A large proportion of recurrent echinococcal cysts in segments remote from the primary focus (43.4%) and even lesions of another share (20%) call into question the role of the fibrous capsule of the primary cyst as the main factor of disease recurrence, which means that it is expedient to improve the method of its heat treatment, pericystectomy and wide use of resection technologies[10].

In 1985–1986, in vitro experimental studies on the effect of low-frequency ultrasound (LFU) on the germinal elements of echinococcus (GEOE)[4] were conducted in the Republican Center for Surgery named after Academician V. Vakhidov[3].

Studies have shown that, LFU has a powerful parasitocidal effect on GEOE. Even exposure of LFU to the GEOE for 1 to 2 minutes, causes a marked alteration of cells and other structures of the germinative envelope. Changes in brood capsules and protoscolexes, accompanied by the destruction of their membrane components, are irreversible.

The chemotherapeutic effect on GEOE is associated mainly with the use of various albendazole derivatives. The number of courses is unpredictable and depends on the success of chemotherapy and ranges from 8 weeks to 18 months.

However, a meager amount of literature has been devoted to the prevention of recurrence of echinococcosis in the postoperative period and, in general, to the prevention of infection by this pathology in a global, organizational direction. This explains the very disappointing situation regarding the prevalence of echinococcosis in the Republic.

Materials and Method

The results of diagnostics and treatment of patients with liver echinococcosis were analyzed at the Department of General surgery, traumatology and orthopedics of the Urgench branch of TMA and the Khorezm regional multidisciplinary medical center for the period from 2010 to 2018. Out of the total number of patients – 261 – a catamnestic analysis was performed in 225 patients. The follow-up volume was 59 patients with recurrent liver echinococcosis.

Relapse of the disease was detected in 52 cases out of 225 follow-up groups, and recurrence of echinococcosis was observed in 7 cases out of 36 patients in the prospective group. The largest number of relapses occurs in the following areas: Khiva, Khanka, Khazorasp. In addition, relapses were found in patients operated on in other regions of the Republic. On average, relapse occurred within 5±0.63 years. Repeated relapses occurred in 28 patients within 4±0.53 years.

In the existing literature there are only single and scattered reports of a direct relationship between the incidence of echinococcosis and the degree of inhibition of gastric acid production[1]. Found literary information about the role of hypoacidity in the development of echinococcosis creates the prerequisites for an in-depth information search in this direction.

Scientific studies of past years have shown that infection with echinococcosis is much more likely in patients with low acidity of gastric juice [12]. Based on the results of these studies, we purposefully conducted a clinical examination of family members of patients who underwent echinococcectomy from the liver. It was necessary to give an answer to the question of what dependence is the probability of infection with liver echinococcosis on the acid-forming function of the stomach in adults, as well as what frequency of infection with this disease in persons with normal gastric acidity among family members operated for liver echinococcosis under the same living conditions. We analyzed the acid-forming function of the stomach in 34 patients who were on inpatient treatment for liver echinococcosis by pH-metry. The indicators of secretion were significantly shifted towards hypoacidicity, which indicates a significant inhibition of the acid-forming function of the stomach in patients with liver echinococcosis.

Since we have provided district-based statistics on the incidence of liver echinococcosis in the Khorezm region, it was also advisable to conduct a similar quantitative study of dispensary data on the examination of family members operated on for liver echinococcosis.

A total of 31 families of our patients were examined.

The total number of examined was 93. The age of the examined ranged from 21 to 57 years, on average - 38±0.8 years.

Results

In general, the examined did not present complaints during the initial examination. Of the 93 people at the initial examination, 3 were diagnosed with gallstone disease, however, none of this group presented any complaints.

Initially, the examination began with ultrasound sonography (US) control. With ultrasound scan, echinococcosis was not found in 84 people (90.3%). In 6 (6.5%) cases, a single echinococcosis of the liver was found, and in 3 people (3.2%), a comprehensive examination using ultrasound scan and X-ray examination revealed multiple and combined echinococcosis of the liver and lungs. In case of a single liver echinococcosis, the average diameter of the cysts was 4.7 cm, and in patients with multiple lesions, the size of the liver cysts was on average 3.9 cm and for the lungs 4.1 cm. Detection of echinococcosis in a relatively initial stage, therefore, is, in our opinion, is extremely important, since the small size of the cysts can be subjected to chemotherapy without resorting to unnecessary surgical interventions.

In 9 patients with echinococcosis detected during clinical examination, the pH value of the gastric juice was checked.

In the main part of patients, members of families previously operated on for echinococcosis, reduced acidity was found (66.7%). This suggests that with a hypoacid state, the risk of infection with echinococcosis is much higher than with normoacid or hyperacidity of gastric juice. Those 3 patients with normal and high acidity, in our opinion, were infected with echinococcosis due to ingestion of a large number of oncospheres along with poorly washed vegetables. This circumstance requires a systematic sanitary-educational work among the population along with medical examination of family members of patients who have previously undergone echinococcectomy.

Discussion

Since 1983, the world practice has been using the anthelmintic drug albendazole and its derivatives for the treatment of echinococcal cysts less than 5 cm in size and anti-relapse prevention after surgical treatment. This provision is also enshrined in a resolution of the congress of the Association of Hepatologist Surgeons of Russia and the CIS countries (2014). Retrospective analysis of medical records revealed that 5% iodine solution and 96% ethyl alcohol were used to treat residual cavities. Subsequently, we used the following scheme for the treatment of residual cavities: treatment with 5% iodine solution, 70% ethyl alcohol, and 0.02% Decasan solution. In addition, with medium and large sizes of the residual cavity and the intrahepatic location, ultrasonic cavitation was used with the equipment SIGMA -01, 1990 (France) with frequency of 26.4-26.6 KHz.

We have developed and proposed a methodology for the use of drugs based on albendazole in the preoperative period, as well as to prevent relapse in the postoperative period. Three days before the operation, we use Zentel in a dose of 10-12 mg/kg of body weight. We assume that the period Of zentel's presence in the blood, according to the data of manufacturers' research, is 8-12 hours [11]. By circulating in the bloodstream, Zentel interferes with the implantation of living protoscolexes in the tissue, and also eliminates the risk of dissemination.

In the postoperative period, a week after discharge from the hospital, we prescribe taking Zentel at a dose of 10-12 mg/kg for 28 days together with simultaneous administration of hepatotropic drugs (Carsil, Essentiale, etc.). After this, a break is required for 14 days. We offer 3 to 4 courses of preventive chemotherapy. For multiple lesions, we use 4 to 5 courses.

If a hypoacid condition is detected, we offer a diet that stimulates the secretion of gastric juice, including broths with spices, mashed vegetables and fruits, boiled low-fat meats, fish and poultry, rye stale bread, cabbage and cabbage juice, peppermint, decoctions of St. John's wort, wormwood, calendula, lemons, butter and vegetable oils, cottage cheese, sour milk, buttermilk, juices. In addition, we recommend multivitamins, drugs containing hydrochloric acid, such as acidin - pepsin, enzyme drugs, biostimulants - aloe, pantocrine and others.

In order to prevent liver echinococcosis, as well as for early detection of the disease, we have proposed a method according to which relatives of the operated patients are invited to the clinic, they are given an ultrasound scan. If echinococcosis is detected, in addition to other studies necessary for the upcoming

operation, an analysis of the acidity of gastric juice is carried out. In addition, we identify the most endemic areas of the region where cases of liver echinococcosis are more common. In all areas of the region, especially in the most endemic, sanitary and educational events are held both among the population and among the medical personnel of district clinics. For this purpose, the media are also used - regional newspapers, radio messages. The interconnection with the veterinary service of the region, as well as with the sanitary and epidemiological bodies.

Thus, a retrospective analysis showed the ambiguity of the results of various method of echinococectectomy from the liver. A rather significant number of recurrences of echinococcosis of the liver is detected. There are several reasons for this. Firstly, the level of acidity of gastric juice matters, low acidity facilitates infection with echinococcosis. Secondly, the method of processing the residual cavity is important, since protoscolexes can remain alive and penetrate deep into the surrounding tissues (metastasis). Analysis of long-term results shows that the detection of recurrent liver echinococcosis most often occurs at 4-5 years after surgery. At the same time, there is a need for a control inspection every six months using ultrasound as a screening method.

The proposed method of surgery, including preoperative chemoprophylaxis, postoperative chemoprophylaxis for three years, a method of treating the residual cavity using LFU with Decasan should, in our opinion, significantly reduce the likelihood of recurrence of liver echinococcosis. Preventive and sanitary-educational work among the relatives of the operated patients, as well as close relationship with the veterinary and sanitary-epidemiological services, in our opinion, can significantly reduce the incidence of liver echinococcosis among the population of the Republic.

Conclusion

A specific study of the incidence of liver echinococcosis in the regions of Uzbekistan is essential to reduce the incidence of this pathology, which is of great social and economic importance. The analysis of the incidence of echinococcosis of the liver in all areas of the Khorezm region. The greatest number of morbidity and relapses is observed in Bagat (17.4%), Khiva (16.2%), Khazarasp (13.0%), and Khanka (11.0%) districts.

In a comparative assessment of various method for treating the residual cavity using devastation and technological method, the proposed method for applying the treatment of the residual cavity to Decasan and ultrasonic cavitation showed impressive efficiency due to the smaller number of relapses.

A complex of preventive measures has been developed to reduce the incidence of liver echinococcosis in the Khorezm region, including postoperative preventive devastation therapy, systematization of sanitary and educational work among the population and medical personnel, a clinical examination of family members of patients operated on for echinococcosis, including a study of gastric acid acidity, use of the media.

Abstract

The Purpose: To examine the state of thrombocytic and coagulation hemostasis among patients with immune microthrombovasculitis**.**

Materials and Method: The study included 75 patients with immune microthrombovasculitis. Among them, rmen - 24 (32%), women - 51 (68%), the average age is 42.4±1.3 years. The control group consisted of 15 practically healthy persons.

Results and Discussion: A study of coagulation hemostasis among patients with immune microthrombovasculitis showed the presence of hypercoagulation shift with the increase of fibrinogen concentration, prothrombin index, shortening of the active partial thromboplastin time and blood clotting time, the appearance of hybrid monolith complexes - level increase of D-dimer positive ethanol test.

Conclusions: The most common clinical form of IMTV is the skin-joint form of the disease (62.2%), 89.3% of patients were admitted with an acute form of the disease. Women get sick twice as often (67.3%) than men (32.7%), the highest incidence is in the young age group from 18 to 49 years (87.3%). There is hypercoagulability in case of immune microthrombovasculitis.

Keywords: *Immune microthrombovasculitis, coagulation hemostasis.*

Introduction

Immune microthrombovasculitis (IMTV) - is an autoimmune disease characterized by generalized vasculitis which involves small skin vessels, the gastrointestinal tract, kidneys, joints, and, rarely, the lungs and central nervous system (CNS). The causes of the disease can include infections of various aetiology, parasitic invasions, various medical products, the introduction of serums, vaccines, etc. IMTV mainly affects microcirculatory vessels, such as arterioles, capillaries, and post-capillary venules[3].

IMTV is a widespread disease from the systemic vasculitis group of immunocomplex nature[11] and in accordance with epidemiological studies[16], IMTV constitutes 59% of allnosologically forms [19]. The annual incidence of IMTV reaches 20-25 per 100,000 of population, and there is an increase in the incidence [14]. Children get sick more often than adults[5] and in accordance with some data, the ratio of IMTV between children and adults is 8:1 – 9:1[17].

The studies of the hemostasis system have led to the conclusion that the leading link in the process of blood

clotting disorders among IMTV patients is the tension of thrombolytic-vascular hemostasis and the acquisition of procoagulant properties by endothelial cells under the influence of immune aggression. In case of hemorrhagic vasculitis, "aseptic inflammation" occurs in small vessels, as well as the formation of immune complexes that circulate within the bloodstream[9]. Under the influence of soluble immune complexes and cytokines activated by them, components of the complement system, aseptic inflammation of micro vessels develops with more or less deep focal endothelial dystrophy and vascular wall disruption[12]. As a result, phlebarteriectasia occurs with divergence of endothelial cells, violation of vascular permeability and its integrity[7]. Then, the secondary hemorrhages of skin blood vessels and internal organs develop.

There was a evident activation of coagulation hemostasis, i.e. a state of thrombophilia with a tendency to hypercoagulation and thrombosis, as well as the development of disseminated intravascular coagulation syndrome in acute situations [13].

In 90 % of cases, the disease debuts with arthritis or arthralgia [15] and joint syndrome is the diagnostic criteria of IMTV [20]. In general, joint damage (usually knee, ankle, wrist) exists among 60-80 % of patients with IMTV, more often develops among adults and combines with myalgia [8]. As an adult, joint pathology takes the form of chronic or migrating intermittent polyarthritis[22].

The high prevalence and increase in the number of patients with IMTV, the severity of the clinical course, determine the important socio-economic significance of this problem.

The Purpose of the Research: To examine the state of thrombocytic and coagulation hemostasis among patients with immune microthrombovasculitis**.**

Materials and Method of the research. The study included 75 patients with IMTV who were under treatment in the Department of Hematology in the multidisciplinary clinic of the Tashkent Medical Academy. Among them, men - 24 (32%), women – 51 (68%), the age range of patients was from 19 to 70 years, the average age was 42.4±1.3 years. The control group consisted of 15 practically healthy persons in comparable age, as well as 6 men (53.4 %) and 9 women (46.6%), whose average age was 39.4±1.2 years.

We divided all the patients under study into 4 groups in accordance with the clinical implications of the disease. The first group included 14 (18.7%) patients with cutaneous form, the second group consisted of 47 (62.6%) patients with cutaneous-articular form of IMTV, the third group included 8 (10.7%) patients with mixed abdominal form and the fourth group included 6 (8%) patients with mixed renal form of the disease.

Research Method

the research method included patient examination, general blood analysis by the hematological analyzer Mindray BC 5000 (China),), blood clot retraction, platelet adhesion and aggregation by the aggregometer Biola Alat-2 (Russia), fibrinogen, prothrombin index (PTI), fibrinolytic activity, activated partial thromboplastin time (APTT) by the coagulometer Humaclot Junior (Germany), antithrombin III, D-dimers by the Roche Cobas C 311 biochemical analyzer (Switzerland).

Results and Discussion

An analysis of the patients distribution by age and gender showed that among patients there was a predominance of women, the number of men was almost half the number of women.

The age composition study of the examined patients showed that the majority of patients were young; 24% (18) were in the age from 18 to 29 years and 60% (45) were patients in the age from 30 to 49 years.

The diagnosis based on clinical symptoms and laboratory data. Patients with a cutaneous form of IMTV were hospitalized with a severe form of the disease. 13 (92.8%) patients of the first group suffered the acute start of the disease. All patients had multiple small-point hemorrhagic rashes on the skin of the lower and upper limbs and within the abdominal area, sometimes of a coalesced character. We observed the maculopapular rash with necrotic skin among 5 (35.7%) patients. 47 patients had the skin-joint form of IMTV, we observed it within the scope of skin lesions in the form of a symmetrical hemorrhagic rash, joint damage. The most characteristic were swelling, soreness, restriction of joint function, often marked symmetrical involvement of the joints: knee, ankle, elbow and wrist. 8 patients constituted the third group with diagnosis of abdominal IMTV on the basis of characteristic spastic pains in various parts of the abdomen, as well as conditions of nausea and vomiting. Abdominal syndrome developed simultaneously with skin rashes. 2 patients had the

enterorrhagia. We found the most severe complications among patients with IMTV refered to 6 patients with kidney damage. The main clinical signs of kidney damage were micro and macrohematuria, proteinuria, cylindruria, edema, and increased blood pressure.

Thus, the analysis of the research results showed that the main part (62.6%) constituted the patients with skin and joint disease, women had the disorder twice as often (68%) as men (32%), the highest incidence is within the young age group in the age range from 18 to 49 years (84%).

Among 75 patients with IMTV who passed treatment in 2019, the state of hemostasis was under study within comparison with the control group (tables 1, 2). In accordance with the table 1, the number of thrombocytes in IMTV group was more high than in the control group, although it remained within normal values. At the same time, there was no significant difference between the thrombocyte values of both groups. The study of thrombocytes functional characteristics showed that the patients of the main group have a distinct increase in the adhesive and aggregation properties of thrombocytes. Thus, in the group of patients with IMTV, the aggregation time increased and constituted 119.3±2.7%, while in the control group it was 66.7±4.1%. this is significantly more high than the initial data. The observed significant activation of thrombocytes aggregation was among 38 patients (88.3%), while 5 (11.7%) patients had the thrombocytes aggregation time within the normal values. The adhesion of platelets in the main group significantly differed from the control group and increased to 62.4±1.2%, and within the control group it was 41.2±0.97%.

Table 1: Thrombocytic indicators among patients with IMTV, M±m.

Indicators of hemostasis	Control group n=20	IMTV, n=43
Thrombocytes (10^9/l)	232,8±9,75	258,8±6,65*
Retraction (of 0.3-0.5 s)	0,32±0,02	0,25±0,02
Aggregation, %	66,7±4,1	119,3±2,7*
Adhesion, 20-40%	41,2±0,97	62,4±1,2* *

Note: * - accuracy in relation to the control group *- p< 0,05; * *-p< 0,01.

The parameters that characterize the platelet link of hemostasis also include the identification of blood clot retraction. The study of the retraction time among IMTV patients showed that the initial indicators were more short than in the control group, which indicates an increase in thrombocyte activity, but without any reliable difference.

In order to assess the state of plasma coagulation hemostasis, we studied blood clotting factors, physiological anticoagulants and products of fibrin degradation.

The studies have shown that among the patients with IMTV, the initial values of coagulation hemostasis indicators demonstrated a state of hypercoagulation. (table 2).

In the direction of hypercoagulation, the indicator of blood clotting time (BCT) changed. In the group of patients with IMTV, the BST was shortened to 2.1±0.13 minutes, which is more than half in comparison to the control group (4.8±0.21 minutes). The research results of activated partial thromboplastin time (APTT) showed that a shortening of this indicator occurred among 55 (73.3%) patients. As can be seen, the APTT in the control group was 35.2±0.54 seconds, and in the group of patients, it decreased to 25.2±0.48 seconds. (p<0.001).

Table 2: Indicators of coagulation hemostasis among patients with IMTV, M±m

Indicators of hemostasis	Control group, n= 15	IMTV, n=75
BCT (5 min)	4,8±0,13	2,1±0,12* *
aPPT, sec (45 sec)	35,2±0,54	25,2±0,48* **
PTI, % (90-105%)	86,4±1,24	104,0±1,33* *
INR	1,25±0,04	0,82±0,03* *
Fibrinogen (2.0-3.5 g/l)	2,4±0,19	4,9±0,17* *
Hematocrit, % (40-50%)	41,2±0,9	48,8±0,82*
Von Willebrand factor	96,2±1,2	118,6±1,8* *
Antithrombin III %	100,3±5,2	87,8±3,1 *
FA, sec(140-240 s)	142,2±6,14	256,2±5,18 ** *
D-dimers µg/ml	0,58±0,03	2,1±1,6*
Ethanol gelation test	negative	positive

Note: * - accuracy in relation to the control group, * - p< 0.05; * * - p<0.01; * * *-p< 0.001

The analysis of coagulation hemostasis state among patients within the IMTV group in accordance with indicators of prothrombin, INR and fibrinogen indicates clearly expressed hypercoagulation. The evidence of

it is a significant increase in the prothrombin index by 104.0±1.33% in the group of IMTV patients, while in the control group it is 86.4±1.24% ($p<0.01$), the average INR values in the main group were significantly shortened in comparison with the control group (1.25±0.04 and 0.82±0.03, respectively, $p<0.01$).

An increase in plasma fibrinogen concentration also characterized the state of hemostasis with a tendency to hypercoagulation, so among patients of the main group it was 4.9±0.17 g/l, and within the control group it was 2.4±0.19 g/l. ($p<0.01$). The hematocrit index in the groups under study did not deviate from the norm and was within the range from 41.2 to 48.8%.

The indicators of coagulation hemostasis also include fibrinolytic activity of blood. In our study, this indicator within the group of patients was significantly more high than in control group. In case of hypercoagulation syndrome, it is important to determine markers of inopexia. Our ethanol gelation test and determination of D-dimer content showed that there is an activation of fibrinolysis processes, which is indicated by an increase in the main group of the fibrinolytic activity indicator almost twice in comparison with the control group. The ethanol gelation test was positive among 61 (81.4%) patients, while within all control group it was negative. The content of D-dimers in blood plasma of patients with IMTV significantly increased, this indicator was almost four times more high than in the control group. It is very important to assess the state of hemostasis in order to study the anticoagulant hemic system, which is to balance shifts in the clotting system. Normally, these important systems of the body are in a state of dynamic equilibrium. For this purpose, the activity of a physiological anticoagulant, antithrombin III (AT III), was under study. In our study, this indicator was more low than the values of the control group and constituted 87.8±3.1% and 100.3±5.2%, respectively.

Thus, our study of the hemostasis coagulation link among patients with IMTV showed the presence of significant deviations in regard to hypercoagulation shift. We indicated it by an increase in the concentration of fibrinogen, PTI, shortening of APTT and BCT, low INR, and the appearance of degradation markers in relation to fibrin-fibrinmonomer complexes (an increase in the D-dimers level, a positive ethanol gelation test).

Conclusions

1. One found that the most common clinical form of IMTV is the skin and joint form of the disease (62.2%), with the acute form of the disease refered to 89.3% of patients.
2. Women get sick twice as often (67.3%) than men (32.7%), the most high incidence is in the group of the young age within the range from 18 to 49 years (87.3%).
3. The study of hemostatic parameters among the patients with IMTV indicates a state of hypercoagulation. The evidence of hypercoagulation state was an increase in the aggregation properties of thrombocytes, an increase in the quantity concentration of plasma clotting factors and fibrin degradation products in the blood, and a decrease in the anticoagulant properties of plasma.

Abstract

Objective of the Study: To characterize the hemorrhagic syndrome in patients with chronic hepatitis and liver cirrhosis of viral cause.

Materials and Method: 80 patients with liver cirrhosis of viral cause have been studied, 20 patients with liver cirrhosis of non-viral cause and 62 patients with chronic viral hepatitis.

Results of the Study: Hemorrhagic syndrome was pronounced in patients with liver cirrhosis of viral cause, and much less pronounced in the group of patients with liver cirrhosis of non-viral cause. In patients with chronic viral hepatitis B and C, bleeding symptoms were much less common.

Conclusions: Severe hemorrhagic syndrome with liver cirrhosis of viral cause requires a detailed study of coagulation and vascular-platelet hemostasis for the prevention and treatment of bleeding.

Keywords: Hemorrhagic syndrome, liver cirrhosis, chronic hepatitis, hemostasis.

Introduction

Hemostasis is an evolutionarily developed, multicomponent protective function of the body. Its physiological significance is mainly to ensure the formation of a fibrin clot and maintain blood in the liquid state[1].

The liver plays an important role in hemostasis; therefore, diffuse lesions of the liver parenchyma are the cause of complex disorders of hemostasis [7]. In liver cirrhosis, changes in the hemostasis system are complex and multidirectional. In the occurrence of hemostasis disorders in liver diseases, complex mechanisms of interaction of platelets, coagulation factors, and the fibrinolysis system are involved[14]. Therefore, chronic or acute liver diseases, including viral hepatitis, alcoholic hepatitis, chronic hepatitis and cirrhosis, often have a profound effect on the hemostatic system[12].

Many liver diseases lead to thrombocytopenia, since protein coagulation factors and hematopoietic platelet growth factor thrombopoietin are produced in the liver[8]. According to many researchers, one of the reasons for the development of thrombocytopenia is an increase in antiplatelet antibodies in liver diseases[10]. Thrombocytopenia in liver diseases leads to an increased risk of bleeding, which may be a contraindication for antiviral therapy, liver biopsy and surgery [5].

Decreased synthesis of coagulation factors by liver cells plays a key role in changes in hemostasis. It also leads to an altered fragile[6] balance of blood coagulation factors, which is the reason for the development of

coagulopathy and the occurrence of hemorrhagic syndrome in liver diseases [13].

Bleeding is the most common clinical manifestation, due to thrombocytopenia and thrombocytopathy, to impaired synthesis of clotting factors, and activation of fibrinolysis. Other actual clinical problems are bleeding in patients with liver cirrhosis[3], bleeding esophageal varices, hematomas, hemorrhagic purpura, nasal hemorrhage, gingival hemorrhage and menorrhagia [2].

Timely diagnosis of hemostatic disorders in patients with chronic viral hepatitis and liver cirrhosis and appropriate hemostatic therapy will reduce the risk of hemorrhagic complications. It is noteworthy that previous researches concerned with the bleeding in chronic hepatitis and liver cirrhosis are few, and their results are contradictory. This explains interest in further research in this area.

Objective of the study: To characterize the hemorrhagic syndrome in patients with chronic hepatitis and liver cirrhosis of viral cause.

Materials and Method

Clinical studies were performed in the departments of Hematology and Hepatobiliary Pathology of the multidisciplinary clinic of the Tashkent Medical Academy, since 2016 to 2019. The study included 162 patients with chronic diffuse liver diseases, including 80 patients with decompensated liver cirrhosis of viral cause (Child-Pugh Class B), 20 patients with decompensated liver cirrhosis of non-viral cause(Child-Pugh Class B), and 62 patients with chronic viral hepatitis of moderate activity.

When establishing a diagnosis of liver cirrhosis and chronic hepatitis of viral cause, past medical history of the patients was taken into account (transfusion of blood components, dental treatment, etc.), as well as characteristic clinical syndromes (hemorrhagic, anemic, astheno-neurotic, icteric, etc.) and laboratory and instrumental studies data. The detection of hepatitis virus markers by ELISA and PCR, blood analysis, the determination of hepatitis B virus DNA (HBV) and hepatitis C virus RNA (HCV) and D (HDV) with the determination of genotypes was mandatory. In patients with chronic hepatitis and liver cirrhosis of viral cause, the viral load was more than 1,000,000 IU/ml.

The diagnosis of liver cirrhosis and the degree of hepatic cell failure has been established with the consideration of WHO recommendations (2008), according to the Child-Pugh classification,and based on diagnostic criteria. In order to establish the degree of fibrosis in patients with liver cirrhosis, an ultrasound scan (US), MSCT, and liver fibroscanhavebeen performed. The survey included patients with chronic hepatitis and liver cirrhosis who did not undergo antiviral therapy.

All patients examined by us were divided into 6 groups: group 1 included 30 patients with HBV liver cirrhosis, group 2 - patients with HBV+HDV liver cirrhosis, group 3 - 30 patients with HCV liver cirrhosis, group 4 - 20 patients with liver cirrhosis with negative results for markers of viral hepatitis. Group 5 included 32 patients with chronic viral hepatitis B of moderate activity, and group 6 - 30 patients with chronic viral hepatitis C of moderate activity.

Among 162 patients included in the study, there were 92 males (56.79%) and 70 females (43.21%). The age of patients ranged from 21 to 69 years, the average age was 48.2±12.1 years. Number of patients of working age accounted for 43.97%.

In order to determine the type of hemorrhagic syndrome, we studied patients' complaints, their past medical history and objective data: gingival hemorrhage, nasal hemorrhage, menorrhagia, bleeding esophageal varices and hematomas.

Research Result

The study included patients with liver cirrhosis of viral and non-viral cause, and chronic viral hepatitis B and C of medium activity. Liver cirrhosis in these patients was classified as decompensated (Child-Pugh Class B).

In order to determine the type of hemorrhagic syndrome, we studied the patients' complaints, their past medical history and objective data. Patient complaints were divided into the following types: anemic syndrome, sideropenia, symptoms of funicular myelosis, icteric syndrome, hemorrhagic syndrome and symptoms of liver failure. In order to identify hemorrhagic syndrome, in addition to patients' complaints, we paid special attention to objective data and a medical history.

The patients' main complaints were divided by the following hemorrhagic symptoms: nasal bleeding, gingival bleeding, skin petechiae, hemorrhoidal bleeding, bleeding esophageal varices, menorrhagia andgastrointestinal bleeding.

Analysis of the clinical manifestations of bleeding according to complaints, medical history and objective data of the patients showed that the hemorrhagic symptoms were very diverse during the examination. For example, epistaxis occurred in 59 (34.3%), gingival hemorrhages in 52 (30.2%), skin petechiae in 46 (26.7%), hemorrhoidal bleeding in 36 (20.9%), bleeding esophageal varices in 35 (20.4%), gastrointestinal bleedingin 29 (16.9%) and menorrhagia in 20 (11.6%) patients (Fig. 1).

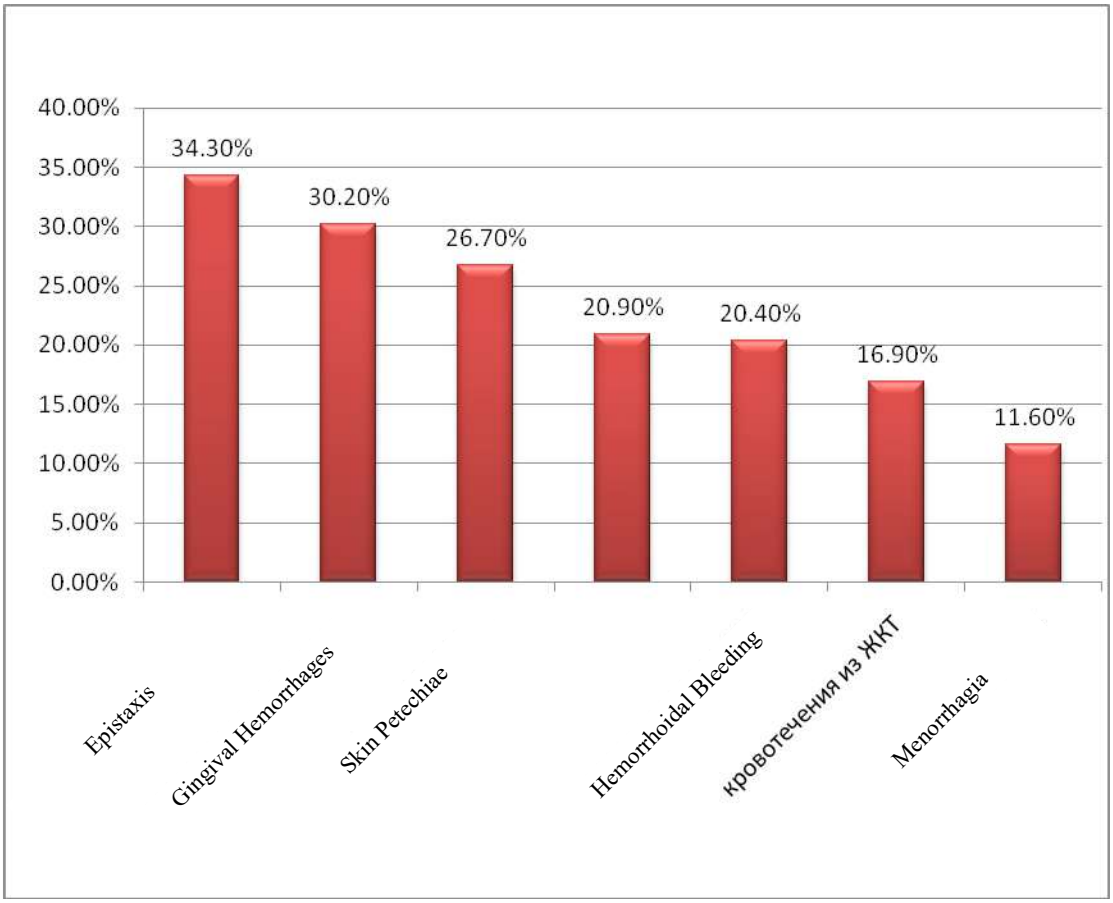

Fig. 1. Degree of incidence of hemorrhagic syndrome in patients with liver cirrhosis and chronic viral hepatitis

Hemorrhagic syndrome with large fluctuations has been found in different patient groups. For example, it was more pronounced in groups 1 and 2. In group 1, symptoms of bleeding occurred in 19 (63.3%) patients, including nasal hemorrhage in 17 (56.7%), gingival bleeding in 17 (56.7%), skin petechiae in 13 (43.3%), hemorrhoidal bleeding in 12(40.0%), bleeding esophageal varices in 12 (40.0%), gastrointestinal bleeding in 10 (33.3%)and menorrhagia in 8 (26.7%) patients.

In group 2, the incidence of hemorrhagic syndrome was highest and was observed in 14 (70.0%) patients. Nasal hemorrhage occurred in 12 (60.0%), gingival bleeding in 13 (65.0%), skin petechiae in 11 (55.0%), hemorrhoidal bleeding in 8 (40.0%), bleeding esophageal varices in 9 (45.0%), gastrointestinal bleedingin 7 (35.0%), and menorrhagia in 5 (25.0%) patients.

In group 3, symptoms of bleeding occurred in 16 (53.3%) patients. Nasal hemorrhage were observed in 16 (53.3%), gingival bleeding in 13 (43.3%), skin petechiae in 12 (40.0%), hemorrhoidal bleeding in 10 (33.3%), bleeding esophageal varices in 9 (30.0%), gastrointestinal bleeding in 7 (23.3%)and menorrhagia in 4 (13.3%) patients.

Group 4 consisted of patients with liver cirrhosis with negative results for markers of viral hepatitis. In this group, hemorrhagic syndrome was much less pronounced

than that with liver cirrhosis of viral cause. A detailed examination of patients' complaints and medical history followed by physical examination has showed that of hemorrhagic symptomsoccurred in 5 (25.0%) patients. Epistaxis occurred in 5 (25.0%), gingival bleeding in 5 (25.0%), skin petechiae in 4 (20.0%), hemorrhoidal bleeding in 3 (15.0%), bleeding esophageal varices in 3 (15.0%), menorrhagia in 4 (20.0%), and gastrointestinal bleeding in 3 (15.0%) patients.

The list of the main complaints of bleeding from patients, and their frequency in different clinical groups are shown in Table 1.

Table 1: Structure of hemorrhagic syndrome in patients with liver cirrhosis and chronic viral hepatitis

Hemorrhagic syndrome	Patient groups					
	Group 1 n=30	Group 2 n=20	Group 3 n=30	Group 4 n=20	Group 5 n=32	Group 6 n=30
Nasal hemorrhage	17 (56,7%)	12 (60,0%)	16 (53,3%)	5 (25,0%)	2 (6,3%)	2 (6,7%)
Gingival bleeding	17(56,7%)	13 (65,0%)	13 (43,3%)	5 (25,0%)	1 (3,1%)	1 (3,3%)
Skin petechiae	13 (43,3%)	11 (55,0%)	12 (40,0%)	4 (20,0%)	2 (6,3%)	1 (3,3%)
Hemorrhoidal bleeding	12 (40,0%)	8 (40,0%)	10 (33,3%)	3 (15,0%)	0	0
Bleeding esophageal varices	12 (40,0%)	9 (45,0%)	9 (30,0%)	3 (15,0%)	0	0
Gastrointestinal bleeding	10 (33,3%)	7 (35,0%)	7 (23,3%)	3 (15,0%)	0	0
Menorrhagias	8 (26,7%)	5 (25,0%)	4 (13,3%)	4 (20,0%)	0	0

Group 5 and 6 consisted of patients with chronic viral hepatitis B and C of moderate activity with no hemorrhagic syndrome. In group 5 of patients with chronic viral hepatitis B, hemorrhagic syndrome occurred in 5 (15.6%) cases: nasal hemorrhage occurred in 2 (12.5%), skin petechiae in 2 (12.5%), gingival bleeding in 1 (3.1%) patients. In group 6 of patients with chronic viral hepatitis C, hemorrhagic syndrome occurred in 4 (13.3%), with nasal hemorrhage in 2 (6.7%), gingival and skin bleeding in 1 (3.3%) patients.

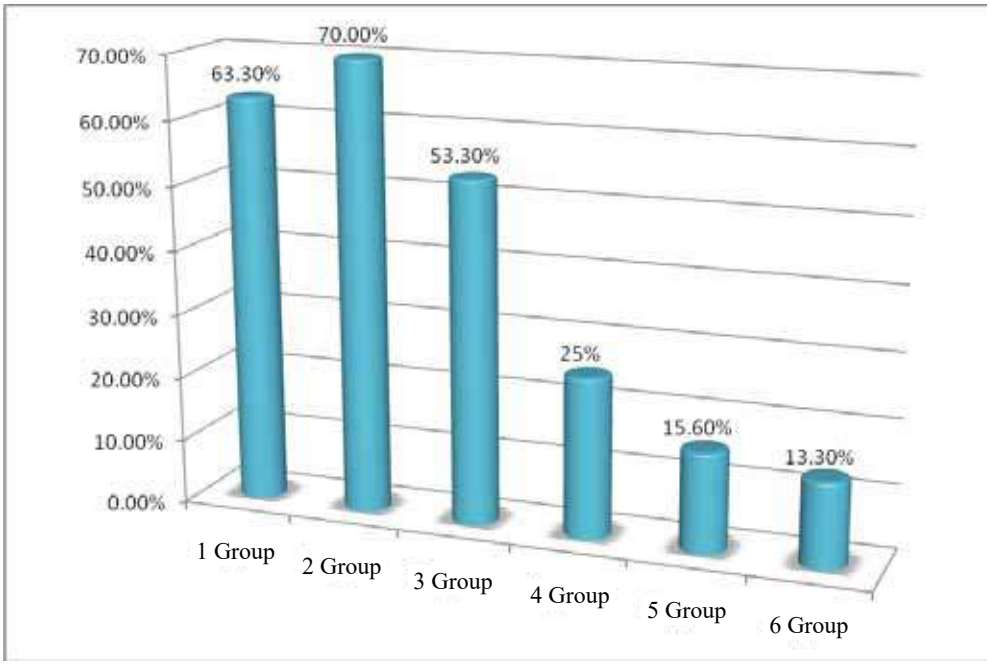

Fig. 2. Degree of incidence of hemorrhagic syndrome in patients with liver cirrhosis and chronic viral hepatitis.

As the above data shows, hemorrhagic syndrome was pronounced in the group of patients with HBV and HBV+HDV liver cirrhosis, in 63.3% and 70.0%, respectively. In the group of patients with HCV liver cirrhosis, bleeding symptoms occurred in 53.3% cases, and in the group with liver cirrhosis of non-viral cause, it was found twice less – in 25% of cases. For example, in chronic viral hepatitis B and C of moderate activity, hemorrhagic syndrome occurred in 15.6% and 13.3% cases, respectively (Fig. 2).

The study of the hemostatic system in the examined patients allowed us to determine the following structure of the incidence of hemorrhagic diathesis in patients with chronic hepatitis and liver cirrhosis of viral cause (Table 2).

Table 2: Nosological structure of acquired hemorrhagic diathesis in patients with chronic diffuse liver diseases

Groups	Acquired coagulopathies		Acquired thrombocytopenias		Acquired thrombocytopathies	
	abs.	%	abs.	%	abs.	%
Group 1 (n=30)	19	63.3	11	36.7	26	86.7
Group 2 (n=20)	13	65.0	9	45.0	16	80.0
Group 3 (n=30)	15	50.0	16	53.3	21	70.0
Group 4 (n=20)	6	30.0	5	25.0	10	50.0
Group 5 (n=32)	2	6.3	1	3.1	15	46.9
Group 6 (n=30)	1	3.3	2	6.7	13	43.3
Total (n=162)	**56**	**36.3**	**44**	**28.3**	**101**	**62.9**

As the Table shows, a study of the vascular-platelet and coagulation hemostasis links demonstrated that the majority of hemorrhagic diathesis in all groups is represented by acquired thrombocyopathies, while thrombocytopenias and coagulopathiesare much less common. Of 30 patients with HBV liver cirrhosis, 26 (86.7%) were diagnosed with acquired thrombocytopathy, while thrombocytopenia in this group was diagnosed in only 11 (36.7%) patients, and acquired coagulopathy - in 19 (63.3%). The same trend was also observed in patients with HBV+HDV and HCVliver cirrhosis. In the group 5 of patients with liver cirrhosis with negative results for markers of viral hepatitis, the incidence of hemostatic pathology was almost 2 times less than that in patients with liver cirrhosis of viral cause. For example, acquired thrombocytopathy occurred in 10 (50%), acquired thrombocytopenia - in 6 (30%), and acquired coagulopathy - in 5 (25%) patients.

Acquired thrombocytopathy was diagnosed in patients with chronic viral hepatitis B in 15 (46.9%), acquired coagulopathy - in 1 (3.1%) and thrombocytopenia and 2 (6.3%) patients. In patients with chronic viral hepatitis C, acquired thrombocytopathy was diagnosed in 13 (43.3%), acquired coagulopathy - in 1 (3.3%) and thrombocytopenia - in 2 (6.7%) patients.

Conclusions

1. The main hemorrhagic symptoms in patients with chronic hepatitis and liver cirrhosis of viral causehave been divided as follows: nasal hemorrhage in 59 (34.3%) cases, gingival bleeding in 52 (30.2%), skin petechiae in 46 (26.7%), hemorrhoidal bleeding in 36 (20.9%), bleeding esophageal varices in 35 (20.4%), gastrointestinal bleeding in 29 (16.9%) and menorrhagia in 20 (11, 6%).
2. Hemorrhagic syndrome has been found in a group of patients with liver cirrhosis of viral cause: with HBV liver cirrhosis – in 63.3%, with HBV+HDV liver cirrhosis – in 70.0%, with HCV liver cirrhosis - in 53.3% cases. In patients with liver cirrhosis of non-viral cause (group 4), hemorrhagic syndrome has been found more than 2 times less often – in 25% of cases.
3. In chronic viral hepatitis B and C, hemorrhagic syndrome was much less common –in 15.6% and

13.3% cases, respectively. This indicated a lesser violation of the hemostatic system than with liver cirrhosis of viral cause.

4. Since theliver cirrhosis of viral cause is followed by pronounced hemorrhagic syndrome, a detailed study of coagulation and vascular-platelet hemostasis is required for the prevention and treatment of bleeding.

The Possibilities of Ultrasound in the Diagnosis of Congenital Dysplasia of the Hip Joint

Nozima Salieva[1], Umida Rustamova[2], Sarvinoz Rakhmanova[3]

[1]MD, PhD, Department of Radiology, Traumatology and Orthopedics Scientific-research Centre, Tashkent, Uzbekistan, [2]MD, PhD, Scientific Secretariat, Traumatology and Orthopedics Scientific-research Centre, Tashkent, Uzbekistan, [3]Undergraduate Student (5th Year), Scientific Researcher, GP Faculty, Tashkent Medical Academy, Tashkent, Uzbekistan

Abstract

Hip dysplasia is still the most common pathology in the structure of orthopedic pathology in children, and its diagnosis is difficult, and even with timely diagnosis, treatment does not always bring success, we were faced with the task of optimizing radiation diagnosis of this pathology based on assumptions about the multiple etiological nature of dysplasia.

To solve this problem, we selected 75 children from our ultrasound clinic. There were 52 girls and 23 boys with an average age of 14 weeks.. Based on the ultrasound study, a technique has been developed to assess the degree of maturity of the skeleton. Ultrasonic standards for the structure of the hip joints for children living in the iodine-deficient region have been developed. Ultrasound signs of somatic, orthopedic and neurogenic forms of hip dysplasia were revealed.

Keywords: *Young children, multiple etiological dysplasia, hip joints.*

Introduction

Congenital hip dislocation remains a topical issue in pediatric orthopedics. Hip joint dysplasia and congenital dislocation of the hip are the most common pathology among all the malformations of the musculoskeletal system that are expected and ranges from 5 to 16 cases per 1000 newborns[1]. The frequency of this pathology according to various authors varies from 3 to 20% (in endemic areas) [2]. In ecologically unfavorable areas, there is an increase in the frequency of this disease compared with the average European level [2].

The late diagnosis of dysplasia and dislocation is associated with poverty and nonspecific clinical symptoms in newborns and children of the first months of life, and untimely treatment, in turn, leads to a significant number of unsatisfactory results [3]. The traditional diagnostic method remains X-ray, recording changes only in bone structures, the number of which in children in the first months of life is relatively small[4]. According to various domestic and foreign authors, an X-ray examination of the hip joints becomes informative at the age of no earlier than 3-5 months of life[5].

Among the many alleged causes of dysplasia are the elderly parents, orthopedic diseases, heredity, bacterial, protozoal and viral diseases of the mother during pregnancy, endocrinopathy, toxicosis of pregnant women, vitamin D deficiency, hormonal changes in the mother, and pelvic delivery of the fetus and some others[6]. In addition, there are few reports in the literature about the effect of perinatal damage to the central nervous system on the formation of the pathology of the hip joint. Neurogenic dysplasia obtained in the experiments of Ratner AY et al. [7] and his staff described, however, the study of radiation signs of neurogenic dysplasia of the hip joint in children was not conducted.

For a long time, the diagnosis of dysplasia and

Associate Professor, Traumatology and Orthopedics Scientific-research Centre, Tashkent, Uzbekistan
e-mail: srahmanova014@gmail.com

dislocation of the hip joints was made on the basis of an examination by an orthopedist and the results of an X-ray examination[8]. However, the use of radiography up to 3 months of age is associated with an unjustified risk of exposure to the child, and the interpretation of radiographs is difficult due to the predominance of cartilage in the elements of the child's hip joint[9]. Therefore, indications for x-ray examination are limited. In recent years, due to the widespread introduction of ultrasound in pediatrics, the situation has changed. This method allows you to visualize soft tissue and cartilage components, there is no radiation exposure and the need for special preparation of the patient. The possibility of using the method as a screening and for dynamic control during therapy is also important[10].

The fundamental work of R. Graf in 1978, which served as the basis for the development of orthopedic ultrasound diagnostics in pediatrics, contains a number of diagnostic method and schemes that can reliably diagnose various degrees of dysplasia and dislocation[11]. However, this work and research by a number of late authors are devoted exclusively to the orthopedic problem and do not contain data on the possibility of a multi-etiological lesion of the joint and their radiation diagnosis[12].

The above arguments determined the purpose of our study, which was to develop ultrasound criteria for diagnosing the results of etiology-related disorders in the formation of hip joints - dysplasia - in children of the first year of life[13].

The aim of the study was to determine the significance of early ultrasonographic diagnosis of congenital hip dysplasia in children.

Materials and Method

We selected 75 children from our ultrasound clinic. There were 52 girls and 23 boys with an average age of 14 weeks (2 to 40). Everyone had a standard assessment with a history and physical examination. Ultrasonography of both hips using a 5 MHz linear sensor of the Siemens Sonoline 1 apparatus (Siemens, Erlangen, Germany) was performed by a pediatric orthopedic surgeon, who then classified the hips according to the Graf method and made recommendations for treatment. After obtaining parental consent, the babies then underwent a second ultrasound from another examiner who did not have a history and physical examination and did not see the first record. Thus, a total of 150 hips were examined, each of which had two ultrasound scans (300 strips in hard copy).

For ultrasound examination of the hip and hip joints, we used the method of R. Graf. In total, including control, 1640 ultrasound examinations were performed. The child was laid on its side, the leg was bent at an angle of 20-30° in the hip joint, which made it possible to obtain a better oblique section.

Since there is no lumbar lordosis in newborns, the optimal scan was when the scan plane (linear sensor) was parallel to the lumbar spine in the projection of the greater trochanter of the femur. Moving the sensor posteriorly allowed us to obtain an image of a mid-section of the femoral head, which has the form of a spherical formation of reduced echogenicity and fine-grained texture.

Normally, the femoral head was centered on a Y-shaped cartilage. The bony part of the roof was visualized at a slight angle to the horizontal line, the cartilaginous part (limbus) was determined as a hyperechoic strip covering the femoral head. The main center line was drawn along the horizontally located edge of the ilium, parallel to it, which corresponded to the center of the acetabulum. The bone bottom line was drawn through the bone protrusion and the Y-shaped cartilage, thus obtaining the angle alpha - the angle of inclination of the bone roof of the acetabulum. The cartilaginous roof line was drawn through the bony protrusion along the base of the limbus and received a beta angle - the angle of inclination of the cartilaginous roof of the acetabulum. The magnitude of these angles and the degree of ossification of the femoral head judged the maturity and anatomical usefulness of the joint.

Results

Indications for ultrasound examination are: symptoms of "click" and "slip" in the first week of life; hip abduction restriction; asymmetry of the gluteal folds; shortening of the leg; violation of hip rotation; birth in the buttock; increased muscle tone in the lower extremities; the presence of pathology of the hip joints in close relatives.

Normally, the joint head is centered in the acetabular cavity. The bony part of the roof is visualized almost horizontally, the cartilaginous part (limbus) is defined as a hyperechoic strip covering the head of the joint. The main line is drawn along the edge of the ilium, parallel to

it, through the center of the acetabulum. The bony roof line runs through the bony protrusion and the U-shaped cartilage and forms an angle alpha. The cartilaginous roof line is drawn through the bony protrusion at the base of the limbus and forms the angle of the betta.

Discussions

According to the results of ultrasound, 72.41% of children were diagnosed with types 1a and 1b of the hip joints (according to G. Reingard). Clinically and sonographically, types 1a and 1b correspond to the age of the child - these are healthy joints. The bony part of the acetabulum is well defined, the bone bay window is slightly flattened or rectangular, the cartilaginous part of the roof covers the head of the femur, the bone-cartilage ratio is greater than or equal to 2/3. The angle α is greater than or equal to 60°. Angle β less than 55° - type 1a; angle β is greater than 55° - type 1b.

Type 2a of the hip joints was diagnosed in 11.6% of children. This is a variant of the physiological delay in the development of hip joints in children under 12 weeks of age, at which the angle α is less than 59°, but more than 50°, respectively, the angle β is more than 60°.

Type 2b of hip joints was detected in 6.33% of children - hip dysplasia in children older than 3 months. The bone acetabulum is underdeveloped, the bone bay window is rounded, the bone-cartilage ratio is less than 2/3, the cartilaginous part of the roof covers the head of the femur. Angle α is less than 59°, but greater than 50°, angle β is greater than 60°.

Type 2c of the hip joints was found in 0.51% of children. This is a variant of severe dysplasia at any age. All components of the joint are underdeveloped. The bony part of the acetabulum is flattened, the bone bay window is rounded or flat, the cartilaginous part of the acetabulum is expanded, but still covers the femoral head. Angle α is less than 49°, but greater than 43°, angle β is greater than 65°, but less than 72°. This type of joint, without appropriate treatment, entails a progressive decentration of the femoral head.

In 0.25% of the child, type 3a of the hip joint was revealed - congenital dislocation of the hip. The bony part of the acetabulum and the bay window are flat, the cartilaginous part of the acetabulum is displaced cranially, since the femoral head cannot be fixed in the acetabulum, its decentration occurs. The structure of the cartilaginous part of the roof is not changed. The angle α is less than 43°.

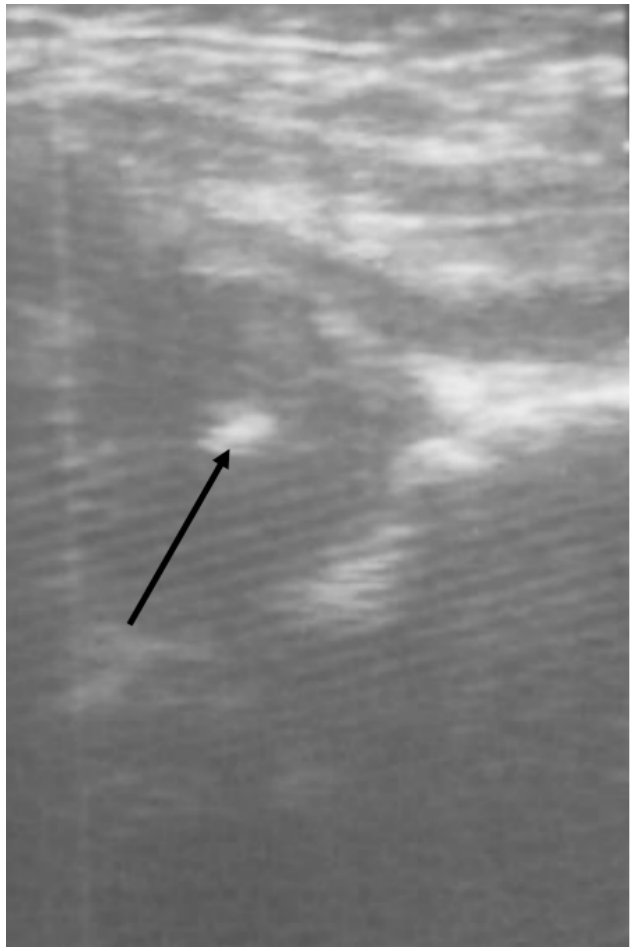

Fig. 1. Ultrasound image of the unchanged hip joint of a child of three months of life.

Note: The angle of inclination of the bone roof of the acetabulum α=68°; the angle of inclination of the cartilaginous roof to the trochanter of the female cavity is β=54°. The arrow shows the core of the ossification of the femoral head.

All children with identified pathology were referred for consultation with an orthopedic surgeon.

As a result, 70% of children with timely diagnosed pathology after the treatment have healthy joints of the first type, 30% of children with preserved pathology were sent for a second course of therapy.

Clinical screening for congenital hip dysplasia during the first year of life is considered a reliable strategy for reducing the incidence of dysplasia with a late diagnosis or hip dislocation, but only clinical screening sometimes leads to late diagnosis. Thus, ultrasound screening was used to further reduce the frequency of late diagnosis. Most ultrasound screening method for congenital hip dysplasia are based on a combination of static morphological assessment and dynamic stability assessment. The combination of universal clinical

screening and selective ultrasound screening is widely used throughout the world. Although it is logical to assume that selective ultrasound screening of high-risk patients should reduce the late diagnosis of congenital hip dysplasia, available studies have not confirmed this assumption. Further studies are needed to elucidate the role of ultrasound in screening for congenital dysplasia of the hip joint.

We have developed and patented an ultrasonic technique for determining the degree of maturity of the bone skeleton by means of the ossification of nuclei of ossification of the capitate and hooked bones of the wrist, which should be visible in a child aged 2 months. If a child over two months of age displays the indicated ossification nuclei and nuclei of the femoral heads, then this condition, with all other normal parameters, is estimated as the age norm (Fig. 1)

If the nuclei of ossification of the bones of the wrists were visualized, and the nuclei of the heads of the femurs were not detected, this condition was defined as a local violation of ossification in the area of the hip joints and a sign of somatic dysplasia of the hip-joint. If the nuclei of ossification were absent either in the carpal bones or in the heads of the femur, then a conclusion was drawn about a systemic slowdown in the ossification of the skeleton. It is these children, that is, those who suffered from local and systemic disorders of ossification and who had clinical signs of hip joint pathology, made up the II (1) group with somatic dysplasia.

Children suffering from somatic dysplasia of the hip joints, in 80.88% of cases had minor changes in the angles α and β, but without going into a state of subluxation and dislocation. This, in our opinion, is of great importance for the following treatment, since in such children, vitamin-D prophylaxis and treatment of rickets or rickets-like disease are primarily needed. The close attention of the pediatrician and the correction of somatic pathology leads to a complete restoration of the joint structure within 2 months after the start of treatment. Subsequently, during follow-up observation, these children were assigned to a group that did not have an uropathic pathology. Consequently, infants suffering from somatic dysplasia do not need to use fixing orthopedic devices, which in this case bring unconditional harm!

Conclusions

The study confirms the need for ultrasound of the hip joints for children under 6 months of age on an outpatient basis, avoiding unjustified radiation exposure. Using the information obtained makes it possible to conduct corrective therapy in a timely manner for all types of hip joints in the early period, followed by their correct formation.

Abstract

The problem of clinical and instrumental evaluation of the surgical treatment effectiveness of chronic generalized periodontitis using RANK-RANKL-OPG biomarkers is discussed in the article. Currently, the important role of Pro - and anti-inflammatory cytokines in the regulation of the immune-inflammatory response has been established [2]. Progressive destruction of bone tissue in patients with periodontal diseases is associated with a combination of cytokines IL-1β, IL-6, TNF and prostaglandins E2. The use of Alhadaya in complex therapy with surgical treatment will allow to control the level of biomarkers of bone inflammation, which will allow to use this method for the diagnosis of periodontal diseases and as the outcome of treatment, in addition to traditional research method (clinical, functional, x-ray, densitometric).

Keywords: *Dentistry, periodontitis, biomarker, RANK-RANKL-OPG.*

Introduction

According to WHO (World Health Organization), periodontal tissue pathology ranks 2nd in the structure of dental morbidity and is the main cause of premature tooth loss[1]. Chronic generalized periodontitis (CGP) develops under the influence of local and general factors, the leading of which is considered bacterial. The impact of periodontal pathogens on the tissues of the periodontal complex triggers a number of responses from the body, leading to the development of inflammation. Currently, the important role of Pro - and anti-inflammatory cytokines in the regulation of the immune-inflammatory response has been established[2]. Progressive destruction of bone tissue in patients with periodontal diseases is associated with a combination of cytokines IL-1β, IL-6, TNF and prostaglandins E2 [3]. These cytokines can activate osteoclastogenesis and bone resorption by osteoclasts. The increased migration of macrophages under the influence of cytokines and their constant presence in tissues exacerbates the destructive processes in the periodontium. It is known that there is a close relationship between the immune and bone systems. The study of the mechanisms of bone resorption associated with the development of periodontitis, Paget disease, osteoporosis, rheumatoid arthritis, multiple myeloma and metastatic bone tumors highlighted the importance of deeper research in the field of osteoimmunology [4].

A breakthrough in understanding the process of bone remodeling was the discovery of a signaling system consisting of the nuclear factor kß activator receptor (RANK), its ligand (RANKL), and osteoprotegerin (OPG) [5]. RANKL is a transmembrane protein – a representative of the family of tumor necrosis factors that plays a key role in osteoclastogenesis, differentiation, activation, and apoptosis of osteoclasts [6]. An important preparatory stage of osteoclast formation is the activation of RANKL, which occurs by binding to RANK located on osteoclast precursors. OPG, being a natural receptor trap for RANKL, competes with RANK for binding to

RANKL [7]. By blocking this process, OPG suppresses bone resorption, giving priority to bone formation. Disorders of the balance of the RANK/RANKL/OPG system were also detected in various osteopathies, as well as in periodontitis. A significant increase in the content of RANKL in the periodontal pocket fluid is registered in the early stages of the disease [8]. In moderate to severe chronic generalized periodontitis, mixed saliva contains a high content of specific markers of bone remodeling-osteoclast activating factor (RANKL) and osteoprotegerin (OPG), which are absent in saliva in healthy individuals[9]. However, until now there are no clear correlations between the success of surgical treatment and the presence or absence of biomarkers of RANK-RANKL-OPG inflammation, so it seems relevant to conduct such a study.

The aim of the study is to increase the effectiveness of surgical treatment of chronic generalized periodontitis according to the RANK-RANKL-OPG biomarkers.

Materials and Method

To achieve this goal, 65 patients with severe chronic generalized periodontitis have been examined. The average age of patients was 35.43±0.68 years. To determine the quality of treatment, biomarkers of inflammation such as RANK-RANKL-OPG have been used.

The state of bone metabolism has also been examineded by determining the content of local regulators in blood plasma - sRANKL, osteoprotegerin (OPG) and sclerostin by enzyme immunoassay, according to the attached instructions.

In the formation, differentiation and activity of osteoclasts, the main role is played by the cytokine system RANKL-RANK-OPG. RANKL is a ligand of the Kappa nuclear factor activator receptor (antigen 254, TNF-1L). RANKL is produced by osteoblastic cells and interacts with the Ranktransmembrane receptor of osteoclasts and their precursors. When RANKL interacts with RANK, the signal activates intracellular cascade mechanisms and affects the NF-kB-nuclear factor Kappa b, which, with the help of TRAF receptors, goes from the cytoplasm to the nucleus and increases the expression of the nfatc1 protein, which is a specific trigger that triggers the transcription of intracellular genes that form the processes of osteoclastogenesis. OPG (osteoprotegerin) is a soluble (false) receptor for RANKL, synthesized by vascular stroma and endothelial cells. OPG is a blocker of RANKL-RANK interaction and, as a result, inhibits osteoclast formation and bone resorption. Sclerostin is a regulator of the canonical Wnt/β-catein signaling pathway of osteoblastogenesis. It is produced by osteocytes and mineralized hypertrophied chondrocytes, binds to LPR-5 (lipoprotein receptor 5), which is a Wnt-coreceptor, which leads to the destruction of the ubiquitin-proteosomal mechanism of β-catenan in the cytoplasm and a decrease in Wnt signaling with a decrease in osteogenesis.

The soluble receptor-activator of factor b was determined by a set of reagents "sRANKL" of Biomedica Medizinprodukte Gmb H and Co K G "(Germany), the osteoclast inhibitor factor – osteoprotegerin (OPG) by a set of reagents" Osteoprotegerin", sclerostin – " Sclerostin "of The same company on a semi-automatic analyzer"Uniplan". All patients gave their voluntary written consent to participate in the experiment. Statistical data processing has been performed using the program STATISTICA 6.0.

Results

Before the surgical treatment of chronic generalized periodontitis, all the patients underwent a study of biomarkers in the blood (the RANK-RANKL-OPG system). So, as an inhibitor of RANKL, we recommend the drug Alhada (black cumin oil). Alhada was appointed on 1 capsule 2 times a day for 6 months. No serious side effects found during patient follow-up. Thus, during the collection of anamnesis and catamnesis of patients, it was found that in 2 patients during the collection of apampesis vitae, chronic kidney disease of stage 2 was detected. Since patients with reduced renal function are particularly susceptible to hypocalcemia, which is accompanied by an increase in the level of parathyroid hormone, such patients were prescribed in addition to Alhadaya and vitamins of group D (calcium D3 nicomed) 1 tablet 3 times a day.

Discussion

Immediately after the use of Alhadaya and surgical treatment of chronic generalized periodontitis, the gums are pale pink, moderately moistened. The depth of the gingival furrow is 0.28±0.003 mm after treatment, there is no mobility of the teeth. The CPR index before treatment was 24.1±1.41, while after surgical treatment and the influence of Alkhaday it was 11.3±0.56 ($p \leq 0.05$). The hygiene index (HI) before treatment was 73.2±2.08, while after complex surgical treatment with Alhadaya

was 45.1±2.12 (p≤0.05). The bleeding index (PBI) before treatment was 2.1±0.05, while after treatment it was 0.8±0.33 (p≤0.01). The gingival index (GI) is 1.9±0.06 before treatment and 0.7±0.15 (p≤0.01) (after complex application of Alhadaya and hirrugic treatment).

After a General analysis of blood mineral metabolism, the total calcium level before treatment was 2.31±0.01 mmol/l, while after treatment it was 2.12±0.01 mmol/l (p≤0.05). Ionized calcium was 1.24±0.041 mmol/l before treatment, and after 1.12±0.007 mmol/l (p≤0.05). Parathyroid hormone before treatment was 56.7±2.14 PG/l, and after treatment 41.5±1.26 PG/l (p≤0.01). Calcitonin before treatment was 2.7±0.24 ng/l, and after treatment-4.3±0.23 ng/l (p≤0.001). Osteocalcin 5.5±0.57 ng/l before treatment, and after treatment 12.5±0.39 ng/l (p≤0.001).

The RANKL content before treatment was 0.23±0.005 pmol/l (p≤0.001) after treatment, the RANKL content was 0.14±0.003 pmol/l (p≤0.001). OPG before treatment was 4.35±0.004 pmol/l (p≤0.001), after treatment was 3.51±0.003 pmol/l (p≤0.001). Sclerostin before treatment was 297±0.4 pmol/l, after treatment was 210±1.2 (p≤0.05).

Osteoprotegerin (OPG) is a soluble receptor for RANKL. It is synthesized by osteoblastic type cells, as well as β-lymphocytes, vascular stroma and endothelial cells. OPG is a competitor to the interaction of RANKL with RANK and therefore, as a consequence, inhibits the formation of osteoclasts and bone resorption.

Sclerostin is produced by osteocytes and mineralized hypertrophic chondrocytes. It binds to the LRP-5/6 receptor, which is a coreceptor of the Wnt/β-catenin signaling system necessary for the stimulation of osteoblastogenesis and osteoblast functions, and has an inhibitory effect

Conclusions

Thus, osteoblasts express a high level of the nuclear factor activator receptor ligand Kappa beta and osteoprotegerin in the patients with chronic generalized periodontitis with reduced bone mineral density . The use of Alhadaya in complex therapy with surgical treatment will allow controlling the level of biomarkers of bone inflammation, which will allow to use this method for the diagnosis of periodontal diseases and as the outcome of treatment, in addition to traditional research method (clinical, functional, x-ray, densitometric).

Comparative Analysis of Clinical and Laboratory Parameters and Assessment of Antiretroviral Therapy Effectiveness in HIV-Associated Cryptococcal Meningoencephalitis in the Case of Immune Inflammation Syndrome

D.A. Mustafaeva[1], L.N. Tuychiev[2], E.I. Musabaev[3], T.S. Zaytseva[1], K.S. Mukhamedov[4]

Abstract

Cryptococcal meningoencephalitis is an opportunistic mycosis. Earlier in medical practice single cases of the disease were encountered, now the problem becomes more and more urgent due to the increase in the HIV infection spread, as persons with impaired immune systems are affected. In most cases, cryptococcosis refers to HIV-associated diseases. However, today there are unexplored clinical, virologic immunological aspects of HIV-associated cryptococcosis. The comparative rarity of the multi-organ nature of the lesion, the lack of objective clinical and laboratory data that allow to timely suspect and confirm a cryptococcal infection, lead to errors in the diagnosis and treatment of this pathology. The main goal of our work is to study the prevalence of HIV-associated cryptococcosis, the clinical and laboratory features of HIV-associated cryptococcosis in patients associated with inflammatory immune restoration syndrome to increase the diagnosis and treatment efficiency in Uzbekistan.

Keywords: *HIV infection, cryptococcal meningoencephalitis, immune inflammation syndrome, antiretroviral therapy.*

Introduction

The development of deep mycoses in HIV-infected people is one of the most pending problems of the last decade. The combination of these two infections has increased over the past 10-12 years, which is associated with both an increase in the incidence of HIV infection and an increase in recorded cases. One of the most important risk factors for the occurrence of HIV-associated deep mycoses is the immunodeficiency state and the likelihood of developing severe clinical forms of the disease is determined by the severity of immunodeficiency. Among HIV-associated deep mycoses in patients with deep immunodeficiency, the infection caused by Cryptococcus neoformans often began to be recorded [1]. Cryptococcosis is recognized as the second most important mycotic infection. HIV-associated cryptococcal infection is detected with unequal frequency in different regions of the world: in Europe - 2-4%, in America - 30%. According to F. Odds (2009), in the world they annually sick from 700 thousand to 1 million people. And according to the Center for Disease Control (CDC, USA), about 1 million cases of cryptococcosis in HIV-infected patients are registered annually in the world [1]. According to large retrospective studies of HIV-infected patients, cryptococcosis occurs from 1.85% in Russia to 9.1% in the United States[8]. In economically developed countries, the cryptococcosis incidence is 30–66 cases per 1 million people per year [2]. Cryptococcal infection occurs mainly in patients with T-cell immunodeficiency and is characterized by frequent damage to the central nervous system. Quite often, cryptococcosis is the first AIDS stage manifestation. This figure varies from 39% in the United States (1992-2000) and 41.7% in Tunisia (1991-2000) to 58.8% in France (after the mid-90s) and 67.2% in Italy (1985-1999).

One of the most common forms is a cryptococcal infection caused by Cryptococcus neoformans (Sanfelice) Vuillemin (1901), especially C. neoformans var. neoformans, less commonly C. neoformans var. Gatii. [3]. The main causative agent of cryptococcosis is Cryptococcus neoformans, less commonly the disease is caused by C. Laurentii and C. Albidus. Pathogenic C. neoformans strains have a pronounced neurotropism, so the clinical cryptococcosis forms in most cases end in damage to the brain and its membranes [9]. A disease feature is the clinical manifestations severity and a very high mortality rate. During the initial therapy period, 10–25% of patients die, another 30–60% die within the next 12 months [6]. Mortality from cryptococcosis in the United States is 12%, and in Africa - 75–90%. The highest frequency of deaths from cryptococcal infection in HIV-infected patients was observed before the introduction of highly active antiretroviral therapy. With cryptococcal meningoencephalitis in HIV-infected untreated patients, it reaches 100%. Without HIV infection specific treatment, with a decrease in CD-4 lymphocytes of less than 100 cells/mm^3, the cryptococcosis incidence is from 4 to 30% and significantly decreases with the early ART prescription [2]. The main diagnostic method for cryptococcal infection is the cryptococci detection with microscopy and/or culture in the study of CSF, blood, and other substrates. Cultural diagnosis is considered the "gold standard" in diagnosis. In this case, the growth of colonies appears on the 3rd - 15th day, and it is difficult to isolate a pure culture of C. neoformans: it is known that pathogens of fungal infections are present in various mycoassociations in samples of clinical material, especially in HIV-infected patients. However, in terms of growth quality, yeast-like fungi are often ahead of mold fungi and it is much more difficult to isolate micromycetes of the genus Cryptococcus in culture compared to Candida sp. Determination of Cryptococcus neoformans antigen in cerebrospinal fluid, blood by latex agglutination test, which according to published data is found in 90% of patients, is still problematic due to the lack of available test systems[3]. Antibodies to the pathogen in blood serum are detected only in one third of patients with cryptococcal meningitis and are sometimes present in the serum of healthy people. Therefore, at present, the microscopic examination of cerebrospinal fluid remains the simplest and most informative laboratory method in the diagnosis of cryptococcosis [4]. According to the literature, the most severe course of disease generalized cryptococcosis forms have[13]. During the initial period of therapy, 10–25% of patients die, another 30–60% over the next 12 months. [14]. In this regard, there is an urgent need for early diagnosis and intensive care of cryptococcosis. The clinical manifestations of cryptococcosis are nonspecific and depend on the localization of the process. The most common clinical signs are febrile body temperature, persistent headache, dizziness, impaired consciousness, less commonly coughing, shortness of breath, rashes on the skin. In many clinical trials with cryptococcal meningitis or meningoencephalitis, about 75% of researchers have noted cases of high intracranial pressure caused by a rapid increase in cerebrospinal fluid [14]. The most characteristic development of subacute meningitis. In some patients, the disease is asymptomatic. Often with a cryptococcal lesion, a disorder of consciousness develops, visual acuity decreases, focal symptoms appear in the form of hemiparesis, ataxia, damage to the cranial nerves. The main feature of the cryptococcal meningitis clinical manifestations, according to a literature review, is negative meningeal symptoms, it is extremely rare for a patient to be clearly positive[11]. Mental disorders were noted in the form of decreased memory, uncriticality, euphoria, depression, changes in personality characteristics and even signs of deep encephalopathy[4]. The disseminated clinical forms of cryptococcal mycosis in HIV-infected people include damage to many organs and systems, especially the membranes of the brain (cryptococcal meningoencephalitis occurs in 80% of cases), as well as the heart, bones, kidneys and adrenal glands, eyes, prostate gland and lymph nodes[3]. Of particular scientific and practical interest are cases of generalized cryptococcosis forms with disseminated damage to almost all organs and tissues. In these situations, deep multiple organ dysfunction often leads to death until the moment when the attending physician can identify unfavorable background mycosis conditions in the form of various variants of immunological insufficiency [1].

Rare non-meningeal forms of infection include damage to the lungs, skin, joints, eyes, adrenal glands, gastrointestinal tract, liver, pancreas, prostate and urinary tract. Skin lesions with disseminated infection are found in 10-15% of HIV-infected patients with cryptococcosis [7].

Clinical guidelines for the treatment of cryptococcal meningitis currently need to be reviewed. The standard of combination of amphotericin B deoxycholate (amphotericin B deoxycholate, amphoto-B) and flucytosine (flucytosine) adopted in developed countries

is not acceptable in low- and middle-income countries, due to the high cost of flucytosine. For this reason, the combination of amphotericin-B and fluconazole (fluconazole) is of interest. According to the literature, antagonism is possible theoretically and in vitro between these antifungal drugs [10]. Such a combination was used for the early treatment of cryptococcal meningitis by an international team of scientists led by Dr. Peter G. Pappas from the University of Alabama, USA. The authors convincingly showed that the early combination treatment of cryptococcal meningitis with amphotericin B and fluconazole is well tolerated, and when using high-dose (800 mg per day) fluconazole also improves the results. In an accompanying editorial, Dr. Harrison T.S. from St.George University in London notes that the worst results in the low-dose fluconazole group could be due to the antagonism between amphotericin B and fluconazole [10]. Using the currently recommended treatment method based on Amphotericin[15], the clinical course of the disease in those who survive is often complicated by a prolonged or recurrent disease. There are unexplored clinical, virologic, immunological aspects of HIV-associated cryptococcosis[4]. The comparative rarity of the lesion multiple nature, the lack of objective clinical and laboratory data allowing to suspect and confirm cryptococcal infection with HIV in a timely manner, lead to errors in making a timely diagnosis, which entails errors in the initial pathogenetic treatment[6].

The question remains open whether prescribing antiretroviral therapy (ART) is possible and necessary shortly after diagnosis of cryptococcal etiology. In the literature, there is only evidence that an antiretroviral drug from the group of protease inhibitors indinavir restrains capsule formation in vitro[14]. The higher thickness of the capsule in patients receiving ART than in patients who have not received therapy or received only antimycotics, is probably associated either with the therapy ineffectiveness or with the fact that the capsule is not only a virulence factor but also protects cryptococcus from the macroorganism[16]. Another major concern for doctors is the of Immune Reconstitution Syndrome (IRIS) development. Quite often, cryptococcosis develops as a primary opportunistic infection against the background of an inflammatory immune system restoration syndrome. IRIS occurs in 15–20% of individuals who develop cryptococcosis initially and only then start ART, which leads to relapse and a more severe clinical course of the disease[15]. The development of more effective prevention/treatment method, as well as ensuring a safe and quick ART start, and its effectiveness in the treatment of antimycotic drugs, is important and is one of the main components of improving the HIV-associated cryptococcosis outcomes in patients. By the present date, the timing of antiretroviral therapy start remains uncertain[17].

Aim of Research: The main objective of this research is to study the prevalence of HIV-associated, identifying the clinical and laboratory cryptococcosis manifestations associated with inflammatory immune restoration syndrome in Uzbekistan.

Materials and Method

To achieve the aim and solve the tasks in the work, a general scientific methodology was used, based on an integrated systematic approach using epidemiological, clinical, microbiological, molecular genetic and statistical method. The prevalence of cryptococcosis in HIV-infected people in Uzbekistan was studied based on statistics from the Republican AIDS Center from 2012 to 2018. A screening method was performed by rapid tests for the presence of C. neoformans antigen in 347 naive adults living with HIV with a CD4 level of ≤100 lymphocytes in quick tests. The immune system state was studied by the total number of T-lymphocytes and their subpopulations in accordance with the differentiation clusters CD3 +, CD4 + and CD8 + lymphocytes using a Partec Cy FLOW Counter cytofluorimeter. HIV virus nucleic acids were detected by the Polymerase Chain Reaction method on a Rotor Gene 6000 TM. The diagnosis was made according to the EORTC/MSG (Europen Organization for Research and Treatment of Cancer/Mucoses Stady Group) criteria based on positive results by the rapid testing method for the presence of CrAg, as well as the determination of the pathogen C. neoformans in a microspy smear stained with Indian ink and culture growth on the Saburo environment. From instrumental research method, a computer tomogram of the brain, lungs, and X-ray examination of the upper and lower respiratory tract were also performed. A retrospective and prospective analysis of the clinical manifestations of 347 outpatient records and medical records was performed. The results of antifungal and antiretroviral therapy were evaluated in 37 patients with HIV-associated cryptococcal meningitis and meningoencephalitis who were hospitalized at the clinic of the Research Institute of Virology and the Specialized Infectious Diseases Hospital and at the Ust'-Izhora

Clinic, St. Petersburg, Russian Federation; then they were observed on an outpatient basis in dispensary departments of the RC AIDS, 14 regional AIDS centers. The research period is from 2012 to 2018. The criteria for selecting patients for the 1st (main) group were: cryptococcal meningoencephalitis and meningitis; adherence to ART and its beginning (no more than 6 months); positive immunological and virologic response to ART with the development of a clinical worsening of the condition with meningeal symptoms. The control group included 17 patients with HIV-associated cryptococcal meningoencephalitis and 20 patients in the main group with HIV-associated cryptococcal meningoencephalitis and meningitis taking ART antiretroviral therapy for a period of 1 to 12 months. The age index of the 1st and 2nd study groups ranged from 19 to 53 years (average 26.3±2.3 years, 83% of men).

Results

According to the research results, the cryptococcosis frequency in HIV-infected patients according to the long-term statistics of the Republican AIDS Center (from 2012 to 2018) amounted to 3.9% of HIV-infected patients with opportunistic diseases. Potential factors for the cryptococcosis development have been studied. Conducted in the case-control study. As hypothetical risk factors for the development of cryptococcosis in HIV-infected people, we included medical factors (HIV infection and its duration, the presence of chronic diseases of the upper respiratory tract, chronic hepatitis C, tuberculosis, diabetes mellitus, frequent hospital treatment, severe immunodeficiency of the patient, the development and presence of the clinical stages of HIV infection), as well as "social and behavioral" (employment, living conditions, being in a penitentiary institution, dependence on psychoactive substances, as well as socio-demographic risk factors for the development of the disease. In the group "case" 37 patients were included with a confirmed cryptococcosis diagnosis and the control group consisted of 23 patients without cryptococcosis who were observed in the same AIDS center or clinic at the same time. The groups were comparable by sex, age, territory of residence, stage of HIV infection, the number of CD4 < 100 cells/μl of lymphocytes, absent or taking ART.

The study revealed that cryptococcosis is significantly more likely to occur in HIV-infected patients living in private uncomfortable homes, where access to clean drinking water was difficult and there was no sewage. A direct relationship was found between the cryptococcosis occurrence and the active use of narcotic substances. The likelihood of developing cryptococcosis was also determined by the severity of immunodeficiency. The duration of HIV infection, a low level of limocytes (CD4≤100), previous hospitalizations created favorable conditions and created a high level of cryptococcal infection risk. The results obtained showed a direct relationship between these signs and the likelihood of developing cryptococcosis (OS 2.659 and 3.711; CI = 1.335-9.517). When examining 347 HIV-infected patients, a low level of limocytes (CD4≤100), serum antigenemia was detected in 11.2%. In 4.3% of patients, high titers were determined (≥1: 1024). High titers of the pathogen subsequently were a marker of poor prognosis. The research determined the time from the onset of symptoms to diagnosis on average 24.5 days passed (from 14-80 days). Cryptococcosis is rarely the only opportunistic infection in HIV-infected patients. Often combined with candidiasis (68% and 59%), cytomegalovirus infection (1.7% and 1.2%), and tuberculosis (17.2% and 15.3%). Severe intoxication and cerebral symptoms in cryptococcal meningoencephalitis were noted in 63% of patients of the first and second groups. Tachycardia (heart rate 88-104 per minute), hypotension (from 100/60 to 80/50 mm Hg), dyspnea (BH 22-38 per minute) were recorded in 48% of the 1st group and 52% of cases in 2nd group of patients. In our study, only 3 patients of the 2nd group and one patient of the 1st group were diagnosed within the first 14-18 days from the start of the disease. Upon admission, all patients complained of severe headache in the frontal and temporal areas, the average duration of which was 14-16 days in both groups. Irritability, nausea, vomiting, dizziness, unstable gait were observed in 47% of patients of the 1st group and 54% of the 2nd group of patients. Visual impairment (double vision) was noted in 5.4% of patients of the 2nd group. In the 1st group of patients, body temperature rose to 38–40°C and remained with the wrong type of temperature curve (88.4±3.21 cases) from 18 to 32 days, weakness (84±3.83), persistent generalized lymphadenopathy (44±4.23), sleep disturbances (87.5±4.11). Arthralgia disturbed 19.7±4.32 patients. Respiratory tract lesions with oropharyngeal mycoses were predominant among group 1 patients, and showed a productive cough in 77.5±3.97 cases (versus 48±3.87 in group 2 patients) and shortness of breath in 67.5±3, 7 cases (versus 24.3±3.45 in patients of the 2nd group). 45% of patients of the 1st group and 27% of patients of the 2nd group showed meningeal symptoms. Focal

symptoms (hemiplegia, nystagmus, anisocoria) were observed in 12.5±3.1 patients of the 1st group and in 7.3±3.7 patients of the 2nd group. Patients were depleted, the skin was pale, marked peeling of the skin in both groups was noted. Peripheral lymph nodes are enlarged to 1 cm, dense, painless. Tachycardia (heart rate 88–104 per min), hypotension (from 90/60 to 80/50 mm Hg), shortness of breath (BH 22–38 per min) were noted. Hypochromic anemia with erythrocyte counts from 2.3 to 3.3×10/12/L, leukopenia from 1.5 to 3.9×10/9/L, shift of the formula to the left (relative neutrophilia), lymphopenia were found in the hemogram in patients with hypochromic anemia from 3 to 7% and high ESR (39–66 mm/h). The number of CD-4 lymphocytes in the blood ranged from 7 to 86 cells/μl. The viral load was 131,000–634,000 copies of HIV RNA in 1ml of blood in the 1st group and 723,000–1,232,000 copies of HIV RNA in 1ml of blood in the 2nd group. Magnetic resonance imaging (MRI) revealed hydrocephalus, arachnoid changes in the cerebrospinal fluid. In patients of the 1st group revealed multiple nodes in the parenchyma of the brain, meninges, basal ganglia and midbrain. In patients of the 1st and 2nd group, cortical atrophy was observed. With repeated MRI performed in 3 patients of the 2nd group after 9-14 days, structural disorders of the basal nuclei of the white matter of the cerebral hemispheres, signs of focal encephalitis appeared.

For diagnostic purposes, all patients underwent puncture of the cerebrospinal fluid (CSF). The results of CSF tests showed a sharp increase in cerebrospinal fluid pressure (190-450 mm water column). Liquor is transparent. Microscopically in the cerebrospinal fluid, mainly lymphocytic cytosis was observed (from 12 to 1824 cells/μl), the protein content was increased (450-1400 mg/l), and glucose was reduced (0.1-2.5 mmol/l). The number of leukocytes in the CSF in 4 patients of the 2nd group was normal. The causative agent was detected by CSF microscopy in 89.1% of patients in both groups. Repeated adequate correction of intracranial hypertension using spinal puncture was performed in 53% of cases of the 1st group and 33% of cases of the 2nd group. Considering that in 5 patients with a three-time study of CSF with a different time interval (from 1 to 3 months), the pathogen was determined, resistance studies were performed in connection with long-term fluconazole therapy. An analysis was made of the IRIS effect on the following factors development: quantitative characteristics of CSF culture, initial CD4 lymphocyte count and viral load before ART, pressure during spinal puncture, leukocytes levels, protein, glucose in CSF.

Cultural diagnosis was performed using standard Saburo medium. Colonies of Cryptococcus neoformans were usually seeded after 48–72 hours. At the same time, cryptococcus was determined microscopically in 70%, culture was isolated in 77%, which made it difficult to evaluate the antimycotic therapy effectiveness in 23% of patients. Obtaining a cryptococcus culture made it possible to determine the sensitivity of the isolated strain to antifungal drugs. The sensitivity of the pathogen during the initial CSF study was 93±3.9 in the 1st group, and 91.2±3.7 in the 2ndgroup to amphotericin B; 89±3.9 in the 1stgroup, and 73±3. 9 in the 2ndgroup to fluconazole. The combination of these drugs was used as an etiotropic treatment in accordance with international recommendations. We used doses of amphotericin B at 0.7–1 mg/kg/day and fluconazole at doses of 800 mg/day, as recommended in modern guidelines. Fluconazole inhibits the synthesis of ergosterol in fungi, has excellent absorption and penetration into the CSF, and is a less toxic drug compared to amphotericin B. This treatment regimen allowed us to more quickly get the initial antifungal effect and the possibility of avoiding the toxicity of amphotericin B considering the therapy duration. Headache disappearance by the 7th day of antifungal therapy was observed in 12% against 18% of the 1st and 2nd groups of patients, and by the 14th day in 69% and 48% of the 1st and 2nd groups of patients. Treatment was considered successful if cerebrospinal fluid cultures were negative after 2 and 10 weeks, or if positive disease dynamics were observed in patients after 2 weeks and no symptoms after 10 weeks. Cryptococcus in CSF was determined by PCR in 31 cases. Before treatment, the microbial load ranged from 17,700 to 6,456,700 copies in 1 μl. During treatment, there was a decrease in load from undetectable values to 2,900 in the 1st group of patients and up to 12.348 copies in the 2nd group. Despite the ongoing therapy, 3 patients (1 from the 1st group and 2 from the 2nd group) did not observe treatment efficacy and the disease continued to progress. These patients in the consolidated phase of treatment switched to introconazole for 8-10 weeks of treatment. After 5–9 days of the consolidated treatment phase, 2 patients experienced deterioration of health, signs of respiratory and cardiovascular failure, cerebral coma developed, which resulted in death on the 42–48th day of the disease. The overall mortality rate was 5%-5.2% of cases, with no significant difference between the groups. The average number of CD4 lymphocyte cells

among patients of the 1st group at the time of diagnosis was 13.7±3.27 cells/μl, while in the 2nd group it was two times or higher (28.1±3, 23 cells/μl). By the 3rd month of specific treatment of cryptococcus, the number of CD4 increased to 56.3±3.7 cells/μl in the 1st group and to 78±3.2 cells/μl in the 2nd group. Patients of the 1st group during the prevention of relapse of the disease for 2-3 months, was prescribed antiretroviral therapy. In the 2nd group of patients, the average number of CD4 cells at 6 months after initiation of ART was 73±3.24 cells/μl, in patients of the 1st group for this period the number of CD4 cells was 103±3.78 cells/μl. HIV RNA in plasma was not detected (i.e., <400 copies/ml) in 8 (44%) patients of the 2nd group and in 15 (83%) of the 1st group at 6 months of ART. The data showed that patients in whom IRIS manifested with cryptococcal meningoencephalitis, had a significantly faster start and more progressive severe course. But the response to treatment with antifungal drugs on the background of ART was faster in the 2nd group.

Discussion

Thus, the cryptococcosis frequency in HIV-infected patients in Uzbekistan was first determined. The low rates of cryptococcosis among HIV-infected people in Uzbekistan are noteworthy. It amounted to 3.9% of HIV-infected patients with opportunistic diseases. This may be due to insufficient quality of diagnosis. For the first time, "medical" and socio-demographic risk factors for the cryptococcosis development in HIV-infected patients were identified. The most significant combinations of risk factors were the combination of the no employment with the fact of frequent hospitalization in hospitals, the lack of supportive prevention of the disease (in 32.6±5.99%), poor social conditions (in 13.7±4.27%) examined in the group observations. The results of the study confirm the direct relationship between the degree of immunodeficiency in HIV infection and the occurrence of cryptococcosis. The disease significantly more often develops with a CD4 T-cell count of ≤100 cells/μl. Also, the importance of the absolute number of leukocytes and lymphocytes in the peripheral blood was revealed, with their reduction, the risk of cryptococcosis in HIV-infected patients significantly increases. The results of the study also confirm the need for rapid testing for CrAg and fluconazole prophylaxis for cryptococcal disease in patients with CD4≤100 lymphocytes. The results of the study are consistent with the literature that cryptococcosis occurs against the background of severe insufficiency of cellular immunity. Therefore, screening with rapid tests for detecting CrAg in all HIV-infected patients with a CD4 level of ≤100 is necessary. The low information content of the specific clinical picture of the disease requires doctors when neurological symptoms appear, and requires microscopic examination of CSF in patients with prolonged persistent headache, even in the absence of meningeal symptoms. Cryptococcal meningitis should always be included in the differential diagnosis of chronic or subacute meningoencephalitis since the clinical features are not specific. In our studies, the typical clinical cryptococcosis manifestations in HIV-infected patients were an acute and chronic process development with high fever, a manifest clinical picture of CNS damage in the form of meningoencephalitis. The specific features of the course of cryptococcal meningoencephalitis in HIV-infected patients is the development of a manifest CNS lesion in the absence of clinical signs of disturbance on the part of the internal organs. The disease is characterized by a severe course in 92.6±5.99% of cases. It should be noted that most patients observed by us (83.0±3.72) had meningeal symptoms, although according to the literature, they are found only in 30.0% of patients suffering from cryptococcosis. None of the patients observed by us in vivo revealed clinical symptoms of lesions of the skin and other internal organs characteristic of a generalized pathological process. However, when conducting mycological studies revealed the presence of C. neoformans in cerebrospinal fluid in all patients of both observation groups. Uncharacteristic changes were CSF. The most demonstrative was an increase in protein from 0.47 to 4.84 g/l in 88% of patients, which indicated an increase in the permeability of the blood-brain barrier. There was also a decrease in glucose from 0.47 to 2.1 mmol/l in 36% of patients. 57% had lymphocytic or mixed pleocytosis ranging from 12 to 293 cells/μl, which indicated a weak inflammatory reaction. Liquor hypertension did not play a significant role in the severity of the course of the disease in both study groups. Increased attention is required not only to the patient's condition, but also to microbiological CSF monitoring with determination of the pathogen sensitivity during treatment. This will allow timely determination of the possible resistance formation to antifungal drugs. Adequate antimycotic therapy performed in the early days determined the positive dynamics of the pathological process.

An early assessment of treatment results (on days 10-14) is possible based on mycological CSF examination and a decrease in the microbial load determined by PCR (decrease after 2 weeks by 10 thousand times).

Maintenance therapy based on fluconazole (200 mg/day) with poor adherence or early cessation of treatment can lead to relapse of cryptococcal meningitis, which was noted in patients of the 1st group (84±4.7). Itraconazole was used as rescue therapy in 3 cases of fluconazole resistance.

Another aggravating factor in the disease development was the significantly expressed degree of immunosuppression (CD4≤100 cells/μl) in the observed patients. An increase in the content of CD4 + cells to a greater degree in patients with HIV-associated cryptococcal meningoencephalitis during ART contributed to faster and more successful treatment, and vice versa, the late ART start in patients with low CD4 counts increases the risk of cryptococcosis and other opportunistic diseases. But despite the increase in the absolute amounts of CD4 + lymphocytes in the main group, the fact is obvious that an increase in their number does not yet prove the normalization of the immune response lost in the early stages of HIV infection. The presentresearch once again shows that antifungal treatment with antiretroviral drugs helps to restore CD4 cell levels more quickly, as well as preventing the inflammatory immunity syndrome development, which can lead to severe cases of generalized forms.

Conclusions

1. It was found that the cryptococcosis frequency in HIV-infected patients was 3.9% of HIV-infected patients with opportunistic diseases.
2. Among the risk factors for the development of cryptococcosis in HIV-infected patients of the main group were socio-demographic (no employment, unsatisfactory housing and utilities) and medical (frequent hospitalization, lack of maintenance prophylaxis with fluconazole). The combination of these factors was the most significant.
3. The presence of a direct relationship between the degree of immunodeficiency in HIV infection and the cryptococcosis occurrence has been determined. The disease significantly more often develops with a CD4 T-cell count of ≤100 cells/μl.
4. The low information content of the specific clinical picture of the disease dictates the need for routine rapid testing for CrAg and fluconazole prophylaxis for cryptococcal disease in patients with CD4≤100 lymphocytes.
5. Cryptococcal meningitis should always be included in the differential diagnosis of chronic or subacute meningoencephalitis since the clinical features are not specific.
6. Characteristic changes in the CSF in cryptococcal meningoencephalitis were an increase in protein, a decrease in glucose levels, without much difference in the compared groups.
7. Microbiological CSF control and monitoring with determining the pathogen sensitivity during treatment allowed to timely determine the resistance formation to antifungal drugs.
8. Antifungal treatment on the background of antiretroviral drugs contributes to a more rapid increase in the level of CD4 cells.

Abstract

During the examination and treatment of 465 patients with acute lung abscesses on the background of diabetes mellitus, a preoperative preparation program was developed that takes into account the phase of the process (group 1 - septic course of the process, group 2 - stabilization, group 3 - remission), the severity of endotoxemia and non-respiratory lung function. Patients of the 1st group against the background of basic long-term intra-arterial catheter therapy used the scheme of correction of non-respiratory function of the lungs that we developed, sanitized purulent foci with an electrolyzed solution of sodium hypochlorite. In 202 (79.9%) of 254 patients of the 1st group, it was effective that allowed to refuse the operation, while only 52 (40.6%) were not operated on in the 2nd, and 26 in the 3rd (31.3%) patients. In parallel, a pronounced normalizing effect was achieved in correcting the degree of violation of non-respiratory lung function against the background of delimitation and stabilization of the process. This allowed in 109 (60.9%) of 179 operated patients to confine themselves to lung resection with 8.7% of postoperative complications in the 1st group versus 18.4% in the 2nd and 24.6% in the 3rd, which emphasizes the effectiveness of our preoperative preparation.

Keywords: *Lung abscess, diabetes mellitus, non-respiratory lung function, diagnosis, conservative and surgical treatment.*

Introduction

Dissatisfaction of surgeons with the results of treatment of acute lung abscesses in patients with diabetes mellitus, due to the continued high mortality (up to 70%)[1] in gangrenous forms, contributes to the emergence of a large number of studies on various issues of the pathogenesis and treatment of this disease [12].

Against the background of the progress of resuscitation and intensive care in recent years in the treatment of acute lung abscesses in patients with diabetes mellitus[3], a combination of signs of disturbances in the activity of various organs and systems, defined by clinicians as multiple organ failure syndrome, began to be noted [9].

In our opinion, among the mechanisms of development of this syndrome[2], insufficient attention is paid to impaired non-respiratory function of the lungs, representing the main protective barrier that prevents the [18]generalization of infection and intoxication with subsequent disorders of almost all vital systems of the organism [17].

The treatment of acute lung abscesses in patients with diabetes mellitus is complex, is long and is accompanied by a large number of complications[19]. There is still no unity in the treatment of this disease. As a rule, they begin with intensive, complex therapy, including antibacterial drugs, non-specific anti-inflammatory drugs, detoxification therapy[13], sanitation of the tracheobronchial tree, and correction of metabolic disorders[7].

The indication for surgery is the absence of the effect of this treatment, carried out within 3 weeks, the chronization of the process that occurs[5], coming, according to various authors, in the period from 6 to 14 weeks from the time of the disease, the presence of life-threatening complications [6]. The weight of these criteria is estimated by various authors is far from unambiguous.

The foregoing determined the purpose and

objectives of this study: to clarify the indications for conservative, preoperative treatment of patients with acute lung abscess with diabetes mellitus, considering violations in non-respiratory lung function to improve immediate and long-term results of surgical treatment.

Material and Research Method

465 patients with acute lung abscesses were observed against diabetes mellitus at the age from 28 to 60 years old, divided into clinical groups[10]. The 1st group consisted of 254 (54.6%) patients with a pronounced clinical picture of inflammatory destructive process in the lung, which against in the background of prolonged selective intra-arterial catheter therapy, carried out targeted correction of non-respiratory lung function according to the method developed by us[12]. The 2nd group consisted of 128 (27.5%) patients with a stable course of the disease who used long-term intra-arterial catheter therapy according to the traditional scheme with generally accepted correction of metabolic disorders [14].

The 3rd group consisted of 83 (17.9%) patients who received purely traditional conservative treatment in other hospitals and transferred to our clinic to continue treatment with remission of the inflammatory process. This division of patients with acute lung abscesses in the presence of diabetes reflects different stages in the development and implementation of method for diagnosing and treating these diseases in our clinic.

The Results Obtained and their Discussion

The majority of patients - 341 (73.3%) were admitted within 2.5 months from the moment of illness, 119 (25.6%) patients were ill for no more than 3 months and only 5 (1.1%) were longer. We have developed a quantitative method for assessing the degree of impairment of non-respiratory lung function (compensated, sub compensated and decompensated) in patients with chronic non-specific inflammatory lung diseases on the basis of integral blood levels of albumin, globulins, total phospholipids and lipids, phosphatidylcholine and sphingomyelin.We used this method, with small additions and changes reflecting the degree of the inflammatory, mainly bacterial, process in the broncho pulmonary system, in the treatment of patients with acute lung abscesses with diabetes mellitus. A comprehensive clinical and biochemical study in patients with acute lung abscesses in diabetes mellitus during the stages both conservative and surgical treatment, led to the conclusion that they have a varying degree of non respiratory lung function impairment, deepening in the early postoperative period due to the presence of a lung abscess in the parenchymaa factor in surgery and general anesthesia.

The main rule in the treatment of patients with acute lung abscesses in the presence of diabetes mellitus was early and adequate endobronchial or transthoracic drainage and sanitation of the purulent-necrotic lesion in the lung. In 54.3% of cases, these rehabilitation method were used simultaneously.

Patients of the 1st clinical group, taking into account the degree of impairment of non-respiratory function of the lungs, used intravenous infusion of fat emulsion preparations (nirpid) and protein-synthetic enhancing agents by daily intraarterial drip of 100ml of a 10% solution of albumin or alvezin with intramuscular injection against the background of basic therapy. retabolil. Conservatively treated with the achievement of a certain positive result were 286 (61.5%) patients with acute lung abscesses associated with diabetes mellitus, 179 (38.5%) patients were operated on. In the first clinical group of 208 people, complete recovery was achieved in 163 (78.4%), and clinical remission was achieved in 39 (18.7%) patients with acute lung abscesses with diabetes mellitus. Disease progression was observed in 6 (2.9%) patients. In the 3rd clinical group, complete cure without surgery was achieved only in 4 (15.4%) of 26 patients, and clinical remission in 8 (30.8%) patients. It should be noted that a positive effect was achieved to a greater extent in the most severe patients.

So, in the 1st group, 202 (97.1%) patients achieved cure and persistent clinical remission. Only 6 (2.9%) patients who were admitted to the hospital with a running process, expressed symptoms of endotoxemia and respiratory failure were found to be ineffective; their disease progressed and they died of septic shock.

In the 2nd clinical group, the results of conservative treatment were more modest: only 16 (30.8%) patients achieved complete cure. Clinical improvement was noted in 20 (38.5%), treatment had no effect in 14 (26.9%) and the progression of the process, resulting in death, in 2 (3.8%) patients.

In the 3rd clinical group, complete cure and clinical remission were achieved in 12 (46.1%) treated, 14 patients (53.8%) were found to be ineffective. In general, conservative treatment was effective in 250 (87.4%) patients. Of these, 183 (64%) achieved a

complete cure, 67 (23.4%) patients refused surgery to achieve clinical remission. In 28 (2.8%) patients, the effect of treatment was not observed, and in 8 (2.8%) the pathological process progressed, therapeutic measures were ineffective, and patients died from various causes.

179 (38.5%) patients with acute lung abscesses were operated on the background of diabetes mellitus. Of these, 46 (18.1%) of the 1st clinical group, 76 (59.4%) of the 2nd and 57 (68.7%) of the 3rd. The main operation was a lobectomy performed in 109 (60.9%) patients. Advanced operations (pulmonectomy, bilobectomy, lobectomy with resection of segments) were performed in 70 patients[18]. The prevalence in the structure of organ-preserving interventions, we explain the preoperative use of long-term intra-arterial catheter therapy, which ensures the delimitation and stabilization of the destructive process in the lung[11].

It should be noted that the performed interventions were rather complicated and traumatic, which caused a number of complications after operations in 32 patients. The main group of complications is associated with impaired bronchial obstruction resulting in atelectasis and pneumonia in the remaining part of the lung (13 and 5, respectively).Empyema on the background of fistula of the bronchus stump occurred in 2 patients. The residual cavity in the early postoperative period, as a result of incomplete expansion of the remaining part of the lung, appeared in 4 (2.23%) patients. Postoperative bleeding was noted in 1 (0.56%) patient. Pulmonary embolism was the cause of death in 3 (1.7%) operated patients. Least of all were complications from the postoperative wound that occurred in 2 (1.12%) patients. Fixing the number and type of postoperative complications, it should be noted that in the 3rd clinical group they were noted in 14 (24.6%) patients, in the 2nd - in 14 (18.4%) patients and in the 1st clinical group - in 4 (8.7%) examined. Analyzing and explaining the results of conservative and surgical treatment of patients with acute lung abscesses against diabetes mellitus, we studied the dynamics of the clinical manifestations of the inflammatory process at the main stages of treatment. 46 (25.7%) of the 179 patients operated on in the clinic received a pronounced clinical presentation of the inflammatory process in the lung, which required intensive preoperative treatment, taking into account the degree of impairment of non-respiratory lung function.

Using method of conservative correction, it was possible to stabilize the process and achieve remission before surgery in 171 (95.5%) patients. Of these, the process was stabilized in 42 (23.46%) patients of the 1st group, remission was observed in 3 (1.68%) of the 1st and 14 (7.82%) patients of the 2nd clinical group, there was no effect from preoperative treatment only in 1 patient of the 1st group, and in 7 patients with a stable course of the disease deterioration occurred. These patients were operated on for vital indications.

Thus, by the time of the operation, the number of patients with acute lung abscesses in the presence of diabetes mellitus with symptoms of severe inflammatory process, decreased under the influence of conservative treatment to 4.47%, with stabilization of the process increased to 54.19%, and remission was achieved in 41.3% the patient, which confirms the effectiveness of the proposed conservative measures, but it is not clear why the results of preoperative treatment in patients with acute lung abscesses of the 2nd and 3rd clinical groups are worse than in patients with more pronounced clinic of the disease..

As indicated above, patients with acute lung abscesses in the presence of diabetes mellitus have a certain degree of impairment of non-respiratory lung function, manifested in various combinations of disorders of both systemic homeostatic[6] and local protective reactions. Considering the fact that the compensated and balanced degree of impairment of non-respiratory lung function is usually a dynamic and reversible process [19], and impairment of non-respiratory function of the lungs of patients with acute lung abscesses during diabetes mellitus can vary, we analyzed the degree of impairment of non-respiratory lung function within the clinical groups [15].It was found that 179 (38.5%) patients of the 1st clinical group had severe and moderate impairment of non-respiratory lung function characteristic of compensated changes, and 75 (16.1%) revealed subcompensated disorders.

Decompensated disturbances of non-respiratory lung function in patients of the 1st clinical group were not recorded. In 98 (21.1%) patients of the 2nd clinical group, compensated violations of the non-respiratory function of the lungs were revealed, disorders of the type of subcompensated recorded in 18 (3.9%) of the examined and less often decompensated were observed in 12 (2.58) %) surveyed.

For patients with acute lung abscesses in the presence of diabetes mellitus in the 3rd clinical group,

a decompensated form was found in 56 (12%) and subcompensated in 27 (5.8%) of them.

The data presented indicate that the stabilization and remission of the process in patients with an acute lung abscesses during diabetes mellitus, which are clinically determined, in most cases is not accompanied by normalization of non-respiratory lung function[1], which requires adequate[10] treatment of patients with acute lung abscesses, considering their degree of disturbances non-respiratory function, which meets the requirements of rehabilitation[14], which provides an increase in the proportion of patients specific weight with clinical recovery and remissions, and for staged surgical treatment reduces the number of inflammatory postoperative complications, improves immediate and long-term outcomes.

Conclusions

1. Conservative treatment was effective in 250 (53.76%) patients with acute lung abscesses in the presence of diabetes mellitus. Of these, 183 (64%) patients achieved complete recovery.
2. The proposed conservative, corrective preoperative treatment made it possible to stabilize the process and achieve remission before surgery in 171 (95.6%) operated patients with acute lung abscesses with diabetes mellitus;
3. Effective preoperative preparation, carried out considering the degree of violation of non-respiratory function of the lungs, limits and stabilizes the inflammatory process, which allowed 109 (60.9%) patients with acute lung abscesses to limit themselves to economical lung resection with 17.9% of complications in the postoperative period.
4. Clinical stabilization and remission of the process, is not always accompanied by normalization of the non-respiratory function of the lungs, which requires rehabilitation of patients taking into account their degree of violation of this activity.

Abstract

The past 5-year data from 222 randomiy selected outpatient cards of hypertensive patients who were followed up at a family polyclinic (n=54) and in a number of rural ambulances (n=168) of the Republik of Uzbekistan were retrospectively analyzed. The physicians from the Tashkent family polyclinic and rural ambulances of a number of the Republic's regions, who had taken 10-month retraining courses for general practitioners, were questioned. Questionnaires were used to study 156 and 119 physicians before and after retraining, respectively. Two hundred and fifty-six hypertensive patients followed up at the family hospital and rural ambulances were interviewed using questionnaires and examined. Then some of them (a study group) took a course of training at a school for the hypertensive patient and the others (a comparison group) did not participate in the education program. All the patients were followed up for 2 years with a subsequent reexamination and study. Most outpatient cards give recommendations for non-drug treatment incompletely. In a number of cases, the physicians who attach importance to the detection and correction of risk factors has substantially increased after education. The patients who had taken training courses were found to be significantly ($p<0,001$) more aware of their having hypertension and the major risk factors of hypertensive disease, to be more adherent to treatment, and to know its adequacy.

Introduction

AH in the world affects about 1 billion people and more than 7.1 million deaths per year are associated with high blood pressure (BP)[1]. According to WHO, about 20% of the world's adult population have problems associated with high blood pressure. Alarming forecasts of WHO experts have been published, according to which, by 2025, a peak in the growth of arterial hypertension (AH) is expected, the incidence of which will reach 29%[2]. adult population of the planet. As a result of a targeted health policy in the second half of the last century, a significant reduction in mortality from CVD was achieved in the countries of North America, Western Europe, Japan and Australia[3]. So, in

1976-1980. in the American population, the number of patients receiving treatment was 31% of all patients with hypertension, and in 2004-2009 already 59%. Control of blood pressure (at a level below 140/90 mm Hg) for the same period was 10% and 34%, respectively [4]. In the CIS countries, the epidemiological situation correlates with global data. Studies conducted in different regions of Russia over the past 20 years indicate that hypertension remains one of the most common diseases. About 30 million people suffer from it, which makes up 20% of the total population[5]. Given the main role of hypertension in the development of coronary heart disease (CHD) and stroke, control of blood pressure becomes an important task for healthcare systems in the vast majority of countries[6]. The widespread prevalence of CVD risk factors is due to the modern pace and lifestyle, characterized by stress, physical inactivity, smoking, excessive salt, calorie intake, insufficient consumption of fruits, vegetables and potassium [7].

The importance of the study of hypertension is directed by the efforts of many clinical studies in Europe and the USA [8]. According to N. Engl (2015), only 5–10% of hypertensive patients in Europe and 25.6% in the United States achieved BP control[9]. Global urbanization and social insecurity lead to the launch of one of the diverse pathogenetic mechanisms for increasing blood pressure - psychoemotional stress[10]. As the Framingham study showed, tachycardia accompanying stress not only contributes to the progression of atherosclerosis, but also increases the incidence of significant cardiovascular complications (CVC) of myocardial infarction (MI), cerebral stroke (CS), and sudden coronary death [11]. According to Russian scientists, psycho-emotional stress activates the sympathoadrenal system and the hypothalamic-pituitary-adrenal axis, creating conditions for chronic inflammation (C-reactive protein, tumor necrosis factor, interleukin-1B, interleukin-6), leading to oxidative stress followed by dissonance between vasoconstriction. and vasodilators, which is manifested by hypertension[13].

The purpose of the study is to increase the effectiveness of prevention and treatment of AH by educating patients in hypertensive schools at the level of the primary health care (PHC). To achieve the goal, the following tasks were formulated: to study patient management tactics, the knowledge of general practitioners about the principles of prevention and treatment, as well as the commitment of patients with hypertension to compliance with non-pharmacological and medical recommendations at the PHC level; to develop a structured program for the education of patients with hypertension with information interventions in the conditions of city family clinic/rural medical center (CFC/RMC); compare the results of patient adherence to treatment, analyze the results of therapeutic and preventive interventions before and after 24 months. observations; the creation of an electronic program of dispensary monitoring of patients with AH in primary care settings.

Materials and Method

A retrospective analysis of data (over the past five years) of 222 randomly selected outpatient records of patients with hypertension, registered in the joint venture (n=54) and in some Polyclinics of the Republic of Uzbekistan (n=168) was performed. Data from a retrospective analysis of outpatient maps are compared with the results of examination of patients (interrogation, examination, anthropometry, blood pressure measurement, determination of cholesterol, etc.). Interviewed by doctors of the Tashkent polyclinic and medical centers in rural areas of the republic, who took 10-month retraining courses for general practitioners. A survey of 156 doctors before training and 119 doctors after training was conducted, as well as a survey and examination of 236 patients with hypertension, consisting of a follow-up in polyclinics and medical centers. In the future, part of them (the main group; n=122) took a course at the school of hypertensive patients, and part (comparison group; n=114) did not participate in the educational program. All patients were under our supervision for 2 years with subsequent re-examination and examination. In the main group (age of patients from 45 years to 71 years, average - 51.75±1.85 years; 29.5% of men, 70.4% of women), the distribution of patients by stages was as follows: stage I AH - 45 (36, 8%) people; Stage II - 62 (50.8%); Stage III - 15 (12.2%). The crisis course of the disease was observed in 40 (32.7%) patients. The comparison group consisted of 114 patients (80 (70.1%) women and 34 (29.8%) men, aged 44-75 years, average - 52.6±1.62 years), treated by the traditional method and not participating in the educational program. In this group, stage I GB was detected in 41 (35.9%) people; Stage II - 61 (53.5%); Stage III - 12 (10.5%) people. The crisis course of the disease was observed in 37 (32.4%) patients. The groups were comparable in terms of the main clinical and laboratory instrumental indicators.

In the main group of patients, 46 (37.7%) patients had an average risk of cardiovascular complications, 63 (51.6%) were at high risk, and 14 (11.4%, $p < 0.05$) were very high. In the comparison group - 41 (35.9%), 62 (54.3%) and 11 (9.6%, $p < 0.05$) patients, respectively.

Schools of hypertension are organized on the basis of the Training and Medical Center at the Tashkent Medical Academy, located in SP 32 of Tashkent and RMC of two regions of the republic; teaching materials are developed taking into account the specifics of the work of family doctors. When compiling the training technology, the level of patient education was taken into account. In our opinion, taking into account the mentality of our population, 10 classes can be considered optimal (1 time per week, preferably on Saturday). Training material should be submitted in accordance with a structured program in a logical sequence according to the sections specified in the training program.

When organizing schools of hypertension, it is necessary to adhere to the following method of conducting classes: a set of patients in groups of 10-12-14 people; Venue - specially prepared thematic room; necessary resources for training: banners, a multimedia projector, phantoms, scales, a height meter, a measuring tape, an apparatus for measuring blood pressure, etc.; presentation of material - interactive conversation-lecture; duration of classes 90-120 minutes with a 15-20 minute break;

Students must be persuaded to keep a diary of patient self-control with the assessment and monitoring of controlled risk factors, the results of blood pressure indicators and a schedule for taking antihypertensive drugs. In order to acquire practical skills for self-monitoring and self-help with an acute increase in blood pressure, pay special attention to classes where patients learn the principles of non-drug and drug treatment of hypertension. To teach the methodology of independent outpatient daytime measurement of blood pressure, pulse counting and other practical skills (determining BMI, staffing an emergency first-aid kit and providing self-help with an acute increase in blood pressure), in order to adequately control blood pressure indicators. This method allows you to assess changes in blood pressure and heart rate in the early morning and during the day several times before going to bed, is easy for the patient, informative and increases patient adherence to treatment, allows you to control the effectiveness of antihypertensive therapy.

Self-ambulatory daytime monitoring of blood pressure is recommended as a mandatory method for the study of hemodynamics on an outpatient basis in assessing the effectiveness of antihypertensive therapy, in the diagnosis of hypertension, especially in hypersensitive patients with high levels of anxiety and depression, as well as in patients without any symptoms.

Results and Discussion

A retrospective analysis of risk factors recorded in the outpatient records of the clinic (n=54) and medical stations (n =168) yielded the following results: burdened heredity was established in the clinic in 34 (62.9%) cases and in medical centers in 88 (52.3%), smoking - in 16 (29.6%) and 47 (27.9%) cases, overweight - in 18 (33.3%) and 35 (20.8%), alcohol abuse - in 9 (16.6%) and 37 (22.0%), hypercholesterolemia - in 21 (38.8%), stress - in 38 (70.3%) and 115 (68.4%), respectively. The most common risk factors such as burdened heredity, stress, overweight, and lack of exercise.

In most outpatient cards, recommendations for non-drug treatment are not given in full. Table salt restriction is recommended by 35 (64.8%) polyclinic doctors and 53 (31.5%) rural doctors; auto-training - 24 (44.4%) and 64 (38.0%); restriction of fat intake - 31 (57.4%) and 71 (42.2%) and 54 (32.1%); weight loss in obesity - 37 (68.5%) and 71 (42.2%); regular physical education - 37 (68.5%) and 67 (39.8%), respectively. A comparative analysis of retrospective indicators of outpatient charts with data from an oral survey of doctors and examination of the same patients revealed a significant discrepancy ($p < 0.001$) of these risk factors. These data allow us to conclude that in most patients the timely detection and correction of risk factors for hypertension were not performed.

Studying outpatient cards, we drew attention to the rules for the appointment of antihypertensive drugs with proven effectiveness. β-Adrenergic blockers in the clinic are prescribed in 44.4% of cases, in medical centers - in 8.9%; diuretics - in 35.1 and 10.7%, respectively; calcium antagonists - in 24 and 5.9%; ACE inhibitors - in 51.8 and 42.2%, respectively. Despite the appointment of first-line antihypertensive drugs, dibazole, Adelfan, Raunatin, etc. were also prescribed, in courses, without a specific regimen and duration of administration. Antihypertensive drugs are regularly prescribed by 35 (64.8%) doctors of the polyclinic and 30 (17.8%) by medical points, by short courses - 19 (35.1%) and 138

(82%) doctors, respectively, the differences in both cases are highly significant (p <0.001).

Anonymous questionnaire of doctors at the polyclinic and medical centers that underwent 10-month retraining courses revealed an underestimation of risk factors and their correction by doctors in patients with hypertension. After training, the number of doctors who attach importance to the identification and correction of risk factors significantly increased (p<0.001). Thus, 46.0% of polyclinic doctors and 30.1% of medical centers recommended a decrease in salt intake before training, 92.3 and 76.1% respectively, after training; weight loss before training - 26.9 and 15.0% of doctors, after - 96.1 and 85.0%, respectively; restriction of fat intake was recommended before training by 20.6 and 16.1% of doctors, after - 94.2 and 43.2%, respectively.

Most doctors do not fully understand the method of modern prevention of hypertension. Reducing the negative factors associated with lifestyle is the main goal of preventing hypertension, an effective way to reduce blood pressure and prevent complications. The role of the general practitioner in convincing patients to follow simple recommendations is extremely large.

236 patients were enrolled in a questionnaire survey of patients under clinical observation for AH. When analyzing questionnaires, the following groups of signs were evaluated: patient awareness of hypertension, blood pressure levels, its complications; the ability to provide self-help with a sharp increase in blood pressure; knowledge of non-drug method of treating AH; possession of practical skills (independent measurement of blood pressure, determination of heart rate, etc.); attitude to taking antihypertensive drugs.

Patients participating in the educational program significantly (p <0.001) improved their knowledge of risk factors and practical skills to improve the quality of AH control (Table 1). In the group of patients who did not undergo training, a special difference in the provision of self-help before being taken under observation and after 2 years of observation was not detected. All 122 patients who completed the training mastered the skills of independent measurement of blood pressure and pulse counting. In the comparison group, these indicators remained almost unchanged. Repeated questionnaires after training showed a significant (p <0.001) increase in the number of patients taking antihypertensive drugs, 82.7% of those trained began to "constantly" and "from case to case" with an excessive increase in blood pressure - 9.0% of trained patients.

The majority of patients in the comparison group do not possess self-help skills with a sudden increase in blood pressure and self-monitoring of blood pressure. In addition, one of the principles of drug antihypertensive therapy (taking drugs with regularity and duration) is not supported. After 2 years of observation, the rules for taking antihypertensive drugs almost did not change. The results of a survey of patients prove the need for training AH patients in a number of skills that allow them to provide self-help in a timely manner with an acute increase in blood pressure and maintain its target level while observing non-pharmacological treatment method and rules for taking antihypertensive drugs.

One of the main links of the ongoing measures for the prevention of hypertension on an outpatient basis should be the increase in the educational level of patients. If a general practitioner takes the time and develops an individual program for non-drug and drug treatment for each patient, then it will be very difficult to implement it, since untrained patients lack motivation for treatment. Only after informing about the principles of prevention of AH and its complications does the patient increase adherence to treatment, they become responsible for their health. The school of hypertensive patients at the PHC level is an ideal and suitable method for increasing the knowledge, abilities and skills of patients for quality control and monitoring of their condition.

Among the factors affecting the effectiveness of treatment of patients with hypertension, along with the clinical features of the course of the disease and the correctness of medical prescriptions (choice of drug, dose, dosage regimen, etc.), the adherence of patients to treatment is of great importance, i.e. completeness and correct implementation of medical recommendations.

Patients who underwent training experienced positive dynamics in the lipid spectrum: the number of patients with hypertriglyceridemia (p <0.001) and hyper-LDL cholesterol (p <0.001) decreased (Table 2). All patients stopped drinking alcohol (p <0.001), quit smoking; physical inactivity was observed only in 30.3% (p <0.001). The number of patients with impaired glucose tolerance decreased (p <0.001).

• Short courses (10-14 days)	19	15,5	-	-	23	20,1	16	14,2

Table 2. Dynamics of controlled risk factors for cardiovascular diseases in patients trained at the school of hypertension

Risk factors	Data before training (n=122)		2 years after training (n=122)		ρ
	Abs	%	Abs	%	
Excessive intake of salt more than 5-6 g/day	10	8,1	3	2,4	<0,001
Smoking	13	10,6	5	4,0	<0,001
Alcohol abuse	11	9,0	-	-	
TG> 2.0 mmol/L	24	19,6	14	11,4	<0,001
LDL cholesterol> 3.0 mmol/L	69	56,5	33	27,0	<0,001
HDL cholesterol <1.0 mmol/L	42	34,4	24	19,6	<0,001
Impaired glucose tolerance	12	9,8	2	1,6	<0,001
Sedentary lifestyle	85	69,6	37	30,3	<0,001

Significant changes in the clinical picture of the disease were also noted: dizziness and headaches began to occur less frequently ($p < 0.001$), there was a tendency to decrease dyspnea during exercise ($p < 0.001$) (Table 3). The number of patients suffering from angina pectoris, as well as those with rhythm disturbances, has not increased.

Table 3. Change in symptoms of hypertension in patients trained at the school of hypertension

Clinical symptoms	Before training (n=122)		2 years after training (n=122)		ρ
	Abs	%	Abs	%	
Dizziness	42	34,4	5	4,0	<0,001
Headache	91	74,5	5	4,0	<0,001
Exertional dyspnea	16	13,1	6	4,9	<0,001
No angina pectoris	71	58,1	71	58,1	>0,05
FC I	30	24,5	33	27,0	>0,05
FCII	21	17,3	18	14,7	<0,05
Heart rhythm disturbances, incl. ventricular and supraventricular extrasystole, atrial fibrillation	14	11,4	14	11,4	>0,05

Trained patients significantly (p <0.001) increased the use of long-acting antihypertensive drugs; ACE inhibitors - from 19.6 to 91.8%; β-blockers - from 29.5 to 39.3%; calcium antagonists - from 6.5 to 59.0%; diuretics - from 13.1 to 66.3%, respectively. Blockers of AT-1 receptors before training were taken in 5.7% of cases; after 2 years of observation, the frequency of administration of these drugs significantly (p <0.001) increased and amounted to 13.1%.

Patients trained in the school of hypertension have a significant (p <0.001) improvement in knowledge of AH risk factors and their knowledge of hypertension, increased adherence to treatment and drug treatment to achieve the target blood pressure level (Table 4). The course of AH was accompanied by a significant decrease in the frequency of hypertensive crises and hospitalization, side effects of drug therapy. In the comparison group, against the background of the prescribed therapy, positive reliable dynamics were noted; patients began to control blood pressure more often, the selection of adequate drug therapy improved, although patient awareness of the presence of hypertension, patient knowledge of the main risk factors for AH, treatment adherence remained low, and the decrease in the number of hypertensive crises was not significant.

Table 4. The main results of the observation of patients who have passed and have not been trained at the school of hypertension

Index	Main group				p	Comparison group				p
	Before training (n=122)		After training (n=122)			Initial data (n=114)		After 2 years of follow-up (n=112)		
	Abs	%	abs	%		abs	%	Abs	%	
AH awareness	66	54,0	121	99,1	<0,001	71	62,2	75	66,9	>0,05
Patient knowledge of the main risk factors for GB	56	45,9	121	99,1	<0,001	36	31,5	38	33,9	>0,05
The incidence of hypertensive crisis	40	32,7	4	3,2	<0,001	42	36,8	37	33,0	>0,05
Hospitalized for emergency	40	32,7	4	3,2	<0,001	42	36,8	37	33,0	>0,05
Permanent independent monitoring of blood pressure	63	51,6	118	96,7	<0,001	25	21,9	32	28,5	<0,001
Drug treatment of hypertension with achieving the target level of blood pressure	14	11,4	101	82,7	<0,001	12	10,5	29	25,8	<0,001
Adherence to treatment	87	71,3	120	98,3	<0,001	24	21,0	25	22,3	>0,05
Side effects of drug treatment of AH	38	31,1	5	4,0	<0,001	40	35,0	38	33,9	>0,05

It should be noted that 118 (96.7%) patients began to independently control blood pressure according to the SADMAD technique and keep a self-monitoring diary, which contributed to increasing adherence to drug therapy, and improved the relationship between the doctor and the patient.

The most difficult thing for patients was the conscious implementation in practice of such measures to normalize a lifestyle as reducing body weight, increasing physical activity, observing the principles of a balanced diet, restricting the use of salt, quitting smoking, and alcohol abuse. After 2 years, 48 (39.3%) patients increased physical activity, 49 (40.1%) - limited the consumption of table salt. Of the dietary recommendations for 98 (80.3%) patients, limiting the intake of animal fats and an increase in the diet of unsaturated fats were easily feasible. In general, these measures were accompanied by a decrease in blood cholesterol, a decrease in the number of patients with impaired glucose tolerance.

The role of independent ambulatory daytime monitoring of blood pressure (SADMAD) in the formation of adherence to treatment was revealed. In the main group of SADMAD in the amount of 10 measurements per day 51 (41.8%) patients performed; 6 measurements per day - 35 (28.6%); 4 measurements per day - 22 (18.0%); 2 measurements per day - 10 (8.1%). SADMAD was carried out before prescribing drugs and against the background of antihypertensive treatment.

After reaching the target level of blood pressure during therapy, subsequent examinations for patients with medium and low risk who regularly measure blood pressure at home should be planned at intervals of 6 months. For patients with a high and very high risk, as well as for patients receiving only non-drug treatment, and for people with low adherence to treatment, the intervals between visits should not exceed 3 months. The regularity of medical examinations that ensure continuous monitoring can be ensured by involving patients in activities related to training and the acquisition of self-control skills.

Treatment of a patient with hypertension is carried out continuously, in most patients - for life, since its cancellation is accompanied by an increase in blood pressure. With persistent normalization of blood pressure for 1 year and compliance with measures to change the lifestyle of patients with low and medium risk, a gradual decrease in the number and/or reduction of doses of antihypertensive drugs is possible. Reducing the dose and/or reducing the number of medicines used requires an increase in the frequency of visits to the doctor and the administration of SADMAD at home in order to ensure that there are no repeated increases in blood pressure.

It should be noted that in a number of scientific papers it has been noted that the effectiveness of educational programs has recently been declining[14]. They only temporarily improve the situation [15], help control blood pressure, but do not affect other risk factors, for example, body weight [17].

Conclusion

1. At the primary care level in most patients with hypertension, risk factors are not fully identified; some of them do not correct the identified modifiable risk factors; the vast majority of patients use antihypertensive drugs in short courses, not observing the regularity and duration of admission.
2. Patients with hypertension are not sufficiently aware of the risk factors (33.9%) that affect the course and prognosis of the disease: do not have the skills of self-control (63.3%) and self-help (75%) with an acute increase in blood pressure; there is a low commitment (24%) of patients to the implementation of medical recommendations.
3. Antihypertensive therapy in patients with hypertension not participating in the educational program does not significantly affect controlled CVD risk factors and does not lead to the achievement of target blood pressure levels (29%).
4. The school of hypertensive patients is an effective system for organizing patient education and conducting complex therapy in the clinic and medical centers; significantly contributes to the prevention of CVD, adequate control of systolic and diastolic BP (96.7%).
5. Adequate pharmacotherapy is optimally possible in patients participating in the educational program. In our study, this training allowed us to achieve the target blood pressure level in 82.7% of patients, reduce the pharmacological burden on the body, and thereby reduce the number of adverse reactions to drug therapy.
6. Due to the insufficient development of personal programs for the follow-up of patients with AH, the

effectiveness of treatment is reduced, the course and prognosis of the disease are aggravated, leading to a deterioration in the quality of life and an increase in the cost of treatment.

7. The introduction of an electronic dispensary monitoring program facilitates the implementation of treatment and prophylactic measures, allows to identify the leading CVD risk factors, and conduct their timely correction and monitoring. With the help of such programs, patients with lesions of target organs and ACS are detected at the early stages of their development, which allows for adequate treatment and prevention of severe complications of hypertension.

Abstract

During pregnancy, there is a significant restructuring of various organs and systems, including liver functions. Due to the increase in circulating blood volume, most indicators of liver function may differ from their level in non-pregnant women. In the liver of pregnant women, the synthesis of a large class of proteins (excluding immunoglobulins), fibrinogen, prothrombin, blood coagulation factors (V, VII, X, XI, XII, XIII), fibrinolytic factors (antithrombin III, proteins C and S) increases. Hepatic enzymes (serum transaminases, γ-glutamyltranspeptidase), as well as the bilirubin content do not change during the physiological course of pregnancy[1].

Keywords: *Pregnancy, cholestasis, syndrome, acid, intrahepatic, preeclampsia.*

Introduction

Alpha-fetoprotein (AFP) is produced by the fetal liver and usually its level in the blood increases[2]. Alkaline phosphatase can be increased in the third trimester, due to its production by the placenta and the development of bone tissue of the fetus[3].

At the end of II and III trimesters, 50% of pregnant women may experience clinically insignificant varicose veins of the esophagus, resulting from compression of the inferior vena cava by the enlarging uterus and a decrease in venous return[4].

Altered hepatic tests are found in 3-8% of all pregnancies [5]. The main causes of liver pathology are very diverse. Traditionally, they are divided into related and not related to pregnancy [6]. The liver pathology that developed during pregnancy includes indomitable (excessive) vomiting of pregnant women, acute fatty hepatosis, pregnant HELLP syndrome, and intrahepatic cholestasis of pregnant women.

Non-pregnancy related liver pathology is represented by acute viral hepatitis, cirrhosis and portal hypertension, liver tumors, bile duct diseases, etc.

A mortality rate of 0 to 25% has been reported among mothers with liver diseases associated with pregnancy. According to Carmen S. G. et al., Liver diseases that occur during pregnancy were observed in 11.24% of pregnant women attending the National Institute of Perinatology in Mexico City over a three-year period. Concomitant liver diseases were found in 10.8% of patients, mainly associated with preeclampsia (9.9%). Only in 0.56%, preeclampsia was caused by a liver disease that existed earlier: acute or chronic HCV detected in this group (0.12%) [7].

Indomitable pregnant vomiting (hyperemesis gravidarum) is the most severe form of nausea and vomiting in pregnant women, leading to dehydration, ketosis and weight loss of over 5%. indomitable pregnant vomiting complicates 0.3–2% of pregnancies[8, 9].

Indomitable pregnant vomiting is not considered a true liver disease, but it is associated with an abnormal functional liver test (FPP) in approximately half of patients, while the increase in serum aminotransferases reaches 200 U/L. Other biochemical abnormalities may also be observed, such as an increase in serum amylase and lipase [10]. The standard of definition is the occurrence of more than three episodes of vomiting per day with ketonuria and weight loss of more than 3 kg or 5% of body weight, the diagnosis is usually made clinically after excluding other causes. Clinical studies of indomitable pregnant vomiting reveal dehydration, acidosis due to malnutrition, alkalosis due to loss of hydrochloride and hypokalemia [11].

Risk factors for developing indomitable pregnant vomiting include hyperthyroidism, psychiatric illness, cystic skidding, pre-existing diabetes, pregnancy in a pregnant woman, multiple pregnancy, increased body mass index[12], and high daily intake of saturated fat before pregnancy[15]. One study also identified female fetus as a risk factor[14]. According to Saad A., Jaquelyn F (2019) in the history of gastrointestinal disorders and asthma play a significant role in the development of indomitable pregnant vomiting[16].

According to other authors, the exact etiology of indomitable pregnant vomiting is unknown. Apparently, there is a direct correlation between the severity and the level of human chorionic gonadotropin (hCG), which reaches a maximum at 10 weeks of gestation. indomitable pregnant vomiting is more often observed in trophoblastic tumors and multiple pregnancy, i.e. with an abnormally high level of hCG. The latter activates the thyroid stimulating hormone receptor (TSR), which leads to the suppression of TSR and an increase in the level of thyroxine (T4). A positive correlation was found between the level of hCG, T4 and severity of indomitable pregnant vomiting[17]

Pregnant Intrahepatic Cholestasis (ChB) is the most common liver related pregnancy disorder. This is a reversible form of cholestasis, which is characterized by itching and an increase in the level of bile acids in serum on an empty stomach or after eating. Intrahepatic cholestasis of pregnant women is spontaneously resolved in the first 6 weeks. after childbirth, but often recurs during subsequent pregnancies [18]. The frequency is 0.2–2%. The highest incidence was recorded in South America and Europe. The incidence of intrahepatic cholestasis in pregnant women is more common among pregnant women infected with hepatitis C virus [19].

The incidence of intrahepatic cholestasis in pregnant women varies depending on geographic location and ethnicity: 3–5% of pregnant women in Chile, 1% in Europe, 0.7% in the UK, 0.3–1.0% in the United States and are rare in African countries. Seasonality indicates a higher incidence in the winter months in some countries. If jaundice is the initial symptom, then a further examination of the pregnant woman is necessary. It has been found that serum autotoxin, lysophospholipase D necessary for angiogenesis and neuronal development during embryogenesis, is a highly sensitive and specific diagnostic marker that distinguishes pregnant intrahepatic cholestasis from other itchy pregnancy disorders and liver diseases associated with pregnancy. Ultrasonography of the liver is necessary to exclude gallstone disease [20].

Kremer et al. A 2010 animal study found that autotoxin, a serum enzyme that converts lysophosphatidylcholine to LPA (lysophosphatidic acid), which causes itching, increased markedly in patients with spoils compared to pregnant women and patients with cholestasis compared to pregnant women without itching. Kremer et al. In another 2015 study in which 145 women participated, it was also reported that increased serum autotoxin activity is a highly sensitive, specific and reliable diagnostic marker for pregnant intrahepatic cholestasis, distinguishing pregnant intrahepatic cholestasis from other itchy pregnancy disorders and liver diseases associated with pregnancy. According to the authors, pregnancy and oral contraception increase serum autotoxin to a much lesser extent than intrahepatic cholestasis in pregnant women. [21].

Intrahepatic cholestasis of pregnancy affects 0.1–2% of pregnant women; in 1–4 women, gestation can be complicated by premature birth, fetal asphyxia, meconium staining of amniotic fluid, and stillbirth. The results of a large Swedish cohort study showed that pregnancy, in which the concentration of bile acid in maternal serum is 40 μmol/L or more, can be complicated by spontaneous preterm delivery[23], the presence of meconium in the amniotic fluid and fetal asphyxia. Another UK cohort study confirms these findings and showed that pregnancy outcomes[22] in women with intrahepatic cholestasis in pregnant women and a serum bile acid concentration of 40 μmol/L or more often lead to fetal death compared to 2205 women with uncomplicated pregnancy [25].

A differential diagnosis of intrahepatic cholestasis in pregnant women is carried out with viral hepatitis, autoimmune hepatitis, primary biliary cholangitis and gallstone disease [26]. pregnant intrahepatic cholestasis first appears at 28-30 weeks of pregnancy in the form of itching, especially pronounced at night. Almost half of patients develop jaundice[27].

Itching of the palms and soles is a key symptom. Skin rash is absent. Jaundice is rarely observed in patients with intrahepatic cholestasis in pregnant women. Serious adverse effects on the fetus are fetal distress, premature birth, prematurity, and fetal death. An increase in serum bile acids to 100 μmol/L or higher is associated with an increased risk of fetal death. Most societies recommend delivering a pregnant woman at 37 weeks because there is an increased risk of fetal death in the last 4 weeks of pregnancy. The risk of relapse in subsequent pregnancy is high and can reach 90% [28].

Intrahepatic cholestasis of pregnant women is more often observed with multiple pregnancy and in women who have previously been treated for infertility. In the etiology of intrahepatic cholestasis of pregnant women, genetic, endocrine and environmental factors[29] play a role. Apparently, an increase in estrogen and progesterone levels due to pregnancy can contribute to the development of this pathology [30].

Additional risk factors include maternal old age, multiple pregnancies, a personal or family history of the disease, preexisting liver disease, and a history of cholestasis when taking oral contraceptives.

Exogenous progesterone also plays a role in pregnant intrahepatic cholestasis. The study showed that 64% of patients who developed intrahepatic cholestasis in pregnant women took orally micronized progesterone to reduce the risk of premature birth. 70% of patients after progesterone withdrawal and 10% of patients after progesterone dose reduction experienced relief of pruritus before childbirth[31].

Many studies have shown that high estrogen levels are associated with the development of intrahepatic cholestasis in pregnant women, such as multiple pregnancies, the effect of ovarian hyperstimulation, and second trimester gestation[32]. pregnant intrahepatic cholestasis shows similar characteristics as in women taking high estrogen birth control pills. High levels of circulating estrogen can cause cholestasis in genetically predisposed women with intrahepatic cholestasis in pregnant women. Several animal studies have shown that sulfate metabolites of progesterone are partial agonists of the farnesoid X FXR receptor (bile acid receptor). Progesterone sulfate metabolites alter the hepatobiliary transport system, disrupting the functioning of the main bile acid receptor in the liver[33].

Multidrug Resistance Protein 3 (MDRP3) is a key carrier of phospholipids across the tubular membrane. A mutation of this gene leads to a loss of function and, consequently, an increase in serum bile acids. The MDRP -3 mutation is located on chromosome 7q 21.1 and was identified in 15% of cases of intrahepatic cholestasis in pregnant women. Altogether, ten different mutations were identified. Heterozygous mutations cause transport dysfunction, while a complete lack of transport function is associated with severe liver disease. The genetic tendency to intrahepatic cholestasis of pregnant women has been proved and there is information about pedigrees in which inheritance is of a limited type by gender of the dominant system.

Some environmental factors also play a role in the etiology of intrahepatic cholestasis in pregnant women, including the level of selenium in the region [34].

Immunological dysfunction also plays an important role in the pathogenesis of intrahepatic cholestasis in pregnant women. Thus, an increase in serum bile acid level causes a change in the immune system from a TH2-mediated response to TH1. As pregnancy proceeds to TH1, the immune response has more adverse outcomes, many risks of pregnant intrahepatic cholestasis are associated with the immune system.

Ovadia et al. conducted a comprehensive meta-analysis including 23 studies that compared perinatal outcomes in women with intrahepatic cholestasis of pregnancy (n = 5557) and healthy control group (n = 165136). The results of meta-analysis demonstrate the relationship of intrahepatic cholestasis of pregnancy with an increase in fetal complications, as described below[35]. Sudden intrauterine death of a fetus, meconium-stained amniotic fluid, spontaneous preterm birth, iatrogenic preterm birth, fetal distress. Maternal bile acids are transported through the placenta to the fetus and accumulate in the amniotic fluid, causing complications. The cause of preterm birth is unknown, but is possibly related to the accumulation of bile acid in the uterine myometrium, which causes increased uterine activity. Sudden death of the fetus is the most

serious complication of IVB; the cause of fetal death is not entirely understood; possibly associated with the toxic effect of bile acids on the fetal heart, causing arrhythmias and chorionic spasm, causing a decrease in the supply of maternal oxygenated blood to the fetus, causing asphyxiation [36].

Acute fatty hepatosis of pregnant women. Acute fatty hepatosis of pregnant women (AHFS), first described by Shihan, is a rare but serious disease, with a frequency of 1 to 7,000 per 16,000 pregnant women [37].

The accumulation of fatty acids in hepatocytes caused by various pathophysiological mechanisms is known as fatty liver disease. For example, metabolic syndrome or obesity, in which lipolysis is suppressed as a result of hyperinsulinemia, therefore, can provoke non-alcoholic fatty liver disease (NAFLD) or more severe non-alcoholic steatohepatitis (NASH). With a prolonged course of the disease, this condition can lead to cirrhosis of the liver. However, when this occurs during the gestational period, it is called acute pregnant fatty hepatosis (AHFS). AHFS is a devastating condition that can rapidly progress to fulminant liver failure with associated coagulopathy or hepatic encephalopathy[38].

The prevalence of acute fatty liver disease is 1 in 10,000-15,000 pregnancies. This life-threatening condition often develops in the second half of pregnancy (range: 27–40 weeks of pregnancy), usually close to delivery. The differential diagnosis is carried out with fulminant viral hepatitis, drug-induced hepatitis, idiopathic pregnancy cholestasis, with Reye syndrome in adults, as well as with hemolysis syndrome and an increase in liver enzymes and a decrease in platelets (HELLP syndrome)[39]. In the UK, it occurs at a rate of 1 in 20,000 pregnancies [40].

The etiology of AHL is completely unknown, and the connection with geographical or ethnic characteristics is also unknown[41].

Risk factors for the development of AHFS include congenital LCHAD deficiency, 1st pregnancy, multiple pregnancy (in patients with AHFS up to 25%), preeclampsia (in patients with AHFS up to 50%) and male fetus (3 times more often), underweight newborns, history of AHLH [42].

Chen et al. Indicated that twin pregnancy can be a protective factor for maternal outcome. Conversely, Knight et al. Came to the conclusion that double pregnancy is at a higher risk of AHL, similar to Davidson et al., Who have demonstrated this condition may increase the risk of AHL [43].

Maternal mortality reached 70%, but more recent estimates range from 7% to 18%, which is secondary to advances in the supportive care of these patients. Maternal complications include postpartum hemorrhage, renal failure, hypoglycemia, disseminated intravascular coagulation (DIC), pancreatitis, and pulmonary edema.

Perinatal mortality reaches 85%, and in more recent data, rates range from 9% to 23%. Due to urgent need, approximately 75% of the births are premature, and the average gestational age at birth is 34 weeks. All infants of mothers with AHFS are tested for defects in the FAO (fatty acid oxidation), because rapid detection and treatment can reduce mortality and morbidity. Relapse of AHB during subsequent pregnancies is rare, but often occurs in carriers of LCHAD mutations[40].

Fat accumulates in the liver due to the excess intake of free fatty acids (FFAs) in the liver, a decrease in the rate of β-oxidation of FFAs in the mitochondria of hepatocytes, excessive formation and absorption of FFAs in the intestines, a decrease in the synthesis of lipoproteins of different densities in the liver itself and a functional liver test caused by liver disease . The normal fat content in the liver does not exceed 5%, and with AGB, it rises to 13-19%. Of great importance for the development of steatohepatosis is insulin resistance [44].

Prevention by prenatal diagnosis after mutations in the family are possible by selecting chorionic villi at 11 weeks of gestation.

Maternal and antenatal fetal death in pregnant women with AHFS are 10% and 45%, respectively [45].

Biochemical signs of LCHAD deficiency are the accumulation of long chain 3-hydroxy fatty acids, such as 3-hydroxylauric acid, 3-hydroxymyristic acid, 3-hydroxypalmitic acid and 3-hydroxy dicarboxylic acid in the systemic circulation and increased excretion of 3-hydroxy dicarboxylic acids in the urine.

It is reported that children with LCHAD deficiency develop sudden death with hypoglycemia, cardio-respiratory failure, acute heart failure, severe neonatal cardiomyopathy, hepatic dysfunction and acute liver failure, skeleton myopathy with rhabdomyolysis. Next, 34% of children with disabilities die between four days

and 10 years after birth. In addition, mental disorders, retardation, developmental disorders, eye abnormalities, and sudden infant death may develop. It is believed that such damage to many organs is associated with the lipotoxicity of the intermediate accumulation of toxic 3-hydroxy fatty acid.

In the medical history of pregnant women with severe AHFS, placental abruption, premature birth, and fetal death were noted.

For the diagnosis of AHFS, the Swansea Criteria have been proposed and validated in large cohort studies in the United Kingdom. These criteria include symptoms and laboratory findings. Six or more of the following criteria are needed to establish a diagnosis of AHFS according to Swansea criteria[46].

1. Vomiting;
2. Encephalopathy;
3. Polydipsia and polyuria;
4. Abdominal pain;
5. An increase in the content of bilirubin (more than 0.8 mg/dl or 14 μmol/l);
6. Hypoglycemia (less than 72 mg/dl or 4 mmol/l);
7. Leukocytosis (more than 11 · 109/l; often 20-30 · 10 * 9/l);
8. Increased levels of transaminases (often 3-10 times higher than normal - more than 42 IU/l);
9. Renal dysfunction (creatinine content of more than 150 μmol/l);
10. An increase in the level of ammonia (more than 47 μmol/l);
11. An increase in the level of uric acid salts (more than 340 μmol/l);
12. Coagulopathy (prothrombin time more than 14 s; APTT more than 34 s);
13. Ascites or hyperechoic structure of the liver during ultrasound examination (ultrasound);
14. Microvesicular steatosis with liver biopsy and histological examination[31]. In the future, jaundice (more than 70% of cases), ascites (40%), fever (45%), headache (10%) and such severe complications as gastrointestinal bleeding (20-60%), PP (50%) develop), DIC (55%), hepatic encephalopathy (60-80%) and acute pancreatitis[5].

Symptoms of liver damage include epigastric pain or pain in the upper right quadrant, probably from hepatomegaly as a result of a stretching of the Glisson capsule. An increase in hepatic enzymes to double normal values classifies severe preeclampsia. Typically, coagulation rates remain normal until the progression of liver failure or placental abruption. Liver damage is a consequence of vasoconstriction, a decrease in hepatic blood flow, leading to hepatic ischemia, periportal hemorrhage, endothelial damage and fibrin deposition in the liver[47].

Recommendations of the American College of Gastroenterology (ACG)[33]:

- Women with AHFS must be delivered promptly; observation tactics are not suitable
- all women with AHFS and their children must undergo molecular testing for LCHAD,
- Children of women affected by AHL should be carefully monitored for the presence of LCHAD, including hypokinetic hypoglycemia and liver enlargement[8].

In a study by Meng et al. involving 43 patients[26] at the center of tertiary levels, prothrombin time, plasma fibrinogen, and platelet counts correlated with recovery time, while white blood cell count, blood glucose, and liver aminotransferase showed no significance in predicting. Transfusion of fresh frozen plasma (FFP), cryoprecipitate, or platelet concentrates in the case of abnormal standard tests such as prothrombin time (PT), activated partial thromboplastin time (APTT), or fibrinogen can prevent further bleeding complications. However, relative fluid overload can lead to acute lung damage and infection resulting from the use of these drugs. In addition, current standard coagulation tests are considered only weak predictors of bleeding in critically ill patients; Therefore, additional method such as thromboelastometry can be used. Thromboelastometry was used in the early prediction of bleeding complications in seriously ill patients. In a report by Crochemore et al., It was found that this method effectively detects a hypocoagulable condition and reduced quality of fibrinogen function at the beginning of an operation. Fibrinogen and prothrombin complex concentrates were administered to the patient and a cesarean section was performed without any major bleeding. Recombinant

factor 7 injection is also recommended along with supportive care in the intensive care unit [26].

Another important point concerns the deficiency of vitamin K, which is observed in newborns born to women with AGB. Cases of severe intracranial hemorrhage due to an early deficiency of vitamin K in a newborn whose mother has been diagnosed with GBV have been reported .

A recent multicenter retrospective study in China shows that male fetal sex, postpartum diagnosis of AHF, intrauterine fetal death, DIC, altered prothrombin time (PT), and activated partial thromboplastin time (APTT) can be potential factors that affect maternal complications [34].

Currently, artificial liver support therapy (ALST), which includes plasma exchange (PE) and molecular adsorbent of the recirculation system (MARS), is relevant. It is believed that the effect of ALST occurs due to the removal of circulating endotoxins, replacement of normal coagulation factors and proteins, stopping coagulopathy and, finally, improving liver function [25].

N-acetylcysteine (NAC), a precursor of glutathione, has some success in patients with Non Acetaminophen-induced acute liver failure, due to its anti-inflammatory, antioxidant, inotropic and vasodilator effects, which contribute to the improvement of vital microcirculation and oxygenation survival, as reported by Mumtaz K. Et al.[34].

A prospective study of 47 patients with this disease showed that new treatments such as plasmapheresis and the use of activated protein C were practiced in specialized centers, with variable results. Plasmapheresis, apparently, can be a promising treatment option for patients with AHFS, since it partially replaces liver function by removing ammonia, endotoxins, bilirubin, and inflammatory cytokines from maternal circulation .

Preeclampsia Preeclampsia is a multisystem disorder that affects 5 to 10% of all pregnant women, in some cases it develops multiple organ dysfunction syndrome, causing impaired renal and central nervous system function, hematological and liver dysfunctions. The disease can progress, causing microangiopathy, which mainly affects the kidneys, liver and brain. Thrombocytopenia, liver dysfunction, microangiopathic hemolytic anemia, acute renal failure, placental abruption, visual impairment, stroke, convulsions and maternal mortality are serious consequences of preeclampsia[7].

Preeclampsia is a complication of pregnancy, characterized by a deep violation of the functions of vital organs and systems, including the liver, which, depleting its reserve capacity as pregnancy progresses, becomes more vulnerable. The liver is a target organ in severe forms of preeclampsia. Preeclampsia is accompanied by severe dyslipidemia: the content of triglycerides of unesterified fatty acids (NEFA), total cholesterol, very low density lipoproteins (VLDL), low density lipoproteins (LDL) is much higher, and the level of high density lipoproteins (HDL) is lower than in uncomplicated pregnancy. Preeclampsia is characterized by a more pronounced than with a normally developing pregnancy, the appearance of unique, different from VLDL, lipoproteins loaded with triglycerides. Perhaps such an overload is associated with an increase in insulin resistance, a decrease in the intensity of β-oxidation in the liver, or a decrease in the activity of triglyceride catabolism due to inhibition of LP-lipase by cytokines.

Dyslipidemia, against the background of a decrease in the content of antioxidants in the blood, predisposes to the development of endothelial dysfunction. NEZHK, having high toxicity, contribute to the formation of free oxygen radicals. A possible mechanism explaining a significant increase in the level of NEFA during preeclampsia is an increase in the content of lipophospholipase in maternal blood flow. Its source in violation of trophoblast invasion is microvillosis membrane. [4].

Angiogenic markers have been identified and can confirm the diagnosis of PE in women without hypertension or proteinuria. These include a decrease in placental growth factor, an increase in serum soluble endoglin, and an increase in the soluble VEGF receptor[35].

However, the identified biomarkers and risk factors for the development of PE are only modestly predictive.

In PE, a generalized spasm of the vessels is observed, which leads to an increase in systemic vascular resistance and a pressor reaction to endogenous vasoconstrictors. Damage to vascular endothelium leads to the deposition of platelets and fibrin in the sinusoids, causing hepatocellular necrosis and hemorrhage in zone 1. Detection of necrosis and hemorrhage in zone 3 is associated with shock in severe preeclampsia. In mild cases of preeclampsia, a moderate increase in serum

AST/ALT/alkaline phosphatase is observed, as well as minor signs of DIC with thrombocytopenia. Jaundice is rare, but in its presence it manifests itself as a terminal and hemolytic reaction in its etiology, and the total serum bilirubin often does not exceed 6 mg/dl[33,37,38].

Conjugated bilirubin, albumin, and PT tend to remain normal. Liver damage, consisting of spasm of capillaries of liver tissue and fibrin deposition within the portal and periportal regions of the liver lobules, can lead to lobular ischemia and necrosis of hepatocytes.[6].

In earlier studies, it was shown that LCHAD mRNA, protein expression, and enzyme activity were reduced in the placenta of pre-eclampic patients. In addition, a decrease was found in mitochondrial oxidation of long chain fatty acids in the placenta obtained in patients with preeclampsia compared with the control group, which indicates that a decrease in the oxidation or defect of placental fatty acid in LCHAD may contribute to the pathogenesis of preeclampsia. Maternal AFLP is highly associated with fetal transfer and LCHAD enzyme deficiency [30].

Since one of the leading values in the pathogenesis of preeclampsia is given to microcirculatory disorders, which, in turn, lead to multiple organ failure, the liver, as an organ with a developed capillary system, is always more or less involved in the process of tissue hypoxia and microcirculatory disorders, the degree of which Depends on the severity of preeclampsia. Currently, impedance hepatography is one of the most sensitive functional method for examining the liver, revealing a violation of microcirculation, which occurs even before the increase of biochemical parameters. This method gives information about blood supply and microcirculation in the liver, about sinusoidal blood flow, the indicators of which correlate with data on morphological changes in liver tissue and its functional disorders. Of course, laparoscopy and puncture biopsy of the liver are invasive and unsafe diagnostic method for pregnant women with preeclampsia. In addition to impedance hepatography, there are also other non-invasive, safe method - such as ultrasound, dynamic hepatobiloscintigraphy and the study of the reticuloendothelial system (RES). The ultrasonic method allows you to evaluate the size of the liver, gall bladder, the presence of obvious pathological conditions - subcapsular hematoma of the liver, and also using echodsitometry it is possible to determine different sections of the density in the liver tissue, which is a criterion for fatty hepatosis. Dynamic hepatobyl scintigraphy is a functional morphological radionuclide study of the liver using a 99mTc-HIDA radionuclide. A feature of the drug is a low radiation load on the patient (0.2 m), which does not limit its use even in pediatric practice. This method allows a comprehensive assessment of both the functional and morphological state of the hepatobiliary system. The most diagnostically difficult cases are severe liver pathology during pregnancy, which are manifested by hepatocellular insufficiency syndrome and in which there is no correlation with the severity of preeclampsia. So, in 40-60% of cases of severe forms of liver pathology associated with pregnancy, there was no classical triad of symptoms characteristic of preeclampsia. So, with HELLP syndrome, an increase in blood pressure up to 160/100 mm. Hg. Art. met from 26-56% of cases, edema was recorded in 55% of patients, pronounced proteinuria - 85% of cases, in some cases, manifestation of preeclampsia occurs in childbirth, followed by rapid progression of clinical symptoms, the development of DIC and severe liver pathology. The manifestation of the complete HELLP syndrome against the background of severe preeclampsia and eclampsia was established in 53.5% of cases [39].

Finally, PE has been recognized as a marker for future cardiovascular disease, given the common risk factors, persistent endothelial dysfunction, and damage to the target organ. In the examined cohort, women with liver dysfunction due to PE and HELLP had a previous history of hypertension and diabetes mellitus, and were more prone to the subsequent development of metabolic disturbances [18].

Obstetric complications in PE include fetal growth restriction syndrome (10–25%), placental abruption, premature birth (15–65%), and fetal death. The condition of the maternal liver associated with preeclampsia/ eclampsia does not require special treatment, and the medical approach is based on the regulation of blood pressure, the reduction of concomitant symptoms and the timely treatment of seizures. After 37 weeks, women with preeclampsia should give birth. If in severe cases a deterioration of the fetus or mother is observed, childbirth should be taken in a period of 24–34 weeks [6].

HELLP syndrome: The term HELLP syndrome was first proposed in 1982 by L. Weinstein. This acronym includes: Hemolysis - the appearance of free hemoglobin in serum and urine; Elevated Liver enzimes - increased levels of AST, ALT; Low Platelets - Thrombocytopenia.

HELLP syndrome occurs in less than 1% of all pregnancies, but in 20% of pregnancies complicated by severe symptoms of PE. HELLP syndrome can occur during urgent delivery (18%), premature birth (53%) or after childbirth (30%). Risk factors include a family history of HELLP syndrome and preeclampsia or HELLP in previous pregnancies, occurring in 10–20% of patients.

Laboratory data are important for determining intravascular hemolysis, peripheral smear schistocytes, elevated FPP (usually ALT), and low platelet counts. All three HELLP elements must be observed in a pregnant patient before they are diagnosed. The level of serum aminotransferases can be increased by more than ten times. At the same time, unconjugated hyperbilirubinemia due to hemolysis may be present.

The pathogenesis of the HELLP syndrome is not entirely clear, but there is probably an abnormal development of the vascular system of the placenta and new defects in the endothelial cells of the mother's blood vessels, which leads to poor perfusion in various organs. Less commonly, LCHAD deficiency in the fetus is involved in its pathogenesis .

Insufficient immune tolerance leading to fetal trophoblast damage in early pregnancy is probably the initial sign of HELLP. Endothelial trauma and fibrin deposition may cause the HELLP microangiopathic process. As a result, hemorrhage and liver necrosis may develop. Maternal risk factors include a high body mass index, treatment for infertility, a history of preeclampsia or HELLP. HELLP syndrome may be the initial manifestation of antiphospholipid syndrome [9]. The main pathophysiological changes in HELLP syndrome occur mainly in the liver. The main link in the development of the syndrome are disorders in the hemostatic system due to damage to the endothelium and intravascular activation of the coagulation system. Deposition of fibrin in the sinusoidal capillaries of the liver leads to central necrosis with the formation of stasis and tension of the glisson capsule. Further progression of the process can lead to rupture of the liver. Subcapsular hematomas and liver ruptures more often occur with prenatal manifestations of the HELLP syndrome. Spontaneous liver ruptures are characterized by high maternal mortality (over 50%). If this vicious circle is not interrupted in time, then within a few hours, DIC develops with fatal bleeding.

Immunohistochemical analysis of the liver with HELLP syndrome showed the presence of large amounts of leukocyte elastase and TNF-α in the area of hepatocyte necrosis, which indicates the role of these factors in liver damage[4].

In approximately 65% of cases, pain is observed in the right upper quadrant of the abdomen or epigastrium, in 35% - nausea and vomiting, in 30% - headache, less often - bleeding and jaundice. In a significant number of cases of HELLP syndrome, pregnant women have no complaints. 85% of patients have an increase in blood pressure. Proteinuria is often found [3]. Excessive weight gain and edema precede the development of HELLP syndrome in 50% of cases.

The pathogenesis of HELLP syndrome has much in common with the pathogenesis of preeclampsia, DIC, and AHFS, which is reflected both in clinical manifestations and laboratory signs, as well as in the morphological picture of liver damage. Such mechanisms include impaired tone and vascular permeability (vasospasm); neutrophil activation, cytokine imbalance (increased levels of interleukin IL-10, IL-6 receptor and transforming growth factor β3 (TGF β3), and the concentration of CCL18, CXCL5 and IL-16 is significantly reduced); fibrin deposition and microthrombosis in microcirculation vessels; increased activity of plasminogen activation inhibitors (PAI-1); violation of the metabolism of fatty acids (long-chain deficiency of 3-hydroxyacylCoAdehydrogenase long chain 3-hydroxyacyl dehydrogenase) (LCHAD), characteristic for fatty hepatosis. Antiphospholipid syndrome and other variants of thrombophilia, various genetic abnormalities that play a role in the development of preeclampsia are of great importance in the development of HELLP syndrome. These anomalies are associated with the presence of polymorphism of genes encoding components of the lipid metabolism system (LPL, ApoE, LCHAD), antioxidant protection (EPHX, LPL, CYP1A1, SOD), immunological protection (HLA-G, TNFα (TNFα), IL-1, IL-10, CD14 receptor, CTLA-4), hemostatic systems (FVL, MTHFR, prothrombin, CBS, PAI-1, GP-IIIA, FXIII, FXVII, fibrinogen), placental factors (STOX1, SERPINA3, ACVR2, IGF- I, IGF-II), and factors involved in the regulation of vascular tone (AGT, ACE, AT1R, REN, PRCP, eNOS, ET-1, ER, Flt-1, ENG, VEGF, PIGF) .

HELLP syndrome usually develops in the third trimester or after childbirth and is associated with increased complications: as maternal (placental abruption, disseminated intravascular coagulation, hematoma and rupture, and acute kidney damage) and newborns (prematurity and low birth weight).

The clinical picture of HELLP syndrome varies greatly. The clinic may be asymptomatic or may appear with symptoms such as pain in the upper right quadrant of the abdominal cavity, enlarged liver, nausea, vomiting, jaundice, or confusion.[41].

Although the etiopathogenesis of this condition remains unclear, histopathological findings in the liver show intravascular deposition of fibrin, which is likely to result in hepatic sinusoidal obstruction, increased intrahepatic pressure followed by liver necrosis, intraparenchymal and subcapsular hemorrhage, and, ultimately, capsule rupture.

In a large retrospective cohort study involving 442 pregnancies complicated by HELLP syndrome, maternal mortality was 1.1%. The clinic is similar to VCB (intrahepatic cholestasis of pregnant women), prematurity remains the most common risk associated with complications from the fetus. According to Gul et al., 72 cases of perinatal mortality accounted for 34% before the 32-week gestation period and 8% after 32 weeks [29].

Cholelithiasis: Gallstone disease (cholelithiasis) is the second most common indication for surgery during pregnancy. Acute cholecystitis can occur in 20% of women under 40 years of age [43].

Risk factors for gallstone disease include an increased body mass index (BMI) (> 25 kg/m2), it is confirmed that 2.7% of women with normal BMI developed gallbladder disease before pregnancy, compared with 11% in women with obesity.

Gallstones are more common during pregnancy because the secretion of cholesterol increases compared with bile acid and phospholipids, thereby causing supersaturated bile. In addition, the volume of the gallbladder increases and emptying decreases, thus leaving an oversaturated bile in the gallbladder with the possible formation of gallstone [8].

Another mechanism suggests that while estrogens increase cholesterol secretion, progesterone decreases the secretion of soluble bile acids, and this contributes to the accumulation of insoluble bile acids predisposing to stone formation [44].

Biliary sludge and gallstones are diagnosed using ultrasound. Biliary sludge, also known as microlithiasis, is described as low-level echoes that shift when position changes and do not have an acoustic shadow, while gallstones have high-level echoes larger than 2 mm in size after postacousticshading[8, 45].

Symptomatic cholelithiasis may have typical signs of biliary colic in the upper right quadrant or epigastrium, abdominal discomfort, bloating, nausea.

Asymptomatic gallstones are found in 3.5% of pregnant women, and in 90% of cases they caused cholecystitis during pregnancy. Despite the predisposition to the formation of bile sludge and stones during pregnancy, cholecystitis occurs in only 1% of pregnant women [46]. Adverse obstetric outcomes include spontaneous abortion and premature birth.

Serious complications are cholangitis, sepsis, jaundice, cholelithiasis, pancreatitis, perforation and the formation of an abscess. In the absence of serious complications, conservative treatment is the initial option with normalization of bowel function, analgesics (opioids or non-steroidal anti-inflammatory drugs) and broad-spectrum antibiotics.

Nonsteroidal anti-inflammatory drugs should be used with caution after 32 weeks because of the risk of developing oligohydramnios and narrowing of the ductus arteriosus. Preferred antibiotics include cephalosporins and clindamycin. However, some researchers believe that a conservative approach is associated with higher relapse rates from 40% to 70%.

A study performed by Jelin shows a higher risk of fetal death (7%) was observed among patients who underwent conservative treatment, compared with patients who underwent laparoscopic cholecystectomy (2.2%).

In case of complications due to common bile duct stones, such as cholangitis or pancreatitis, endoscopic retrograde cholangiopancreatography with sphincterotomy and stone removal is a safe method with minimal risk of exposure to fetal ionizing radiation. Optional cholecystectomy can be performed after childbirth.

A review comparing conservative and surgical treatment for gallstone disease showed multiple remissions in the group that received non-surgical treatment, with 27% of them eventually having surgery, 19% in the first, 60% in the second and 10% in the third trimester. The frequency of preterm birth (3.5% and 6%) and fetal death were 2.2% and 1.2%, respectively. Cholecystectomy is recommended in the second trimester, due to the risk of termination of pregnancy in the first trimester and the risk of premature birth in the third trimester [48].

Cholecystitis: Diseases of the biliary system occupy one of the leading places among diseases of the digestive system and are found mainly in young people[3]. Chronic cholecystitis is one of the most common human diseases, takes third place after cardiovascular disease and diabetes. According to the VI World Congress of Gastroenterologists, 10% of the world's population suffers from chronic cholecystitis. In developed countries, the frequency of the disease is 10-15% and doubles for every decade [49]. During pregnancy, conditions arise that impair the function of the liver and biliary tract, which is associated with an increase in the load on the liver due to the neutralization of the vital products of the fetus, the mobilization of energy resources, and the need to strengthen metabolic processes. Pregnancy becomes a provoking factor contributing to the development of the disease[3].

The main role in the development of chronic cholecystitis is played by two factors: infection and stagnation of bile due to dyskinetic disorders. The latter, as a rule, determines the clinical manifestations of the disease. Hypomotor dyskinesia is characterized by a flaccid contractile ability of the gallbladder and ducts, as a result of which an insufficient, very small amount of bile enters the duodenum. Pregnant women are characterized by hypomotor disorders, since the main hormone prevailing in the second half of pregnancy is progesterone, which relaxes all smooth muscle organs (the main physiological meaning of its action in the pregnant woman is relaxation of the uterus, obstruction of premature birth, miscarriage). The basis of hypomotor dyskinesia is insufficient, weak emptying of the gallbladder. It is motor disorders that determine the clinical manifestations of chronic cholecystitis in pregnant women, and not inflammation.

Chronic cholecystitis (XX) worsens during pregnancy in 30-35% of women, and in most cases in the third trimester of pregnancy. In 88% of cases, the disease manifests itself in pain. Depending on the gallbladder dysfunction, pregnant women complain of dull, aching, bursting or sharp pains in the right hypochondrium, radiating to the right shoulder blade, shoulder or collarbone. Along with the pain of patients, feelings of nausea, bitterness in the mouth, vomiting, heartburn, bloating, and unstable stools are disturbing. In the second half of pregnancy, 25% of women associate the appearance of pain with fetal movement[3].

Clinical and biochemical blood tests should be evaluated in pregnant women with caution, since neutrophilic leukocytosis can only be a leukemoid reaction to pregnancy[50]. Peripheral blood tests usually do not show abnormalities. In some cases, moderate leukocytosis with a shift in the leukocyte formula to the left and an increase in ESR are noted. An increase in the activity of transaminases (ALT and AST), alkaline phosphatase and g-glutamyl transpeptidase (GGT), hyperbilirubinemia, and hypercholesterolemia is sometimes found in a biochemical blood test [61].

Buddy Chiari Syndrome. Baddi-Chiari syndrome (BCS) is defined as obstruction of the outflow of hepatic veins and is sometimes associated with myeloproliferative disorders. Up to 20% of cases of BCS occur in women who took oral contraceptives, were pregnant or gave birth in the previous two months. Because pregnancy alone is a prothrombotic condition; a physiological decrease in protein S concentration may explain the increased incidence of BCS during pregnancy. These patients have a risk of exacerbation during pregnancy due to an increased concentration of female sex hormones. Clinical signs include pain in the upper right quadrant, jaundice, and ascites. Dopplerography is very important for diagnosis. Treatment includes anticoagulation at the beginning, identifying the causes of the procoagulant, and bypass or liver transplantation in extreme cases[8].

Risk factors for developing BCS include injuries, hypercoagulant conditions, myeloproliferative disorders, oral contraceptives, and pregnancy. With BCS, abdominal pain, hepatomegaly and ascites are usually observed. Doppler sonography in most cases is enough to establish a diagnosis[2].

Thus, a review of recent literature in recent years on the pathology of the hepatobiliary system in pregnant women has shown that this problem is relevant and requires further study. The development of medical

science and practice today allows you to correctly establish the type of liver pathology by applying modern research method, although some of them are invasive. However, very often the pathology of the hepatobiliary system can first manifest itself during pregnancy, which limits both diagnostic and therapeutic options. Given the importance of this problem, the influence of the pathology of the hepatobiliary system on pregnancy and perinatal outcomes, and further studies to better understand the mechanism of development of these complications are relevant.

Abstract

Background: Achilles tendinopathy (AT) describes an overuse condition which common experienced by dancers. The reason is because dance is a physical activity involving short explosive runs, turns, jumps, leaps and weight bear on metatarsal heads which forcefully contract the calf muscles and this causes more pressure on Achilles tendon. However, lack of studies on AT in dancers has been reported.

Objectives: To find out the prevalence and risk factors of Achilles tendinopathy among recreational ballet dancers.

Method: Quantitative approach, non- experimental and descriptive research design was conduct on a sample of 53 female and male recreational ballet dancers. Ages varied from 15- 30 and at least with 2 years of ballet dancing experiences were selected by purposive sampling from the ballet dance company or studios. Screening tools and prevalence sheet priority given to the subjects to fill in to select appropriate population who passed the study's inclusion and exclusion criteria. Then researcher required to palpate the Achilles tendon area to confirm the problem before distribute the questionnaire form to ballet dancers. All the data were using percentage and mode to analyze. Results: Our findings show 28.3% of the recreational ballet dancers had AT and footwear is the highest average risk factors among training duration, limited warm up and cool down, and muscle strength. Besides that, our findings also show BMI, unfamiliar choreography, training surface, medication, flexibility and lower limb abnormalities are not the risk factors that cause them to have AT.

Conclusion: AT is common among recreational ballet dancers and footwear is the highest average of risk factors among the four risk factors. These findings provide clearly

Information for dancers, teachers, sport therapists, health professionals and parents to prevent or treat the injuries more effectively and help to develop strategies aimed at reducing the prevalence of ballet injuries.

Keywords: *Achilles Tendinopathy, Ballet dancers, Calf muscle, Heel pain, Physical therapy, Questionnaire, Training surface.*

Introduction

Achilles tendinopathy (AT) describes an overuse condition[1] that causes pain, swelling and stiffness of the Achilles tendon[2] Achilles tendon is the strongest tendon in the human body connecting the heel with the calf muscles[3] . "It is used in locomotion by controlling the lowering of the forefoot to heel strikes and heel off the ground during walking and jumping"[4]. "AT results when the demand placed on the Achilles tendon is greater than its ability to function"[5] and it is common in runners, track and field and racquet athletes as well as soccer and volleyball players[6]. Besides that, Achilles tendon has been suggested for dancer one of the most sensitive parts of the body [7] because ballet dancers

Lecturer, Department of Physiotherapy, Faculty of Health Sciences, MAHSA University, Malaysia
e-mail: physioraul@gmail.com

force their turnout, leading to increased pronation in the mid foot and hind foot, dancing on pointe, on demi-pointe, or in plié are places force on the Achilles tendon. Therefore, pain and injury involving Achilles tendon are also common among ballet dancers[8]. "AT which is not limited to the athletic populations is the most frequently reported injury related to the ankle and foot in different sports" [9]. The reason is because "recreational sports activities are getting more and more popular and athletes are being pushed to enhance their performance; hence injuries in sports are increasing"[6]. Around 35% of highland dancers had tendonitis injury, 18% of ballet dancers will suffer an Achilles injury at some stage in their dance life and around 30-40% may suffer an Achilles or arch tendon damage in Irish Dance[10].Besides that, a systematic review done by Hincapie CA, Morton EJ and Cassidy JD (2008)[11] showed that the foot and ankle sustained the majority of injuries within the lower extremity and reported incidence rates are between 17% and 67%. Another study claimed that AT is considered an injury common to the dance community, although the prevalence and incidence of AT has not been specifically identified in the dance literature[12]. This condition will cause pain, swelling, weakness and stiffness of the Achilles tendon in the morning[13], impaired ability to perform strenuous activities[14] and will affect almost all the foot movements of the dancer. This condition will also result in financial outlay by the dance company[15], owing to dancers unable to dance or time loss from dance class, rehearsal, or performance[16]. Current treads on assessment are Ultrasonography, MRI, palpation, passive and active range of motion, Thompson's test and single leg calf raise[17]. Treatment for Achilles tendon injury in ballet dancers are conservative with rest, refraining from dancing, and local treatment such as ice and adhesive strapping, anti-inflammatory drugs, local injections, thermotherapy, laser therapy and stretching exercises[18]. Previous research had described several risk factors for Achilles tendon injury in Football, Cricket and Badminton Players and runners[19]. There is no evidence about whether recreational ballet dancers have the same risk factors of AT as studies on AT in recreational dancers are lacking. Achilles tendon injury will affect the dancers' ability to perform at an optimum level and will cause pain to be felt when walking or running. Therefore, it is importance to identify the risk factors in order to help develop strategies aimed at reducing the prevalence of ballet injuries and makes it clear information for dancers, teachers, sport therapists, health professionals and parents to prevent or treat injuries in recreational ballet dancers[20]. To fill the gap in the literature, population will be on recreational ballet dancers of both genders, will use purposive sampling because to minimize bias and this sampling is commonly used, moderate cost, and the sample will meet a specific objective. In addition, the questionnaire to be established by review of researcher will add in those questions which previous research had recommended getting more clear information about the risk factors.

Method

This study will utilize a Quantitative approach, non-experimental, descriptive research design to find out the prevalence and risk factors of AT among recreational ballet dancers. This study was conducted for a period of four months. The first month was allotted for proposal revisions, and acquisition of necessary permissions and approvals. The second month was the implementation of the study. The third month includes data collection, preparation and analysis and the final month covers the writing of the results and final paper presentation. Before starting the procedure, the researcher sends the informed letter to the Dance Company to get the permission to conduct the study. An informed consent form (IFC) will be provided to each subject stating their willingness to participate in the study. During the study, researcher give priority to the screening tools and prevalence sheet to all the dancers who are willing to give consent to select the appropriate population who passed the study's inclusion and exclusion criteria. After selecting the dancers who are suitable to conduct this study, Achilles tendon area was palpated to confirm the problem. The questionnaire will be given to the dancers at that movement. On the questionnaire dancers will indicate the BMI, training hours in a week, unfamiliar choreography, duration of warm up, stretching and cool down exercises, type of floor surfaces, shoes type during practice, medication history, flexibility, foot posture, and calf muscle strength. The instrument utilized in this study is purely questionnaire-based. A self-developed questionnaire was adopted from researchers whom carried out similar studies. To enhance content validity, experts in Kinesiology, Growth and Development and Physical Therapy reviewed the questionnaires and then the questionnaires were adjusted based on their recommendations. The measures used to determine the factors influencing the likelihood of sustaining an injury were one questionnaire. The one questionnaire administered by the researcher were factors of AT. To develop content reliability, a pilot test will be

conducted on 6 female or male dancers aged 15- 30. Upon completing the questionnaire, the dancers were asked to identify any question they found unclear or confusing. The questionnaire was then adjusted thereby making it easier to understand for the participants in the study. After 2 weeks, the questionnaire was conducted again on the same dancers to prevent the recall bias and enhance the reliability. The screening tools and prevalence sheet also provided to obtain the subject's name, age, gender, ethnic, occupation, company/studio name, ballet grade/level, and number of years in ballet dance, any Achilles tendon injuries/pain, and symptoms of AT, time of injury, doctor diagnosis, surgery history on lower extremity, history of joint instability, details of treatment received, and any other musculoskeletal disorder. All descriptive information was analyzed using measures of central tendency such percentage and mode as measure of dispersion. The statistical treatment of data used Statistical Package for Social Sciences (SPSS) v Version 24.

Results

A total of 108 recreational ballet dancers were recruited and 53 subjects met the inclusion criteria. A total of 53 (100%) female subjects with age range: 15-19 years (n=42, 79.2%), 20-24 years (n=9, 17%), 25-30 years (n=2, 3.8%) participated in the study. Figure 3.1.1 shows the prevalence of Achilles tendinopathy was 28.3% (15/53) among recreational ballet dancers. A number of extrinsic and intrinsic risk factors have been identified in Table 3.1.1 for ballet dance related AT, including BMI, training duration, unfamiliar choreography, limited warm up and cool down, training surface, footwear, medication, flexibility, lower limb abnormalities and muscle strength. Not only that, Figure 3.1.2 shows footwear is the highest average of risk factors (57.77%) among training duration, limited warm up and cool down, and muscle strength. The BMI of 53.3% (n=8) recreational ballet dancers were under normal weight status (18.5- 24.9) which clearly shows that most of the ballet dancers are under normal weight status. For the training duration of recreational ballet dancers, 40% (n=6) dancers usually practiced 0-3 hours of ballet dance per week. However, before they were injured 46.7% (n=7) of dancers practice more than 9 hours of ballet dance per week. During the period to cope with exam or competition or performance, 46.7% (n=7) of ballet dancers practiced more than 9 hours per week. This result shows that there was a sudden increase of training duration., For the unfamiliar choreography, 60% of recreational ballet dancers do not feel difficulty in moves in the choreography will cause them to get injured. The result of limited warm up and cool down shows that, before ballet dance there are 7 (46.7%) of recreational ballet dancers use 0-5 minutes to warm up and 7 (46.7%) of dancers use 5-10 minutes to do stretching exercise. However, after the ballet dance 7 (46.7%) of dancers do not perform any cool down or stretching exercises. These results clearly indicated that there is a limited duration of warm up and stretch before ballet dance and lack of cool down exercises after ballet dancing. Next, the result of training surface showed that 13 (86.7%) of recreational ballet dancers are using sprung wood as a floor surface during practice time in studio and there are 13 (86.7%) dancers get injured on ballet studio instead of examination hall, competition area or home practice. For the footwear, 53.3% (n=8) dancers usually wear soft shoes for practice whereas for the shoes that causes pain on Achilles tendon, there are 60% (n=9) dancers having pain when wearing pointe shoe to dance. About the tightness of the shoe ribbon, 60% (n=9) dancers proper fit to tie the shoe ribbon. The result of medication shows that 15 (100%) of recreational ballet dancers do not take any medication like OCP, HRT, Fluor quinolone antibiotics, high blood pressure medication, and DM medication. The result of lower limb abnormalities and flexibility shows that 53.3% of recreational ballet dancers have normal foot posture in standing upright position. 66.7% of dancers having normal hamstring flexibility and 53.3% of dancers having normal calf flexibility. Therefore, most of the recreational ballet dancers are having normal foot posture and flexibility. The muscle strength of 33.3% (n=5) recreational ballet dancers able to do 20-24 single heel rises on right side, which clearly indicate the weakness of the right lower limb muscles, although 33.3% (n=5) recreational ballet dancers are able to do more than 25 single heel rises on both sides.

Discussion

In the present study, 53 recreational ballet dancers with age range from 15-30 have completed the questionnaire. The aim of this study was to investigate the prevalence and risk factors of AT among recreational ballet dancers. In this descriptive study, the prevalence rate of 28.3% was observed which suggests that AT is common among the recreational ballet dancers because this result is higher than the prevalence in ballet dancers done by Hullachan (2008) where a prevalence of 18% was reported. Regarding the BMI of the respondents in

this study, most frequently recreational ballet dancers (53.3%) are under normal weight status and none of the dancers are overweight or obese as this indicate that BMI is not the risk factors of AT among recreational ballet dancers. This result agrees with a prior study by Longo, U.G., et al. 9) which reported that weight and height did not have influence in the development of AT. Another study by Franceschi, F., et al. (2014) also stated that, significant associations found for AT in people who were overweight or obese compared to normal weight. Furthermore, previous research stated that unfamiliar choreography is one of the contributing factors to AT because they have "insufficient time to become accustomed to the movements and fine-tune their technique accordingly". Although difficulty choreography will cause AT, but according to our findings, most of the recreational ballet dancers (60%) do not feel difficulty in the moves. Therefore, unfamiliar choreography is not one of the risk factors of AT among recreational ballet dancers. Based on the result of this study, training surface is not one of the risk factors of AT among recreational ballet dancers because most of the dance floor they commonly used for practice is sprung wood. According to Motta-Valencia, K. (2006), sprung wood as a floor surface during practice are advantageous for dancing because they are built with layers of different materials and a specific resiliency. Hence, the most important properties of ballet dance surfaces are resiliency, surface friction and shock absorption. The reason that causes them more prone to overuse injuries is the floor material which lack of spring. According to the result of current study, most of the dancers are having normal flexibility therefore flexibility is not one of the risk factors of AT. The reason is because normal flexibility in the hamstring and calf muscles will not cause tension in the Achilles tension and impact the functioning of ankle joint. A study done by Rabin et al shown that limited flexibility of the gastrocnemius and soleus increases absorption work by the plantar flexors during walking and running, which may lead to increased strain on the Achilles tendon. Another study by Miller and Royal Surrey County Hospital (2017) stated that having poor flexibility like tight calf muscles and/or hamstring are the causes of AT. In this report, most of the dancers are having normal foot posture instead of flat arch in standing upright position. This result indicates that lower limb abnormities is not one of the risk factors of AT among recreational ballet dancers because normal foot posture does not lead to an increase torsional stress on Achilles, whereas flat arch foot posture prone to Achilles tendonitis. According to Carey, Achilles tendon has been stressed due to the flattened arch pulls on calf muscles and it will cause the tendon to become inflamed and painful if continuous stress applied on the heel and tendon. Another studies by Footbionics also found that there was a correlation between excessive pronation and increased strain on the medial portion of the tendon. "People who taking medicines from a group called fluoroquinolones will have an increased risk of developing AT. It is also more common in people who have high blood pressure, high cholesterol or diabetes". The reason is because fluoroquinolone antibiotics have toxic effect that may cause tendonitis or spontaneous rupture of the Achilles tendon. However, current study find out that 100% (n=15) of recreational ballet dancers do not take any medication like OCP, HRT, Fluoroquinolone antibiotics, high blood pressure medication, and DM medication. Therefore, medication is not one of the risk factors that caused them to have AT. In current study, most of the recreational ballet dancers are having limited duration of warm up and stretch before ballet dance and lack of cool down exercises after ballet dancing. This result clearly indicates that limited warm up and cool down are one of the risk factors of AT among recreational ballet dancers because each of the dancers do not take about 15 minutes for warm up before the class and cool down after the class and also stretching exercises. According to a study done by Malliou, P., et al. (2007), there is an important co-relation between the rate of injuries and the duration of the warm up and cool down because the result shows that, the number of injured instructors appears significantly smaller when they take part in warm up and cool down about 15 minutes. Another study by Woods also stated that, before beginning the activity, a warm up and stretching protocol should be applied within 15 minutes in order to increase blood flow to the tissues, reduce injury and increased flexibility. Furthermore, training duration is also considered one of the risk factors of AT among recreational ballet dancers because in present study result shows that there was a sudden increase of training duration from about 3 hours ballet dance per week to more than 9 hours per week during the season to cope with exam or competition or performance. This result agrees with prior study that dancers are having risk of sustaining an injury when dance more than 8 hours per week due to overwork and fatigue. Martin, S. also claimed that pre-professional dancers are especially easily to get Achilles tendonitis when they increase their training, like starting a summer intensive.

In another study which done on runners by Hein, T., et al. (2014), overtraining is described as a major risk factor for AT, including excessive training distance, changes in training routines, increases in training intensity and faster training pace. Besides that, footwear is also one of the risk factors of AT because current study result shows that most of the dancers are feeling pain on Achilles tendon when wearing pointe shoe for practice. Pain is noticeable when wearing pointe shoe because "Achilles tendon is stressed when on pointe or demi pointe due to the forceful contraction of the gastrocnemius and soleus muscles". However, for the tightness of the shoe ribbon, current study result shows that most of the dancers are proper fit therefore shoe ribbon is not excessively tightened around the ankle which do not cause further compression on Achilles tendon . Muscle strength is also one of the risk factors of AT among recreational ballet dancers because 33.3% dancers are unable to perform more than 25 single heel rises on right sides although another 33.3% of dancers are able to do more than 25 single heel rises on both sides. This result clearly indicates that there was reduced muscle strength over the right lower limb. There are many reviewed articles have reported 25 raises for a general healthy population but as a recreational ballet dancer more raises should be performed for both lower limb. The reason is because the dancer spends a good deal of time with releve (ankle plantar flexed) movement, therefore more raises to perform is important for dancers to improve the calf muscle strength and prevent more stress on Achilles tendon and lead to AT. Mahieu, N.N., et al. (2006) showed increased risk of AT with reduced plantar flexion strength in the calf muscles due to decreases of the ability of the Achilles tendon to absorb high forces during intense stretch-shortening cycles. Our findings clearly demonstrated that training duration, limited warm up and cool down, footwear and muscle strength are the risk factors of AT among recreational ballet dancers whereas BMI, unfamiliar choreography, training surface, medication, flexibility and lower limb abnormalities are not the risk factors that cause them to have AT. Furthermore, results also have shown that footwear is the highest average risk factors (57.55%) among the four risk factors. The weakness of the current study is unable to recruit male recreational ballet dancers and small number of samples collected in the study because most of the male dancers are participating in other dance forms besides ballet dance. On the contrary, major strength of current study is the fact that information was collected by questionnaires form which has validity and reliability. The questionnaires form also been established by review of researcher with reference to recommendation of previous study. Besides that, subjects also able to answer the questionnaires themselves without any incomplete data or claimed that they do not understand the questionnaire. Secondly, our study clearly provided a preliminary data on the prevalence and risk factors of AT among recreational ballet dancers where previous study was mentioned there was a lack of studies on AT among ballet dancers.

Conclusion

In a nut shell, 53 recreational ballet dancers in age range from 15 to 30 are participated in this study with completed the questionnaire which establish by researcher. We found that AT is an overuse condition which commonly reported among recreational ballet dancers with the prevalence rate of 28.3%. A number of extrinsic and intrinsic risk factors have been identified in this study such as BMI, training duration, unfamiliar choreography, limited warm up and cool down, training surface, footwear, medication, flexibility, lower limb abnormalities and muscle strength but our findings clearly demonstrated that training duration, limited warm up and cool down, footwear and muscle strength are the risk factors of AT among recreational ballet dancers. Besides that, among this four risk factors, footwear is the highest average of risk factors (57.55%) for AT. According to this findings, it indicates the risk factors of AT among recreational ballet dancers and shows the highest average of the risk factors among the four risk factors of AT which provide clearly information for dancers, teachers, sport therapists, health professionals and parents to prevent or treat the injuries more effectively and help to develop strategies aimed at reducing the prevalence of ballet injuries.

Abstract

Introduction: Elimination of persistent and extensive defects of the anterior wall of the trachea is one of the urgent problems and continues to be the subjects of researches and discussions of the thoracic surgeons, plastic surgeons and otolaryngologists. The authors presented the results of treatment of 118 patients with extensive defects of trachea in subglottic division of the larynx and soft tissues of the neck after laryngo-tracheostomy or tracheostomy.

Materials and Method: The authors consider that the choice of the method of plastic surgery or reconstruction of the tracheal defect is determined individually in each case. If the size of the defect of the trachea is up to 2x4 cm, the sufficient depth of the trachea lumen corresponds to the lumen above and below the stoma, the common axis of the trachea and the distal part of the larynx are without displacement and deformation of the lumen, then a skin-muscle plasty of the defect with the substitution of local tissues is recommended.

Results: Local three-layer or four-layer skin-muscle plastic operations were performed in patients with defect sizes from 1.0 sm to 2.0 sm wide and from 2.0 sm to 4.0 sm long, with a defect depth of more than 8 mm, i.e. anterior-posterior size of the tracheal lumen and a stable formed lumen of the respiratory tract in the zone of plastic contraction without the presence of a protector (T-shaped stent or tracheostomy cannula). Eleven patients with extensive defects of the anterior-lateral walls of the trachea and distal larynx underwent complex reconstructive operations using microsurgical techniques.

Conclusion: The use of displaced flaps allows: to form a mucous membrane in the defect area without tension of the lateral walls of the trachea (the first layer); to close the defect (or to cover the cartilaginous implant) with a well blood-supplied second flap. A complex-compound prefabricated flap (Delta-pectoral skin-fascial-cartilaginous flap) can be used in the presence of a persistent defect and formed tracheal lumen at this level, without signs of restenosis of the respiratory tract, in the absence of inflammation and infection of tissues around the defect. The skin-muscle-bone revascularized complexes of auto-tissues correspond all the requirements of tracheal surgery, allowing to reduce the risk of infectious and trophic complications.

Introduction

At the present time there is a tendency for increasing of the long-term ALV (artificial lung ventilation) cases, which is associated with the development of the level of resuscitation life support[1]. Concerning this fact there is an increase in the number of patients with CST (cicatricial stenosis of the trachea), so the relevance of this theme causes no doubt[2]. On the third day of the ALV in the cartilaginous half-rings of the trachea pathological changes are observed[10], which are specific for chondrolysis, sequestration and necrosis[3]. These pathological processes cause the cartilage to loss its support function, which further leads to the narrowing of the tracheal lumen[13]. The occurrence frequency of cicatricial stenosis of trachea after conducting resuscitation actions, accompanied by prolonged lung ventilation, and later tracheostomy, according to different authors' data, ranges from 1 to 25%[13]. Endoscopic examination is the main in the detection of stenotic diseases of the respiratory tract[7].

In specific CST, the main method of treatment is a circular resection of the trachea with the formation of an anastomosis for restoration of the respiratory tract integrity. If the patient has tracheomalacia, the volume of surgery intervention expands. In some cases, resection should be avoided for staged reconstructive operations with the formation of respiratory tract lumen on the T-shaped stent. Distinct respiratory disorders may require tracheostomy or endostenting. Also the implantation of auto-tissues and fixing of biocompatible ceramic rings is possible. Hybrid and biodegradable stents have been developed, but the assessment of their clinical effectiveness is not sufficient, so they are not widely used. Thus, the diagnosis of CST should be aimed at identifying not only the stenosis of the respiratory tract lumen, but also intramural changes in the tracheal wall, including tracheomalacia.

Plasty of extensive defects of the cervical trachea involves the restoration of not only soft tissue defect[12], but also mucous membrane and tracheal skeleton function[7]. The latest requires sufficient supply of wholesome skin, free of hairs, in the reconstruction zone[6]. The absence of such areas near the tracheal defect (sharp dystrophic or cicatricial changes)[2] requires the use of tissues taken from other areas of the patient's body (the formation of the Filatov's stem, the displacing of skin-fascial flaps on the vascular pedicle, autotransplantation of complex flaps on microvascular anastomoses)[4].

A large number of possible tissues and materials, as well as method for surgeries aimed at eliminating the defect[5] of the cervical trachea are proposed[11]. The main requirements for them are clearly formed: they must have sufficient size, provide a frame function and the possibility of evacuation of the discharges, as well as be resistant to infection [9]. Despite of this, the problem is relevant and continues to be the subject of researches and discussions of thoracic surgeons, plastic surgeons and otolaryngologists[14]. The choice of a method for eliminating the tracheal defect depends on its size, the depth of the respiratory tract lumen and the state of the surrounding tissue defect[8]. At a small size of the defect, with the depth of the respiratory tract more than 1.5 cm, and non-specific cicatricial process around the defect, it is possible to use local plasty[7].

Materials and Method

In the Department of Lungs Surgery and Mediastinum at SI "RSSPMCS named after acad. V. Vakhidov" in the period from 2008 to 2019, 118 patients with defects of the anterior wall of the cervical trachea were hospitalized. Previously all patients underwent the stages of endoscopic coagulation, bougienage of tracheal stenosis with the subsequent plasty of the trachea with the formation of the lumen by the T-shaped stent.

In patients with persistent extensive defects of the anterior wall of the trachea and soft tissues of the neck, with a defect size not exceeding 2 sm in width and up to 4 sm in length, a three-layer skin-muscle plasty was carried out with a simultaneous elimination of the defect by local tissues. At the presence of large defects, we use prefabricated scin-fascial and scin-muscle flaps.

Results

Local three-layer or four-layer skin-muscle plastic operations were performed in patients (n=91) with posttraheostomy defects of the anterior wall of the trachea and soft tissues, with defect sizes from 1.0 sm to 2.0 sm wide and from 2.0 sm to 4.0 sm long (Fig. 1), with a defect depth of more than 8 mm, i.e. anterior-posterior size of the tracheal lumen and a stable formed lumen of the respiratory tract in the zone of plastic contraction without the presence of a protector (T-shaped stent or tracheostomy cannula).

After plasty of the defect we performed an intraoperative fiber-optic bronchoscopy through the endotracheal tube by pulling it in subglottic part of the

larynx for visual inspection of the sutured defect. At the same time, the tightness of the created anterior wall in the form of a skin insert, the mapping of layers, the presence or absence of deformation and/or contraction of the trachea in the plastic zone were investigated.

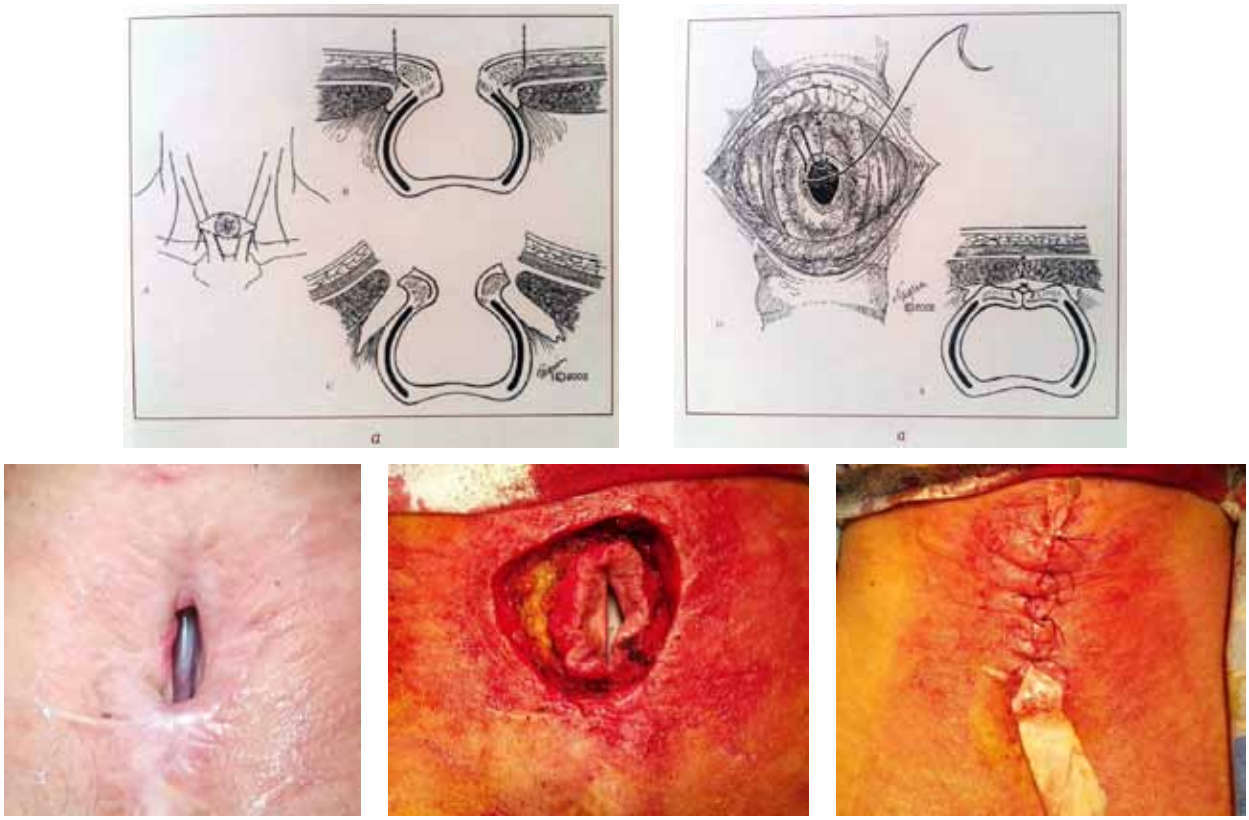

Fig. 1 Scheme and intraoperative photos of four-layer skin-muscle plastic.

Discussion

In the case of insufficiency of the sutures in local plasty, restenosis and large size of the defect of the anterior wall of the trachea, we performed plastic surgery with displaced flaps, including implantation of the autorib cartilaginous graft.

At three-layer skin-muscle and skin-muscle-cartilaginous plasty, the suturing of the muscles as a second layer often leads to a stenosis of the trachea lumen and reduces the depth of the respiratory tract in the defect area. The significant cicatricial process of surrounding soft tissues prevents the approach of the wound edges. In this case, the solution of the problem is the use of displaced flaps from the surrounding areas. The most acceptable are: lateral, upper-lateral and supraclavicular flaps.

In 11 patients with an extensive defect of the anterior-lateral walls of the trachea and the distal part of the larynx, the plasty with the use of displaced flaps on the vascular pedicle were performed. In 2 cases with defect sizes of more than 5x3 cm, the plasty was performed with the use of a pre-fabricated skin-fascial-cartilaginous delta-pectoral flap on the vascular pedicle (Table 1).

The use of the displaced skin-fascial flaps on a vascular pedicle for closure of the defect of the trachea can allow to restore the mucous membrane area of the trachea defect without the use of surrounding cicatricial tissue and cover the defect with a second flap with no tension on the wound edges.

Table 1: Plasty of tracheal defect by displaced flaps

Type of plasty	Used flaps in plasty of:		Number
	Mucosa of the trachea (first layer)	The wound defect (second layer)	
Plasty with two displaced flaps	Upper-lateral flap	Lateral flap	3
Displaced flap + free skin graft	The supraclavicular flap	Free skin graft	3
Closure of the defect + displaced flap	Skin flap from the edges of the defect	The supraclavicular flap	3
Delto-pectoral flap (DPF) + autorib cartilage	DPF skin+cartilage	Free skin graft	2

Clinical Example: Patient A., 42 years old. Diagnosis: Posttracheostomy cicatricial stenosis of the upper third of the trachea. Defect of the anterior wall of the trachea.

Patient with persistent open defect of the anterior wall of the trachea and soft tissues of the neck. The patient has previously undergone several operations: 1) plastic surgery of tracheal lumen on the T-shaped stent (14/10/2015); 2) closure of the lower 2/3 of the defect with skin-muscle plasty (03.02.2017); 3) re-stenting with a T-stent due to restenosis (29.08.2018).

This time the defect is eliminated by two stages with the use of rotational skin-fascial neck flaps. Initially, a skin-fascial supraclavicular flaps on the left and on the right were formed (12.11.2019). We raised the skin-fascial flaps and sewn back with the abandonment of rubber outlets ("biological straightening of the flap"). (fig. 2).

Figure 2. Stage 1- formation of flaps.

Figure 3. Stage II – plasty of the defect of the trachea

The next stage – the plasty of the anterior wall of the trachea by previously formed skin-fascial flaps (20.11.19).

The edges of the previously formed skin-fascial flap on the left were isolated and rotated to form the neo wall of the trachea. The sutures of the previously formed supraclavicular skin-fascial flap on the right were excised, a flap with good blood supply, was moved to the defect area without tension to close to the tracheal defect the second layer (fig. 3).

The control TBFS in the dynamics - the skin insertion is determined on the anterior wall of the trachea 2 cm below the vocal cords, hermetically. The lumen of the trachea in the defected area is wide (fig. 4).

Fig. 4 Tracheobronchoscopy 8 days after plastic closure of tracheal defect.

Clinical example of plasty of extensive defects of trachea with prefabricated delto-pectoral flap on a vascular pedicle.

Patient P., 28 years old, with a diagnosis: Cicatricial stenosis of the upper and middle third of the trachea. Extensive cicatricial defect and deformation of the anterior wall of the trachea and soft tissues of the neck. Cicatricial stenosis of the left main bronchus. Bronchiectasis of both lungs. Anamnesis: in 1992, at the age of 2 years, she was hospitalized to the regional hospital in Fergana with inflammatory process of lungs. Had an intensive care for 7 days on ALV, tracheostomy was done. In a subsequent, since 1992 up to the present time the patient has undergone multiple surgeries for cicatricial stenosis of the trachea in Moscow, Khabarovsk, at the Otolaryngology Department of the Tashkent State Medical Institute. MSCT of the thorax dated 09.06.2016: an irregular thickening of the trachea walls to 8-10 mm with stenosis of the lumen throughout a minimum diameter of 9 mm. Stenosis of the left main bronchus to 5.8 mm. Half-rings of the trachea are calcified. Due to the fact that the patient had multilevel tracheal stenosis, the defect was large and in the middle of the defect there was a connective tissue septum on the posterior wall. First, it was necessary to fix a T-shaped stent to expand the middle part and align the tracheal axis (Fig. 5). It took about 1.5 months.

a **b** **c**

Figure 5. Multifocal cicatricial stenosis of the trachea. Extensive cicatricial defect of the anterior-lateral walls of the trachea and soft tissues of the neck (a). A week after the fixing of the T-stent (b). After 6 weeks (c).

Due to the presence of extensive defect of the anterior wall of the trachea and soft tissues of the anterior surface of the neck, the plastic surgery was performed by a prefabricated Delta-pectoral flap. The size of the defect was 3 sm wide and 8 sm high, the depth of the lumen was 1.2 sm. The axis of the respiratory tract was broken, the distal division of the larynx and upper third of the trachea in the projection of the defect had the direction of the axis from behind to forward in the sagittal direction, and the middle third of the trachea in a retrosternal area had the axis direction from front to back in the sagittal direction.

We have improved the method of forming a pre-fabricated flap. As a supporting tissue in this case we had used an autorib-cartilaginous skeleton, implanted into the composition of the flap. Depending on the parameters of the tracheal defect, a part of the cartilage was taken from the area of connection of 6th and 7th ribs, according to the generally accepted technique in the plastic surgery. Subsequently the formed cartilage framework was implanted subfascially into the distal part of the delto-pectoral flap.

Stages of surgery:

Stage I. The formation of prefabricating delto-pectoral flap with implantation of autorib-cartilaginous skeleton into the distal part of the flap (Fig. 6).

a **b** **c**

Figure 6. Delto-pectoral flap marking (a). Preparation of rib cartilage (b). Condition after the implantation of rib-cartilaginous graft (c).

Figure. 7. A month after the pre-fabrication of a delto-pectoral flap with implanted cartilage before lifting and rotating the flap.

No indications of restenosis were observed for a long period during the observation. So it was decided to perform the 2nd stage of the surgery: the displacing of the previously prepared skin-cartilage flap with the closure of the lower 2/3 of the tracheal defect with the formation of the mucous membrane.

Stage II. Raising the pre-fabricated flap with the formation of a round stem. The substitution of the defect of the trachea with the restoration of the mucosal membrane (on account of the flap skin) and cartilage skeleton (on account of implanted autorib cartilage). Closure of the donor area and the fascial part of the flap with split skin (Fig. 8).

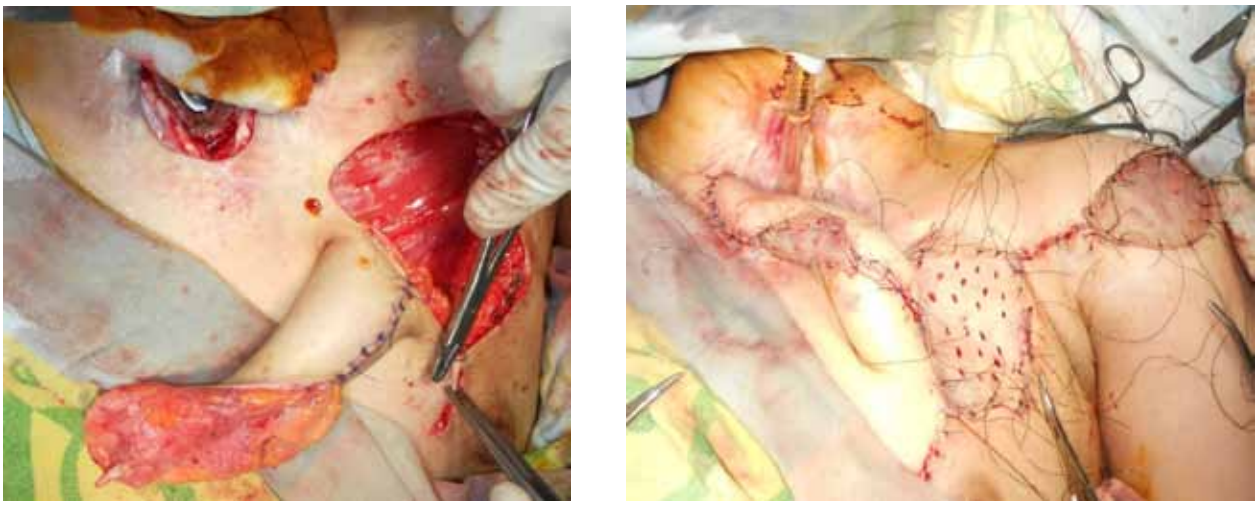

Figure 8. Raising of previously formed pre-fabricated flap. Suturing of the tracheal defect.

Stage III. The final plasty of the tracheal defect (Fig 9, 10).

Biological preparation of the flap is followed by cutting off its pedicle with suturing along the axis of the trachea from the left side and strengthening the frame by autocartilage.

On 22.12.2018 partial plasty of the defect of the trachea by pre-prepared skin-fascial cartilage flap was performed. The postoperative period proceeded without complications. Primary healing of wound was noted. Sutures were removed on the 14th day after the surgery. Diagnostic TBFS was conducted: the trachea is wide, stable. The patient was observed for a long period, indications for restenosis were not observed.

a **b** **c**

Figure 9. Biological preparation of the flap (a). Amputation of the flap (b). Suturing of the flap along the axis of the trachea from one edge (c). The arrow shows the implanted autoccartilage.

On 11.01.2009 the plasty of the residual defect of the cervical trachea under the local anesthesia was performed by suturing the fabricated delta-pectoral flap on the right side with full closure (Fig. 10).

a **b** **c**

Figure 10. Complete closure of the tracheal and soft tissue defect in 2 weeks. Before surgery (a). Suturing the flap on the right side (b). Extensive defect is completely closed by the flap.

MSCT shows that the wide lumen of the trachea is visualized with a deformation in the middle third, which does not significantly affect the passability. Inside of the displaced flap, the autorib cartilage is traced, running diagonally from left to right, crossing the longitudinal axis of the formed anterior wall of the trachea (Fig. 11).

Figure 11. MSCT of the trachea after the 3-rd stage of the surgery.

At bronchoscopic control the tracheal lumen is also wide with a deformation in the middle third, up to 11 mm in diameter in the narrowest part.

In future, it is planned to cut off excess flap tissue. Thanks to the multi-stage plastic surgery, we managed to eliminate the extensive defect of the trachea and soft tissues, because of which the patient had been suffering for 26 years and was limited both physically and mentally, and the result of it undoubtedly is the main basis for improving the quality of life.

Conclusion

Thus, the choice of the method of plasty or reconstruction of the tracheal defect is determined individually in each case. If the size of the defect of the trachea is up to 2x4 cm, sufficient depth of the trachea lumen corresponds to the lumen above and below of the defect, and the single axis of the trachea and the distal part of the larynx is without displacement and deformation of the lumen, then a skin-muscle plasty of the defect with the substitution by local tissues is used. Rotational skin-fascial flaps also can be used, including pre-implantation of the cartilage frame. The indication for the use of displaced flaps for plasty of the tracheal defect is a satisfactory depth (more than 1.5 sm) and defect size not more than 4x2 sm. With a significant cicatricial process around the defect (as a result of repeated surgical interventions) and inability to use the Bokstein method, the using of skin-fascial displaced flaps on the vascular pedicle is known to be effective.

The use of displaced flaps allows: to form a mucous membrane in the defect area without tension of the lateral walls of the trachea (the first layer); to close the defect (or to cover the cartilaginous implant) with a well blood-supplied second flap. A complex-compound prefabricated flap (Delta-pectoral skin-fascial-cartilaginous flap) can be used in the presence of a persistent defect and formed tracheal lumen at this level, without signs of restenosis of the respiratory tract, in the absence of inflammation and infection of tissues around the defect. When using displaced flap to form a mucous membrane in the area of the tracheal defect, it is advisable to use the first stage of biological preparation of this flap, which consists in its separation and re-fixation by sutures to the mother bed. The task of this stage is to strengthen the axial circulation and increase the survival of the flap. The main stage is performed on the 12-14th day after the first stage.

Abstract

Objective: Breast milk (ASI) is a nutrient that is produced from cellular secretion and transportation activities in the breast organs. The development cycle of the organ of ASI secretion begins to form from the neonate, puberty to pregnancy [1]. Until now, several assumptions that state that the production of breastfeeding of a nursing mother are influenced by various external and internal factors. External factors involve the environment, sociodemography, and even sociocultural[2].

Method: The volume of milk assessed on days 7th, 8th, 9th, postpartum. Milk volume measured through pumping using a Medela Swing Double Pump electric breast pump for 15 minutes, the weighted milk is then returned for drinking to the baby using new media (spoon or cup feeding). Sociodemographic variables, obstetric history, and lactation history were measured using an observation form, postpartum is then grouped into two groups; breastfeeding mothers with optimal and sub-optimal milk production. The relationship between variables was tested by the chi-square test and logistic regression test.

Results: Occupational variables ($p < 0.049$; OR = 2.61), initiation of early breastfeeding ($p < 0.022$; OR = 2.73), frequency of breastfeeding ($p < 0.003$; OR = 4.62), duration of breastfeeding ($p < 0.018$; OR = 2.76) demonstrates relationship with milk volume.

Conclusion: This research succeeded in proving several external factors such frequent and timing that supported the mechanical mechanism of breast milk production.

Keywords: *Early Breastfeeding Initiation; Breastfeeding Barrier; Breastfeeding Duration; Milk Volume.*

Introduction

Breast milk is a nutrient produced from the activity of cellular secretions and transportation of the breast organs. The development cycle of the organ of ASI secretion begins to form from the neonate, puberty to pregnancy.[1] Several assumptions state that various external and internal factors influence the production of breast milk for a nursing mother. External factors involve the environment, sociodemography, and even sociocultural.[2] Internal factors involve psychosocial, cognitive, affective, obstetric, and biological history.[3]

Extensive work to establish factors that affect timing and initiation of breastfeeding. Various studies have shown that breastfeeding predictors differ around

the world. Notice in Australia, Iceland, Ireland, Scotland, and the US that breastfeeding rates are higher among older women with higher education.[4] Besides, higher-income is also associated with high rates of breastfeeding in countries such as Sweden[5], and rural Jamaica.[6] By comparison, a study in Zhejiang China that examined breastfeeding initiation and prevalence found that younger mothers with lower education and family income were more likely to breastfeed.[7] According to Kogan, breastfeeding rates depend on multiple factors, including socio-economic and demographic factors. Mother's age, employment, income and not smoking contribute to higher breastfeeding rates.[8]

There are many reasons mothers chose not to breastfeed their children. Fear of pain, physical distress, lifestyle constraints, and embarrassment have all described as reasons a woman prefers not to breastfeed.[9] The most common reason that is also a factor for mothers not giving breast milk is the lack of milk production. Mother's causes before age 6 could be more linked to maternal factors. Community factors constitute 20% of mothers' reasons to avoid exclusive breastfeeding. Community help is one reason mothers avoid early breastfeeding. Some studies also shown that mothers consider social support as a more important factor than health care.[10] Often, insufficient support from family, friends, and health providers may be a cause for women to choose not to breastfeed or quit breastfeeding.[11] Therefore, this study aims to see whether there is a difference in milk production between all the risk factors mentioned, namely, sociodemographics, obstetrics, and lactation history.

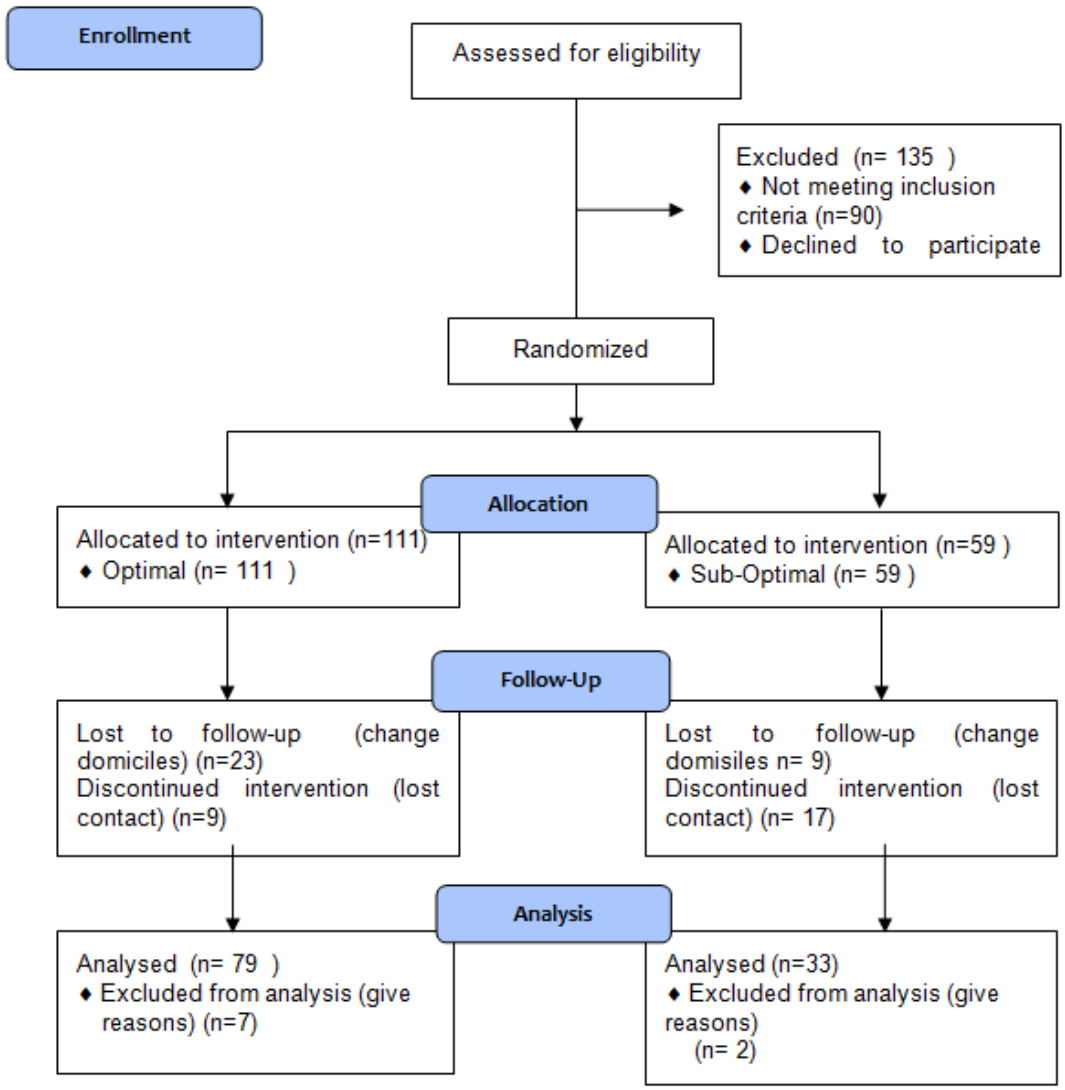

Figure 1: Flow Diagram of the medical research ethics

Methodology

Samples: Mothers who met the inclusion criteria, namely third-trimester vaginal delivery, had no history of pregnancy complications or risky, delivered at the study site, willing to be observed until the study period ended. Mothers who are willing to participate sign an informed consent accompanied by their respective families. Collection of variables, including sociodemographic characteristics, obstetric history, and lactation history, were measured using an observation form at the beginning of recruitment at the final antenatal care examination. The volume of milk assessed on days 7, 8, 9, postpartum.

Statistical Analysis: This study uses a cross-sectional study design. A total of 113 research samples were selected purposively at two primary healthcare clinics (Kassi-Kassi and Jongaya Clinic) with a large number of visits of pregnant women with relatively low coverage of exclusive breastfeeding in the city of Makassar, South Sulawesi, Indonesia in the month of April-December 2019.

Milk volume measured through pumping using a Medela Swing Double Pump electric breast pump for 15 minutes, the weighted milk is then returned for drinking to the baby using new media (spoon or cup feeding). The volume of milk is calculated and multiplied by the frequency of breastfeeding for three days and then averaged. The measurement results classified into two; optimal breast milk production ≥ 440 ml/day and sub-optimal <440 ml/day[12].

Sociodemographic variables (age, education, occupation), obstetric history (parity, baby birth weight, sex), and history of lactation (initiation of early breastfeeding, frequency of breastfeeding, and duration of breastfeeding) were analyzed using the chi-square test. Multivariate logistic regression analysis used to assess which risk factors were correlated with the amount of milk. The medical research ethics committee approved all research procedures of the Medical Faculty of Hasanuddin University number 171/UN4.6.4.5.31/ PP36/2019.

Results

A total of 113 participants who were successfully analyzed depicted in table 1. The sociodemographic variables referred to in this study include age, education, and occupation. Education transformed into two categories; higher education equivalent to DIII and S1, low equivalent to elementary, junior high, high school. Work also transformed into two categories into work and non-work. Bivariate analysis demonstrates insignificant relation on several sociodemographic variables, except for job ($p<0.049$).

Working is one of the common barriers to breastfeeding for many breastfeeding mothers. Parting with the baby will reduce the frequency and duration of breastfeeding. Although alternative milk pumps exist, not all biological reflexes replaced with mechanical stimulation. The odd ratio shows that mothers who do not work have a volume of milk production 2.61 times more than mothers who work.

*Chi Square Test alternatif Fisher's Exact Test

Obstetric variables in this study include parity, baby sex, baby birth weight. These three variables are not significant for milk production. Lactation variables include the history of Early Breastfeeding Initiation, frequency of breastfeeding and duration of breastfeeding. All three showed a positive significance with milk production. Mothers who give birth and get Early Breastfeeding Initiation are at least 2.73 times higher potential to produce more milk volume than those who do not get Early Breastfeeding Initiation. Mothers who breastfeed more often (more or equal to eight times per day) have a potential of 4.62 times to produce more milk volume than mothers who breastfeed less than eight times per day, as well as the duration of each breastfeeding process, has an Odd ratio of 2.76 times higher. The duration reported in this study is an estimate based on the subjective assumptions of the mother and the average results of data collection for seven days analyzed in the transformation of categorical data more/ equal to and less than 15 minutes for one breastfeeding session.

Table 2. Logistic regression risk factor for milk production

Factors	p	Odds Ratio	95%CI
Working mother	0.034	2.969	1.086-8.114
No Early Breastfeeding Initiation	0.018	0.345	0.143-0.830
Breastfeeding frequency < 8 times per day	0.025	3.390	1.164-9.876
Breastfeeding duration < 15 minute per session	0.041	2.559	1.039-6.303

*Variable(s) all entered on step 1(based on table 1), after performing 6 step of backward likelihood ratio method, tested correlation and controlling confounder, the last fit model explained milk production among breastfeeding mothers.

After conducting a simultaneous analysis using multiple logistic regression, by entering all the variables at the beginning of the test step to consider the possibility of confounders and intercorrelations between variables,

the results shown in Table 2, which most determine the volume of milk production is the frequency of breastfeeding (OR: 3.390), working mother (OR: 2,969), duration of each breastfeeding session (OR: 2.559), and initiation of early breastfeeding (OR: 0.345).

Even though a working mother gives birth without early breastfeeding initiation, she still able to maintain the volume by breastfeeding more frequent and extended duration of each session. Two mechanical factors frequency of sucking and duration of sucking will ensure emptying of the breast and increase production supplies. Both activity as if perfect rhythm between the need and availability of milk with infants.

Discussion

The ratio of mothers who produce optimal milk volume is 2.3 to sub-optimal; this means that more than 113 research subjects can breastfeed optimally. Sociodemographic factors occupy an obvious path within the conceptual framework of milk production, such as age, education, and employment. This study shows that more than half of mothers in the age range of 20-30 years have optimal milk production, but mothers aged over 30 years also record similar facts. Research conducted at the Department of Nutrition at the University of California shows that "older" primiparous mothers (24 years or more) produce less milk in the first week of postpartum than younger primiparas (16-23 years). This research assumes that breast milk produced "depends on the amount of functional tissue in the breast," which may decrease with age. In Sweden, reporting that breastfeeding rates are declining, one of the factors that inhibit exclusively breastfeeding mothers for more than two months is primipara under the age of 25 years.[13]

In another study also revealed that young age and marriage at less than 20 years not only have an impact on the maturity of the mother's soul in babysitting but affect the mother's performance starting initiation of breastfeeding faster.[2]

Education, in many studies, is a favorable variable to study. Education assumed as the basis for everyone to form normative behavior. This research shows that mothers are generally highly educated (equivalent to D3, S1-2), meaning that mothers have sufficient intellectual power to support their skills in breastfeeding and caring for babies. Although statistically, there is no difference between mothers with high and low education in terms of milk production, this is because traditions and habits heavily influence the context of breastfeeding in a particular family or culture. The element of milk production is in the body and breast tissue, which logically has nothing to do with the external aspects of education.

One study showed that the context of breastfeeding practice is influenced by traditional practices even though they (mothers) lack education or lack understanding of the ins and outs of milk production. Breastfeeding is a derivative of habits passed down from generation to generation, views on breast function and the quality of milk produced and the standards of behavior that exist in a community or tribe to be determinants of breastfeeding can be well accepted and implemented or not.[14] However, in other studies, data found that mothers with high status have higher production than those with low education.[15] In various searches, it is rather difficult to find studies that specifically study the relationship between education and milk production. However, studies examining the relationship between a mother's knowledge and the success of breastfeeding for up to six months are numerous. Some of them prove that educated mothers (72% secondary and 90.9% graduated) are more likely to give colostrum to their babies than those who are illiterate (38.9%). Although the duration of exclusive breastfeeding and breastfeeding is not related to mother's education, knowledge about breastfeeding is very important for parents with higher education (63.6% and 52.8%) compared to parents who are illiterate or have low education. Other studies in developed countries also show the fact that highly educated mothers (62.0%) more exclusively breastfeed for up to two months than low education (38.0%) (Cato et al., 2017). In Europe, a comparison of cross-sectional studies conducted between 2006-2016 revealed that early breastfeeding initiation and shorter breastfeeding duration found in mothers with less education than those with higher education based on the ISCED (International Standard Classification of Education) education classification.[16]

The provision of breast milk for six months requires high commitment. One of the most challenging commitments fulfilled for mothers is the attachment of time between themselves and their babies. Everyone will naturally experience boredom in the same activities every day, especially for six months. The most significant barrier is working mothers. Work reported as the most frequent reason to stop breastfeeding.[17]Breastfeeding and working require more effort and commitment.

Many workplace policies that are not in line with the extended maternity leave policy make this situation more difficult.[18] In this study, significant work related to milk production. The Odd ratio shows that working mothers are 2.62 times lower risk of producing milk compared to mothers who do not work. This pathway can be explained through separate time-feeding scenarios starting when the mother returns to work. Maintenance of milk production can be done by breastfeeding on demand, breastfeeding periodically, and pumping periodically. Leaving baby with grandmothers appears in a different situation in feeding style. Grandma does not have superior soothing ability compared to their mother with her breasts. Choices that can be taken by working mothers are pumping milk. Dairy milk requires a storage medium, care that is more troublesome than direct breastfeeding. Grandma also certainly is not always painstaking in preparing dairy milk. If the workplace situation does not allow mothers to leave the office more often for breastfeeding purposes, then direct breastfeeding will be replaced by alternative dairy milk.

Giving expressed breastmilk has different dimensions for each person. It started with the availability of breast pumps, how to pump, the storing method, the defrosting process, the feeding process after pumped, and many other dimensions that must overcome. Not to mention dealing with the composition of expressed breast milk, which has decreased the quality of macronutrients during storage. Degradation of some macro components of fat and calories observed in frozen milk stored for three months under -20 degrees Celsius.[19] Even, the mechanical obstacles in the process of pumping milk. Some natural reflexes will disappear, such as mother-baby bonding that reinforces neuro-response to hormonal secretions.

The pumping mechanism is different from the suction mechanism in infants; pumping tends to have a constant rhythm. Some milk pumps have developed pumping technology with different rhythms following the baby's suction pattern, suction strength, and adjustable flow. This type of pump is usually much more expensive than pumps in general, and not all mothers can afford to buy or rent. Although the suction technology in a milk pump resembles a baby's suction rhythm, it still leaves several natural scenarios such as skin to skin touch and lactogenesis, which only develop optimally through direct breastfeeding. However, no studies have yet found that review differences in the speed of milk secretion indirect breastfeeding and pumping; the loss of intimacy between mother-baby interaction during breastfeeding is clearly of different quality.

The phase of lactogenesis is progressive in pregnancy. Lactogenesis in the first is different from the second pregnancy. The process of repetitive Lactogenesis characterized by an increase in the quality of lactation. Primipara is one of the risk factors for inhibition of Lactogenesis II and reported that primipara has a potential 3.16 times more likely to experience delayed lactogenesis II compared to multipara.[20] Hampering the phase of Lactogenesis II, i.e., no discharge of milk beyond 72 hours postpartum, can result in the cessation of breastfeeding before six months.

This study did not show differences between primipara and multipara in the two milk production groups. The number of mothers who had optimal milk production was higher in both groups because the proportion of research subjects belonging to optimal milk was 2.3 times the sub-optimal group. Specific findings in Thailand are specific to other areas of rural northern Thailand.[21]Transferred milk volume and breastfeeding duration did not vary significantly between multipara and primipara. Babies in the primipara community took much longer to get the same amount of milk on day 15 and day 45, but the period of subsequent breastfeeding was shorter and more like that of other partners' babies. Perhaps they need more time before breastfeeding is known. Babies' weights and lengths were identical at each time between classes. Research in Nigeria also found that maternal age, parity or social status did not impact breastfeeding patterns.[22]

Research with different results shows that women who have previously breastfed had significantly different breastfeeding experiences than those who were first. They have a shorter duration of breastfeeding, have a more considerable delay in labour until the first attempt at breastfeeding, are less likely to breastfeed at least eight times in the first 24 hours, and have more breastfeeding problems during their breastfeeding period. These variables might contribute to the finding that first time mother who had received formula milk while still in the hospital, delayed Lactogenesis, and reduced the likelihood of achieving their intended breastfeeding goals, as well as shorter breastfeeding duration.[23]

The percentage of sexes of female babies is higher than male babies. Gender data in this analysis helps to identify the baby's own birth prevalence. Scientifically

found no difference in the amount of milk between the sexes of female and male, because the need for infant nutrition is directly proportional to the increase and growth of baby's weight in the first year. Many myths have also developed among the community that baby boys are stronger at breastfeeding than baby girls; this may connote the nature of the male identic with the power. To some extent, this myth will lead to the natural perception that a baby girl is breastfeeding less than a baby boy. Although empirical evidence illustrates that male babies breastfeed more than female babies is still rarely found, so it is necessary to emphasize the focus of the problem is on the mother and their behaviour.[24]

Infant birth weight is also not related to milk production because birth weight influenced by many things including; maternal factors such as maternal age, parity, teenage pregnancy, smoking history [25]; nutritional factors such as haemoglobin levels and folic acid deficiency, history of HIV infection, abortion and unwanted pregnancy.[26]

Variable early breastfeeding initiation is a decisive contributory factor that affects the amount of milk production. The initiation process carried out as early as possible to provide the broadest possibility for babies after birth to get the best of the skin-to-skin breast crawl process, utilizing all of their instinctive abilities within a period of 30 minutes to 1 hour after delivery. Before the breastfeeding instincts fade after 8 hours, new-borns tend to fall asleep more. Early Breastfeeding Initiation is the right start for mothers and babies to start learning to suckle and breastfeed. Along with the process and time goes to know each other until breastfeeding formed. Early Breastfeeding Initiation ensures that every baby gets colostrum rich in vitamins and protective factors.[27] Neonatal abstinence in early breastfeeding initiation has a higher frequency of NOD2 gene mutation, which causes a decrease in immune function compared to opposite.[28]

The suction on the nipple stimulates the secretion of prolactin and oxytocin so that the initial initiation is a precursor of milk secretion, the faster and more prolonged the process of Early Breastfeeding Initiation takes place, the more consistent the milk produced. In this study, Early Breastfeeding Initiation was significantly related (p-value <0.02) to milk production. The Odd Ratio reveals that mothers who initiate early breastfeeding 2.73 times more produce milk than mothers who do not initiate early breastfeeding. In the Early Breastfeeding Initiation intervention study with a combination of direct breastfeeding and regular breast milk pumps, the average volume of milk was higher on the third and seventh days (73.9mL and 225.2mL) compared to the control group that only did direct breastfeeding (25.4mL and 69, 2mL) (Fok et al., 2019). This research will reinforce the previous statement that barriers to working mothers eliminated by regular milk pumping. Early Breastfeeding Initiation also prevents the occurrence of "delayed lactogenesis II" on the third day of postpartum, and significantly precursors of increasing milk volume.[30]

The frequency of breastfeeding a baby is different in each phase of time. At the beginning of the first-third month, babies can suckle 7-9 times per day or more than 12 times. This tight connection dismissed the mother chance to leave her baby even if an several hour. Usually, hungry babies will cry at intervals every 1.5 to 3 hours. However, babies who are getting bigger will have a longer breastfeeding interval. The duration also varies depending on the adaptation of each baby. In this study, the frequency of breastfeeding significant related to milk production, as well as the duration of breastfeeding. Milk production increases 4.62 times more for women who breastfeed more often, and 2.76 times for women who breastfeed longer. Meaning the frequency of breastfeeding and duration of breastfeeding (every one breastfeeding session) is a critical point in increasing milk production, it related to the process of breast drainage. The longer the breastfeeding duration, the more it will ensure each breast is empty, thus increasing the supply of milk volume.[31]

Nevertheless, the nature of breast milk production is quite adaptive to baby. Research reveals that breast adaptability to baby suction compare to no other. Babies who sucking fast rhythms but short time, are having the same quality to suckle slowly and long time. Both of these adaptation models ensure the baby gets the same quality milk composition between the foremilk hindmilk.[31],[12]

In addition to drainage and frequency, lactation techniques will support mother for prolonged breastfeeding. The most important corrected technique regarding to positioning and attachment.[32] These two crucial points, especially in new-borns, need to assist by the midwife. Incorrect position resulted in many problems, such as blister nipples, hard nipples, swollen, and painful sensation when suckled.[33] Each mother's pain adaptation differs depending on prior

knowledge and perception of physiological pain during lactation. Inadequate physiological response during the breastfeeding process adds to the anxiety that will ultimately make the mother vulnerable to falling in postpartum depression cases. The performance of breastfeeding will decrease in women who experience postpartum depression, several factors that contribute include age, working mother, socioeconomic status, number of children, and family support[34].

Inappropriate lactation management, giving them the opportunity for early breastfeeding cessation. Most women who breastfeed and experience constant nipple pain can achieve normal milk production. Breastfeeding length and frequency are the same as pain-free mothers. The longer period of breastfeeding in pain groups, however, is correlated with lower milk production rates.[35]This study emphasizes that emptying the breast when expressing milk or direct feeding will keep the baby's milk required.[31] Although the sociodemographic barriers addressed in this study are not statistically related to milk production, working mothers, early initiation, frequency and length of breastfeeding are findings that preserved the milk production pathway through external mechanisms.

Conclusion

This research succeeded in proving several external factors such frequent and timing that supported the mechanical mechanism of breast milk production. Therefore the midwife and all other breastfeeding support program must provide a better assisted education in breastfeeding management, and other feeding alternative among them who still face unavoidable barriers such as working mothers.

Abstract

Sanitation is the provision of facilities and services for disposal of human waste such as urine and feces. To reduce diseases arising from poor environmental sanitation, efficient technology that can be utilized by communities in coastal areas and small islands is one of the facilities what is needed for access to sanitation is a septic tank. This study aims to determine the sanitary conditions of communities in coastal areas and small islands and to determine the effectiveness of appropriate technology for floating septic tanks in coastal areas and small islands. The quality of wastewater that is important to know is Total Suspended Solid (TSS), Chemical Oxygen Demand (COD), Temperature and Hydrogen Power (pH).

Keywords: *Effectiveness; Septic Tanks; Floating; Coastal; Small Islands.*

Introduction

Sanitation is a public health effort that focuses on supervision of various environmental factors that affect the degree of human health, so it prioritizes efforts to prevent various environmental factors so that the emergence of disease can be avoided.[1] Sanitation is also a process to maintain a clean and hygienic place, especially the availability of clean water, solid and liquid sewage systems.[2]

People living in coastal areas and small islands everyday life they are exposed to health risks, among others, the lack of availability of clean water.[3] Human behavior in using latrines and adapting to the environment is one of the factors in shaping the culture of society.[2] Healthy water is a necessity for people on this planet. This includes people who live on the coast and on small islands. People on the coast and small islands, however, find healthy water very difficult to find because of limited water resources. In addition, available surface water also appears to have been polluted by domestic wastewater.[4] Water quality has a direct effect on health, given the nature of water which is easily contaminated by various microorganisms and easily dissolves various materials.[5] The nature of such conditions is very easy to function as a medium for distribution or spread of disease. There are several diseases that fall into the category of water borne disease, or diseases carried by water. While the types of microbes that can spread through water are quite a lot including bacteria, protozoa and metazoan.[6]

Based on the results of laboratory tests conducted on cutlery samples, it was found that all samples contained bacteria. This is caused by several factors that cause the presence of germs (bacteria) in eating utensils, namely the quality of washing water.[7] Well water on these small islands is vulnerable to contamination, especially on small islands and densely populated areas where the limited availability of land prevents people from building standard septic tanks.[4]

The impact of waste disposal is not only for humans but also for biota in marine waters, aquatic ecosystems are being degraded by anthropogenic pollution on a global scale.[8] Such as Hg concentration in mackerel. Hg concentration in mackerel is 1.346 mg/kg while blood clams range from 0.772 to 3.111 mg/kg.[9]

It is important to evaluate the level of groundwater threats posed by the on-site system and review the strategies available to limit further groundwater degradation.[10] To minimize the occurrence of contamination of water in the area of small islands and coastal areas, it is necessary to treat domestic wastewater before being discharged into water bodies, one of which is the re-engineering of septic tanks with an appropriate technology approach. Septic Tank Engineering with the appropriate technology approach is an urgent need to address the problem.[11] A septic tank that is commonly used in the community is a conventional septic tank. However, the use of septic tanks is still not optimal because the processing efficiency has only reached 65%, causing only 22.5% of the total organic pollutants that can be processed.[12]

The quality of wastewater that is important to know is Total Suspended Solid (TSS), Chemical Oxygen Demand (COD) and Hydrogen Power (pH). The level of treatment carried out before the waste is discharged into water can contain organic and inorganic materials which are generally measured by parameters, COD, TSS and others.[13] COD describes the total amount of oxygen needed to chemically oxidize organic material, both biodegradable and biodegradable (non-biodegradable) biodegradable to CO2 and H2O. The results of COD research in waters in the upstream, middle and downstream successively value is 62.176 mg/l; 69.176 mg/l and 64.48 mg/l. COD values in uncontaminated waters are usually less than 20 mg/l, whereas in polluted waters can be more than 200 mg/l. pH indicates the need for pretreatment to prevent interference with conventional wastewater treatment processes.[14]

Method and Materials

This research was carried out on the coast and small islands. This type of research is descriptive research based on the quality standards set in PUPR PERMEN No. 4 of 2017 which refers to the planning of the building under the septic tank according to the Indonesian National Standard (SNI).

Floating septic tank prototype planning includes, the criteria for planning a black water effluent treatment tank consisting of two parts. Based on the source of waste, the first tub is a reservoir of waste water from the toilet. Solid and liquid waste that enters through a small pipe that enters tub 1 and is station 1 (inlet). Station 1 is connected to the goose neck closet from the household toilet will be decomposed in tub 1 which is station 2 at the top. This section is where the aerobic process takes place and the middle is the path and the bottom part is where the anaerobic process occurs. During crossing at station 2, the waste will decompose into gas, water and mineral mud with a breakdown time of at least 3 days. Station 2 is like two connected by a tub 1 by using pipe model of T.

The top part of the tub is where the aerobic process takes place, the middle part is the path and the bottom part is where the anaerobic process takes place. During crossing the tub, waste will decompose into gas, water and mineral mud.

At outlet or station 3 is part of the outermost pipe or large pipe is a pipe overflow. A waste quality inspection sample will be conducted at the outlet. One of the factors that become a balance in choosing the type of floating septic tank is the limited land.

Septic tank design is made by utilizing a drum with a volume of around 200 liters, which is equipped with pipes and pipe accessories for complementary components and design improvements (Figure 1).

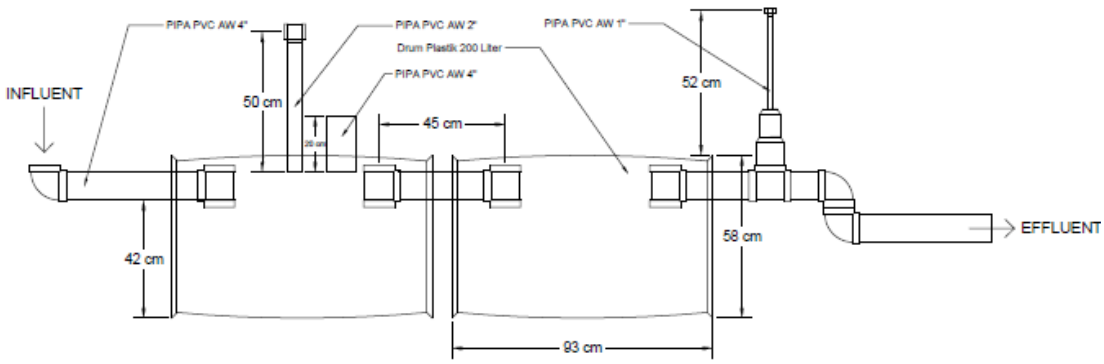

Figure 1. Floating Tank Septic Tool Design

Characterization in waste management from biological, physical, chemical and fluorescence types is combined with information about the system, design, tank type, tank management and number of users. From various studies that have been conducted several biological characterizations show that the total concentrations of coliform and Escherichia coli (E. coli) are: 103-108 and 103-107 MPN/100 mL.[15]

Other research results also provide new quantitative evidence that septic tanks are a real problem for water quality in coastal areas during ecologically sensitive periods, especially where waste is discharged directly into the flow network.[16]

Results and Discussion

From the results of interviews with people in the research area, the level of public knowledge about waste treatment, especially liquid waste, is still very low (Table 1). The survey found that 85% of the residents directly disposed of domestic liquid waste directly into water bodies and 15% were channeled into drainage. Based on the level of knowledge and habits of the community, using the instrument ask respondents about the need for fulfilling clean water that is used daily.

Table 1. Survey Results Based on Clean Water Sources.

Indicator	PDAM/ Gallon	Groundwater (Well)
Clean Water Source	44%	64%
Drinking/cooking water sources	88%	12%
Water Source for Washing/Bathing	25%	75%

The condition of community houses still does not meet these health requirements because of land limitations and the economic conditions of the community. Most people work as fishermen and scavengers used goods. The lack of sanitation in the community greatly influences the emergence of various diseases caused by the environment such as diarrhea and skin diseases.

For defecation, most residents make facilities without septic or directly discharged into water bodies. At low tide the dirt will stay and become a place to fly flies, dirt will disappear at high tide.

To reduce the risk of diseases arising from community sanitation conditions that are still lacking in need of good handling include the procurement of integrated waste treatment facilities that can be used by all local communities (Table 2).

Table 2. Types of Diseases Often Affected in the Community

Diseases Often Experienced by Communities	Diarrhea	Skin disease	Fever
Percentage of respondents	45%	36%	19%

Table 3. Survey Results of Domestic Liquid Waste Management in the Study Area

Type of Liquid Waste	Disposed of directly into water bodies	Streamed Through Drainage/Septic Tanks
Gray Water	75%	25%
Black Water	70%	30%

The results of waste management are still very lacking, this is due to lack of public awareness, land conditions and inadequate facilities of the waste management system (Table 3).

One of the main threats to groundwater and surface water quality is the impact of poorly designed, constructed or maintained wastewater treatment systems.[5] Sources of pollutants originating from septic tanks are recognized as significant contributors to pathogen flow and nutrient loads, but there is little research data in the UK that assesses the potential risks posed by septic tank effluents (STE) on water, human and health quality.[15] In recent years, the potential for groundwater pollution from septic systems on site has emerged as a serious problem in the United States.[10]

Conclusions

From the results of research on obesity that has been carried out the sanitary conditions of communities in coastal areas and small islands are still very lacking so that diseases arising from the environment are still very high, waste management with floating septic tanks in the management of domestic black water waste is effectively used, the levels of the parameters COD, TSS, temperature and pH are safe to dispose of into water bodies. Environmental management and appropriate technology is needed to minimize the occurrence of environmental pollution due to direct disposal of waste into water bodies.

Abstract

Objective: The aims of this research is to notice maternal and perinatal outcomeon pregnant women with covid-19 infection at Dr. Wahidin Sudirohusodo Hospital During the Period of April-July 2020.

Method: This research is using descriptive method which is by taking data from the pregnant women with covid-19 infection at Dr. Wahidin Sudirohusodo Hospital during the period of April 1st – July 12th 2020. The data covers the age, gestational age, amount of parity, symptoms, pregnancy complication, supportive examination results such asneutrofil score, limfosit, CT-scan Thorax, method of delivery, baby's APGAR score, covid baby status, maternal death, perinatal death.

Results: There are 26 pregnant patients characteristic subjects with covid-19 infection, mostly 20-35 years old, aterm gestational (>37 weeks), multiparity, low educational background, unemployed, mostly with no symptoms, increasing limfositneutrofil ratio rate >3,13. Good maternal outcome, there are no maternal death in this research. Perinatal outcome from 24 babies, 5 babies are confirmed covid-19 positive and all are in good condition.

Conclusion: This research concludes good maternal and perinatal outcome.

Keywords: *Maternal Outcome, Perinatal Outcome.*

Introduction

Global pandemic caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) or Coronavirus Diesease 2019 (COVID-19) has developed by the increased death rate, which also assures the identified vulnerable population in the society. From the data of Covid-19 Acceleration Handling Task Force in Indonesia by July 12th 2020, there are 75.699 people confirmed to be positive, 36.638 people confirmed to be recovered, and 3.606 people confirmed to be departed. In the first research, which described the clinical characteristic and investigate the possibility of SARS-CoV-2 vertical transmission on nine pregnant women with Covid-19 that have been confirmed by laboratory examination, showed that the effect of COVID-19 on pregnant women are similar to adult women who are nor pregnant and there are no evidence of vertical transmission because SARS-CoV-2 is not detected by amniotic fluid, umbilical cord blood and neonatal throat swab from the six cases.[1]

To date, the largest series reporting pregnancy and neonatal outcomes, with 99 COVID-19 infected pregnant women, shows that having COVID-19 during pregnancy are not related to the increase of damaging risks such as spontaneous premature birth. Among the 100 neonatusdelivered by these women, not even one is infected by SARS-CoV-2.[2]Based on very rare data until today, conflicting evidence from nucleic acid based assays and anti body test on neonatus delivered by mother with Covid-19 has appeared to cause further controversy for the vertical transmission risk during pregnancy.[1,2]Due to the foetus and the newborns, innate and adaptive immune system immaturity make them susceptible to infection.[3]Factors dysregulationsuch as cytokines and cascades May have damaging consequences on the developing and brain function. Therefore, not being able to notify whether the infection agent is able to infect nowborns with vertical transmission is interesting.[4]

Pregnant women and their babies need to be evaluate as potentially risky group in today's COVID-19pandemic. From gathered limited information about this novel coronavirus and drastically increasing disease burden, it is necessary for scientific information about this disease to be Sharedbriefly and practically. Result data of infected women and pregnant women perinatal with SARS-CoV-2 are limited to some reports and case series. The size of small samples and the findings are vary. The changes of policies in countries hit by pandemic, developing clinical management guidance, and uncertainty about the reliability of the result make the reports difficult to be interpreted. Therefore, this research is conducted so it is possible to notice maternal and perinatal external result on pregnancies with COVID-19.

Method

This research is using descriptive method by taking the data on pregnant women infected by Covid-19 at Dr. Wahidin Sudirohusodo General Hospital during the period of April 1st – July 12th 2020. The data covers the age, gestational age, amount of parity, symptoms, pregnancy complication, supportive examination result such as neutrofil ratio, limfossit, CT-scan Thorax, method of delivery, baby's APGAR score, baby's covid status, maternal death, perinatal death.

Result

During the period of April 1st – July 12th 2020, there were 26 covid-19 infected pregnancy cases obtained at Dr.Wahidin Sudirohusodo Hospital. Table 1 showsthat the characteristic of pregnant patients with covid-19 are to those with the age of 20-35 years old, which are 20 cases (76.9%). On the age <20 years old and >35 years old, 6 cases were found (23.1%).In terms of the gestational age, the most pregnancy cases with covid-19 are at the aterm gestational age of (>37 weeks) are 22 cases (84.6%). There are 4 cases (15.4%) in cases with Preterm pregnancy (<37 weeks). From the amount of parity, the most cases happen to be on the multipara, which are 17 people (65.4%). And on the nullipara there are 9 cases (34.6%). Most of the subject in this research have low educational background, which are 15 cases (57.7%) and unemployed subjects, which are 17 cases (65.4%).

Table 1. Research Subject Characteristic

Characteristic	Pregnancy with Covid-19	
	N	%
Age		
20-35 years old	20	76.9
<20/> 35 years old	6	23.1
Gestational Age		
< 37 weeks	4	15.4
> 37 weeks	22	84.6

Table 2 shows pregnancy case with covid-19 taken from supportive examination. Rated parameter is the limfositneutrofil ratio and Thorax CT-scan. The cut off

point of neutrofil and limfosit ratio used in this resaerch is 3.13. In the research subject it is known that limfosit and neutrofil ratio generally increased >3.13 which are 7 cases (34.6%). From the Thorax CT-scan done by the research subjects, there are 6 cases (23.1%) with pneumonia, but caused no death on the mothers and there are 20 cases (76.9%) with no radiological disorder or also know as normal.

Table 2. Laboratory and Radiologic Findingson Pregnancy with Covid-19 at Dr. Wahidin Sudirohusodo Hospital during the period of April-July 2020

Laboratory and Radiologic Findings	Pregnancy with Covid-19	
	N	%
Neutrofil Limfosit Ratio (NLR)		
< 3,13	7	34.6
> 3,13	19	65.4
CT chest		
Pneumonia	6	23.1
Normal	20	76.9
Total	**26**	**100**

From Table 3, it is known that maternal external result is taken from the delivery method, most of the method are by cesarean section which are 17 cases (70.8%). From those with cesarean section, 11 of them come with Obstetric Medical indication, which are previous post cesarean section (8; 47.1%), severe preeclampsia with eclampsia impending sign (2; 11.8%), and macrosomia (1; 5.9%). There are also other cases like 1 case of abortus at the gestational age of 12 weeks and 1 conservative treatment case for dypepsia. There are 6 cases (35.3%) of cesarean section for covid-19 infection.

Table 3. Maternal Outcome on Pregnancy with Covid-19 at Dr. Wahidin Sudirohusodo Hospital during the period of April-July 2020

Maternal Outcome	Pregnancy with Covid-19	
	N	%
Mode of delivery		
Vaginal delivery	7	29.2
Caesarean delivery	17	70.8
Outcome		
Life	26	100
Died	0	0
Total	**26**	**100**

Table 4 shows that perinatal external result of pregnancy with covid-19. From 24 baby external result, there are 5 babies (20.8%) confirmed to have positive covid-19 and normal APGAR score. 1 baby (4.25%) was born with severe asfixia from mother with severe preeclampsia pregannacy complication But with negative status of Covid-19. And there were 16 babies (66.7%) born with negative covid status.

Table 4. Perinatal Outcome of Pregnancy with Covid-19 at Dr. Wahidin Sudirohusodo Hospital during the period of April-July 2020

Perinatal Outcome	Covid-19 Status of the Baby	
	Positive	Negative
APGAR Score		
Normal	5 (20.8%)	15 (62.5%)
Asphyxia	0 (0%)	1 (4.2%)
IUFD	0 (0%)	3 (12.5%)
Outcome		
Life	5 (20,8%)	16 (66.7%)
Died	0 (0%)	3 (12.5%)
Total	5	19

Discussion

Pregnancy cases with covid-19 during the period of April 1st– July 12th 2020 at Dr. Wahidin Sudirohusodo General Hospital are generally patients with no symptoms (OTG), 18 people (69.2%). This findings suit to the research in China that there were 23.3% of pregnant women with Covid-19 that showed no symptoms during the peak of the pandemic in the Province of Hubei, China.[2]There are also 8 patients with symptoms, the experienced symptoms of coughing (2; 7.72%), coughing followed with the experience of Hard breathing (4; 15.4%), anosmia (1; 3.84%), diarrhea(1; 3.84%). This goes along with the research in China that indicates that infected patients' clinical characteristic during their pregnancies show similarity with other infected adult who are not pregnant.[2] From the total of 26 cases, there were 9 patients (34.6%) that came with complication complaints during their pregnancies. 4 cases (15.4%) of severe preeclampsia, 1 case (3.84%) of chronic hypertension, 1 case (3.84%) of hypertiroid, and 1 case (3.84%) of B hepatitis. All pregnancy complications are not related to covid-19. The increasing of the NLR in this research is in line with the research conducted in Spain, where the NLR is increasing on pregnant women infected by Covid-19 and decreasing after clinical condition treatment.[5] The research in China

showed that patients with covid-19 have increased value of neutrofil and decreased value of limfosit on severe phase.[6]The Thorax CT-scan examination did not show radiological disorder or also know as normal. On the contrary, in every research in China, they found radiological disorders on the Thorax CT-scan, which is 96.3 & of Ground glass opacity.[2]

Maternaloutcome pregnancy with covid-19 showed all subjects in the research were in good condition and discharged after two swab test and confirmed to be negative. This suits the research that shows majority of pregnant women with Covid-19 on their third trimester and deliver the babies by cesarean section, showed no maternal death. On a contrary, pregnant women by respiratory infection virus like H1N1 reported to have 4-5 bigger possibilities to develop into severe disease compare to non pregnant women on common population.[7]In this research, there are 3 babies (12.5%) who passed away from mothers who experienced fetal death in the womb (KJDR). External perinatal of 5 babies that confirmed to be positive are in good condition. This also suits the research in Cinawhich perinatal outcomeis good with mothers infected by Covid-19.[2]

Conclusion

There are characteristics of 26 pregnant patients infected by Covid-19, where most of them are 20-35 years old, aterm gestational age of (>37 weeks), multiparity, low educational background, unempleyed, most of them show no symptoms, increasing rate of neutrofillimfosit>3.13. Good maternal external result, no maternal death in this research. Parinatal external result from 24 babies, 5 of them are confirmed to be covid-19 positive and all of them are in good condition.

Abstract

Objective: To determine the effect of pravastatin administration on endothelin-1 levels in patients at high risk of preeclampsia.

Method: There are 70 subjects in this research that consist of 34 subjects with the risk of high preeclampsia who get aspirin and 36 subjects of research to get Aspirin and Pravastatin. Subjects are given therapy started the gestational age of 12-19 weeks in 6 days until 36 weeks of pregnancy. Endhotelin-1 levels prior to administration of therapy compared with the levels of endothelin-1 after the administration of treatment.

Results: The test results show the administration of aspirin or aspirin and Pravastatin is shown to provide the changes were significant at levels of endothelin-1 after the administration of treatment. It is characterized by the decrease in the levels of endothelin-1 which were significantly ($p < 0.005$). But by assessing percentage decrease in the provision of aspirin with pravastatin give change levels of endothelin-1 is large (45.74%) compared with administration of aspirin alone (28.8%).

Conclusion: From this study it can be concluded that endothelin-1 levels before administration of aspirin and pravastatin were 86.18 ng/L and after administration of 46.76 ng/L. Giving aspirin and pravastatin 20 mg in patients with high risk factors of preeclampsia provide reduced levels of endothelin-1 is greater than the prevention of preeclampsia that is used when it is only aspirin.

Keywords: *Patient risk of high preeclampsia, Aspirin, Pravastatin, Levels of Endothelin-1.*

Introduction

Preeclampsia is a multisystem disorder in pregnancy that is characterized by hypertension and proteinuria after 20 weeks period of gestation. Abnormalities that occur in 5 stars - 7 % pregnancies, with figures incidence of 23.6 cases per 1,000 births in the United States the United t.[1] Preeclampsia is a specific pregnancy disease and is still the leading cause of maternal-neonatal mortality and morbidity worldwide, accounting for more than 70,000 - 80,000 maternal and 500,000 perinatal deaths.[2]

The imbalance of pro and antiangiogenic factors as well as the activation of mediators of immunity that contribute to excessively inflamation is a major cause. The etiology of preeclampsia is unclear, but several recent studies have shown that an imbalance between angiogenic factors (*Vascular Endothelial Growth Factor* (VEGF) and *Placental Growth Factor* (PLGF)) and anti-angiogenic (*Soluble fms-like Tyrosine kinase 1* (sFlt-1) and *Placental Growth Factor* (PLGF)) and anti-

angiogenic (*Soluble fms-like Tyrosine kinase 1* (sFlt-1) and *Placental Growth Factor* (PLGF)) *soluble endoglin* (s-eng)) plays an important role in the pathogenesis of this disease.[2]

Endothelin 1 (ET-1) is an isoform primary that produced by endothelial humans and peptide 21-amino-acid is a vasoconstrictor potent. Levels of ET-1 in plasma increased in pregnant women normotensive, but women with preeclampsia had levels of ET are much higher. Endothelin-1 has proven be the holder of the key to the activation signal molecular that caused stress oxidative in patients with preeclampsia that inhibits the release of ET-1 is one of the alternative in preventing the occurrence of preeclampsia.[3]

The International Study Collaboration conducted a meta- analysis of the effectiveness of antiplatelet agents (especially aspirin) for the prevention of preeclampsia. Low- dose aspirin (60-150 mg per day) can reduce the risk of preeclampsia by 24%.[4]On the other, Ahmed et al propose a statin as a new therapeutic strategies in which case it is based on studies of experimental animals showed that pravastatin (inhibitor coenzyme-A reductase 3-hydroxy-3-methilglutaril) has a protective role in the uteroplacental circulation and blood vessel cells.[5]

When this, pravastatin has demonstrated the effect of protection against endothelial cells vaskular induces the expression of H eme O ksigenase (H O -1) and inhibits cytokine release from anti-angiogenic factor sFlt-1 and zinc. Increased levels of sFlt-1 and zinc causes a decrease in VEGF and PlGF free on placental cells and endothelial vessels of blood which ultimately resulted in systemic vasoconstriction and endothelial dysfunction vessels of the blood of the mother.

Therefore, the purpose of the research is to determine the effect of administration of aspirin and pravastatin on the levels of endothelin - 1 in patients Be risk of high preeclampsia .

Material and Method

Design of study: This study was a quasi-clinical trial with randomization, which carried out clinical trials on control groups and cases during the 1- year study period.

Population of study: Samples of research are taken from a woman pregnant at high risk of preeclampsia with age pregnancy 12 weeks - 19 weeks 6 days of the visit to the clinic of the General Hospital of Makassar and Jumpandang Baru health care center. Sampling was carried out by block randomization in the administration of therapy. The provision of interventions carried out *single blinding* that participants can determine the allocation of the group based on the amount of drug that is given.

Study Interventions: This study was conducted to assess the effect of giving pravastatin to pregnant women who are at high risk of preeclampsia. Subject tests are given aspirin 1 x 80 mg orally until the age of term pregnancies as a treatment standard (group A), while the group of samples are given intervention in the form of aspirin 1 x 80 mg orally plus pravastatin who consumed 2 times a day until the age of term pregnancies in the same time (group B).

Randomization: If the patient agrees to be a participant in this study, it is mandatory to sign the research consent sheet. Participants will then be randomized into two groups: those who receive a combination of pravastatin and aspirin, and those who receive aspirin only. Participants will take the drug until the end of pregnancy Endothelin-1 levels will be checked before and after drug administration.

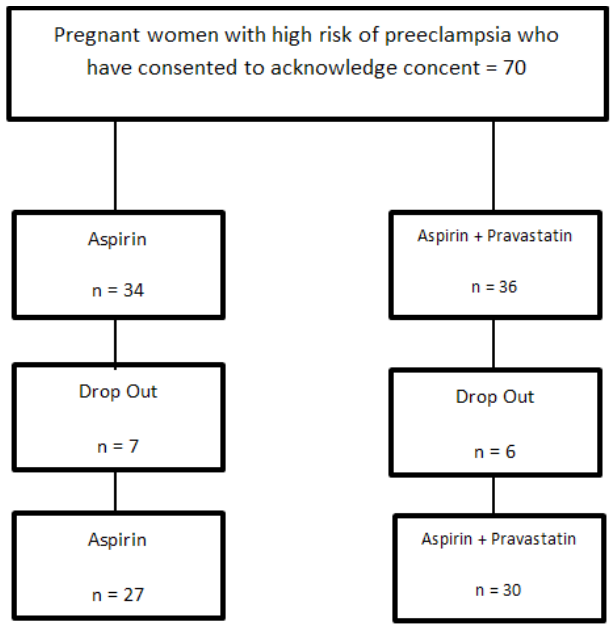

Figure 1. Flowchart of screening of participans

Study Outcomes: Results of the study is expected to provide information about the profile levels of endothelin - 1 on a mother pregnant as well as the effect of giving aspirin and pravastatin on the levels of endothelin - 1 in patients Be risk of high preeclampsia .

Sample Size: In the study of this, a large sample in each group of the intervention and the control is determined by a formula as follows

$$n1 = n2 = \left[\frac{(Z\alpha + Z\beta)S}{X1 - X2}\right]^2$$

N is total samples required for each intervention and control groups . Zα is a type I error, which is 5% with a one-way hypothesis with a constant value of 1.64 . Zβ is k esalahan type II set at 10% by value of the constant 1.28 . S is s impang raw (Verdonk et al., 2015) with a value of 0.42 . X1 - X2 is s elisih minimum considered significant at 0.21 . So the value of n in this study are:

$$n1 = n2 = \left[\frac{(1.64+1.28)0.42}{0.21}\right]^2 = 34$$

Statistical Analysis: Data were collected and have been analyzed and then processed by computer using SPSS. Normality test was performed with Kolmogorov-Smirnov (samples> 50). If a normal distribution is obtained (p> 0.05) a paired T test is used and if an abnormal distribution is obtained (p <0.05) the Wilcoxon test is used to compare the average serum Endothelin - 1 level before and after drug administration in each each sample and control group . Then if a normal distribution is obtained (p> 0.05) an unpaired T hypothesis test is used and if an abnormal distribution is obtained (p <0.05) the Mann-Whitney test is used to compare the average difference in serum Endothelium - 1 levels between sample groups with a control group.

Ethical Approval: Before the study is conducted, the researcher asks the feasibility of conduct of the Commission of Ethics Research Biomedical on Human Faculty of Medicine, University of Hasanuddin Makassar and has been approved by the number of register 601/ H4.8.4.5.31/PP36- KOMETIK/2018 by chairman Prof. Dr. dr. Suryani As'ad, M.Sc., Sp.GK and secretary Dr. Agussalim Bukhari, M.Med ., Ph.D., Sp.GK .

Differences Endothelin-1 se is not the provision of treatment

Table 3. Differences in Endothelin-1 before and after administration of aspirin alone with aspirin and pravastatin.

Variable	Aspirin + Pravastatin (Mean±SD)	Aspirin (Mean±SD)	P value
Endothelin-1 Pre- intervention	86.18±129.46	109.61±199.33	0.948 [b]
Endothelin-1 Post Intervention	46.76±95.1	78.04±166.97	0.655 [b]

b: *mannwhitney* test

Changes Endothelin-1 prior to and throughout has been the provision of treatment:

Table 4. Changes in Endothelin-1 levels before and after administration of aspirin alone with aspirin and pravastatin

Variable	Endothelin-1 Pre-intervention (Mean±SD)	Endothelin-1 Post Intervention (Mean±SD)	Percentage of Decrease (%)	P value
Aspirin + Pravastatin	86.18±129.46	46.76±95.1	45.74	0.008 [c]
Aspirin	109.61±199.33	78.04±166.97	28.8	0.046 [c]

C: *Wilcoxon* Test

Based on *mannwhitney* test, table 3 shows the p-value have no differences s of endothelin-1 level before and after therapy in both groups of treatment ($p > 0.05$). The intervention that is given to the subject of research at the given on samples with endothelin pre-intervention were homogenous. So the intervention is given in the sample with endothelin start of the homogeneous.

Based on Wilcoxon test, the administration of aspirin or aspirin and pravastatin shown to provide the changes were significant at levels of endothelin-1 after the administration of treatment . It is characterized characterized by a decrease in the levels of endothelin-1 were significantly ($p < 0.005$). But by assessing the percentage decrease in the provision of aspirin with

pravastatin give change levels of endothelin-1 is large compared with the administration of aspirin alone.

Discussion

Preeclampsia is a specific hypertensive disease in pregnancy which involving multisystem. Usually, after gestation age of 20 weeks, most often in the near term, can be superimposed with other hypertensive disorders. Preeclampsia, the most common form of high blood pressure (*BP*) which could complicates pregnancy, is mainly determined by the incidence of new onset hypertension and the presence of new onset proteinuria. However, although both of these criteria are regarded as classical definitions of preeclampsia, some women come with hypertension and multi-systemic signs that usually indicate the severity of the disease without the presence of proteinuria.[6]

If proteinuria is not present, the diagnosis of preeclampsia is enforced when there is hypertension with thrombocytopenia (plateletcount less than 100,000 per microliter), the presence of impairedliver function (increased levels of liver transaminases in the blood totwo times from the normal concentration), the new development of renal insufficiency (increasecreatinineserum greater than 1.1 mg/dl or doubling thecreatinine serum with outany other kidney disease), the presence of a lung edema,or a brain disorder or new onset visual impairment.[6]

Table 2 showed that both the sample and the control Group have the most age in the 20 – 35 years old, in which the sample Group consist of 23 Samples (62.9%) and 17 sample for the control Group (50%). In the Sample group, the most parity count is ≥ 1 as many as 29 Samples (80.6%) and similarly to the control group as many as 31 Samples (91.2%). Further, most samples's education in sample group were elementary which is 22 Samples (61.1%) and the control group found that most of the samples at the advanced education were 19 Samples (55.9%). Then, based on body mass index (BMI) both the sample and the control was found mostly in obese condition which are 22 Samples (61.1%) and 18 Samples (52.9%) respectively.

In particular in table 3 only obtained risk factors with a history of hypertension and previous preeclampsia history in sample groups as much as 7 Samples (19.5%) and 14 samples (38.8%) as well as in a control group of 11 samples (32.4%) and 13 samples (38.2%).

Based from table 1 and table 2, the age, the number of parity, the education status, the body mass index and the previous history of the disease such as hypertension and preeclampsia was not found a meaningful differences in both Research groups, where the value of p > 0,005 on each research variable. This finding indicating that both groups have the characteristics of respondents who are homogeny.

In this study, endothelin-1 levels were the aim. Thus, the study does not found meaningful differences on the levels of endothelin-1 before and after therapy in both groups of treatment. Even if theendothelin levelon the control group(aspirin) much higher than the treat group (aspirin + pravastatin), however, the levels are not so much distinct. This is due to a spread of data that may be too broad due to the range in the sample rate because of the difficulties to control several factors due to the research limitations namely race, ethnic, dietary and previous history of illness. This is evidenced by the unusual data spread from the beginning in both groups in statistical tests. Based on a study by Rahman Shah (2007) endothelin-1appears to have a diverse role as a vascular and growthmodulator and as a mediator in many cardiovascular and non-cardiovascular diseases. ET-1 is the primarily a paracrine substance that acts locally which appears to contribute to the maintenance of basal vascular tone. Moreover, it is also activated in some diseases, including congestive heart failure, arterial hypertension, atherosclerosis, endothelial dysfunction, coronary artery disease, renal failure, cerebrovascular disease, pulmonary arterial hypertension, and sepsis. The increased concentration of *ET-1* can be attributed to increased activity of endotheline-modifier enzymesand to indicate endothelial damage in the circulation of pregnant women with preeclampsia.

After the intervention was found a decreased level in endothelin-1 for both groups with aspririn or pravastatinintervention which there was decreased levels of endothelin-1 by 28.8% in the Control Group (aspirin) pre- intervention from 109.61±199.33 to 78.04±166.97. However, the decrease in endothelin-1 in the sample group (aspirin + pravastatin) is greater than 45.74% from the rate of 86.18±129.46 to 46.76±95.1 after intervention. Based on the findings of this study was observed that both the administration of aspirin and aspirin and pravastatinom could reduce the levels of endothelin-1. Nonetherless, due to the absence of normal value from Endothelin-1, it is not yet clear whether the decrease in the rate is up to normal value or only decrease

its level from the initial rate. This is one of the limitation of this study. This is in line with the research conducted by Raditya Ery Pratama, dkk(2018) in Surabaya which proves that the combination of pravastatinom and standard therapy lowers Endothelin-1 levels.

This research is able to provide data on Endothelin-1 levels after aspirin therapy in high-risk preeclampsia groups. Further, this data shows that there is a decrease in the level of endothelin-1in the group of aspirin but the level of endothelin-1 after therapy is quite relatively high. The data can be an initial input, that perhaps the aspirin is not good enough to suppress endothelin-1 in order to prevent preeclampsia, as it is known that the preeclamicpatomecanism is multifaktorial, not only caused by the increasing in endothelin-1.

The results of this research are as well as the study conducted by Costantine*et al* for *the Eunice Kennedyshriver National Institute of Child Health and Human Development Obstetric-Fetal pharmacology Research Units Network (OPRU),* where it publishes a pilot of a multicenter, *double-blind*, placebo-controlled test, random of the woman with a single pregnancy with gestation age 12 to 16 weeks which randomly receives either 10 mg of pravastatindaily (n = 10) or placebo (n = 10).[7] Four women in the group given the placebo had high preeclampsia with a concentration of *sFlt-1 (soluble fmslike tyrosine kinase-1);* Three of them showed severe conditions compared to the pravastatin given group. Thus, pravastatinshows beneficial benefits in preventing the occurrence of preeclampsia.[7] In addition, there are also numbers of preeclampsia incidence and lower premature births, concentration of sFlt-1 and sENG (Endotelin) decreased in subjects who administered pravastatin. Although the difference for these results does not achieve statistical significance.[8]

Another study by Hassanain*et al* (2018) reported 4 patients having significant hypertension (90-105/155-200 mm Hg) with proteinuria ranging from 840 to 2990 mg/24 hours later administered daily pravastatin(40 mg) since the first day of admission Hospital.[6] Then in line with the effects of proangiogenic pravastatin, little but not significantly lowered the anti-angiogenic factor *sFlt-1 (soluble fmslike tyrosine kinase-1)* and $_{S}$*ENG (soluble Endoglin*) which was observed in the group given pravastatincompared to placebo group.[6]

For Evidence-Based Preeclampsia Prevention found that therapy with 150 mg of aspirin in high-risk women subjected to preeclampsia (based on algorithms that utilize maternal factors and biophysical and biochemical measurements) that began at gestation age 11 to 14 weeks lowered preeclamsia incidents compared to women who received placebo.[9]

Apart from the data limitation of aspirin, in 2013, the *American College of Obstetricians and Gynecologists (ACOG)* recommends administering daily aspirin (80-100mg) for women with preeclampsia history in previous pregnancies before gestation 34 weeks age or preeclampsia history in the previous two pregnancies.

Low-dose Aspirin given to pregnant women with high risk of preeclampsia may decrease preeclampsia incidence of up to 10-24%, lowering the incidence rate of IUGR by 20%, and premature delivery by 14%. However studies have shown that low dose aspirin administration does not lower the preeclampsia incidence at gestation age more than 37 weeks.[10] Similarly, other studies, stating that low-dose aspirin is useless to prevent preeclampsia in patients with chronic hypertension.[7] Therefore, it is preferred to give pravastatinom to decrease the incidence of preeclampsia.

This study shows the administration of aspirin and Pravastatinand aspirin proved to provide significant changes in endothelin-1 levels after administration of therapy is in the Group ofPravastatinom ($P < 0.05$, $p = 0.008$) and on the control group (Aspirin) ($P < 0.05$, $p = 0046$). However, a greater reduction in endothelin-1 levels was given to the group of pravastatin. Therefore, pravastatinis more preferred as a therapy to lower endothelin-1 levels in prevention of preeclampsia cases.

Some recent studies have also added pravastatinas an agent other than low dose aspirin to prevent preeclampsia. Pravastatin is chosen due to the basis of preeclampsia pathogenesis having similarities with cardiovascular disease i.e. systemic endothelial dysfunction.

Pravastatin is chosen from various other statins drugs due to its hydrophilic properties. Its protein binding is the lowest therefore drug interactions are also minimal (Lecarpentier*et al*, 2012). Oral absorption is about 40-75%, passing the first metabolic rate in the liver. Excretion of pravastatinin the form of intact through the liver and kidneys (secretion in tubule). The average absorption time is 2.4 hours with a bioavailability of 18%. The time to reach the maximum concentration in plasma averages one hour after oral administration.[11]

Statins act pleiotropic on various mechanisms: reverse angiogenic imbalance by increasing vascular endothelial growth factor (*VEGF*) and placental Growth Factor (PLGF), and reduce antiangiogenic factors such as *soluble fmslike tyrosine Kinase-1 (sFlt-1)* and *soluble Endoglin (sENG)*.[6]

Pravastatin is a competitive inhibitor of a *3 hydroxy-3-methyl-glutaryl-coenzymeA*reductase which is an enzyme catalyzing step limiting levels in the synthesis of cholesterol. Pravastatin is the most hydrophilic polar compound among current statins and is therefore considered to have limited ability to traverse the placenta. It is also the most powerful inhibitor of sterol synthesis.[6]

All of the biological effects of pravastatin can restore maternal endothelial dysfunction so that maternal vascular reactivity can be reduced. It can prevent maternal systemic vasoconstriction so that blood pressure will not increase.[11]

Abstract

Objective: The high prevalence of smokers in Indonesia has led the government to issue various policies. One of the policies issued by the government to reduce or limit the prevalence is the cigarette advertisement policy. The purpose of this systematic review is to develop a model of cigarette advertisement policy in preventing children smoking habits in Palu City, Indonesia.

Method: This research used a systematic literature review. Various references were collected from online database including reports, journals, and books in the last 10 years. The journals were mostly from the scholarly journals. The articles were screened according to the research objectives. The keywords used are cigarette advertisement policy and children smoking habits.

Results: This study showed that the use of a model of cigarette advertisement policy is very effective in preventing children smoking habits. Cigarette advertisement regulation policy is the government's commitment to protect children, as an effort to protect the younger generation from cigarette advertisements that are intense and have a very large influence on smoking behavior. Cigarette advertisements are proven to encourage children to try cigarettes, repeating the behavior so that it eventually becomes a habit.

Conclusions: This paper concludes that a model using cigarette advertisement policy is effective for prevent children smoking habits. Further recommendation will be provided.

Keywords: *Cigarette Advertisement Policy; Children; Smoking.*

Introduction

Some of the motivations behind smoking habits are to get recognition (anticipatory beliefs), to eliminate relief (reliefing beliefs) and to think that their actions do not violate the norm (permission beliefs or positive)[1]. The higher death rates caused by smoking and the high social costs incurred due to the effects of smoking encourage the need to optimize the implementation of government policies in changing the behavior of cigarette consumers. On the other hand the cigarette industry contributes significant revenue to the government as well as providing employment for the community as well as tobacco farmers. An alternative way out of the phenomenon as mentioned above, basically is not an easy and simple problem, because it will require a large amount of data and information regarding the attitude of the smokers towards government warnings. In addition, data and information on opportunity costs arising from the reduction of cigarette industry output are also needed, as well as public opinion about the government's social responsibility in tackling the tendency to consume cigarettes[2].

Demarketing policies of the government and the cigarette industry aim to reduce the level of cigarette consumption in the community. In accordance with Government Regulation No. 81 of 1999 concerning the Arrangement of Cigarette Billboards, and even permanent warnings are contained in every cigarette package. Government protection as a decision maker (dicision maker) in the form of regulations that affect the public interest, both the cigarette industry and the public. This policy product can meet social expectations and demands. Public policy is real action, not just what you want to do. Advertising arrangements aim to persuade people not to consume harmful products[3].

WHO (World Health Organization) data in 2015 shows that the prevalence of active smokers in the world currently reaches 17.4%. Indonesia ranks first in Asia based on the number of smokers over the age of 15 years with the prevalence of 38.5% of Indonesia's population smoking, namely 73.3% of the male population and 3.8% of the female population. The National Basic Health Research (Riskesdas) data in 2018 shows that the prevalence of Indonesian smokers in the population aged 10-18 years continues to increase, namely in the Riskesdas data in 2013 of 7.2%, 2016 National Circular Survey data of 8.8% and in the data Riskesdas in 2018 increased to 9.1%. The Riskesdas data in 2018 explained that the prevalence of smokers every day and sometimes age ≥ 10 years in Central Sulawesi was 31.2%. The number of smokers in Central Sulawesi exceeds the National Prevalence of 28.8%.

Data from the Palu City Health Office revealed that smokers under the age of 20 (<20) in the last three years continued to increase, namely in 2015 as many as 153 children smoked, in 2016 there were 315 children smoked, and in 2017 there were 1,073 children smoking. Data from the Palu City Health Office further explained that of the 13 Puskesmas in Palu City, the highest number of smokers under the age of 20 (<20) was found in Talise Health Center with a total of 748 smokers smoking, then at the PuskesmasBirobuli with the number of smokers as many as 101 children smoked, as well as Mamboro Health Center with the number of smokers as many as 49 children smoked.

Seeing the problem above, the researcher was interested in conducting research on how a model of cigarette advertisement policy in preventing children smoking habits in Palu City, Indonesia?. The purpose of this systematic review is to develop a model of cigarette advertisement policy in preventing children smoking habits in Palu City, Indonesia.

Method

This research uses literature review. Literature sources of this review are generally obtained by searching through the internet in various national and international journals, and e-books. Generally the journal is indexed by Google Scholar, Scopus, Elsevier, Science Direct, and others. Generally the literature collected is in accordance with the themes raised and published in the last 10 years and some longer journals and textbooks for additional literary needs. About 100 articles and using English are reviewed. The cigarette advertisement policy is the main guide, and children smoking habits are in addition. The articles were filtered and found as many as 50 articles in accordance with the purpose of the study. The keywords used are cigarette advertisement policy and children smoking habits.

Results

This study showed that the use of a model of cigarette advertisement policy is very effective in preventing children smoking habits. Cigarette advertisement regulation policy is the government's commitment to protect children, as an effort to protect the younger

generation from cigarette advertisements that are intense and have a very large influence on smoking behavior. Cigarette advertisements are proven to encourage children to try cigarettes, repeating the behavior so that it eventually becomes a habit.

Cigarette advertisements as a promotional medium for cigarettes and various types are very potential to shape the attitudes and behavior of teenage smoking. Knowledge about cigarettes is obtained through cigarette advertisements, both the latest types of cigarettes and the dangers of smoking itself.

Most children like cigarette advertisements on TV and when they see advertisements on TV, there is a feeling to try the cigarette brand in the ad. Sometimes cigarette advertisements do not encourage enthusiasm to smoke and smoke not because they see advertisements on TV or in print media, and the artists they idolize never star in. Sometimes smoking is not because seeing an ad on TV or in print and cigarette advertising does not make the spirit to smoke. And sometimes like cigarette advertisements on TV and when seeing advertisements on TV, there is a feeling to try the cigarette brand in the ad, and the idol artist has starred in cigarette advertisements.

Children are affected by cigarette advertisements on TV, such as buying interest to try the cigarette brands displayed on these advertisements and affect the child's mindset of smoking because cigarette advertisements give a positive impression that makes children more confident, so this shows that children are exposed to advertisements cigarettes will have the opportunity to behave more smoking than respondents who are not exposed to cigarette advertisements.

Cigarette advertisements are packaged as attractive as possible by raising the theme of friendship, friendship and togetherness. Cigarette advertisements are made very attractively and creatively touching the psychological side that shows the image of brave, macho, trendy, cool, togetherness, relaxed, optimistic, male, full of adventure, creative, critical and various other things that boast and represent the conscience of young people and adolescents . This shows that it effectively affects children to behave in smoking.

Advertising is a very effective promotional media in shaping public opinion in the field of cigarettes, therefore almost all cigarette entrepreneurs can spend large amounts of funds for advertising purposes each year, experts at WHO (World Health Organization) state cigarette advertising can stimulate someone to start smoking, can inhibit smokers who want to quit smoking or reduce their cigarettes, can stimulate smokers to smoke more, and motivate smokers to choose certain brands of cigarettes.

The onslaught of cigarette advertisements in electronic media (audiovisual) has a big influence, especially for novice smokers who are generally children. Cigarette advertising and sponsorship is a comprehensive strategy undertaken by the cigarette industry to influence children and adolescents.

Seeing advertisements in the mass media and electronics that show that smokers are a symbol of virility or glamor make children often triggered to follow the behavior of such advertisements. The cigarette industry can enter people's lives by becoming the main sponsor of various sports shows on television, organizing music events on various campuses and schools that attract the attention of many children and adolescents who are one of the objects of cigarette industry advertising targets, offering scholarships for high achieving students. Cigarette advertisements usually contain scenes that present natural beauty, fitness, success. Though smoking itself can cause pollution that pollutes the environment and damage health.

Discussions

There are very few studies that assess the equity of tobacco control interventions or policies affecting young people. The most consistent price or tax increases have a positive equity impact. There is a need to strengthen the basic evidence for the impact of tobacco equity on intervened youth groups[4].

The impact assessment of one of the tobacco control policies recommended by WHO is contained in the MPOWER term (Monitor tobacco use and prevention policies; Protect people from tobacco smoke; Offer help to stop using cigarettes; warn about the dangers of tobacco; enforce advertising bans, promote tobacco and sponsor sponsorship), at least one interesting result in children aged 0-12 years. The main outcomes were: perinatal death, premature birth, hospital asthma and respiratory infections in the hospital[5].

Weekly smoker experiments, plain packaging increases visual attention to health warnings from cigarette branding. Daily smokers, even relatively early

smokers, seem to avoid health warnings on cigarette packs. Adolescents who have never smoked are aware of special health warnings on the type of cigarette pack, a finding that might reflect their decision not to smoke[6].

Exposure to electronic cigarette advertising reduces children's perception of the dangers of smoking. An updated meta-analysis of three studies with 1935 children found that exposure to various types of e-cigarette advertisements (glamorous, healthy, flavorful, not scented) had a lower danger than smoking one or two tobacco cigarettes[7].

The high school environment, targeted advertising makes black people more promotions and lower prices for leading menthol cigarette brands. This evidence contradicts the manufacturer's claim that the availability of promotions is not based on race or ethnicity. It also highlights the need for tobacco control policies that will limit gaps in retail marketing exposure to cigarettes[8].

Higher cigarette prices will reduce the smoking prevalence rate of black, Hispanic, female subpopulations faster than the overall youth population and other youth subpopulations. In addition, this study concludes that a smoke-free air law will reduce the prevalence of smoking for the youth population as a whole with the greatest reduction in the male subpopulation[9].

Awareness of health risks and support for a smoke-free spiritual policy is very high in Ghana. Exposure to tobacco advertisements or promotions is limited and most smokers try to quit. Whether this finding is the cause or effect of the current low prevalence of smoking is still uncertain[10]. The most comprehensive review of motivational interviews to stop smoking is done to date. These findings indicate that the motivational interview approach to stop smoking now can be effective for adolescents and adults. However, useful comparative efficacy tests need to be carried out[11].

Implementation of important steps to reduce WHO FCTC demand is significantly associated with lower smoking prevalence, with a reduction in tobacco-related morbidity and mortality in the future. These findings validate the call for strong implementation of the WHO FCTC in the WHO Global Action Plan for Prevention and Control of Non-Communicable Diseases 2013-2020, and in advancing United Nations Sustainability to Development Goal 3, setting global targets for reducing tobacco use and premature death from non-communicable diseases to one-third in 2030[12].

About one in ten high school students are smokers, one in three smokers smoke more than once per day, and a quarter of nonsmokers ever smoke in China. Smoking rates are higher among students from the Tujia nation than Han. This study provides some important information for future tobacco control programs between secondary school students in ethnic minority autonomous regions and minority settlements in multi-ethnic countries[13].

Very low levels of educational attainment by fathers, smoking more and also consuming drugs, low academic achievement, having permission from parents to smoke, and attending public schools are all related to increasing the higher risk of smoking in the school environment[14]. Siblings and friends who smoke can have an important influence on children's cognitive vulnerability at the age of 9-10 years to smoke. While some differential findings based on gender are observed, this may not be enough to guarantee separate preventive interventions. However, further research is needed[15].

Having a smoker in the family affects not only the children's intentions and attitudes towards smoking, but also the effectiveness of smoking prevention education. Especially it is difficult to increase "intention not to smoke as children", "intention to refuse cigarettes when offered", "attitude away from smokers", and "desire that their families not smoke". Smoking prevention education programs become less effective, in situations that mentioned in raising awareness and attitudes to smoking among elementary and junior high school students[16].

Productivity losses due to premature death and illness caused by smoking are estimated at $ 2.84 billion and $ 941 million respectively. The findings support a strong need for tobacco control and prevention programs to reduce the health and economic burden caused by smoking in Alabama. This result is used by state health workers to describe the true costs of smoking in Alabama and to advocate for improved tobacco control policies[17].

Conclusions

Based on the results of this study, it can be concluded that a model using cigarette advertisement policy is effective for prevent children smoking habits. Further recommendation will be provided.

Abstract

Objective: The average child first tries and is accustomed to smoking when sitting in seventh and eighth grade junior high school (SMP) or around the age of 12-13 years. In TTM Model (Transtheoretical Model), there are 5 stages of TTM. The purpose of this systematic review is to develop a model of transtheoretical in controlling smoking behavior in junior high school students in Palu City, Indonesia.

Method: This research used a systematic literature review. Various references were collected from online database including reports, journals, and books in the last 10 years. The journals were mostly from the scholarly journals. The articles were screened according to the research objectives. The keywords used are transtheoretical model and smoking behavior in junior high school students.

Results: This study showed that the use of a transtheoretical model is very effective in controlling smoking behavior in junior high school students. There are 5 stages of TTM, namely pre-contemplation (contemplation to stop smoking), contemplation (contemplation to stop smoking in the next 6 months), preparation (contemplation to stop smoking in the next 30 days), action (already stopped smoking in 6 months), and maintenance.

Conclusions: This paper concludes that a model using transtheoretical is effective for control smoking behavior in junior high school students. Further recommendation will be provided.

Introduction

Smoking behavior has become a culture in the Indonesian nation. Teenagers, adults, even children are familiar with these deadly objects.Very massive exposure to cigarettes can negatively affect the quality of life of 83.4 million Indonesian children. There is already plenty of evidence that shows that children are targeted

by the cigarette industry to make them loyal customers in the future. In addition to influencing health, the impact of cigarette consumption can also erode the economy and cause social impacts.

The school environment is considered important to be intervened because the school setting is considered more efficient in carrying out actions, very good for developing emotional, academic, cognitive, and other behaviors that support health. The average child first tries and is accustomed to smoking when sitting in seventh and eighth grade junior high school (SMP) or around the age of 12-13 years. Due to including early adolescents, they try smoking because of high curiosity, as well as environmental influences and peers who are very strong in their age. This shows that child smokers are increasingly caused by regulations or policies that are still obtuse.

In TTM Model (Transtheoretical Model), there are 5 stages of TTM, namely pre-contemplation (not thinking to stop smoking), contemplation (thinking to stop smoking in the next 6 months), preparation (thinking to stop smoking within the next 30 days), action (has stopped smoking in 6 months), and maintenance (has stopped smoking for more than 6 months)[1].

WHO (World Health Organization) data in 2015 shows that the prevalence of active smokers in the world currently reaches 17.4%. The National Basic Health Research (Riskesdas) data in 2018 shows that the prevalence of Indonesian smokers in the population aged 10-18 years continues to increase, namely in the Riskesdas data in 2013 of 7.2%, 2016 National Circular Survey data of 8.8% and in the data Riskesdas in 2018 increased to 9.1%. The data presented shows that there is an increase in the prevalence of smokers aged ≥ 10 years in Central Sulawesi, by 30.7% with the number of smokers every day at 26.2% and smokers sometimes at 4.5%.

Data related to age starting smoking every day for ages 10-14 years, the city of Palu ranks third largest in Central Sulawesi at 13.5%. Many factors cause the interest of junior high school students to buy and consume cigarettes in Palu City.

Seeing the problem above, the researcher was interested in conducting research on how a transtheoretical model in controlling smoking behavior in junior high school students in Palu City, Indonesia?. The purpose of this systematic review is to develop a model of transtheoreticalin controlling smoking behavior in junior high school students in Palu City, Indonesia.

Method

This research uses literature review. Literature sources of this review are generally obtained by searching through the internet in various national and international journals, and e-books. Generally the journal is indexed by Google Scholar, Scopus, Elsevier, Science Direct, and others. Generally the literature collected is in accordance with the themes raised and published in the last 10 years and some longer journals and textbooks for additional literary needs. About 150 articles and using English are reviewed. The transtheoretical model is the main guide, and smoking behavior in junior high school students are in addition. The articles were filtered and found as many as 100 articles in accordance with the purpose of the study. The keywords used are transtheoretical model and smoking behavior in junior high school students.

Results

This study showed that the use of a transtheoretical model is very effective in controlling smoking behavior in junior high school students. The research on motivation and method for stopping smoking is based on the concept of the Transtheoretical Model (TTM) developed by Prochaska & Diclemente. There are 5 stages of TTM, namely pre-contemplation (contemplation to stop smoking), contemplation (contemplation to stop smoking in the next 6 months), preparation (contemplation to stop smoking in the next 30 days), action (already stopped smoking in 6 months), and maintenance.

The process of changing smoking cessation can be adapted through six stages of behavior changethrough a transteoritic model, which is a theory that ratesindividual readiness to act or behave healthily, and make a strategy or process of changeto help individuals through the stages of changeto the action and maintenance stage. According to this theory,individuals who are most likely to succeed in changing behavior are individuals who conduct business based on strategies that are appropriate to the readiness stage to replace. The basic theory of the transteoritic model isbehavior change is a process andeveryone is at a different level related to motivation and readiness to change. With regard to smoking behavior, this model identifies five stages of preparedness can be applied to all types of behavior change.

First, precontemplation can be defined as a state of individuals who do not have the desire to change behavior. Most individuals are onthis stage is not even aware that they have behavior problem. Thus, the individual is in stages this is very difficult to be motivated to change behavior. For example, a smoker refuses to put an end to smoking because he feels he does not have the smoking behavior problem that he maintainsso they don't have thoughts or considerations to stop smoking.

Second, contemplation is the condition of a person conscious or start thinking about the existence of a problem of behavior that is maintained, but not yet made commitment to action. At this stage, a smoker starts to think of a time when he has to end smoking behavior due to various negative effects of cigarettes began to be felt because they have not been able to make a commitmenttowards smoking behavior, they will look for the moment and the right conditions to motivate to stop smoke. The process of change that occurs at this stage includes consciousness raising, which is the condition of the individual who discover and learn new facts, ideas and tips that support change towards healthy behavior; dramatic relief, which is feeling negative feelings, such as fear or anxiety about the risk of implementationunhealthy behavior; environmental reevaluation, namely being aware of the negative influence of that behavior unhealthy or positive influence of healthy behavior in the environment around individuals; and self-reevaluation, namely realizing that behavior change is important as part of self identity.

Third, preparation, which is the stage when individuals intend to change behavior in the near future. At the stage, this smoker is ready to quit. Process of change what happens at this stage is self-liberation, the individual make a strong commitment to change. In some cases, smokers start to make plans to stop such as determining when to stop or reducing the amount of cigarette use. Some individuals begin to think of strategies that were carried out on her day must stop.

Fourth, action, as a stage when individuals begin change his behavior to resolve the problem. The act of changing behavior and the factors that support it requires a commitment totime and energy. Most individuals will prove themselves that he is able to put an end to smoking because they have prepared themselves with strategies to deal with the urge to smoke again. Smokers have taken action to quit and are still within the first six months of the smoke-free period. This stage involves several behavioral change processes, namely contingency management, namely increasing appreciation for new healthy behaviors and reduce appreciation towards unhealthy behavior; helping relationships, that is, seeking and using social support for healthy behavior change; counterconditioning, i.e. replace unhealthy thoughts and behavior with alternative behaviors that support change behavior; and stimulus control, which is to throw reminders that can lead individuals to get involved in unhealthy behavior and added a reminder that leads to healthy behavior.

Fifth, maintenance, which is the stage when individuals keep changing behavior from possible relapse (returning to behavior that has been abandoned). Smokers compare the benefits they have gained from stopping smoking with a desire to return to smoking. The process of behavior change at this stage is the same with the action stage. If someone is able to remain free of addictive behavior for more than six months, people it is assumed to have been in the maintenance phase of stopping smoking. Similarly, someone who has stopped smoking but is still on the first year of his smoking-free period.

The sixth, termination, is the last stage which can be applied to addictive behavior. On at this stage, unhealthy behavior will never be back and the individual has no fear relapse. Even though the individual feels depressed, anxious, bored, lonely, angry, or stressed, they are sure that they will not return to behavior old unhealthy as a solution problem. Relapse or recurrence is more a rule of addictive behavior, so the theoretical model describes the stages of change behavior.

Discussions

The study results will provide valuable information regarding how each predictor variable is connected and path through adoption of smoking cessation behavior. By understanding mechanisms of behavior change, health professionals could develop effective smoking cessation interventions with consideration of roles of self-efficacy in the smoking cessation behavior change[2].

The students in the experimental group were given Transtheoretical Model-based planned education, and students in the control group were not given any education. As a result of last tests of the experimental and the control groups, it was observed that there was a statistically significant difference between measurements of "Social interaction and habit strength" (p=0.003),

which is a subscale of it and "Temptation scale total score" (p=0.004), "Being able to cope with the social environments and negative sense (p=0.03), "Being able to cope with the habit strength" (p=0.001), which are subscales of "Self-efficacy scale", "Processes of change scale" total score, and its subscales: "Conscious raising" (p=0.006), "Dramatic relief" (p=0.001), "Environmental reevaluation" (p=0.035), "Self-reevaluation" (p=0.007)[3].

As the change stages progressed, the scores of Decisional Balance sub scale Coping Pros and mean scores of the subscales Habit Strength and Weight Control of Self-Efficacy Scale scores increased in a statistically significant (p<.01)[4].This program has the potential to be applied as stand-alone practice or as part of more intensive interventions to promote substance use cessation[5].

Evidence for the validity of the TTM as it applies to tobacco use is strong and growing; however, it is not conclusive. Eight different staging mechanisms were identified, raising the question of which are most valid and reliable. Interventions tailored to a smoker's stage were successful more often than nontailored interventions in promoting forward stage movement. Stage distribution is well-documented for U.S. populations; however, more research is needed for non-U.S. populations, for special populations, and on other TTM constructs[6].

A TTM-based intervention programme was potentially effective in passive smoking prevention by improving knowledge, experiential and behavioural processes and self-efficacy among pregnant women and women with young children. A higher percentage of mothers with young children had progressed in stages of change post-intervention compared with pregnant women[7].

Given the relative ease of dissemination, these programs could be applied as stand-alone practices or as part of more intensive interventions[8].In Chinese high school students suggest tailored health education and practical interventions should be adopted to reduce sedentary time and thereby improve the efficacy of health promotion[9].

The results provide support to the advantages of increased self-efficacy and the role of decisional balance for the intervention program development for smoking cessation[10].This smoking cessation program increased self-esteem, attitude toward smoking, perceived control over smoking and decreased smoking per day among male high school students. Therefore, schools and parents should focus on developing these factors to encourage students to quit smoking[11].

Nearlytwo-thirdsof smokers in Turkey and more thantwo-thirds in Thailand were in the precontemplation stage during the last survey wave assessed. The proportion of smokers in the preparation stage increased in Turkey but declined in Thailand. Identifying stages of cessation helps guidepopulation-basedtargeted interventions to support smokers at varying stages of change toward quitting[12].

The program was effective in smoking cessation and influencing stages of change but did not change psychosocial factors such as self-efficacy and stress. It is suggested a program should be developed to change psychosocial variables on a long-term basis. It is also desirable to involve peers and families of adolescents who smoke when planning programs to enhance social support[13].

Furthermore, the results showed that measures of self-efficacy decreased, while temptation increased from precontemplation to action stages. The pros of smoking behavior increased toward action stage, while the cons decreased[14].A higher overall prevalence of adolescents in precontemplation stage for smoking cessation was observed. Such group displayed more unfavorable smoking-related behaviors and characteristics than adolescents in other stages. The evidence is limited due to the lack of studies in adolescents living in low-income countries[15].

Transtheoretic model is a significant tool for smoking cessation with its ability to use different models of behavior changes. This flexibilitaly of Transtheoretic model makes the model treatment of choice in different addictions. In this review we focus on the features of Transtheoretic model[16].

Conclusions

Based on the results of this study, it can be concluded that a model using transtheoreticalis effective for control smoking behavior in junior high school students. Further recommendation will be provided.

Abstract

The tradition of herbal medication by plants and products of natural origin in the treatment of various diseases exists thousands of years. Currently, despite the achievements of chemistry and biotechnology, the relevance and popularity of the herbal medicine is quite high. The therapeutic effect peculiarity of the medications from herbal medicinal raw materials is that the therapeutic effect does not occur immediately and is not always obvious, as in case of medications producted by chemical synthesis. However, medications which contain biologically active substances (BAS) of plant origin, unlike synthetic ones, do not cause allergies, are low-toxic, have a favorable effect on the body, and do not have side effects during the continuous use.

Keywords: *Capsule, average, herbal medicine, extract, ferula.*

Introduction

Ferulatenuisecta (lat. *Fērulatenuisēcta*) is popular in folk medicine of Central Asia, the medicinal raw material of which is the milky juice of roots, gums and resin[1]. It acts as a antifatigue, antibacterial, anti-inflammatory, antifatigue and antitumor medication. One can use ferula both internally and externally. One takes an infusion for internal use. Ferula can be used for internal use in order to debride a wound, and it is also can be used to lubricate wounds, tumors, boils, and trophic ulcers. It is possible to make compresses by a warmed bandage on the sore spot.

The Institute of the Chemistry of Plant Substances named acad. S. Yu. Yunusov of the Academy of Sciences of the Republic of Uzbekistan has developed a technology for the sum determination of terpene compounds and then the production of a dry extract. We found the estrogenic activity within the screening study of extracts, sum and separate compounds of Ferulatenuisecta.

Materials and Method

In order to make Summary in respect to the composition and technology of capsules of Ferulatenuisecta dry extract, we put under study the main physical, chemical and technological properties of the substance samples . These properties are interrelated and can influence the process of high-quality capsules production with the necessary therapeutic effect in a certain way. The substance-powder of Ferulatenuisecta dry extract and the encapsulated mass were subject to physical, chemical and technological research. From the technological properties of the dry extract, the fractional composition, porosity, flowability, tap density, angle of natural slope, compressibility, compression ratio and residual moisture were under study.

The research findings of dry extract technological properties showed unsatisfactory values of flowability and angle of natural slope, which will obviously have a negative impact on the filling process of capsules, so we had the task to improve these indicators by the optimal selection of the excipients and technological process.

Table 1: The results of the technological properties study in relation to dry extract of Ferulatenuisecta

№	The indicators under study	UOM	Results
1.	**Fractional Composition:** +1000 -1000 + 500 - 500 + 250 - 250 + 150 - 150 +125 - 125	µm, %	 2.2 20.1 45.3 12.4 11.6 8.4
3.	Tap density	kg/m^3	452,00±2,07
4.	Flowability	10^{-3} kg/s	0,55±0,83
5.	Angle of natural slope	degree	72.00
6.	Compressibility	H	70,0±5,0
7.	Residual Moisture (70^0C)	%	5.00

In case of capsules development[2], where dry extract is the main substance (which, as a rule, does not have a satisfactory value of the flowability index), one can use the method of pre-wet granulation in order to select the optimal technology, as well as to improve the technological indicators. As for the completeness and objectivity of the paper, we decided to select the optimal composition and technology of the capsular pharmaceutical dosage form.

As the principal vehicle, we selected microcrystalline cellulose (MCC)[3] of the following brands, "MCC-101" and "MCC-102" these MCC brands are most popular in the production of medicines among domestic pharmaceutical enterprises. MCC-102 is superior to MCC-101 by its technological parameters, which makes it possible to use it for tableting by direct compression, but from an economic perspective, the price of MCC-102 is 50% higher than MCC-101. Also, potato and corn starches were used as vehicle, both of these excipients also have leavening property, which in turn can improve the flowability index[4]. As excipients we also used: lactose monohydrate (as a moisture-absorbing and adsorbing agent), aerosil[5] (as a fluidity-enhancing and adsorbing agent), talc, magnesium stearate, calcium stearate (as antifriction substances that improve the flowability).

In addition, we used the following excipients as for the pre-wet granulation method: ethyl alcohol (various concentrations), starch paste (various concentrations) and purified water.

After that, we made a number of experiments on the composition selection with the subsequent preparation of various masses in order to fill the capsules. The following table shows the most optimal compositions of encapsulated masses in terms of both technological indicators and the highest economic profitability.

Table 2: The compositions of capsules selected with the use of various excipients

Name of medications and excipients	Quantity of medications and excipients, mg				
	1	**2**	**3**	**4**	**5**
Dry extract	40	40	40	40	40
MCC-102	295				
MCC-101		295	200	195	198
Corn starch			155		155
Potato starch	60	60			
Lactose				155	
Talc				5	2
Aerosil	2	2	2	2	2
Magnesium stearate	3	3	3	3	3
Average weight	400	400	400	400	400

In the selection of the encapsulated mass various compositions and their subsequent preparation, we have consistently studied the technological properties obtained by both dry blending and pre-granulation method. The research results of the encapsulated mass technological properties you can find in table 3.

We used purified water; ethyl alcohol of 40, 70, 96% concentrations; 3, 5, 10% starch paste as moistening agent. We obtained granulated masses with each binding agent. The results of the experiments showed that the most optimal binding agent was 5% starch paste.

Table 3: The research results of the encapsulated masses technological properties obtained with various excipients

№	Verifiable indicators	Units of Measure	Compositions				
			1	2	3	4	5
1	Fractional composition, µm						
	+1000	%	-	-	-	-	-
	-1000 +500		0.60	0.49	8.20	6.20	6.40
	-500 +250		3.40	3.51	12.10	9.55	9.55
	-250 +150		10.15	9.45	12.75	18.46	18.7
	-150 +125		65.45	72.14	54.25	47.24	47.0
	-125		20.4	14.41	12.7	18.55	18.35
2	Flow ability	10^{-3} kg/s	6,4±1,1	3,8±0,2	2,6±0,1	2,8±0,2	6,7±0,2
3	Angle of natural slope	degree.	40	58	60	65	45
4	Tap density	kg/m^3	560±0,8	520±0,8	720±1,8	638±3,1	670±2,1
5	Residual moisture (70°C)	%	4	3.5	4-5	4-5	3

The production of granules by pre-granulation worked in accordance with the following method: the substance and excipients separately passed through a sieve with a hole diameter of 150 µm. We weigh the desired amount, after we mix the substance and excipients for 40 minutes, after we granulate them by wet granulation in the desired amount of starch paste as a binding agent. We line the resulted wet mass by a thin layer on a baking tray with parchment paper and place it in exsiccator, we dry it at a temperature of 60-70°C up to the optimal relative humidity of the mass (3.6-3.0%). We pass the dried mass through a sieve with a hole diameter of 1000 µm by pressing, thus we form granules. We powder the resulted prepared granules with magnesium stearate, talc and aerosil pre-sifted through a sieve with a hole size of 125 µm. The resulted mass goes to the capsule filling process.

On the basis of technological properties research results, we have proposed the most optimal composition of capsules with Ferulatenuisecta dry extract:

Dry extract	– 40 mg
MCC-101	– 198 mg
Corn starch	– 155 mg
Talc	– 2 mg
Aerosil	– 2 mg
Magnesium stearate	– 3 mg
Average weight	**– 400 mg**

The next stage of our research was to study the quality indicators of capsules with Ferulatenuisecta dry extract and encapsulated mass by the method given in the literature.

Description: Hard gelatine capsules of bright red color, with volume №1. The encapsulated mass in the form of granules with adelomorphous shape, of brown color.

Identification: The ultraviolet spectrum of the solution obtained for quantitation within the range from 230 nm to 290 nm has a maximum absorption at (260±2) nm.

Shake 0.4 g of the powder poured from the capsules with 8 ml of glacial acetic acid for 5 minutes and filter it through a paper filter (GOST 12026-76). Add 0.2 ml of vanillin solution to sulfuric acid to the filtrate, and a blue-green staining appears (a sesquiterpene ferutinin residue).

Weighing of the average mass. In order to weigh the average mass, we weigh 20 unopened capsules together and determine the average weight of the capsule. Then weigh each capsule separately and compare it with the average weight. The deviation of the each capsule mass should not exceed±10% of the average mass. Then carefully open the same 20 capsules, remove the contents

as completely as possible and weigh each shell. For soft capsules with liquid or pasty contents, we wash the shell with ether or other suitable solvent before weighing with the following air removal of the solvent. Determine the average mass of the capsule contents. Unless there are no any specified instructions in the individual monographs, the mass deviation of each capsule contents from the average mass should not exceed±10%, with the exception of two capsules, in which a deviation is possible of up to±25. If more than 2 capsules, but not more than 6 have deviations from the average weight within the range of 10 to 25%, then we determine the contents of each capsule and the average weight of the contents of 60 capsules with 40 capsules in addition. No more than six capsules out of 60 can have deviations from the average weight of more than±10% and there should not be any capsules that have a deviation in the mass of the contents of more than±25%. We use the contents of 20 or 60 capsules for quantitation of medicinal substances and other indicators under individual monographs.

Disintegration: One can determine it by a special laboratory identifier.[6] The device design consists of a "basket", a vial with a volume of 1 l (for liquid), a thermal device that maintains the temperature of the liquid within (37±2)°C, an Electromechanical device that supplies the basket with a reciprocating motion by a frequency of 28 to 32 cycles per 1 min.

The main part of the device consists of a rigid basket with a mesh bottom which supports six cylindrical glass tubes, whose length is (75.5 - 79.5) mm, internal diameter is (20.7-23) mm and wall thickness is (1.0 - 2.8) mm. The glass tubes locate vertically and two plastic plates hold them (at the top and bottom) The parameters of plates are: a diameter (88-92) mm, thickness (5-8.5) mm, it has six holes with diameter (22-26) mm. The holes are equidistant from the center of the plate and from each other. A square grid with cells of size (1,8 - 2,2) mm and a stainless steel wire of diameter (0,57 - 0,66) mm fixes to the lower plane of the plate. The rods hold the plates in vertical position along the entire circumference. Another rod fixes in the center of the plate upper plane, which allows you to attach the basket to a mechanical device. You can raise and lower the basket by it. The time of movement up and down should be the same.

We select 16-18 capsules for the test. One sample is in each tube. We lower the basket into a container with liquid and turn on the device. At the end of the specified time, we withdraw the basket. Examine the state of the samples. All the tested samples must completely disintegrate. If 1-2 capsules do not fall to pieces, we repeat the test with the remaining samples. At least 16 of the 18 selected samples must completely disintegrate.

One can consider that sample have passed the test if it leaves no residue, or a residue is in the form of a soft mass that falls in parts at the slightest touch of a glass stick.

The findings: the tested capsules completely disintegrate within 14 minutes.

Quantitation: We place about 0.4 g (precisely weighed amount) the powder poured from the capsules in a measuring flask with a capacity of 100 ml, add 80 ml of 96% alcohol and shake for 10 min., then bring the volume of the solution with the same solvent to the mark, filter it through a paper filter (blue tape), discarding the first 10 ml of filtrate. We transfer 1 ml of filtrate to a measuring flask with a capacity of 25 ml, bring the volume of the solution with 96% ethyl alcohol up to the mark and mix. We measure the optical density of the resulting solution by a spectrophotometer at a wavelength of 260 nm in a cuvette with a layer thickness of 10 mm. We use 96% ethyl alcohol as a reference solution.

At the same time, we measure the optical density of the ferulen work standard solution. We calculate the content of ferulen in one capsule, in grams (X) by the formula:

$$X = \frac{D_1 a_0 * 100 * 1 * 2 * b}{D_0 * a_1 * 100 * 1 * 50} = \frac{D_1 * a_0 * b}{D_0 * a_1 * 2}$$

Where:

D_0 is the optical density of the ferulene work standard solution;

D_1-optical density of the test solution;

a_0 - dose weight of the ferulen work standard, in grams;

a_1 - dose weight of the powder poured from the capsules, in grams;

b-the average weight of one capsule in grams.

The content of ferulen in one capsule should be from 0.036 g to 0.0044 g (in terms of feerutinin from 0.009 g to 0.011 g) with count of one capsule average weight.

Table 4: The quantitation metrological description of capsules with dry extract of Ferulatenuisecta

Series	Dose weight, g	Findings		Metrological description
		By dose weight, g	In one capsule, g	
011117	0.400	0.160	0.040	X_{avg} = 0,159 t(95%,4)=2,78 S^2 = 0,00000525 S = 0,00229±DX = 0,00636±DE = 4,006 P = 95
021117	0.405	0.158	0.039	
031117	0.410	0.156	0.038	
041117	0.41	0.162	0.039	
051117	0.40	0.160	0.040	

Note: Preparation of the solution with the work standard of ferulen. We place about 0.04 g (precisely weighed amount) of ferulene (in terms of ferutinin 0.01 g) in a 100 ml volumetric flask, add 80 ml of 96% alcohol and dissolve with continuous stirring. Then we bring the solution volume with the same solvent to the mark and mix. We transfer 3 ml of the resulted solution to a measuring flask with a capacity of 25 ml, bring the volume of the solution with 96% alcohol to the mark and mix. The solution must be freshly prepared.

Packaging: 10 capsules in a contour – cell package in accordance with GOST 64-074-91 (All-Union standard) from polyvinyl chloride film in accordance with GOST 25250-88 or imported and printed lacquered aluminum foil in accordance with TU 48-21-270-78 or imported or 10, 20, 30, 50 and 100 in polymer vials (banks) in accordance with GOST 64-15390981-02:2003 from low-pressure polyethylene in accordance with GOST 16338-85E or high-pressure polyethylene in accordance with GOST 16337-77, the vials must have labels made of label paper by GOST 7625-86e or writing paper by GOST 18510-87e.[7]

We place packs, contour cell packages by 1 [no. 10(1x10)], by 2 [no. 20(2x10)], by 3 [no. 30(3x10)] pieces together with the instructions for use in a pack (pencil case) of box cardboard in accordance with GOST 7933-89E or other imported and with packing lists on accordance with OST 64-7-382-84 placed in a box of box cardboard in accordance with GOST 8273-75 or bagged by GOST 2228-81E. The boxes or stops are pasted with a parcel made of wrapping paper by GOST 8273-75 or tied with cotton threads in accordance with GOST 6309-87 or twine made of bast fibers by GOST 17308-88, the ends of which are pasted with a label made of label paper in accordance with GOST 7625-86E or writing paper in accordance with GOST 18510-87E.

The identification of stability and capsules shelf life. The purpose of stability investigation is to obtain data on changes over time in the quality of the medication under the influence of various environmental factors, such as temperature, humidity and light, as well as to establish the frequency of repeated studies of the active substance or the shelf life of the medication and recommended storage conditions[8].

The stability tests of the Pharmaceutical Dosage Form must be in the intended packaging for presentation on the market (including, if necessary, any secondary packaging and container labels).

The use of rational packaging[9] is the main way to prevent a decrease in the quality of encapsulated medications in storage. Therefore, the type selection of packaging and packaging materials is individual in each case in accordance with the physical and chemical properties of the substances within the capsules.

One of the most important requirements for packaging materials is the protection of capsules from light, atmospheric moisture, air oxygen, and microbial contamination. Today, we use the traditional packaging materials such as paper, cardboard, metal, and glass for capsule packaging. Along with the traditional materials, film packages made of cellophane, polyethylene, polystyrene, polypropylene, polyvinyl chloride and various combined films on the basis of them are popular. The most promising film contour packages, which are produced on the basis of combined materials by the method of thermal welding, are strip pack (tape) and cellular pack (blister).

In order to make tape packaging it is popular to use laminated cellophane tape in various combinations, aluminum foil, laminated paper, laminated polyester or nylon polymer film. One can make packaging by heat welding of two-placed materials. The special machines make such packs. As a thermoforming film, hard (non-plasticized) or weakly plasticized polyvinyl chloride (PVC) with a thickness of 0.2-0.35 mm or more is most popular for usage. PVC film is well formed and heat-bonded with various materials (foil, paper, cardboard, covered with a thermolak layer). The film covering by polyvinyl chloride or ethylene halogenation reduces gas and vapor permeability. For hygroscopic medicines, we recommend to use polypropylene, but it is more difficult to form. In addition, it is more tough than PVC. Polystyrene is also well formed, but is unpopular due to its high water permeability. In order to close the cells, aluminum foil is quite popular. On the inside, it is covered with glue or thermal adhesive film, on the outside-with varnish. Aluminum foil is impervious to water vapor and gases, well protects the medications from the fragrance permeation. The packaging, one layer of which is aluminum foil, provides high tightness.

The main function of containers, packaging and capping is to isolate a separate dosage (portion) of a medication not only from other dosages of the same medical product, but also from the effects of so-called environmental factors: light, atmospheric air pressure, atmospheric natural gases and vapors, as well as from the evaporation into the surrounding atmosphere of other medical products, chemicals and products that one stores in the same or in neighboring rooms. In other words, one determines the suitability of a package by four properties: protection, safety, compatibility, and performance (functioning and/or delivery of medicines). In case of the packaging/capping system assessment, we must consider the following factors: design materials of the packaging/capping device; surface treatment and/or technological additives; active ingredients and vehicles that are part of the Pharmaceutical Dosage Form; sterilization and/or other similar processes; finally, storage conditions.

Storage conditions have a great influence on the stability of medicinal substances within capsules and on their physical and chemical parameters.

An increase in air temperature and the effect of direct sunlight have a negative impact on the quality of capsules. Therefore, one stores the capsules at room temperature in a dry, protected from light place.

Stability tests should include studies of such characteristics in respect to the finished medicinal product that are subject to changes during storage and may reasonably affect quality, safety and/or efficacy. One should study physical, chemical, biological and microbiological properties (in accordance with the specific situation). Thus, the study of medical product stability is an additional source for development and improvement of the requirements that determine the quality of medical products.

One stores the hard gelatine capsules with a dry extract of the Ferulatenuisecta at room temperature (20±5)°C, humidity (60±5)%. These conditions correspond to the natural method of storage, the research duration is1 year with intermediate quality checks every 6 months the research continues. The findings show the value of the verifiable indicators within the normal range, and one can also note that the various containers and packaging materials selected for capsules storage ensure safe storage and stability of the medical product. Thus, we can recommend the packaging materials used in the experiments for further use.

Also, one of the most popular research method within the stability identification of medical products is the method of “accelerated ageing”. The essence of the method is to increase the storage temperature at the expense of a thermostat usage, and in the presence

of more advanced equipment that can also control humidity indicators and automate the process, one can achieve more accurate research results. In accordance with the experiments results, the optimal temperature for the capsules was 40°C, as at the storage temperature of 50–60°C, the quantitative indicators of the capsules showed some changes. The packaged capsules were put in a thermostat (40°C) and every 46 days (corresponding to 6 months of storage at room temperature) passed the quality indicators examination. As a result of the experiments, the shelf life of capsules with dry extract of Ferulatenuisecta was 184 days (on the basis of 2 year storage at room temperature), the results are in the table.

Table 6: The capsules shelf life identification by natural storage

Types of packaging GOST, OST, TU	Verifiable indicators	Primary results	Shelf life, months	
			6	12

Conclusions

One selected the optimal composition of the encapsulated mass and the subsequent study of the technological properties, the findings showed an improvement in the flowability and angle of natural slope after the addition of excipients and pre-wet granulation. Also, on the basis of the obtained optimal composition, the average weight of capsules was 0.4 g and the size of the most optimal gelatin capsule in accordance with the volume № 1.

There were complex experimental studies in respect to the main quality indicators of developed capsules in accordance with the State Pharmacopoeia of XI edition, notably: organoleptic properties, average mass, mass uniformity, disintegration, authenticity, quantitation. One determined the shelf life and stability of capsules by the method of "accelerated aging" and natural storage[10].

We selected the packaging and storage conditions for the received capsules, and the shelf life of the capsules was 2 years.

Comparative Analysis of Human Kidney Venous Vessels at Various Method of Radiation Research

Abuselim Vezirkhanov[1], Edgar Kafarov[1], Oleg Zenin[1]

[1]Associate Professor, Chechen State University, Grozny, Chechen Republic, Russia, Penza State University, Penza, Russia

Abstract

The aim of the study was to conduct a comparative assessment of the spatial characteristics of the kidney veins in a planar projection, in stereo projection, and according to the results of computed tomography after 3D modeling. To compare and identify the truth of the morphometric parameters of the renal veins, as well as the options for their formation during x-ray and computed tomography, 136 corrosive preparations of the kidney veins were made, which were taken as a control group. To identify the degree of similarity of the renal veins parameters on corrosion preparations, X-ray diffraction patterns (2D) and on computed tomograms (CT) with a helix pitch of 1.0 and 2.5 mm after 3D modeling, a comparative assessment of the obtained parameters was performed (degree of the angle similarity - simPhi; the degree of length similarity is simLen; and the general degree of similarity is sim). It was revealed that the greatest degree of parameters similarity was found between corrosive preparations and computed tomograms of kidney veins with a spiral pitch of 1.0 mm, which was 98.0%. Studies have shown that the informational content of x-ray examination of the kidneys' veins depends on the options for the formation and location of blood vessels in the gates of the kidney relative to the frontal, horizontal and sagittal planes. The informativeness of computed tomography studies does not depend on the options for the formation of renal veins, it determines the step of the spiral.

Keywords: *Kidney, renal veins, 3D - modeling.*

Introduction

Today in the literature there are single and conflicting data[2] on the morphometric indicators of human renal venous vessels[13]. The ambiguity of this information[9] depends on various methodological approaches used[6] in the study of these vessels[4]. Thus, morphometric indicators[3] obtained in the study of autopsy material do not always correspond to the data of radiation diagnostics[14]. There are frequent discrepancies in the data of X-ray diffraction patterns[5] with anatomical preparations[15]; in addition, there have been cases of the absence of certain sections of the intraorgan kidney veins[11] on the X-ray diffraction patterns[16].

Today, the clinic uses computed tomography[21] to study the vascular bed of the kidney[20]. However, this method does not always allow obtaining the exact parameters of blood vessels, since after 3D reconstruction[19] their true sizes may be lost[18], and sometimes some anatomical details important for diagnosis are missing or artificially formed structures[14] sometimes appear[17].

Materials and Method

We have made 136 corrosive preparations of the kidneys' venous channel of people in the age range from 22 to 90 years who died from diseases not related to kidney pathology. As the mass for pouring, Styracryl, Protacryl + Kraplak was used to simulate a radiopaque substance. To compare and identify the truth of the morphometric parameters of the renal veins, as well as the options for their formation during x-ray and computed tomography, the corrosion preparations of the kidney veins were taken as a control group[4].

Research Algorithm:

1. On corrosion preparations, 5 of the most common renal vein formation variants were identified.
2. Corrosive preparations of the kidneys veins were

subjected to digital radiography on an apparatus Clinodigit Compact X - FRAME, (Italy). The current strength was 200 mA, the voltage was 65 kV, the exposure was 300 seconds, and the focal length was 120 cm.

3. Corrosion preparations of the kidneys veins were subjected to computed tomography scanning using the Light Speed VCT apparatus (Germany). The current strength was 132 mAs, the voltage was 140 kV, the spiral pitch was 1.0 and 2.5 mm, followed by 3D modeling.

4. Corrosion preparations of the venous vessels of the kidneys, their lengths and diameters were measured on corrosion preparations of kidney veins, X-ray angiograms and computed tomograms.

5. To identify the degree of similarity of the renal veins parameters on corrosion preparations, X-ray angiograms (2D) and on computed tomograms (CT) with a helix pitch of 1.0 and 2.5 mm after 3D modeling, a comparative assessment of the obtained parameters was performed (degree of similarity of the angle - simPhi; degree of similarity of length - simLen; and general degree of similarity - sim).

The degree of similarity of corresponding vectors' pairs was revealed. Each category of the studied parameters was associated with a characteristic vector. We used the cosine measure of vectors proximity[1]. For this, they began to determine the function $simPhi(V_i, V_j)$ according to the formula 1.

$$simPhi(V_i, V_j) = \frac{\arccos(cos\theta)}{\frac{\pi}{2}} * 100\% \quad (1)$$

Further, the function $simPhi(V_i, V_j)$ between corresponding vectors V_i и V_j uses the cosine of an angle.

The cosine of the angle, knowing the corresponding coordinates of the vectors, was revealed through the scalar product according to the formula 2.

$$cos\theta = \frac{\vec{V_i} \cdot \vec{V_j}}{|\vec{V_i}| \cdot |\vec{V_j}|} \quad (2)$$

the scalar product was calculated by the formula 3:

$\vec{V_i} \cdot \vec{V_j} = \sum_{k=0}^{N} V_i^k * V_j^k$, где N – was the rank of the corresponding vector (3)

$|\vec{V_i}|$ и $|\vec{V_j}|$- the lengths of the corresponding vectors V_i и V_j.

We determined them according to the formula 4:

$$|\vec{V_i}| = \sqrt{\sum_{k=0}^{N} V_i^k * V_i^k} \quad (4)$$

As a result, simPhi was revealed - this is the degree of similarity of the angles of venous vessels. Identification of the correspondence and similarity degree of the venous vessels parameters by angle was insufficient. For this, an additional measure of correspondence and similarity of vectors along the length of venous vessels was introduced, i.e., a function $simLen(V_i, V_j)$ was revealed according to the formula 5:

$$simLen(V_i, V_j) = \frac{\min(|\vec{V_i}|, |\vec{V_j}|)}{\max(|\vec{V_i}|, |\vec{V_j}|)} * 100\% \quad (5)$$

Further, to reveal a comprehensive measure of correspondence and similarity of the two studied vectors, the formula 6 was used.

$$sim(V_i, V_j) = simPhi(V_i, V_j) * simLen(V_i, V_j) \quad (6)$$

6. All digital material obtained, and the data of instrumental research method were processed using variation statistics method using a workstation with an Intel Core2Duo T5250 processor 1.5 GHz, RAM up to 2 GB on a Windows 7 platform. In the course of work, the Excel application package from *Microsoft Office 2007*.

Results

It was revealed that in 32.4% of cases, the renal vein is formed from the upper and lower pole veins. The average diameter of the renal vein was 26.2±1.3 mm. The fusion angle of the upper and lower pole veins was on average 21.2±1°. The length of the superior pole vein was on average 18.2±0.9 mm, and that of the inferior pole vein was 27.2±1.3 mm. According to the analysis of X-ray angiograms from the same corrosion preparations of the kidney veins, the average diameter of the renal vein did not differ from the parameters obtained on the corrosion preparations of the kidney and amounted to 26.4±1.3 mm. The average angle of confluence of the upper and lower pole veins was less than on corrosive preparations and amounted to 20.2±1°. The length of the superior pole vein averaged 17.2±0.8 mm, and the length of the inferior pole vein 26.4±1.3 mm. According to the analysis of computer tomograms (spiral pitch 1.0 mm with 3D modeling), the average diameter of the renal vein was 26.3±1.3 mm, not significantly different from the data on corrosion preparations. The average fusion angle of the upper and lower pole veins also did not differ

from the data obtained by morphometry of corrosive preparations and amounted to 20.1±1°. The average length of the superior pole vein did not differ from the data on corrosive preparations and amounted to 18.3±0.9 mm. However, analysis of computed tomograms (2.5 mm pitch) showed significant differences in average values. So, the average diameter of the renal vein was significantly different and was 28.2±1.4 mm. The fusion angle of the upper and lower pole veins on average significantly differed from the parameters obtained on corrosion preparations and amounted to 16.7±1°. The average length of the superior pole vein was 16.4±0.8 mm, and that of the inferior pole vein was 24.3±1.2 mm, which was less than with corrosive preparations.

A comparative analysis of renal vein morphometry data on radiographs and computed tomograms with data on corrosion preparations showed that the similarity degree of the parameters was: simPhi - (3D, 2D) - 98,2%, simPhi - (3D, KT1) - 98,5%, simPhi - (3D, KT2,5) - 89,9%, simLen - (3D, 2D) - 97,8%, simLen - (3D, KT1) - 99,3%, simLen - (3D, KT2,5) - 96,5%, sim - (3D, 2D) - 96,0%, sim - (3D, KT1) - 97,8%, sim - (3D, KT2,5) - 86,8%.

In 25.4% of cases, renal veins are formed from the ventral and dorsal veins. It was revealed that the average diameter of the renal vein is 10.8±0.5 mm. The average fusion angle of the ventral and dorsal veins was 27.2±1.3°. The length of the ventral vein averaged 33.2±1.6 mm, and the dorsal vein 39.1±1.9 mm. Analysis of x-ray diffraction patterns showed that in 14% of cases, the shadow of the ventral vein in the frontal projection was visualized as an upper pole, and the dorsal as a lower pole (orthogonal principle of the depth of location). In 26% of cases, the shadows of both veins were projected onto each other, giving out the projection of a single trunk (orthogonal principle of competing lines). Morphometric analysis of computed tomograms (spiral pitch 1.0 mm) did not reveal significant differences from indicators obtained on corrosive preparations of kidney veins. However, computer tomograms (spiral pitch 2.5 mm) revealed that the average diameter of the renal vein did not differ significantly from the data of corrosive preparations and was 13.2±0.6 mm. The fusion angle of the ventral and dorsal veins differed and averaged 26.5±1.3°. The average length of the ventral vein was 26.2±1.3 mm, and that of the dorsal vein was 23.4±1.1 mm, which was significantly less than on corrosion preparations.

When comparing morphometry data, the degree of similarity was: simPhi - (3D, 2D) - 84.2%, simPhi - (3D, CT1) - 99.7%, simPhi - (3D, CT2.5) - 84.9%, simLen - (3D, 2D) - 84.0%, simLen - (3D, KT1) - 99.9%, simLen - (3D, KT2.5) - 79.7%, sim - (3D, 2D) - 70, 8%, sim - (3D, KT1.5) - 99.7%, sim - (3D, KT2.5) - 67.7%.

In 8.4% of cases, the renal vein is formed from the superior pole, inferior pole and dorsal central veins. The value of the diameter of the renal vein averaged 9.1±1.0 mm. The fusion angle of the upper and lower pole veins averaged 18.1±0.9°. The confluence angle of the upper pole and dorsal central veins was 29.3±1.4°. The fusion angle of the dorsal central and lower pole veins averaged 28.1±1.4°. The length of the superior pole vein was on average 21.1±0.1 mm, while the diameter was 8.4±0.4 mm. The length of the dorsal central vein averaged 12.8±0.6 mm, and the average value of its diameter was 5.5±0.2 mm. The length of the inferior pole vein averaged 14.8±0.7 mm, while its diameter averaged 8.1±0.4 mm.

Analysis of x-ray diffraction patterns showed that in 18% of cases, the shadow of the dorsal central vein was visualized as the central one (orthogonal principle of the depth of location), located in the same plane with the rest of the veins. The average diameter of the renal vein was 9.4±0.4 mm. The fusion angle of the upper and lower pole veins averaged 17.2±0.8°. The fusion angle of the upper pole and dorsal central veins was on average 13.2±0.6°, and the dorsal central and lower pole veins 14.1±0.6°. The length of the superior pole vein was, on average, 20.2±1.0 mm, and its diameter 8.7±0.4 mm, which did not significantly differ from that on corrosion preparations. The length of the dorsal central vein averaged 9.3±0.4 mm, and its average diameter was 5.8±0.2 mm. The length of the inferior pole vein was on average 13.1±0.6 mm, and its average diameter was 8.5±0.4 mm.

According to the analysis of computed tomograms (spiral pitch 1.0 mm), it was revealed that the average values of their morphometry data did not differ significantly from those on corrosive preparations. However, analysis of computed tomograms from the same corrosive preparations (2.5 mm pitch) showed significant differences in morphometric parameters and the appearance of non-existent parts. So, in 6.2% of cases, a central vein and insufficient visualization of interlobar and arc veins were visualized on computed tomograms. The diameter of the renal vein was on average 11.3±0.5

mm. The fusion angle of the upper and lower pole veins was on average 17.1±0.8°. The confluence angle of the upper pole and dorsal central veins was 27.3±1.3°. The fusion angle of the dorsal central and lower pole veins averaged 26.4±1.3°, which was significantly different from morphometry data on corrosion preparations. On average, the length of the superior pole vein was less than on corrosive preparations and was 19.4±0.9 mm, and its diameter was 10.2±0.5 mm. The length of the dorsal central vein was also less and amounted to 10.4±0.5 mm, while its diameter was on average equal to 7.1±0.3 mm. The length of the inferior pole vein was on average 12.3±0.6 mm, while its average diameter was 10.3±0.5 mm. A comparative analysis of morphometry data showed that the degree of similarity was: simPhi - (3D, 2D) - 79.1%, simPhi - (3D, CT1) - 99.8%, simPhi - (3D, CT2.5) - 95.5 %, simLen - (3D, 2D) - 70.2%, simLen - (3D, KT1) - 99.7%, simLen - (3D, KT2.5) - 93.0%, sim - (3D, 2D) - 55.5%, sim - (3D, KT1) - 99.6%, sim - (3D, KT2.5) - 88.8%.

In 4.2% of cases, renal veins are formed from the ventral, dorsal and lower pole veins. In 13.0% of cases on X-ray diffraction patterns from the same corrosive preparations, the ventral veins were visualized as upper pole, dorsal veins as central (the principle of location depth). On x-ray angiograms, these veins were falsely projected in the frontal plane in the form of an upper pole, central and lower pole vein. In 16.0% of cases, when the veins are located in the same projection, the shadows are subtracted, and the ventral and dorsal veins overlap each other, which creates the false impression of a single venous trunk (the principle of competing lines).

Discussion

Based on the researches, it was established that certain options appear on the radiograph[10], which is consistent with the opinion of a authors' number[16]. According to the results of our research, variants were observed, as a rule, where the shadows of the kidneys veins were projected in the same geometric plane[11]. In axonometry, they are called competing lines, giving a single shadow in one plane[16]. If a separate image element (a section of a kidney vein) was an object of perception, then options in a planar projection were visualized relative to the depth of the venous vessels[7]. On radiographs of corrosive preparations of the veins of the kidney, the true parameters (angles of fusion of the veins, lengths of the kidneys veins and their diameters) were distorted. Analysis of computed tomograms with a helix pitch of 1.0 and 2.5 mm, followed by 3D modeling, revealed possible distortions of the spatial organization of the venous vessels of the kidneys, which depend on the helix pitch (changes in diameters, angles of vascular fusion). According to the study, after 3D - modeling, computed tomograms do not contain some important anatomical structures for diagnosis, and sometimes artificially formed parts appear in the form of additional (non-existent) venous vessels[4], which we met in 28.6% of cases and is consistent with data from several authors[10].

Conclusion

A comparative assessment of the spatial characteristics of the kidney veins in planar projection, in stereo projection, and according to the results of computed tomography with increments of 1.0 and 2.5 mm after 3D modeling showed that the highest degree of the parameters similarity was found between corrosion preparations and computed tomograms of kidney veins with a spiral pitch 1.0 mm, which was equal to 98.0%.

Studies have shown that the informational content of x-ray examination of the kidneys veins depends on the options for the formation and location of blood vessels in the gates of the kidney relative to the frontal, horizontal and sagittal planes. The informativeness of computed tomography studies does not depend on the options for the formation of renal veins, it determines the step of the spiral.

Specifics of Left Ventricular Remodeling and Daily Blood Pressure Profiles in Young and Middle-Aged Servicemembers Dealing with Arterial Hypertension

Botyrkhon Salikhov[1], Bakhromkhon Alyavee[1]

[1]Associate Professor, The Republican Specialized Scientific and Practical Medical Center for Therapy and Medical Rehabilitation, Tashkent, Uzbekistan

Abstract

Objective: Investigating structural and geometrical parameters, specifics of LV remodeling, as well as daily BP profiles in young and middle-aged service members dealing with hypertension Stage 1 and Stage 2. A group of 86 male subjects has been researched, including 52 young (26-44 y/o) and 34 middle-aged (45-55 y/o) subjects with AH. The cardiac function has been evaluated through echo cardiography, and daily BP monitoring has been carried out. The ***results*** of the study have shown that young and middle-aged servicemen with AH have a normal LV geometry (59.6% of young subjects (31), 55.9% of middle-aged subjects (19)), and concentric LV remodeling has been observed in 40.4% of young subjects (21) and in 22.1% of middle-aged (15) subjects with AH. According to data obtained during 24-hr BPM,as compared to the normal LV geometry group, in the concentric LV remodeling groups the occurrence of the dipper AH profile has decreased both in young (28.5% vs. 39%) and middle-aged (40% vs. 47.7%) subjects.

Keywords: *Arterial hypertension; echo cardiography, left ventricular remodeling, 24-hr arterial blood pressure monitoring.*

Introduction

Arterial hypertension (AH) is a leading mortality and disability risk factor among CVDs, being far ahead of other risk factors. It has been confirmed by many authors, as they note that in 2015, AH was the most common cause of premature death, killing 10 million and disabling more than 200 million people (5).

An important morphological and functional change, which characterizes thetarget organ's state, is left ventricular (LV) myocardial remodeling. This and other changes consist in LVH (left ventricular hypertrophy), which results from structural and functional modification of the heart, which adapts to increased hemodynamic load and neurohumoral activation.

Echo cardiography of the heart and vessels is still the most advanced non-invasive methodof diagnosing left ventricular remodeling. The diagnostics plays an important role in evaluation of left ventricular myocardium mass, which is an important life expectancy prognostic factor for AH and other patients [Mancia, G.]. The most common method used to classify types of LV remodeling in AH patients is the A[1]. Ganau classification (1992), according to the 2013 ESC/ESH Guidelines, which relies on LVMMI and left ventricular wall thickness[6]. A gradual increase in the LV wall thickness and progressing concentric LV hypertrophy lead to an increased risk of cardiovascular complications[12].

AH in service members attracts closer attention, because high blood pressure (BP) can affect contract servicemen's ability to properly carry out their professional duties and therefore undermine national security and defense capability[8].

Materials and Method

A group of 86 male AH patients, who are service members, have been examined. Group 1 comprises 52 young servicemen aged 26 to 44 y/o (median age – 36.25±5.1 y/o); Group 2 consists of 34 middle-aged servicemen with AH aged 45 to 55 y/o. median age of the group is 47.5±2.6 y/o. Age distribution was made

according to the WHO classification pattern, which deems the age of 18 through 44 as young and the age of 45 through 59 - as middle age. Also, the subjects were divided into subgroups according to the type of LV remodeling.

Male subjects aged 20 through 60 years old and suffering arterial hypertension Stage 1 and Stage 2 have had all inclusion criteria[2]. Non-inclusion criteria are: female gender, old and senile age, non-sinusoid heartbeat, symptomatic AH, diabetes type 1 and/or type 2, IHD, malignant neoplasms, cardiac insufficiency, acquired or inborn cardiac defects, hepatic, renal and/or respiratory insufficiency.

The structural/functional state of the heart has been evaluated through echocardiography with the use of a Neusoft ultrasound system (made in China) in the B- and M modes while relying on the standard method. Left ventricular mass (LVM) has been calculated according to a cubic formula recommended by ASE experts (2015): LVM (g) = 0.8 × (1.04 × ((LV EDD + 3CLV + IVS)^3 – (LV EDD)^3)) + 0.6. [11]. The LVM (LVMMI) index has been calculated as a ratio between LVMMI and TBSA (total body surface area)[4]. LV geometry has been evaluated as recommended by experts from the American Society of Echocardiography Association and from the European Association of Cardiovascular Imaging, as the method help calculate LVMMI and relative left ventricular myocardial thickness (RLVMT, unit = (2x3C LV)/(LV EDD)).

Based on LVMMI and RLVMTIvalues, the following LV remodeling types have been specified: normal geometry LV remodeling (NGLVR): LVMMI is within the normal range with TBSA less than 0.42; concentric LV remodeling (CLVR): LVMMI is within the normal range with TBSA more than 0.42; concentric LV hypertrophy (CLVH): LVMMI exceeding the normal value with TBSA more than 0,42; eccentric LV hypertrophy (ELVH): LVMMI exceeding the normal value with TBSA less than 0.42 [9].

The 24-hr blood pressure monitoring procedure has been conducted with the help of a Shiller BP-102 system and according to the generally accepted method, and it has continued for 24±1.5 hours on average. Based on nighttime BP decreases, four daily BP profiles have been specified: *dippers* (DI>10%<20%), *non-dippers* (DI<10%), *over-dippers* (DI>20%) and *night-peakers* (DI<0).

Data obtained during research has been processed for statistical purposes on a Pentium-4 computer with the help of the Microsoft office Excel-2012 package and integrated statistical processing functions. Parametric and non-parametric variation statistics method have been used with calculation of the mean indicator being studied (M), standard deviation, relative values (frequency, %), statistical significance of measured values, with mean values compared, has been measuredthrough the use of Student's-t test with calculation of error probability (P).

Results and Discussion

The analysis of the study has shown that young and middle-aged servicemen with AH had normal LV geometry and concentric LV remodeling. Particularly, 59.6% of young subjects (31) and 55.9% of middle-aged subjects (19) with AH have had normal LV geometry, while 40.4% of young subjects (21) and 44.1% of middle-aged subjects (15) with AH have had concentric LV remodeling. No cases of eccentric or concentric LV hypertrophy have been revealed.

Meanwhile, LVM in young subjects with AH and normal LV geometry is 151.2±10.1g, in young subjects with concentric LV remodeling – 165.7g±11.4g ($P<0.01$), and LVMMI is 73.5±5.6g/$m^2$and 80.2±6.1g/m^2respectively ($P<0.05$).

Middle-aged AH patients with normal LV geometry have shown a LVM of 154.7±9.9 g, those with concentric LV remodeling – 166.6g±11.3g ($P<0.01$).

Middle-aged subjects with concentric LV remodeling have demonstrated the highest left ventricular posterior wall thickness (LVPWT) – 1.18±0.06cm, in young subjects, LVPET has been 1.11cm±0.03cm ($P<0.05$). Young and middle-aged subjects with normal LV geometry have shown a LVPWT of 1.08±0.05cmand 1.09cm±0.04cm respectively.

As to inter ventricular septum thickness (IVST), geometry changes have not caused any increase; on the contrary, a slight increase has been observed in patients with normal LV geometry: respectively, the normal LV geometry and concentric LV geometry young-age groups have had an IVST of 1.04±0.06cm and 1.02±0,07cm. In middle-aged subjects, it has been 1.07±0.0cm and 1.05±0.07cm respectively. The insignificant increase in these characteristics in subjects with normal LV geometry may be due to the septum's anatomic features,

as it has a convex shape, and depends on what part of the septum these indicators refer to.

Thus, LVM, LVMMI, and LVPWT tend to increase in patients with LV remodeling. There is a direct correlation between left ventricular mass and occurrence of cardiovascular events[15].

Concurrently, ejection fraction (EF), which reflects cardiac contractility, has been similar in all study groups (P>0.05) (Table 1).

Table 1: Echo cardiography test results in young and middle-aged service members diagnosed with AH

Note: * P<0.05, ** P<.01 differences between the subgroups, • P<0.05, •• P<0.01 differences between Group 1 and Group 2.

Concentric remodeling (normal LVM with an increased relative wall thickness) is characterized by peripheral vascular resistance, low cardiac index and high arterial stiffness[14]. Concentric LV remodeling is believed to be the earliest stage of the pathologic process that precedes left ventricular hypertension[13].

The results justify the necessity of early AH diagnostics and administration of strict and effective anti-hypertension therapy to servicemen. In turn, these measures help stabilize the left ventricle's state and stop the progress of the disease in patients dealing with the process of LV remodeling.

Table 2: 24-hr blood pressure monitoring indicators in young and middle-aged servicemen with AH

BP (mmHg)	Young		Middle-aged	
	Normal LVG (31)	Concentric LVR (21)	Normal LVG(19)	Concentric LVR(15)
SBP, daytime	152.4±6.1	160.9±5.95**	153.3±5.4	165.9±5.4**
DBP,daytime	85.1±5.12	92.8±5.9**	86.0±5.58	93.2±4.47**
SBP, nighttime	132.9±6.2	147.8±8.5**	139.3±3.04	149.4±8.3***
DBP,nighttime	77.12±5.2	85.7±6.4**	79.8±4.5	88.5±6.4**
SBP, 24-hr	142.5±8.3	155.1±8.8**	148.5±7.9	157.7±4.4***
DBP, 24-hr	83.4±8.4	89.5±8.1	84.3±4.5	87.4±5.9
Mean pulse pressure	66.4±3.5	78.4±4.9**	66.6±6.9	77.87±5.33**

Note: * P<0.05, ** P<0.01 are differences between the groups

Hemodynamics indicators (SBP, DBP, MAP, HR) have been studied in all the groups, and the results are shown in Table 2. BP checks in service members dealing with AH, based on the type of LV remodeling, have helped reveal the following specific features: all groups of AH subjects with concentric LV remodeling have shown an increase in SBP, DBP, MAP, and HR (P<0.01) (except 24-hr HR in the middle-age group relative to AH with normal LV geometry). These indicators were relevant in the young age group (P<0.01).

Also, the analysis of SBP, DBP and mean hemodynamic pressure in the middle-age group of servicemen has revealed a transition from normal LV geometry to concentric LV geometry, but the results have not shown any relevant differences. Based on the above, it is possible to track the relationship between the indicators and the LV geometry; i. e., as these indicators grow, the LV geometry shifts toward remodeling, which is a primary precursor to hypertrophy in itself.

24-hr blood pressure monitoring of servicemen with AHis necessary not only for analysis of prognostically important indicators and daily BP profiles, but also for adequate AH control, because it gravely affects military capacity.

Table 3: Distribution of AH patients according to daily BP profile types

24-hr BP monitoring	Young		Middle-aged	
	Normal LVG (31)	Concentric LVR (21)	Normal LVG(19)	Concentric LVR (15)
Dipper	12 Patients – 39 %	6 Patients – 28.5%	9 Patients – 47.4%	6 Patients – 40%
Non-dipper	18 Patients – 58%	13 Patients – 62%	9 Patients – 47.4%	9 Patients – 60%
OVer-dipper	1 Patient – 3 %	0	1 Patient – 5.2%	0
Night-peaker	0	2 Patients – 9.5%		0

It has been observed that compared to subjects with normal LV geometry, concentric LV remodeling groups, both young (28.5% vs. 39%) and middle-aged (40% vs. 47.7%), have shown a lower occurrence of the *dipper* profile. And vice versa, the occurrence of the *non-dipper* profile has increased in subjects with concentric LV remodeling in both the middle-age (62% vs. 58%) and young (60% vs. 47.7%) groups. Finally, 9.5% of young subjects with concentric LV remodeling have had the *night-peaker* profile (see Table 3).

The results of the study show that a shift from the normal LV geometry changes the daily AH profile, increasing in the number of *non-dippers* and generating *night-peaker* profile cases[7]. In turn, these indicators lay ground for unfavorable prognoses, because they are associated with cardiovascular complications (myocardial infarction, CVA, cardiac insufficiency)[3].

Thus, early diagnostics of AH and effective treatment of servicemen can help keep the LV in a healthy state. However, absence of concentric and eccentric hypertrophy signifies an appropriate pharmacological control of AH indicators in service members. It is known that most scientists consider insufficient lowering of BP during sleep and its dramatic increase in the morning to be an independent risk factor of left ventricular hypertrophy and consequently, cardiovascular complications.

That is exactly why it is important to evaluate nighttime BP levels. Daily BP profile changes accompanied by increased *non-dipper* profile occurrence should be regarded as unfavorable factors, which should also be taken into account when administering a drug therapy. The goal of the treatment, which is part of arterial pressure control therapy, is reversal of the remodeled left ventricular myocardium in this group of patients to reduce the risk of cardiovascular complications.

Conclusion

1. Ithasbeenfoundthatsomeyoungandmiddle-agedservicemenwith AHhaveanormalLVgeometry (59.6% (31) ofyoungand 55.9% (19) ofmiddle-agedsubjects), andconcentricLVremodelinghasbeenobservedin 40.4% (21) of youngand 44.1% (15) of middle-aged subjects.

2.ComparedtothenormalLVgeometrygroup, inc on

centric LV remodeling groups the occurrence of the *dipper* AH profile has decreased both in young (28.5% vs. 39%) and middle-aged (40% vs. 47.7%) subjects.

3. The occurrence of the *non-dipper* AH profile has increased in middle-aged subjects with concentric LV remodeling (62% vs. 58%), as well as in young subjects (60% vs. 47.7%). In 9.5% of the subjects with concentric LV remodeling, the *night-peaker* profile has been observed.

4. 24-hr blood pressure monitoring has revealed at rend of increasing BP along with a change in LV geometry from normal tore modeling.

Features of Pain Syndrome of Patients with Brucellosis if Damaged Nervous System

Sokhiba Khakimova Ziyadullayevna[1], Dildora Atokhodjaeva Alisherovna[1]

[1]Associate Professor, Samarkand State Medical Institute, Samarkand, Uzbekistan, Course of Neurology and Neurosurgery Postgraduate Faculty, Samarkand Medical Institute, Samarkand, Uzbekistan

Abstract

The article presents the features of the clinical course of chronic brucellosis at the present stage, the issues of diagnostics and treatment, taking into account the results of our own observations of patients with damage of the nervous system and musculoskeletal system. There is characteristic of clinical and epidemiological, laboratory and instrumental diagnostics of chronic brucellosis, the issues of etiopathogenetic therapy are considered.

Keywords: *Brucellosis, diagnostics, treatment, Milgamma.*

Introduction

The steady increase of the brucellosis incidence is becoming a global problem in the world[1]. Brucellosis is a particularly dangerous and socially significant infection, that causes significant economic damage and a high level of disability of patients[3]. Disorders from the nervous system in chronic brucellosis (CB) are one of the most common, and lesions of both the central nervous system are detected, the clinic of which fits into the syndromes of arachnoiditis, meningoencephalitis, myelitis, and the peripheral department in the form of polyneuropathies, radiculopathies, plexitis, neuritis[6].

At the present stage of treatment of patients, three directions are distinguished: specific treatment with brucellin, pathogenetic and symptomatic therapy[4]. Currently, the most attention is paid to the issues of rehabilitation[7] treatment, which is the most promising direction in the treatment of patients with peripheral form of chronic brucellosis[8].

The aim of the study is to improve the pain treatment with damage of the nervous system of patients with brucellosis[4].

Materials and Research Method

Under our supervision, there were 32 patients complaining of pain, which are: women - 85%, men - 15%. The age division is: from 24 to 30 years - 11.5%; from 30 to 40 years old - 19.2%; from 40 to 50 years old - 15.4%; from 50 to 60 years old - 38.5%; older than 60 years - 15.4%, the age of patients - from 39 to 84 years (53.7±2.3). The duration of the disease ranged from 0 to 52 years: 51.6%, patients were ill for up to 5 years, 19.4% of patients - 5-10 years, 10-15 years - 9.6%, 19.4%.

All patients were divided into two groups: the main - 24 patients who received traditional treatment with the addition of Milgamma and the control group - who received only traditional treatment.

Clinical and epidemiological examination with specific laboratory diagnostics (enzyme-linked immunosorbent assay with antibodies to brucellosis pathogens (Br. Abortus, Br. Melitensis), Haddlson plate agglutination test, Rites agglutination test in test tubes, indirect hemagglutination reaction with brucellosis diagnostic, Coombs antiglobulin reaction, Burne skin-allergic test). From additional method, clinical, biochemical and instrumental (radiography of the joints and spine) studies were carried out. The dynamics of pain perception was evaluated on a 10-point visual analogue scale (ВАШ) before and after drug administration.

Results and Discussion

In the primary epidemiological diagnosis of brucellosis in most patients (61.5%), the professional nature of the disease with a contact path of infection was

established: 38.5% were workers at the meat processing plant who received specific prophylaxis irregularly, with long interruptions, and also did not always use personal protective equipment (gloves), often noted scratches, cuts, bruises in the processing of raw meat. Veterinarians accounted for 7.6%, who are infected by contact with sick animals (cattle, pigs). 11.4% were milkmaids, possibly infected while caring for cattle, and were also in contact with sick animals, their excreta. In 3.7% of the patients, a presumably mixed (aerogenic and alimentary) route of infection was observed (they were engaged in shearing sheep, where there were cases of brucellosis among animals, as well as raw milk and dairy products were consumed). In 37.5% of patients, an alimentary route of infection was observed: eating unboiled milk and raw dairy products: feta cheese, cream, sour cream, etc.

As a result of a clinical examination, taking into account the timing of infection and the epidemiological history, we found chronic brucellosis with a combined lesion of the osteoarticular and nervous systems in 65.3% of patients, and a primary lesion of the osteoarticular system in 35.6%. The changes are identified during radiography of the joints, which indicating a deeply advanced process: deforming arthrosis of the knee joints - in 46.1%; deforming arthrosis of the hip joints - in 33.6%; humeroscapular periarthrosis - in 27.7%; deforming arthrosis of the wrist joints and joints of the hands - in 30.5%; deforming arthrosis of the interphalangeal and metatarsophalangeal joints of the feet - in 11.5%; degenerative-dystrophic changes in the spine (osteochondrosis, subchondral osteosclerosis, deforming spondylosis, uncovertebral arthrosis) - in 80.2% of patients (Fig. 1).

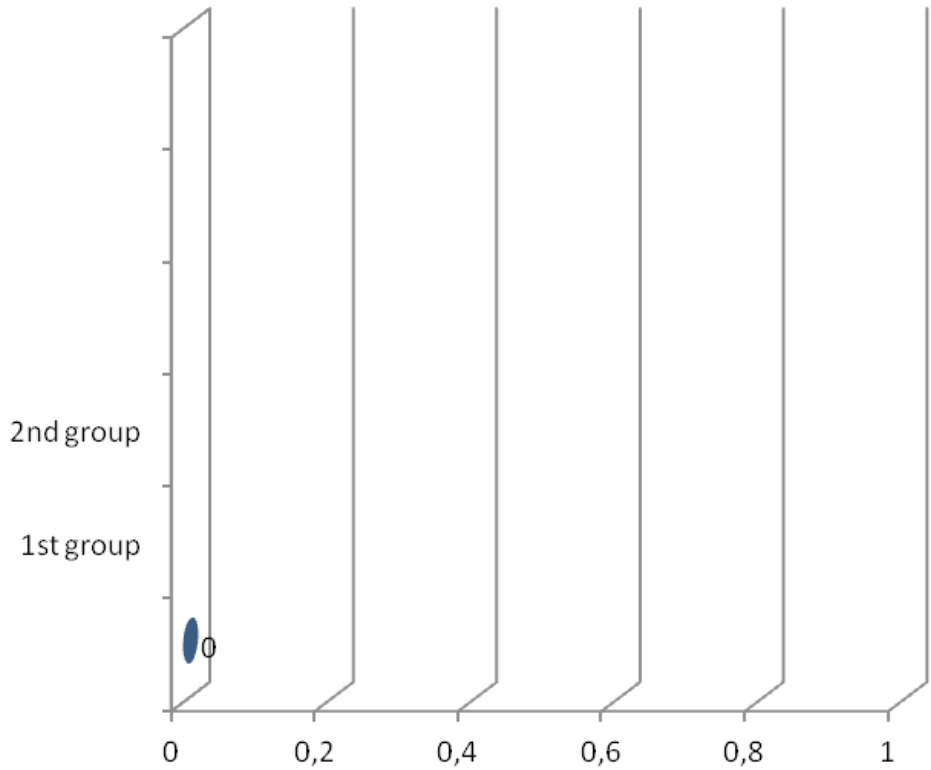

Fig. 1. Changes identified during joint radiography

The most common and characteristic for brucellosis is the defeat of the sacroiliac joints - sacroileitis, which is rare in rheumatism and other infectious diseases, which allows the patient to suspect a brucellosis process[7]. Changes in the sacroiliac joints rarely attract the attention of practitioners in connection with the presence of concomitant symptoms from the muscles, sacral and sciatic nerves, therefore, sciatic nerve neuritis or osteochondrosis of the lumbosacral spine with radicular syndrome is more often diagnosed.

Lesions of the soft skeleton in most cases manifest as inflammatory nodules[9] in the connective tissue, the so-called fibrositis, pathognomonic for brucellosis, especially for primary chronic forms[4]. They can form in the form of seals of various sizes and soreness everywhere, where there is connective tissue: in subcutaneous fat, fascia, aponeurosis, periosteum, surrounded by joints, nerve trunks and roots, they may later dissolve or remain in the form of scars[9].

The development of the clinic of modern brucellosis was reflected in the features of damage of the nervous system[1]. Lesions of the peripheral nervous system became softer, and the central nervous system became rarer or not observed at all[10]. So, in chronic brucellosis (8.7%), neurological syndromes often occur with a variety of diffuse symptoms, complex types of disorders of sensitivity and motor sphere (for example, the type of brain tumor, multiple sclerosis, stem encephalitis, etc.); the most common symptoms of a functional nature in the form of neuralgia (35.6%)[4]. In patients with chronic brucellosis observed by us, lumbar ischalgia, neurodystrophic form, cervicalgia, sensorimotor polyneuropathies and other disorders were recorded in 30.5% of cases.

The clinical and epidemiological diagnosis was confirmed by the results of specific laboratory diagnostics: by IFA in 46.2% of patients, antibodies to the causative agents of brucellosis (Br. Abortus, Br. Melitensis) of the IgG and IgM classes were determined, in 57.7% - by the positive Hedlson agglutination test. In 46.1% of patients, a positive Rite agglutination reaction was determined in the titer from 1/200 to 1/800; as well as in 34.6% of patients, positive results were simultaneously observed both in IFA and in the agglutination reaction of Rite and Hedlson. It is important that the Byrne allergic skin test in all patients (100%) with chronic brucellosis was positive.

The revealed "spread" of the frequency of positive serological reactions in chronic brucellosis is natural and indicates the need to use at least two method[4]. The coincidence of positive IFA results with Rite agglutination reaction was found in 46.0% of cases, with indirect hemagglutination reaction - in 37.0%; with the Coombs antiglobulin reaction - in 100%[11]. The Burne test refers to tests of the third level of diagnosis to detect the sensitization of the body to brucella, its degree reflects the final stage of the interaction of the antigen and the immune system[9].

The tactics of treating patients with chronic brucellosis is determined by the phase and form of the disease and the state of the reactivity of the body, which confirmed by the results of clinical, laboratory and instrumental examination. The issue of prescribing antibacterial therapy, which is not indicated for chronic inactive and residual brucellosis, as well as for the prevention of relapse, remains controversial in real practice. Indications for the appointment of antibiotic therapy are not sufficient only positive serological tests and allergy tests, and most importantly - a clinical exacerbation of chronic brucellosis infection. We used etiotropic therapy for the treatment of patients with chronic brucellosis during exacerbations: tetracycline antibiotics (iv videoccin or doxycycline per os) - in 77.9%; aminoglycosides (gentamicin) - in 56.7%; III generation cephalosporins (ceftriaxone) - in 23.7% of cases.

But still, the leading principle in the treatment of chronic brucellosis is pathogenetic using non-steroidal anti-inflammatory drugs[4] (diclofenac, ortofen, etc.), given the persistence of the inflammatory process, desensitizing agents (mainly groups of mast cell membrane stabilizers - ketotifen, azelastine, lodoxamide, etc.) as well as metabolic correction preparations (B vitamins, almiba, nicotinic acid, pentoxifylline, cytoflavin, reamberin, remaxol, etc.)[2], taking into account oxidation-reduction disorders that correlate with the degree of adjustment allergic organism [11].

During a recurring course of the disease, as well as with a chronic process, immunotropic therapy is indicated, taking into account the degree of immunological rearrangement of the patient's body with brucellosis. The appointment of immunocorrective therapy is considered necessary 1-3 weeks after taking antibiotics[11]. It is recommended to use immunocorrectors of various groups: immunomodulators of endogenous origin (immunoregulatory peptides obtained from central organs of the immune system (thymus and bone marrow), cytokines, interferons, immunomodulators of exogenous origin (pyrogenal, zymosan, prodiogisan, lycopid, bacterial lysates), synthetic immunomodulators (levamisole, pentoxyl, methyluracil, immunofan), cycloferon, an interferon inducer[12].

Patients were divided into 2 groups: in the main group (22 patients), milgamma was prescribed in combination with the above traditional treatment, in the control group (10 patients) only traditional therapy

was performed. The effectiveness of treatment was evaluated on the 10th day and 24th day on the visual analogue scale, as well as after 3 and 6 months (Fig. 2). Throughout the study, according to the visual analogue scale, there was a tendency to a higher efficiency of the milgamma combination in relation to traditional treatment, however, this difference reached the level of statistical significance only by the 24th day. Using the neuropathic pain scale, it was shown that only against the background of combination therapy, such characteristics of pain as intensity and severity significantly decreased, pain tolerance improved. A significant and moderate effect against the background of the introduction of milgamma was observed in 66% of patients, in the control group - in 34% ($p < 0.05$). 3 months later pain was absent or was minimal in 63% of patients in the main group and in 50% of patients in the control group ($p < 0.05$). The results obtained indicate that the complex of B vitamins can potentiate the analgesic effect of non-steroidal anti-inflammatory drugs and contribute to a more rapid and persistent regression of pain.

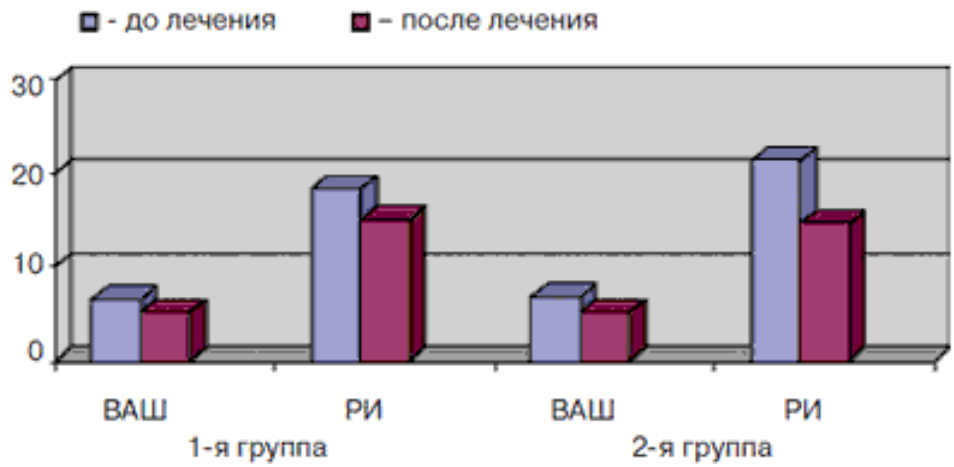

Fig. 2. Dynamics of pain according to VAS before and after treatment

According to the general clinical impression scale against the background of the use of combination therapy, including milgamum, on the 10th day a significant effect was noted in 6 patients (25% of the patients who entered the study), satisfactory (moderate - in 19 (41%), minimal improvement - 8 (17%), no improvement - 7 (17%). In the control group, a significant effect was observed in 2 patients (10%), satisfactory - in 4 (24%), minimal improvement - in 9 (41%), lack of effect - in 5 (25%). The effectiveness of therapy, initial intensity and length flaccidity, the presence of symptoms of loss, the severity of vertebral syndrome were not affected by the age.

Conclusions. Thus, the diagnosis and treatment of chronic brucellosis in the practice of a neurologist is a difficult task and is determined by the incidence rate in the region, both among animals and among people, the professional readiness of practical doctors and the availability of diagnostic technologies. At the same time, it should be taken into account the epidemiological history, the predominance of latent and primary chronic forms of low activity with damage to the joints and nervous system (with characteristic polyofocal), autonomic reactions, the presence of fibrositis, prolonged subfebrile condition, which determine the clinical differential diagnosis. Specific diagnostics are determined by various methodological levels - from the isolation of the pathogen to the determination of its antigens and antibodies, as well as the degree of sensitization to brucella. Hence, the treatment of chronic brucellosis depends on the activity of the infectious process, which requires the appointment of antibacterial agents and reasonable immunotropic therapy.

The received results confirm the efficacy and safety of milgamma preparations in the treatment of pain in patients with damage to the nervous system in brucellosis. They suggest that high doses of neurotropic vitamins as part of milgamma preparations can potentiate the analgesic effect and contribute to a faster

regression of the pain syndrome. The peculiarity of our study was that, firstly, we showed the effectiveness of a complex of B vitamins (using the example of a milgamma preparation) with such a severe form of back pain as vertebrogenic radiculopathy. Secondly, we found that milgamma effectively acts on the neuropathic component of brucellosis pain. Thirdly, it is shown that the addition of a 14-day course of oral administration of the drug milgamma compositum to the 10-day course of intramuscular administration of milgamma promotes a more complete manifestation of the therapeutic potential of the drugs. Finally, the data obtained indicate that the effectiveness of the combined course of treatment with milgamma can be observed not only in the short, but also in the medium term (3 months), which was also facilitated by its prolongation by oral administration of the milgam compositum tablets.

Abstract

One uses the labor migration in various sectors of the economy. A high degree of stress on the health of shift workers leads to rapid fatigue and the development of irreversible pathology. Within the observation of two groups during the 52-day shift, the 1st group-before the start of shift work, the 2nd group - after the completion of shift labor organization, one put the labor activity under study, and there was time study of key functions performed by workers. The body of shift workers functions with a constant level of stress in regard to regulatory adaptation mechanisms to the circumstances of the industrial and climatic environment. In the study of employees ' health, there was a decrease in performance at the end of the 1st month of shift work with confirmed Vascular and autonomic dysfunctions within the cardiointervalography. In accordance with the cardiointervalography and measured physical strength by the method of dynamometry, there were dynamic indicators in groups at the stage of warming-up and during the completion of works. The study of cardiointervalography revealed a negative impact of labour conditions on the cardiovascular system. In accordance with the results of the study, the proposals may increase the workforce productivity.

Keywords: *Functional reserves, shift method, compensatory adaptation, labor productivity, cardiointervalography.*

Introduction

At the current rate of economic growth[1], there is a need for industrial development within the Far North regions by the means of labor reserves[2] from all over the country and abroad. The shift workers suffer a high level of stress in respect to the regulatory mechanisms.[3] In order to ensure stable workforce productivity, it is necessary to set vital indicators in regard to a level that depends on the organization of labor. The body functions that mainly depend on the organization of shifts are the cardiovascular, respiratory and other life support systems.

Materials and Method of Research

One used a comprehensive approach in order to study the body reserves of shift workers. In addition, one applied to method in order to reduce the level of stress at the commencement and end of works.

One managed the work in accordance with the research plan of Industrial University of Tyumen and Tyumen state medical University and it is part of the program «Adaptation recovery mechanisms to the conditions of Arctic». Within the research, one examined the parameters of functional indicators within the cardiovascular and respiratory systems of the workers' bodies, as well as the stock of physical health reserves of workers who operate on oil-field equipment by shifts [3,4]. In accordance with the results of the study, it is possible to develop measures that contribute to the improvement of job performance during the various periods of adaptation. The research method of heart rate variability was cardiointervalography, since it is highly informative, both under familiar environmental conditions and under extreme conditions. During the study, one performed the analysis of the R and P waves in their standard lead, and we measured the morphofunctional reserve by the dynamometry. The key base was the research results

in the summer period of shift works, which constitutes 52 days, the average daily air temperature is +12 ^{0}C. In order to study the indicators of the body fatigue and adaptation, we formed 2 groups, the 1st group refered to the time before the start of work, the 2nd group refered to the time at the end of works, one conducted the study by the method of dynamic observation in respect to the state of workers during the adaptation period and the entire shift time.

Research Results

Currently, the national economy has a rapid growth due to the increase in demand for oil and gas production, thereby it stimulates the increase of pipeline and transport flow. Within the pipeline operation at the Sporyshevskoye oil field, Gazpromneft-Noyabrskneftegaz (JSC) developed a plan to increase the amount of oil product transportation and oil production in order to meet the required volumes. The shift set-up workers of oilfield equipment ensure the continuity of oil production within the infrastructure of PJSC «Gazprom». One uses the oilfield equipment for unconstrained production profile, transportation and storage of oil. For this purpose, more than 100 oil wells located on the territory of the Sporyshevskoye oil field participate in the process of maintenance. This equipment is under continuous service of at least 56 shift workers, their shift change happens every 52 days.

In this mode, the oil production has a full year time span, the productivity directly depends on changes in the climatic conditions of labor migration, all this affects the functional adaptation reserves, as well as the phases of work capacity within the scope of professional activities. At the beginning of the shift period, the workers pass the adaptation stage, and during this time period there is a high stress level of compensatory and adaptive reactions[5]. The increase in work capacity occurs during the next work cycle, which constitutes the period of two weeks[6]. Under the dynamics changes analysis in accordance with the indicators the increase is up to 14%, but by the end of the first working month, there is a decline in labor activity due to occurrence of vascular and autonomic dysfunctions[7]. Under the cardiointervalography output (hereinafter- Cardiointerval recording), one found that when the period of adaptation starts, the body of workers passes through the phases of warming-up and fatigue. In order to analyze the variability of heart rate under the usual environmental conditions, in order to assess the adaptation of the cardiovascular system, and in case of functional loads during shift works, it was advisable to use the method of cardiointervalography[2]. The cardiointervalography group's indicators are in table 1.

Table 1. Cardiointerval recording indicators for heart rate variability

Indicators of Cardiointerval recording	1 Group (n=56) start of the shift period	2 Group (n=56) end of shift period
In prone position		
M (modal value)	15,97±0,25	17,1±0,06*
Mo (mathematical expectation)	0,93±0,01	1,57±0,01*
Amo (mode amplitude)	33,3±1,42	31,34±0,39
ΔX (range)	0,58±0,04	0,83±0,01
IN1 (stress index)	93,84±4,32	70,2±1,79*
VBI1 (vegetative balance index)	118,16±2,60	93,89±2,09*
VICP1 (validity indicator of the control process)	52,68±1,3	46,05±0,70*
VRI1 (vegetative rhythm indicator)	5,97±1,10	5,02±0,08*
In the upright position		
M (modal value)	14,29±0,28	15,54±0,10
Mo (mathematical expectation)	0,86±0,01	1,1±0,01*
Amo (mode amplitude)	44,03±2,1	39,28±0,61
ΔX (range)	0,53±0,05	0,77±0,01
IN2 (stress index)	171,11±8,20	120,19±5,53*

Indicators of Cardiointerval recording	**1 Group (n=56) start of the shift period**	**2 Group (n=56) end of shift period**
IN2/IN1	2,13±0,08	2,22±0,05
VBI2 (vegetative balance index)	191,6±6,36	144,13±5,73*
VICP2 (validity indicator of the control process)	78,87±3,18	65,13±1,41*
VRI2 (vegetative rhythm indicator)	8,06±0,49	6,57±0,19*
In prone position		
M (modal value)	16,13±0,22	17,19±0,03*
Mo (mathematical expectation)	0,93±0,01	1,17±0,01*
Amo (mode amplitude)	33,74±0,74	30,48±0,33*
ΔX (range)	0,59±0,01	0,83±0,01*
IN3 (stress index)	91,82±1,55	68,09±1,48*
IN2/IN3	2,17±0,07	2,27±0,07
VBI3 (vegetative balance index)	115,61±1,85	91,08±1,83*
VICP3 (validity indicator of the control process)	53,38±1,85	45,11±0,56*
VRI3 (vegetative rhythm indicator)	5,77±0,28	5,02±0,07*

Under the study of indicators in relation to workers, one found that the shift workers of the 1st group have:

- Increased heart rate at rest 87.3±1.52;
- Increase in A_{MO} (mode amplitude) 33.3±1.42; p<0.05;
- Range (0.58±0.04; p<0.05);
- Maximum stress index (93.84±4.32; P0, 05).

In accordance with the observations results, it became possible to establish moderate sympathicotonia, the tonicity predominance of sympathetic segment Fig. 1.

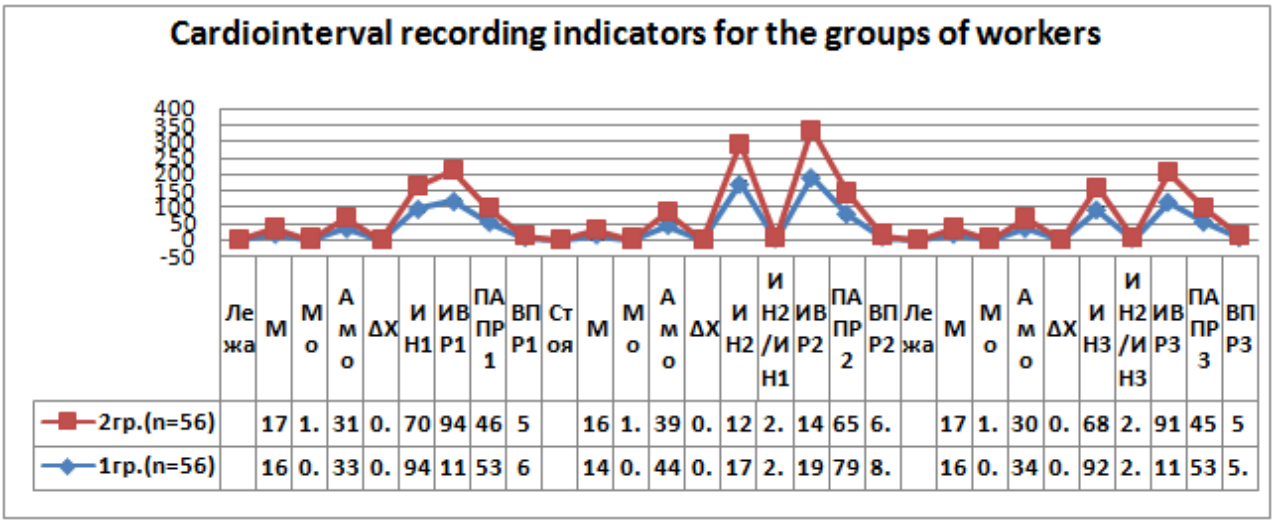

Figure 1. Cardiointerval recording indicators for the groups of workers

In the study of groups by the method of cardiointervalography, one determined the influence of vegetative reactivity on the indicators of the lower margin of the sympathetic type. One observed the vegetative activity within the range (1.83±0.08; P0, 05).

One observed the increase in VBI among the subjects of the 1 group under study at the stage of adaptation (vegetative balance index) – which is a direct indicator of the control loop activity (118.16±2.60; P0, 05). The high values in figure 2 confirm this statement:

- vegetative rhythm indicator - VRI (5.97±0.10; P0, 05);
- validity indicator of the control process (52.68±1.3; P0, 05).

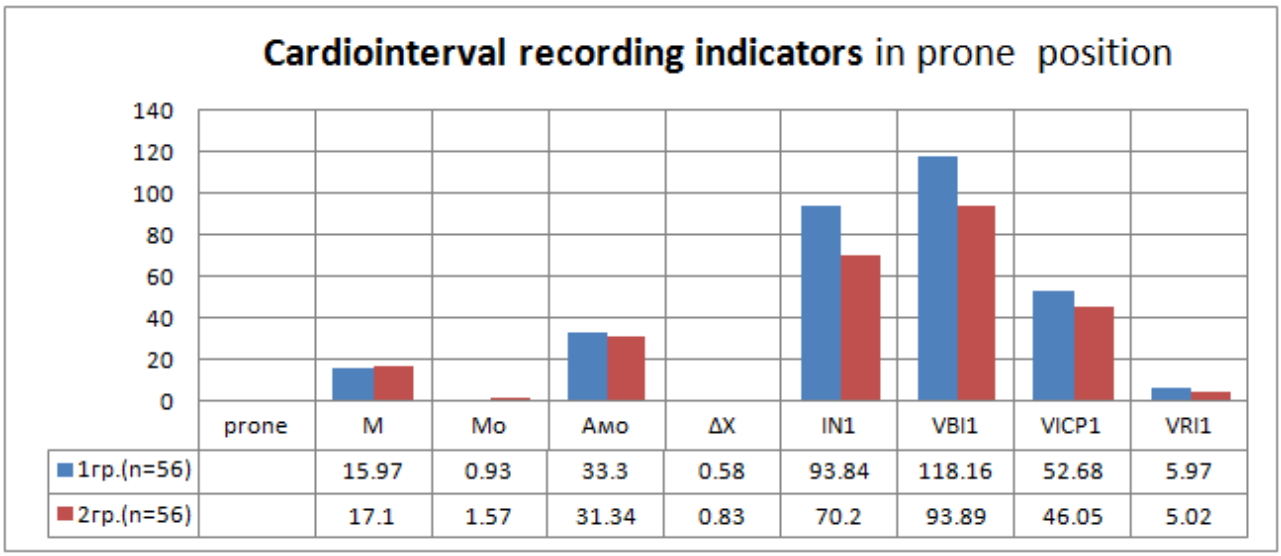

Figure 2. Analysis of vegetative reactivity in prone position during the shift period.

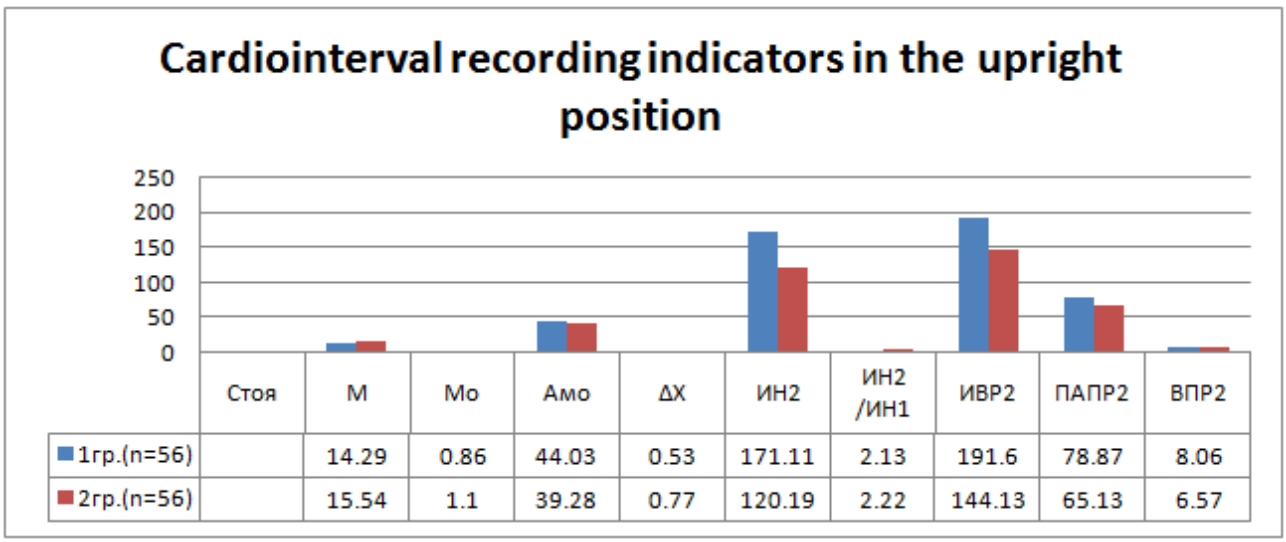

Figure 3. Analysis of vegetative reactivity in the upright position during the shift period.

The analysis output for test in the upright position differs by groups under study.

At the adaptation stage in group 1 Fig. 3:

- heart rate indicators - (94.17±1.9; p<0,05);
- the maximum level of VBI - (191,6±0,05; p<0,05);
- maximum values of the stress index (IN) 171,11±2,4; p<0,05;
- the mode amplitude increased (44,03±2,11; p<0,05).

In accordance with the results of the study, in accordance with the data on 2 group of workers at the stage of constant work, one observed the decrease in heart rate (97,1±1,5; p<0,05), with minimal stress index and large values of the variation range.

In prone position, the characteristics data for adaptation within group 2 belongs to Fig. 4:

- decrease in heart rate (74,2±1,6; p<0,05);
- minimum VBI - (91,08±0,04; p<0,05);
- minimum values of the stress index (68,09±1,6; p <0,05);
- decrease in the mode amplitude (30,48±1,91 p<0,05).

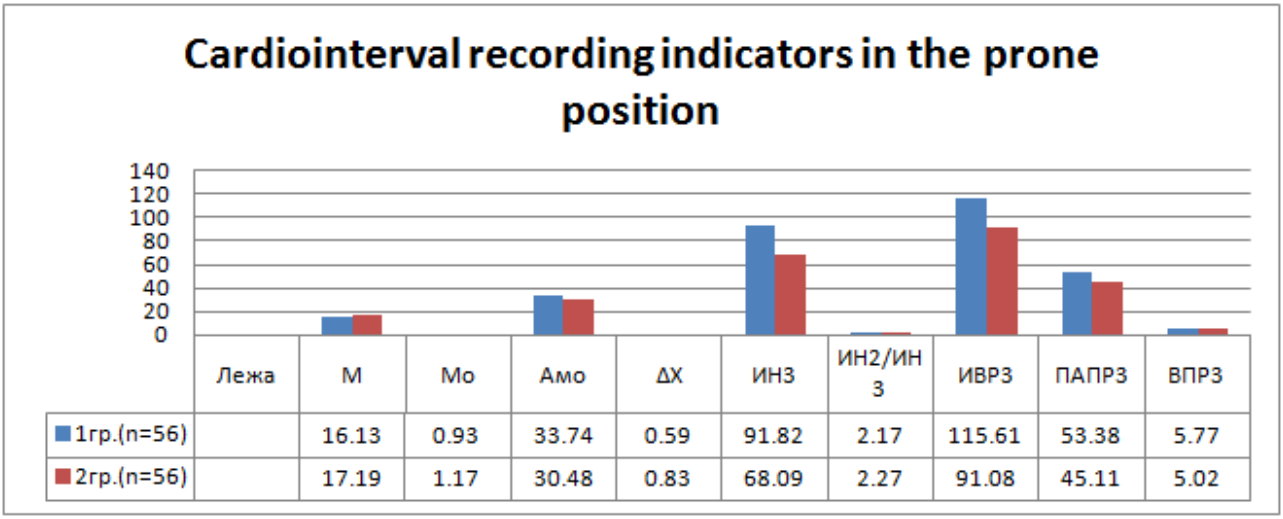

Figure 4. Analysis of vegetative reactivity in relation to the orthostasis of workers in prone position

The research results of orthostasis showed the same type of reaction in respect to the cardiovascular system within all groups, at the beginning of shift work in group 1, and at the end of shift work in group 2, one has observed:

1. Heart rate explicitness;
2. Decrease in range;
3. Increase in modal value;
4. Decrease in stress index.

In accordance with the method of cardiointervalography and the method of dynamometry in relation to physical strength determination[8], the set-up workers of oilfield equipment had satisfactory results at the stages of the shift period start and end[9].

One registered the condition of eitonia as the general state of the workers body regulatory systems and the vegetative reactivity in relation to orthostasis, see Tab. 2.

Table 2. Vegetative and morpho-functional criteria within groups of workers.

№	Criteria	1 Group, n=56	2 Group, n=56
1	Vital capacity (l)	3,95±0,02	3,89±0,02
2	Heart rate (b/min)	74±0,62	78±0,34
3	SBP (Systolic blood pressure) (mm Hg)	125±0,42	130±0,62
4	DBP (АДД) (mm Hg)	80±0,82	86±0,73
5	PP (mm Hg)	45±0,52	44±0,4
6	IN1	93,84±4,32	70,2±1,79*
7	VBI1	118,19±2,60	96,89±2,09*
8	VICP1	52,68±1,3	46,5±0,70*
9	VRI1	5,97±0,10	5,02±0,08*
10	IN2	171,11±8,20	120,19±5,53*
11	VBI1	191,6±6,36	144,13±5,73*
12	VICP2	78,67±3,18	65,13±1,41*

№	Criteria	1 Group, n=56	2 Group, n=56
13	VRI2	8,06±0,49	6,67±0,19*
14	IN3	91,82±1,55	68,09±1,48*
15	VBI3	115,61±1,85	91,08±1,83*
16	VICP3	53,38±1,85	45,11±0,56*
17	VRI3	5,77±0,28	5,02±0,07*
18	Right hand strength (kg/body mass)	47±0,12	50±0,41
19	Left hand strength (kg/ body mass)	45±0,21	48±0,28

Under the analysis of all indicators one revealed a change in the correlation coefficient:

- in the first group from 0.27 to 0.691;
- in the second group from 0.3 to 0.71.

The indicators highlight the dynamics of shift workers adaptive capabilities, which requires a high level of body functional stamina[9]. As a result of shift works the vital health indicators of shift workers will decrease[10]. Thus, within the comparative analysis of functional values, one underlines the criteria of work capacity dynamics and develops the suggestions for workforce productivity optimization.

Analysis of the functional indicators disorders among the shift workers indicates their acclimatization nature, the contrast of climatic factors, the severity of the labor process and the functional reserves of the body as an instability of physiological functions. A significant factor is the state of shift workers psychophysiological status[8].

Conclusions

1. The shift work method influences the health, causes the deterioration of functional activity. One observes the greatest responsiveness of the cardiovascular system both at the beginning and at the end of adaptation in relation to the work process within both groups.
2. Due to insufficient compensatory and adaptive responses, there is no complete adaptation to environmental factors and in accordance to the calculations under study, one observed such conditions among 78% of set-up workers of specialized equipment, and at the end of the shift work period, there is an increase in 22% of workers, as the fact of adaptation.
3. The level of energy consumption during respiration of shift workers increases, due to a decrease in effective external respiration.
4. At the beginning of the work process, the workers had a higher heart rate at rest by the Cardiointerval recording (91,1±1,51; $p<0.05$ and an increased mode amplitude (33.3±1.42; $p<0.05$). It indicates a high level of stress in respect to the regulatory systems.

One recommends the work safety service to prevent the onset of fatigue by control of labor modes within the production process in order to optimize the workforce productivity. Restoration of the body functional constants serve as the basis for the improvement of work capacity indicators. In accordance with these patterns, one can manage the processes of fatigue and recovery and thus increase the level of efficiency among the shift workers.

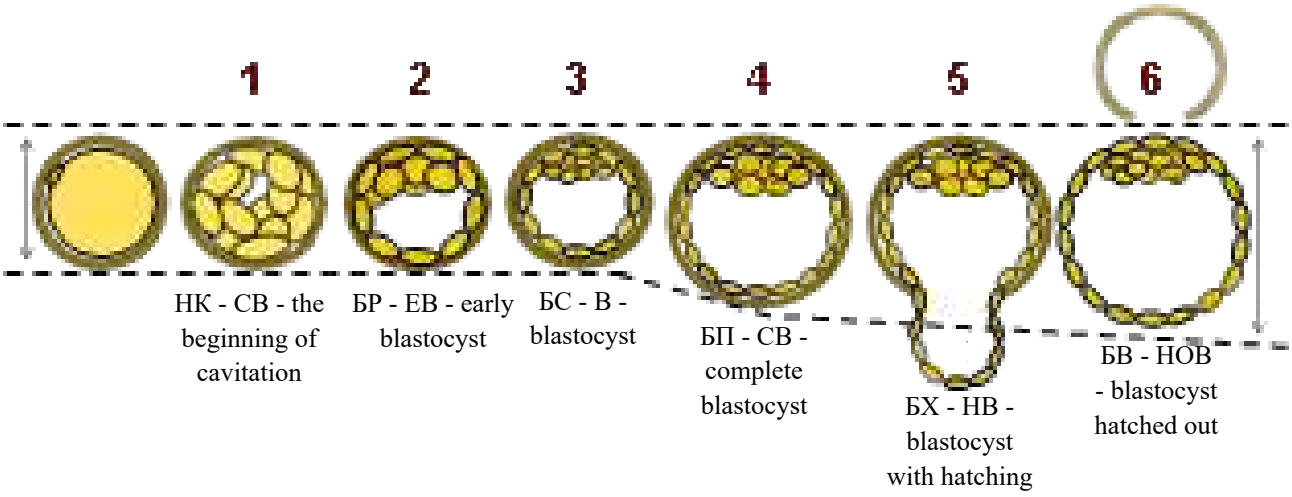
Abstract

Freezing embryos of excellent and good quality allows you to maintain reproductive potential for patients in the future and achieve pregnancy using one stimulation cycle. Cryopreservation of embryos can be carried out at any stage of development. Vitrification as a method of cryopreservation combines the use of highly concentrated solutions of cryoprotectants and rapid (almost instantaneous) cooling by immersing samples directly in liquid nitrogen. Due to this, the main goal of vitrification is achieved - the absence of the formation of ice crystals, which can damage the cell structure. The advantages of vitrification are as follows: a high concentration of cryoprotectants and a high cooling/thawing rate eliminate the damage caused by the formation of intracellular ice, as well as the undesirable osmotic effects of dehydration and rehydration due to extracellular crystal formation.

Keywords: *Embryo, blastocyst, cell, pregnancy, icm1, te1.*

Introduction

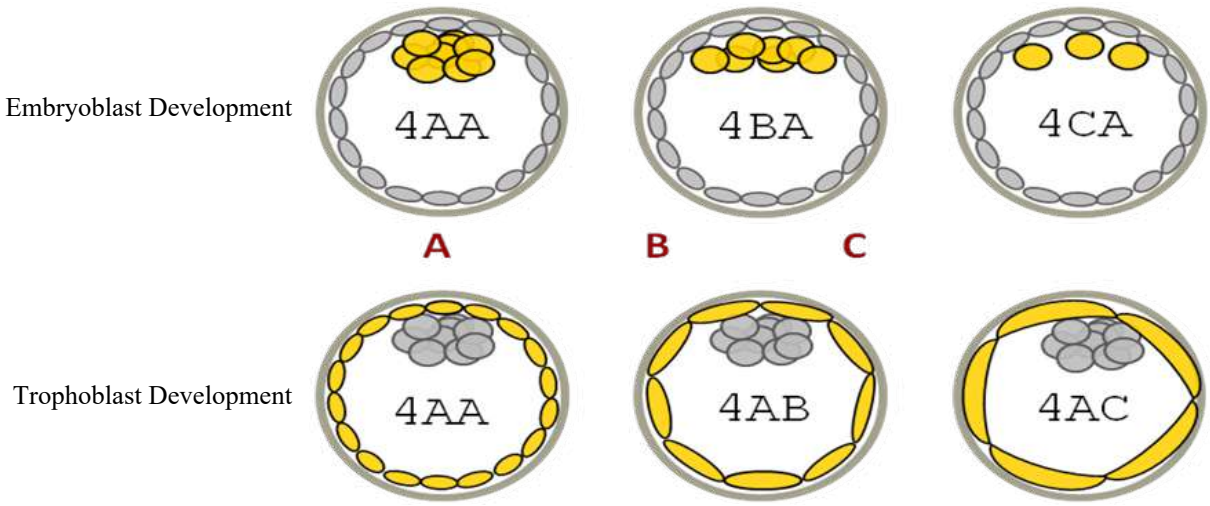
The main criteria for the effectiveness of the vitrification system is the survivability of the embryos. According to the data of the Vienna Consensus (The Viennaconsensus: report fan expert meeting on the development of ART laboratory performance indicators, 2017), the survival rate of blastocysts (embryos of 5-6 days of preimplantation development) is 90% or more[1].



Objective of the Research: Efficiency of various types of carriers for embryo freezing and embryo survivability after thawing under the ART programs.

Materials and Method

The work has used human embryos, the study of which has been carried out in compliance with international ethical and legal standards for the treatment of human embryos [Art. 18 of the Council of Europe Convention on the Protection of Human Rights and the Dignity of the Human Being while Using the Advances in Biology and Medicine, 1997][2]. The study of embryos has been carried out as part of in vitro fertilization cycles at the embryological laboratories of "IDK Medical Company" CJSC. The use of germ cells and human embryos in scientific research has been authorized by the ethics committee of the Samara State Medical University of the Russian Ministry of Health. Embryos have been identified under the control of a stereo microscope (Nikon, Japan). For incubation under conditions of 5% O2, SOOC incubators (Australia) have been used. Vitrolife (Sweden) have been used to cultivate embryos up to 5-6 days of embryonic development. Irvine Scientific environments (USA) and environments of open CryoTop (Japan) and closed CryoTip (USA) types have been used for vitrification of embryos. The fundamental difference between open and closed carriers is the presence/absence of direct contact of the vitrified object with liquid nitrogen. Before freezing, blastocysts of 5-6 days of cultivation have been assessed according to the international classification[6]. Blastocyst assessment takes into account three main parameters: the percentage



of expansion (increase) of the embryo (blastocyst), the development of internal cell mass and trophectoderm.

Assessment of intracellular mass has been performed under an inverted microscope: (A) densely filled with many cells; (B) weakly grouped with several cells; and (c) very few cells. The following classification has been used for trophectoderm: (A) many cells forming a cohesive epithelium; (B) few cells forming a loose epithelium; and (C) very few large cells. After thawing, the blastocysts have been subjectively assessed according to the degree of repeated expansion of the blastocoel, the degree of cell reorganization, and the degree of cell survivability by two embryologists.

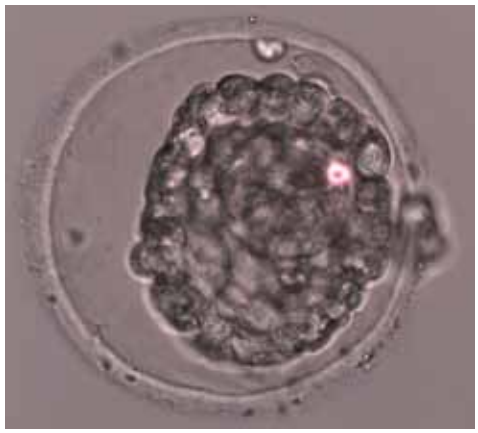
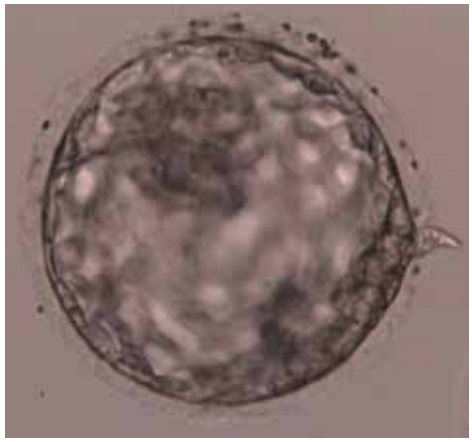
Pic. 1. Blastocyst Assessment by D. Gardner (1999)Illustartions: R.Shafei, 2008

Statistical processing of the results has been performed on a computer in the environment of statistical calculations R (R v.3.5.3, R Studio v.1.1.463), the primary data input has been performed using MS Excel spreadsheets. Descriptive statistics method, tests for comparing proportions, including an exact binomial for small samples and a single-sample proportional test with continuity correction for large samples have been used.



Research Results and Discussion



Picture 3. 5-day embryo, stage of collapsed human blastocyst, 10X eyepiece, 20X lens (immediately after thawing)

Picture 4. Blastocyst embryo, 4AA, 10X eyepiece, 20X lens (2 hours after thawing)

Picture 5: 5-day embryo, stage of collapsed blastocyst, 10X eyepiece, 20X lens (immediately after freezing)

Picture 6: Blastocyst embryo, 4AA, 10X eyepiece, 20X lens (2 hours after thawing)

The pictures show embryos immediately after freezing and after 2 hours (Pic. 3-6). 1-2 hours are needed to restore the blastocyst and to morphologically assess its viability. If the embryo has more than 50% intact cells, then it is considered viable.

Table №1. Embryo survivability depending on embryo developmental stage

30	<NA>	<NA>	<NA>	133	37.68
	Total			**1406**	**94.49**

From table 1 it follows that a total number of 1406 embryos have been analyzed at different stages of development. The embryo survival range is quite wide and ranges from 75 to 100%. It should be noted that embryos of the 6th degree of expansion, namely, hatched blastocysts, demonstrate the lowest survival rate. Probably this is due to the lack of a fertilization membrane and the cytotoxic effect of cryoprotectors on trophectoderm cells. The number of embryos in this group is extremely small to draw any unambiguous conclusions on this subject.

In more numerous groups (more than 100 cases), the survival rate has been more than 95%, which indicates a high degree of cryotolerance of excellent and good quality embryos. Nevertheless, we considered it necessary to conduct a further, more detailed analysis of the dependence of the frequency of pregnancy on the stage of the frozen blastocyst (degree of expansion, the severity of ICM and TE). On the basis of the degree of expansion, the indicators of the pregnancy rate (PR, positive ultrasound) increase with an increase in the degree of expansion from the stage of onset of cavitation of the blastocyst to increased blastocyst (degree of expansion 4), reaching a maximum in hatched blastocysts lacking a fertilization membrane. This trend is quite natural: an embryo with a higher level of organization and cell differentiation gives higher PR indices. However, the decline in the blastocyst group with the 5^{th} expansion degreeis noteworthy; these are embryos that have been frozen during hatching. Apparently, embryos of this developmental stage are the

most vulnerable to the effects of the freezing procedure. The difference in the proportion of positive ultrasound has significantly differed between the stages ($p < 0.01$). That is, the percentage of PR-positive ultrasound scan has been growing from morula (20.0%) to 6-blast (66.7%) with a slight "failure" at the stage of expanded [5] blastocysts (37.5%). Carrying out a comparative analysis according to the following criterion — the degree of development of intracellular mass (ICM), we have obtained the expected results: the higher the degree of compaction of cells in the ICM, the higher the PR indices. In blastocysts with ICM A (581 embryos), the PR rate has been 51.3%, in blastocysts with ICM B (334 embryos) - 39.8%. The differences are significant at $p = 0.004$. It should be noted that in the group of blastocysts with intracellular mass C (there are extremely few or no cells), we have received 50% of PR. This indicator can hardly be considered objective due to the extremely small group (4 embryos), since embryos with a similar morphology, as a rule, are not supposed to be frozen. The pronouncement of trophectoderm, the degree of development of which is most significant in the process of implantation, directly correlates with the PR data. When analyzing 918 embryos, we have found that blastocysts with class A trophoctoderm (318) give the most indicators - 57.5% of PR, blastocysts with class B trophoctoderm (553) - 42.9% of PR, with class C trophoctoderm - 27.7% of PR. These differences are significant at a level of $p < 0.01$.

To assess the effectiveness of different carriers, the following criteria have been taken into account: survival rate, average transfer embryo/s score, average number of transfer embryos, pregnancy incidence rate, birth rate and loss (table 1).

Table 1. The main criteria for the effectiveness of the cryoprogram of embryos between open and closed types of carriers

	Closed carrier (CryoTip)	Open carrier (CryoTop)	p
Average age of the patient, years	34,1	33,5	
Number of thawed embryos	611	678	
Survivability, %	84,8%	95,1%	<0,0001*
Average score of embryos/transfer	3,9	4,1	
Average number of embryos/transfer	1,2	1,3	
PR, % (per transfer)	39,5	44,2	0,001*
Birth rate, % (per clinical pregnancy)	72,7	67,3	0,003*
Loss, % (per clinical pregnancy)	27,3%	24,3%	0,044*

In 2015-2016, 1289 embryos were thawed on the types of carriers under consideration. Embryo survivability on closed carriers has been 84.8%, on open - 95.1%, and this difference is statistically significant ($p < 0.0001$). The average transfer embryo score in group I has been 3.9, in group II - 4.1. The average number of embryos per transfer is 1.2 and 1.3, respectively. The pregnancy rate has been statistically significantly different ($p < 0.0001$) and has amounted to 39.5% (group I) and 44.2% (group II). The birth rate for clinical pregnancy, taking into account the known outcomes, has been 72.7% in group I, 67.3% in group II, and losses have been 27.3% and 24.3%, respectively. Birth rates and losses have a statistically significant difference.

Conclusion

Thus, conducting a comparative statistical analysis, the influence of all components of the blastocyst assessment—the stage, the degree of ICM development, and the pronouncement of trophectoderm—on the degree of survival and the level of pregnancy rate, has been disclosed. Embryos with the highest level of development of intracellular mass A and trophectoderm A give the highest results[3]. Unexpected results have been obtained on the PR in the group of embryos with intracellular mass C (50%), they can hardly be considered natural given the small number of cases (4).[4] The degree of expansion of blastocysts also shows a

direct relationship with PR, with the exception of stage 5 preimplantation development blastocysts (blastocysts with hatching). Apparently, this energetically active process for the embryo (when the embryo expands at regular intervals) is extremely important. The embryo is trying to find the most favorable place for rupture of the membrane of fertilization and exit from it. In fact, this stage of development is a kind of critical period of development for the embryo[5]. Accordingly, at this moment, it seems to be the most vulnerable to the impact of internal and external factors. Vitrification in a certain way at this moment is the very external factor that determines lower PR indices in embryos of this developmental stage[6].

According to the results of the analysis, the use of open carriers in cryopreservation allows us to conclude about a higher level of embryo survivability. Most likely this is due to direct contact of the object with liquid nitrogen and a high freezing rate, which can be a decisive factor in determining the success of vitrification on an open carrier. Clinical indicators (incidence of clinical pregnancy, childbirth and pregnancy loss), which directly depend on the level of survivability, also demonstrate a statistically significant difference in favor of using open carriers in embryological practice[7].

Changes in Blood Counts of Patients with Chronic Atrophic Rhinitis

Anvar Shadieva[1], Maxzuna Nasretdinova[1], Hurram Karabaev[2]

[1]Associate Professor, Samarkand State Medical Institute, Republic of Uzbekistan, Samarkand,
[2]Associate Professor, Tashkent Pediatric Medical Institute, Republic of Uzbekistan, Tashkent

Abstract

Chronic atrophic rhinitis among all ENT organ diseases happens in 10% of cases. This process is very rarely diffuse and mainly from an ailment, the nasal cavity and nasopharynx are sometimes tracheal membranes. The aim of the study was to study the indicators of a general analysis of blood, iron and ferritin in the blood. A study was conducted of 20 people with a diagnosis of atrophic rhinitis. After the initial reaction, expressed in the form of increased bone marrow production, a significant predominance of lymphocytes sets in again.

Based on this, it can be concluded that a degenerative shift with an increase in the number of lymphocytes should apparently indicate a chronic infectious irritant.

Keywords: *Subatrophy, crusts, ferritin, iron, neutropenia.*

Introduction

It is probably impossible to find a person in the whole world who would not know what a runny nose is, although [1]this is a fairly common occurrence.[3] Very few treat the common cold, and in vain, because one of the complications of this disease can be atrophic rhinitis[6], which implies an inflammatory disease of the nasal cavity and nasopharynx [9]. The occurring changes in the nasal mucosa are dangerous, and can lead to further changes in bone tissue[2]. The causative agents of atrophic rhinitis are infections, which indicates a negative effect on the body[3]. Subatrophic rhinitis occurs in 10% of patients with chronic diseases of the nasal cavity, and is characterized by a prolonged course, unexpressed symptoms of dryness and itching in the nose, and difficulty breathing[11]. Chronic diseases can provoke this condition. Chronic subatrophic rhinitis occurs due to endogenous and exogenous factors[15]. Diseases of the gastrointestinal tract, genitourinary and nervous systems are common causes[13]. They contribute to the development of pathogenic (pathogenic) microflora, the accumulation of cell breakdown products in the body. In this case, the regulation of restoration of the epithelium of the nasal cavity is disrupted, the cells begin to be replaced by connective tissue[16]. The atrophic process is very rarely diffuse.

The nasal cavity and nasopharynx sometimes suffers from an condition is inherent in the lake, when all layers of the wall of the nasal cavity are deeply affected. With subatrophic rhinitis, epithelial cells undergo mainly dystrophic changes, their number sharply decreases, they are unable to secrete a sufficient amount of protective mucus. Atrial epithelium loses its excretory function[9], and its pH (acidity) rises, which contributes to the development of pathogenic microbes [14]. Clinical signs of the disease develop gradually and at the same time, a bacterial runny nose worsens.[4] Mucous secretions acquire a purulent appearance (green color). Thickening occurs, the formation of crusts and the blood supply to the mucous layer is disrupted, degenerative changes in the tissues begin[7]. One of the leading causes of chronic atrophic rhinitis is long-term exposure to various environmental factors[8], which is especially important for residents of ecologically unfavorable territories, as well as for workers of harmful industries[14].

The main clinical manifestations of the disease occur with prolonged inhalation exposure to industrial factors, such as wood, coal dust, gaseous products formed during the cooking of metals, processing of petroleum products, etc. It is known that after 2-3 years of working in harmful production, workers note the appearance of typical symptoms of chronic atrophic rhinitis. Subjective

complaints are confirmed by objective research data: a decrease in the speed of mucociliary transport (saccharin test), a decrease in the temperature of the mucous membrane of the anterior divisions of the nasal septum, a violation of secretory function (a test with weighing) is determined. The main clinical manifestations of chronic atrophic rhinitis include a feeling of dryness in the nasal cavity, itching and abundant formation of dry crusts, which are found not only in the anterior, but also in the posterior part of the nasal cavity (differential diagnosis with anterior dry rhinitis). The fetid smell that bothers some patients is probably due to the presence of specific bacteria.

The sense of smell is impaired, weakness, anemia, and panic attacks occur periodically due to repeated episodes of nosebleeds[15]. Prolonged constant irrigation and adverse microclimate can lead to further damage to the structures of the nasal cavity, up to perforation of the nasal septum [17]. The disease is often associated with similar atrophic processes in the pharynx. Diagnosis of chronic rhinitis is based on the patient's subjective complaints and objective examination data (including endoscopy of the nasal cavity). For the purpose of differential diagnosis, it is necessary to perform allergological studies (test panel), make a seeding of the separated nasal cavity to determine the flora and sensitivity[1], as well as conduct computer tomography of the paranasal sinuses (to exclude pathological foci in the paranasal sinuses, the initial manifestations of some autoimmune diseases)[6]. Equally important is a violation of the blood supply to the mucous membrane of the nasal cavity, often associated with age-related changes. Diseases such as heart disease, pulmonary emphysema, tumors of the chest cavity, which make it difficult to drain blood from large veins and develop congestion in the mucous membrane of the upper respiratory tract, also play a large role in the development of atrophic rhinitis. The development of this disease can provoke prolonged use of vasoconstrictor nasal drops.

An important role is assigned to the hereditary factor. Separately, it should be said about the development of atrophic rhinitis in children. Teenagers are at risk during puberty, especially girls. Most likely, this is due to sharp hormonal bursts in the body, as well as vitamin deficiency and a decrease in immune resistance. As international medical experience shows, all atrophic processes in the body are interconnected. Therefore, together with damage to the nasal mucosa, they can detect similar processes in the esophagus or stomach.

The aim of the study was to study blood counts in patients with chronic atrophic rhinitis.

Materials and Research Method

In the clinic of the Samarkand Medical Institute from 2017 to 2019, 20 people were examined, of which 11 men and 9 women with a diagnosis of chronic atrophic rhinitis aged 15-70 years. Patients were divided into 2 groups. The first group of patients was 9 patients, after surgical interventions on the septum and nasal cavity. Complained about the formation of crusts in the nose, atrophy, dry mucous membrane, weakness, respiratory failure. The second group of patients was 11 patients who had not previously been operated on on the nasal cavity and nasal septum. Complained of dryness and crusting of the nose. All of them had signs of atrophic lesions of the nasal cavity, but had not previously been on an outpatient appointment with an otorhinolaryngologist.

The patient underwent a study of a general analysis of blood, iron, and ferritin in the blood. As a rule, a study of plasma for iron and ferritin is carried out from 8 to 10 in the morning. The analysis is given on an empty stomach. The day before the blood sampling, you should refrain from eating fatty foods and drinking alcohol. It is performed in conjunction with studies on hemoglobin, transferrin, total iron binding capacity of serum (OGSS) and ferritin. The results are needed to detect iron deficiency, diagnose and monitor the treatment of anemia, hereditary hemochromatosis, infections, systemic inflammatory diseases and malabsorption of substances in the intestine. Blood sampling is performed from a vein. Within 30 minutes before the fence, you need to refrain from smoking and physical activity, to avoid feelings and emotional stress. To get the correct results 7-10 days before the blood donation, it is necessary to stop taking food supplements and medicines containing iron.[6] The study is carried out by the colorimetric photometric method (with ferrozine). Normally, in men, the iron content in serum is 11.6–31.3 μmol/L, in women - 9.0–30.4 μmol/L [7].

The term of the analysis does not exceed 1 business day. The determination of iron is carried out by the colorimetric method, often using ferrosin[2]**.** Diagnosis of chronic rhinitis is based on individual patient complaints and objective examination data, including endoscopy of the nasal cavity [3].Taking into account one of the main links in the pathogenesis of atrophic rhinitis the principles of treatment are formulated: 1) stimulation of

local and General blood circulation, i.e. increased supply of the mucous membrane with nutrients; 2) moistening of the nasal mucosa and preventing the formation of crusts; 3) combating local pathological microflora.

One of the main points is the systemic effect on the trophism of the nasal mucosa is considered mandatory, but this is a ineffective method of treating atrophic processes. Some authors recommend irrigation with infusions of medicinal herbs (sage, calendula flowers, walnut leaves, tree aloe), often recommend peach, olive oil, retinol acetate and other oil drops.

Results of the Study

Summarizing and summarizing the data of the blood picture, we can reduce them to the following: the total number of leukocytes in 57.5% of cases was normal, in 25% there was little expressed leukocytosis and in 17.5% some leukopenia. The neutrophilic group of leukocytes was characterized by a decrease in the percentage and was characterized by degenerative forms of both segmented cells and stab cells. The number of rod-shaped in most hemograms was reduced and only in 12 cases, slightly increased, although degeneration was quite pronounced. The number of eosinophils in the overwhelming majority of patients 64% was normal in others, but it gave some fluctuations in one direction or another. The number of monocytes, with few exceptions, did not have any particular deviations, but it is difficult to note a certain regularity in the changes in their percentage content on our material.

Analyzing the hemograms of patients with atrophic rhinitis shown here, we tried to find any relationship between the clinical picture of the disease and blood changes. The most interesting in our material is the fact that the number of neutrophils appeared to be significantly lower than the average norm. Any irritation produces a functional change in the leukocyte formula. The longer and more intense the irritation, the more it acts on the leukopoietic organs**.**

Table 1: Revealed altered hemogram parameters in patients with atrophic rhinitis

	Leukocytosis	Lymphocytosis	Ferritin reduced less than 10 ng/ml	Fe in the blood is reduced less than 5.83 µmol/l
1 group (n= 9)	7	6	8	9
2 group (n =11)	8	7	11	11
Total 20	**15**	**13**	**19**	**20**

As can be seen from table 1 in the first group of patients, characterized by more vivid clinical phenomena and the duration of suffering, the decrease in the number of segmented and the presence of a shift is presented more sharply. Obviously, the irritation that caused these changes had a depressing effect on the production of the neutrophilic moiety. In the second group with less pronounced clinical symptoms, the irritating moment probably did not cause this oppression, and we have some neutropenia with a slight shift or normal blood counts.

In the study of serum iron in the blood in all examined patients, we revealed low rates. Normally, in patients, normal values of iron for an adult patient are indicators from 5.83 to 34.5 µmol/L. In 11 patients, the indicators were in the range of 4.35 µmol/L, in 9 patients 6.35 µmol/L. A certain degenerative shift in these sufferings indicates the constancy of the cause acting on the body. Under physiological conditions, ferritin reflects the iron content in the blood. So 1 µg/l of blood ferritin corresponds to 8 mg of deposited iron. In 2 groups of patients, a decrease in blood ferritin below 10 ng/ml was also noted.

Two large systems, the opposite in nature of the lymphocytes and ferritin in the blood, are closely related to each other. With a decrease in the total number of leukocytes with neutropenia and a degenerative shift, lymphocytosis occurs, and against this background, a decrease in iron and ferritin in the blood is detected. A certain degenerative shift indicates the constancy of the cause acting on the body. The absence of a neutrophil core shift always speaks against infection.

In the aforementioned disease, after the initial reaction, expressed in the form of increased bone marrow production, a significant predominance of lymphocytes sets in again.

Conclusion

Based on this, it can be concluded that a degenerative shift with an increase in the number of lymphocytes should apparently indicate a chronic infectious irritant. But less pronounced changes not only do not exclude infection, but confirm our conclusion by the fact that the infection, which is an irritant, has not yet acquired the significance of a chronic factor in these patients due to certain conditions. Although in patients with chronic atrophic rhinitis, a decrease in iron and ferritin in the blood is also observed, which basically can and is the main factor causing the formation of dryness and crusts in the nose.

Abstract

Work-related musculoskeletal disorder is (WMSD) defined as injuries or disorders of the musculoskeletal system, which includes muscles, nerves, tendons, joints, cartilages, and spinal discs that may be associated with exposure to risk factors in the workplace. This study is to determine the prevalence of work-related musculoskeletal symptoms and analysis of risk factors among the academicians of university in Malaysia. Index Terms–Academician, Work-related Musculoskeletal Symptom Work-related musculoskeletal symptoms (WMS) has been identified as "occupational cramps" or "occupational myalgia", in relation to an occupation or work-related activities.

Keywords: *Musculoskeletal Symptoms, muscles, nerves, tendons, joints, cartilages.*

Introduction

This study is to determine the prevalence of work-related musculoskeletal symptoms and analysis of risk factors among the academicians of university in Malaysia. Index Terms–Academician, Work-related Musculoskeletal Symptom Work-related musculoskeletal symptoms (WMS) has been identified as "occupational cramps" or "occupational myalgia", in relation to an occupation or work-related activities[1]. Work-related musculoskeletal symptoms that can be presented in an occupation are pain, ache, numbness, tingling or any discomfort[2]. The symptoms are arising from repetitive, continuous, and unnatural movements in relation to work[3]. The prevalence of work-related musculoskeletal symptoms present in different anatomical areas are differs from each field of profession. Those musculoskeletal symptoms could be a sign of WMS. Those symptoms often occur as a consequence of their interaction with the working environment in fulfilling the demands of task in physical, psychosocial, environmental, and cognitive demands[4]. It has been suggested that a linkage exists between work-related musculoskeletal symptoms and risk factors involving one's occupational conditions and physicality[5] suggest these symptoms causing difficulties in performing job-related tasks and activities of daily living (ADL). According to the statistics from Ministry of Education Malaysia (2019)[6], it shown that the academicians in higher learning institutions throughout Malaysia in 2010 are 64,882 and it has increased to 90,483 in 2017[7]. The roles of academicians are significant in the higher learning academic system of Malaysia to deliver knowledge and to produce qualified students. Since the population is getting larger and the various studies shown that prevalence of work-related musculoskeletal symptoms of other teaching profession is also high, the academicians is needed to be studied on this issue[8]. As Conclusion, the academicians in Malaysia might at risk of having work-related musculoskeletal symptoms as other teaching professional. It cause various disadvantage towards the academicians, university and healthcare system[9] .However, there is paucity of the prevalence of work-related musculoskeletal symptoms among academicians of universities in Malaysia. Thus, the prevalence of musculoskeletal symptoms among academicians in university is conducted[10].

Methodology

This study utilized a quantitative approach, non-experimental, Cross-sectional research design7. This research design use to describe the result in quantitative or numeric data, which is prevalence of work-related musculoskeletal symptoms by study the population of academicians in university.It is the most suitable to use for the aim to measure the prevalence of a problem which is work-related musculoskeletal symptoms in this study, by taking a cross-section of the population of the academicians in a university [11]. The survey is designed by using Microsoft Word 2010 for printed form and also prepared in online form through Google Forms Website at https://docs.google.com/forms/u/0/. The questionnaire is distributed via email given the internet link of online form or in printed form to the academicians. The targeted population is full time academicians of both genders, from 23 to 60 years old, with minimum one year of teaching experience. Teaching experience is required for at least a year as this study is going to investigate whether they have any trouble from the past 12 months in any region of the body[9]. Exclusion criteria Subjects who reported any musculoskeletal injuries such as fracture and soft tissues injuries and recent surgery in any of the regions of the body within 12 months were excluded. Any neurological condition, systemic disorder and cardiovascular condition are also excluded from the study[12]. This is to minimize the individual cause that might be affecting the result of the study rather than the occupational factor. The subject is academicians recruited from a university from six faculties by using non-probability sampling method convenience sampling that whoever passed the study's inclusion and exclusion criteria[13]. The six faculties are Business, Dentistry, Engineering, Medicine and Biomedical Science, Pharmacy and Physiotherapy. The sample size is determined by using the sample size calculator powered by Survey Monkey Website [14]. The final sample size is able to reach as much as 84 subjects. This study reviewed by the Faculty of Health & Sport Sciences Research Review Committee, MAHSA University (FRRC)[15]. All procedures, assessment, tools that used in this study have been approved by the FRRC. Informed Consent Form is provided to each subject stating their willingness to participate in the study[16]. The main tool of this survey study is the general type of Nordic Musculoskeletal Questionnaire (NMQ)[17]. The questionnaire was prepared in two forms which are printed and uploaded in Google From. The subject was identified as the academicians in a university based on the targeted population needed with a sufficient amount of sample size, the convenient of the location and time for researcher to travel to the research site. After filling of the questionnaire was carried out into two ways, either through Google Form Website or through a questionnaire filling session in the academicians' office. For faculty of physiotherapy, medicine and biomedical science and business, the responses are collected through Google Form Website, while faculty of medicine and biomedical science, pharmacy and dentistry are having a questionnaire filling session in the office. For those faculties that were having a questionnaire filling session in the office of the academicians the researcher would brief the academicians about the study aims, study process, questionnaires and to obtained informed consent before the questionnaire begin. The subject was also allowed to ask question to the researcher if having doubts. The variables under the descriptive data are age, gender, faculty, years of teaching, hours of working per week, preferred teaching instrument, and the prevalence of work-related musculoskeletal symptoms were collected. All the data, statistics is analyzed by using statistic software IBM SPSS Version 21.

Results

The main result of this study shows that the general prevalence of work-related musculoskeletal symptoms among academicians in university is as high as (n=62) 73.8%. This result involves symptoms in any nine region of the body as stated in the general Nordic Musculoskeletal Questionnaire; nearly three quarters of the academicians are having the work-related musculoskeletal symptoms. Only (n=22) 26.2% academicians are free from any WRSS from all the nine body regions.

Table No. 1: Demographical Data Collected

Gender	**Frequency**	**Percentage (%)**	**Mode**	
Female	39	46.4	Male	
Male	45	53.6		
Total	**84**	**100.0**		
Age (years)	**Frequency**	**Percentage (%)**	**Mode**	**Median**
23-30	13	15.5	31-40	31-40
31-40	45	53.6		
41-50	12	14.3		
51-60	14	16.7		
Total	**84**	**100.0**		

The table shows the total number of subjects are 84 academicians .Table 4.1 shows that Age range of the academicians is from 23 to 60 years; there are 13 academicians (15.5%) at 23-30 years, (53.6%) 45 academicians at 31-40 years,(14.3%) 12 academicians at 41-50 years, and (16.7%)14 academicians 51-60 years. The mode and median of age is at 31-40 years. These show that most of the subjects are in 31-40 age groups (53.6%), while age 41-50 years is the least (14.3%). The table illustrate about the prevalence of the work-related musculoskeletal symptoms at any time during the last 12 months from the highest to the lowest. It is followed by shoulder (42.9%), neck (40.5%), lower back (27.4%), knees (26.2%), ankle/feet (22.6%), wrists/hand (15.5%), hip/thigh (11.9%) and elbow (6.0%). The highest prevalence of work-related musculoskeletal symptoms for the last 12 months is at the shoulder (40.5%), while the lowest is at elbow (6.0%). The top three regions highest in prevalence is shoulder (42.9%), neck(40.5%), lower back (27.4%). The least three region in prevalence is elbow (6.0%), hip/thigh (11.9%) and wrists/hand (15.5%). The body region that has the highest symptoms at any time during the last 7 days is Neck (23.8%) while the lowest is also elbow again (2.4%) among all the regions. The top three regions highest in prevalence is neck (23.8%), shoulder (22.6%) and lower back (21.4%). The least three region in prevalence is elbow (1.2%), hip/thigh (6.0%) and wrists/hand (6.0%).By comparing this result with studies on school teachers, this result (73.8%) is within the range of school teachers which is 40% to 95%. This results suggest that most of the academicians in university is at high risk of develop WMSD according to the relative body regions. The results investigating the body region that have work-related musculoskeletal symptoms at any time during the last 12 months, whether that symptom affects normal activity and whether it presents during the last seven days. Shoulder, neck and lower back had commonly become the top three highest regions. The three common body regions of top three highest ranking are similar with the systemic review of WMSD among school teachers12. Both the academicians and the primary and secondary school teachers are having the same three common work-related musculoskeletal symptoms on shoulder, neck and lower back with slight difference in the ranking. The contributed factors are prolonged sustained sitting during reading, marking assignment, office meeting; prolonged standing up during teaching sitting13. The second result is the prevalence of the work-related musculoskeletal symptoms at any time during the last 12 months. From the 73.8% of academicians, the top three regions that having the highest ranking is shoulder (42.9%), neck (40.5%) and lower back (27.4%). Next, the body region that has the highest symptoms at any time during the last 7 days is neck (23.8%), shoulder (22.6%), and lower back (21.4%). Erick and Smith (2011) stated that the neck region is the first most common region to have symptoms . The ranking result of the body region that has the highest symptoms at any time during the last 7 days which is neck (23.8%) is parallel to the finding of Erick and Smith12. The ranking for the result during the last 12 months is slightly different due to different methodology used in various articles. Some articles investigate whole body region, some just specifically check

Table 2

Have you at any time during the last 12 months have trouble in :			
Parts of body	**Frequency**	**Percentage (%)**	**Ranking**
Neck	34	40.5	2
Shoulder	36	42.9	1
Upper Back	23	27.4	4
Elbow	5	6.0	9
Wrists/Hand	13	15.5	7
Lower Back	32	38.1	3
Hips/Thigh	10	11.9	8
Knees	22	26.2	5
Ankle/Feet	19	22.6	6

During the last 12 months,have you been prevented from carrying out normal activity because of this trouble in:			
Parts of body	**Frequency**	**Percentage (%)**	**Ranking**
Neck	10	11.9	2
Shoulder	8	9.5	3
Upper Back	7	8.3	4
Elbow	1	1.2	7
Wrists/Hand	5	6.0	6
Lower Back	17	20.2	1
Hips/Thigh	5	6.0	6
Knees	7	8.3	4
Ankle/Feet	6	7.1	5
Have you at any time during the last 7 days have trouble in:			
Parts of body	**Frequency**	**Percentage (%)**	**Ranking**
Neck	20	23.8	1
Shoulder	19	22.6	2
Upper Back	12	14.3	4
Elbow	2	2.4	8
Wrists/Hand	5	6.0	7
Lower Back	18	21.4	3
Hips/Thigh	5	6.0	7
Knees	6	7.1	6
Ankle/Feet	10	11.9	5

Discussion

There is also a lot of study which presented similar prevalence. Shoulder and neck pain among the academicians also can contribute by writing on the whiteboard, sometimes overhead and using computer[14]. This study found most of the academicians preferred using both projector and whiteboard (63.1%). Besides, there are more academicians choose to used projector (29.8%) than whiteboard (7.1%). The use of projector compare to writing on whiteboard might be able to reduce the incidence of shoulder and neck pain during teaching. The teaching instrument among the academicians and teacher in Malaysia most likely is different. The academician writing on the board is comparatively lesser but more on using the projector while teaching. The usage of computer might be more for the academicians such as typing in repetitive movement and reading assignments compare to manual marking on paper. The prevalence of neck pain among school teachers is significant positive associated with improper and static postures, sustained sitting and standing[15]. Other risk factors that were significant associated with neck pain are age, female, years of teaching, regular exercise and job satisfaction. Besides that, chronic neck pain was associated with multiple joint pain and daily living activity limitation. Incidence of neck pain increased with the amount of neck flexion. Regarding the low back pain, academicians found to have lower prevalence (27.4%) compare with primary school teachers of Klang valley, Malaysia (40.4%) in a similar cross-sectional study by using Nordic Questionnaire[16]. The main factor that contribute to low back pain among the primary school teachers is lifting load (28.0%);second is prolonged sitting (25.2%).Besides, poor mental health (OR 1.11, 95% CI 1.06-1.15) was also is the risk factor to low back pain. This might indicate that the academicians have a lesser or different risk factor of low back pain .Next, the academicians probably have lesser lifting load factor compare to primary school teachers. The used of teaching and assignment material of university are mostly in electronic form while the school in Malaysia mostly used books. The needs of carrying

books and students assignments probably are higher compare to academicians in university. The student age group for academicians and primary school teachers is much different as the university students are relatively independent compare to young children. The risk lifting load might be reduce for academicians as it could be assisted by the students in university during teaching or co-curriculum activities. The lifting work most likely need to be done by the teachers themselves in school as the students are still young children . The availability of the office also found to be significantly associated with low back pain[13]. Teacher who does not have their own office in the school are more likely to develop low back pain compare to those who have (AOR=0.52, 95%CI: 0.33, 0.81). This explained other reason for the lower prevalence of lower back pain among academicians compare to teachers. The working environment of the academicians in private university most likely is better compare to usual government school in Malaysia. Design and type of the chair and table size could affect the sitting posture increase risk of low back pain. Better ergonomic design of chair would provide better rest for the academicians in sitting and after teaching in standing. In terms of psychological factor, teachers who were unhappy with their working culture and environment were 1.82 times more likely to experience LBP (AOR=0.55, 95%CI: 0.36, 0.86)[13]. According to the previous symptoms presented, the next finding is the body region that has been prevented from carrying out normal activity at any time during the last 12 months. Lower back (20.2%), neck (11.9%), shoulder (9.5%) is the top three body region that are disabling among the academicians in university. These three regions again ranked as the top three as the first result. However, lower back is the most disabling region among all. Low back pain disability was significant associated with female gender (OR: 2.47, 95% CI: 1.52-3.99, $p<0.001$) and history of low back injury (OR: 3.01, 95% CI: 1.92-4.74, $p<0.001$) among teachers in Botswana. Besides, low back pain disability was also associated with psychosocial job demands, job insecurity and supervisor support. However, not all factors remained statistically significant when evaluated in the logistic regression model[12]. In terms of activity limitation, standing and ADLs are found to be more disabling compare to other activities among the teachers[16]. The work performance and activity limitation related to low back pain among the academicians should be studied in future. Next, elbow, wrist/hand and thigh/hips are commonly rank as three lowest prevalence among all nine regions. The elbow is the least among all nine regions at any time during the last 12 months (6.0%), last seven days (2.4%) and affecting normal activity during the last 12 months (1.2%)17. also found that elbow and wrist have lower prevalence. For thigh/hips, the pain of this region and the lower extremities are least to be concern even among the teachers as there is no study specifically study about the work-related musculoskeletal symptoms in thigh/ hips. The might explained by the prevalence of thigh/ hips is relatively low compare to other regions.

Conclusion

The main result shows the prevalence of work-related musculoskeletal symptoms among academicians in university is as high as 73.8%. This findings suggest that most of the academicians in university is at high risk of develop work-related musculoskeletal disorder especially on shoulder, neck and lower back region with slight variance in ranking. Shoulder is the highest at any time during the last 12 months .Neck has the highest prevalence at any time during the last seven days. Lower back is found to be affecting normal activity at any time during the last 12 months. Next, elbow, wrist/ hand and thigh/hips are three common region ranked as the lowest prevalence. Elbow is the least among all nine regions at any time during the last 12 months, last seven days and affecting normal activity .As conclusion, the academicians in university Malaysia is at risk of having work-related musculoskeletal symptoms as other teaching professional. This study presented the prevalence of the work-related musculoskeletal symptoms among academicians in university .It might use to apply to other academicians and other educators in Malaysia as well. According to the result in this study, we will be able to identify that shoulder, neck and lower back region that academicians suffer from work-related musculoskeletal symptoms . The information analyzed under this study would be useful in understanding the prevalence and given a direction to investigate the possible risk factor among academicians in develop evidence based practice for education on preventive measures in workplace and ergonomic guideline for academicians to prevent work-related musculoskeletal symptoms.

Pre-Clinical Study of General Toxicity of the Medication "Fitin-S"

Kamola Mirzaakhmedova[1], Shakhida Ziyayeva[2], Abdushukur Yunusov[3], Gulchekhra Karimova[4], Rustam Karimov[5]

[1]PhD, MD, Senior teacher, Department of Pharmacology & Physiology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [2]PhD, MD, assistant professor, Department of Pharmacology & Physiology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [3]PhD, MD, assistant professor, Department of Pharmacology & Physiology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [4]MD, Senior lecturer, Department of Pharmacology & Physiology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan, [5]PhD, MD, teaching assistant, Department of Pharmacology & Physiology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Abstract

A pre-clinical study of the general toxicity of the medication "Fitin-S" has shown that it is referred to class IV of low toxic compounds. The medication "Fitin-S" does not have aaccumulative and local irritant action. At multiple intramuscular administration to rats and rabbits it does not influence the behavior and the dynamics of animals growth, does not cause a toxic effect on the composition of peripheral blood, kidneys' and liver's function as well as on the pathomorphology of animals organs and tissues. There is a slowdown in the process of blood coagulation in rabbits at doses of 16 and 32 mg/kg during the whole study period. In 1 month of a recovery period all the indicators have been changing within physiological norm. All the aforementioned data allows us to make a conclusion that the medication does not cause a toxic effect on the organism of animals.

Keywords: *General toxicity, medication "Fitin-S", acute toxicity, cumulation, chronic toxicity, local irritant action, pathomorphological study.*

Introduction

The purpose of studying the medication "Fitin-S" is to establish the nature and severity of its damaging effects on the body of experimental animals and assess its safety.

Materials and Method

The study of acute toxicity of the medicationshas been carried out according to the method of Litchfield and Wilcoxon on white mice, both sexes, weighing 20±2.0 g of 6 animals in each group, 150 mice has been used in total[2]. All pharmacological studies have been performed on healthy sexually mature animals (mice) exposed to the quarantine of at least 10-14 days[1].

The medication tested has been injected intravenously, subcutaneously and intramuscularly as a single dose of 100 to 10000 mg/kg. The animals were monitored hourly during the first day of the experiment in the laboratory, while the survival rate during the experiment, general condition, possible convulsions and death were used as indicators of the functional state of the animals. At the end of the experiment, the average lethal dose (LD50) has been calculated and the toxicity class has been determined[3]. The study of accumulation of "Fitin-S" has been carried out according to the Lim's method, which allows to evaluate not only accumulation, but also addiction. The objective of the study was to identify a possible accumulative property in the solution of the medication tested. The trials have been performed on 10 mice of both sexes weighing 20±2.0 g. The medications have been administered intramuscularly according to the scheme for 24 days from 0.1 to 1.15 from LD_{50}[4].

The general toxic action of "Fitin-S" at multiple intramuscular administration has been studied in 40

non-linear white rats (males and females) with the initial weight of 110±10 grams and in 16 gray-colored rabbits of both sexes with the initial weight 2,0±0,2 kilograms. Animals were in vivarium on a normal diet. The trial animals have been divided into 4 groups: 10 rats (5 males and 5 females) and 4 rabbits (2 females and 2 males) in each. The medication has been administered intramuscularly daily (7 days a week) for 30 days to rats at doses of 20, 40 and 100 mg/kg and to rabbits at 8.0, 16.0 and 40 mg/kg. The control animals have been injected with distilled water in a bioequivalent volume. All animals have been kept in standard vivarium conditions on a full-fledged food and water diet.

The condition of animals during chronic intramuscular administration has been evaluated by the following parameters of peripheral blood: haemoglobin contents, gr/dl; the number of red blood cells,10^{12}/l; reticulocytes,%$_0$; thrombocytes, 10^9/l; leucocytes,10^9/ land leukogram; liver function evaluation - by glucose content,mmol/l; total protein,gr/dl; alanine - and aspartate - aminotransferases (AlAT, AsAT) in blood serum. Biochemical tests have been performed using test kits from CypressDiagnostica, Belgium. Renal function has beenevaluated by diuresis with a water load (5% of body weight) for 4 hours, blood urea, urine acidity (pH), the presence of nitrites, glucose, leukocytes etc. in the urine (qualitative reactions) with the Combina kit, Germany, and by urinary sediment.

Hematological and biochemical studies were performed after 10 and 30 days post the day of the experiment. At that time animals were weighed. At the end of the experiment some animals have been decapitated and the material has been taken for pathomorphological studies according to the list approved by Pharmacological Committee of the Republic of Uzbekistan[5]. The rest of animals has been left to study the recovery process.

The general direction of changes in the coagulation process under the influence of medication has been assessed by the records of thromboelastograms performed on the thromboelastograph Tromb-2.

The "open field" test is a study of behavior due to the animal being in an unfamiliar open space, which it cannot leave. The animal is put in the central square, and the latent period of exit from it is recorder. The number of squares into which the animal entered is registered (horizontal motion activity - HMA), as well as the number of rises on the hind limbs ("upright posture" – VMA), the number of holes the animal sniffed(exploratory activity - EA), the number of washes (number of grooming acts -NGA) and defecations (number of bolus - NB). Based on these parameters, motion activity, orientative-motion activity, anxiety and autonomic reactions are evaluated. The above parameters are fixed for 4 minutes from the moment of placing the animal[7].

The conjunctival sample is a very sensitive test and, in some cases, even discloses the reaction of animals to an allergen at mild allergization and negative skin tests. The trials have been performed on 12 rabbits, weighing 2,0-2,5 kg, which have been instilled with 0,1 ml of 0,5 and 5% medication solution in the left eye, and with 0,1 ml of distilled water in the right eye (a controlled one). The reaction has been recorded in 15 minutes (quick reaction) and in 24-48 hours (delayed hypersensitivity) and evaluated according to the following scale (in points). Besides, the level of hyperemia, swelling, and lacrimation have beenregistered[8].

The local-irritant action of "Fitin-S" has been studied on 12 rats weighed 150±10 grams. The animals have had their hair clipped on both sides of the spinal column (4 areas) 2x2 cm in size.0,5 ml of Fitin-S in 0,5 and 5% solutions have been applied on two clipped areas on the left side of the back. The medication has been applied for 10 days. The controlled areas were the right clipped areas to which distilled water has been applied in the same volume. The monitoring has been carried out for 14 days. The skin reaction has been recorded daily according to the skin sample scale in points[8].

Statistical processing of the obtained data has been carried out with the definition of the Student's criterion using statistical programs WindowsExcel 2010.

All experimental animals have been kept in the same conditions and on a common diet with free access to water and food.

Results

The general action and "acute" toxicity of "Fitin-S" have been determined in mice at a single intravenous, intramuscular and subcutaneous administration. Each dose of the substance has been studied in 6 animals. The monitoring has been conducted for 14 days.

The medication has been administered to mice intravenously at doses of 200, 300, 400, 500 and 600 mg/kg in the form of a 0.5% solution, intramuscularly and

subcutaneously at doses of 100-500-1000-2500-2700-2800-2900-3000-3300-3600 mg/kg as a 5% solution.

When studying the acute toxicity of the medication "Fitin-S" with intravenous administration, a 5% solution of the medication has been diluted with 0.9% sodium chloride in a ratio of 1: 1; 1: 5 and 1:10. The obtained solutions of the "Fitin-S" medication have been administered intravenously at doses from 100 to 400 mg/kg in a volume not exceeding 0.5 ml per animal weight[3]. As can be seen from the data in table 1, after administration of the medication at doses causing toxic phenomena, convulsions and death of some mice have been observed within 72 hours. The average lethal dose (LD50) of intravenous administration of the "Fitin-S" medication to mice has amounted to 347 (320 ÷ 460) mg/kg.

The results of studies with subcutaneous and intramuscular administration have shown that "Fitin-S" at doses of 100-1500 mg/kg does not cause changes in the general condition of the animals. When the medication is administered at doses of 1800-2500 mg/kg, after 30-60 minutes there has been a decrease in the motion activity of animals, while the response of mice to external stimuli has remained unchanged, and no lethal outcome has been observed. With the introduction of the medication at doses of 2800-3600 mg/kg after 60-120 minutes, anxiety of mice, shortness of breath, short-term convulsions and the death of some animals during the day has been registered.

Discussion

Thus, the study of the acute toxicity of "Fitin-S" has shown that the medication is referred to class IV of low toxic compounds. The LD_{50} during intravenous, intramuscular and subcutaneous administration to mice has amounted to 347(320÷460) mg/kg respectively, 2560 (2266÷2893) mg/kg and 2900(2566÷3277) mg/kg.

When choosing the doses for the study of chronic toxicity of pharmacological substances their accumulative effect should be taken into account. That's why before conducting experiments on chronic toxicity we have been studying the accumulation via sub-chronic toxicity according to the method of Lim and co-authors which allows to evaluate not only accumulative properties but also addiction, and we have determined the accumulation index, the ratio of LD50 with a single administration to LD50 with a multiple administration.

The studies conducted have shown that the accumulation index $K_к$ has amounted to$K_к=LD_{50n}/LD_{50,}$ 2944/2560=1,15. In other words, the medication "Fitin-S" does not have the accumulative effect, the accumulation rate is 1,15.

The local-irritant effect of the medication has been studied on rats and rabbits. The results of monitoring have shown that "Fitin-S" in 5 and 10% concentrations does not cause even the slight reddening of the conjunctiva of the rabbit eye in either 15 minutes or 24 or 48 hours. Application of the medication for 10 days on the skin of rats also does not cause irritation, redness, swelling or other visible changes on the skin and the effect of "Fitin-S" is estimated at 0 points.

According to this a conclusion that the medication "Fitin-S" in 5 and 10% concentrations does not have the irritant effect on the conjunctiva of rabbits and on the skin of rats can be made.

The results obtained at daily intramuscular administration of "Fitin-S" to rats and rabbits are represented in Tables 3-4. As can be seen from the data given in tables 3-4, in 10 and 30 administration at all the studied doses there has been no significant deviations in the composition of the peripheral blood of rats and rabbits in the hemoglobin content of erythrocytes, in the number of blood cells themselves, their precursors (reticulocytes), and leucocytes. Leukocyte counts in rats and rabbits are within the physiological norm.

Based on this, it can be concluded that "Fitin-S" at the studied doses with intramuscular repeated administration does not have a toxic effect on the quantitative composition and morphology of the peripheral blood of experimental animals.

*P < 0,05 to control

Diuresis after 10 days and 30 days of the experiment under conditions of water load did not differ significantly in the experimental and control rats. In rats, the state of nitrogen metabolism, the criterion of which is the urea content in the blood serum, did not deviate from the control after 10 days and 1 month of the experiment. In the urine during the entire experiment, both in the experimental groups and in the control group, no changes in the studied urine parameters have been detected. The acidity of urine in all the studied groups has not been changing during the entire experiment and its pH was 6.0-7.0. No pathological changes in urine sediment have been detected.

The results obtained have led to the conclusion that the medication "Fitin-S" with chronic administration does not have a toxic effect on renal function in the studied doses.

The liver function in experiments on rabbits and rats has been studied with the use of the most sensitive tests. The levels of total protein, glucose, and enzyme activity (AsAT, AlAT) in the blood serum of all experimental rats after 10 and 30 days of the experiment have not differed from the control (Table 4.5).

Thus, the medication "Fitin-S" at intramuscular daily administration at the studied doses does not have a toxic effect on liver function.

As the medication "Fitin-S" is supposed to be applied parenterally, it was important to find out how the process of blood coagulation changes at multiple application. The experiments have been held on 12 chinchilla rabbits, males and females weighing 2,0±0,2 kg. The blood has been studied in 10 and 30 days post the administration of "Fitin-S" at doses of 8,0, 16,0 and 40,0 mg/kg.

The results of the impact of the medication "Fitin-S" on the process of blood coagulation are represented in table 6. Thromboelastogram data indicate that after 10 and 30 administrations, "Fitin-S" does not affect the blood coagulation process at a therapeutic dose of 8 mg/kg. With an increase in the therapeutic dose by 2 and 5 times (16 and 40 mg/kg), the blood coagulation process changes, which is expressed in an increase in the indicator K, the time of clot formation, which depends on the concentration of thrombin formed and the amount of fibrinogen; and a decrease in MA, a decrease in the elasticity of the clot (E) and the index of hypercoagulation Ci, which indicates a slight decrease in the process of blood coagulation.

Table 6: The dynamics of changes in blood coagulation of rabbits with chronic administration of the medication "Fitin-S" M±m; n=4)

TEG Indicators	Control	In 10 days/dosemg/kg			In 30 days/dose mg/kg

*P ≤ 0,05 to control

Thus, the intramuscular administration of the medication "Fitin-S" to rabbits at a therapeutic dose of 8 mg/kg does not cause anyeffect, andat doses of 16.0 and 40.0 mg/kg leads to a slight slowdown in blood coagulation process throughout the entire period of administration (30 days).

The study of the effect of the medication "Fitin-S" on the central nervous system and peripheral nervous system in the open field test has shown that after 10 days of administration of "Fitin-S" for 4 minutes, it has not changed the horizontal and vertical motion activity of rats at doses of 20, 40 and 100 mg/kg. After 30 days of the experiment, a sedative effect has been observed, which was expressed in a reduction in the number of intersections (horizontal activity) and the number of postures (vertical activity) and the number of "holes" (exploratory activity). Throughout the entire experiment, "Fitin-S"has not significantly affected the vegetative reactions of the body (the number of "boluses", the number of washings).

Table 7: Impact of "Fitin-S" on behavioral reactions of animals in the "open field" test (M±m; n=6)

Medication, dose, mg/kg	Latentperiod, sec	Motion activity		Quantity		
		Horizontal, number ofintersections	Vertical, number ofpostures	Holes	Washes	Bolus
In 10 days

*P ≤ 0,05 to control

The study of integral indicators has shown that the dynamics of the body weight of the experimental animals at the studied doses after 10 and 30 days of the experiment has not differed from the control. Throughout the experiment animals were active, neat, they ate food normally, drank water, their hair was smooth, shiny. The behavior of experimental rats has not differed from the behavior of control groups of animals.

A macroscopic examination of sacrificed animals has disclosed the correct location of the internal organs. There is no free fluid in the pleural and abdominal cavity. Tissues of the lungs, stomach and intestines are also of a normal color, without signs of edema, hemorrhages and ulcerations. Pancreas, kidneys and adrenal glands are unchanged.

At the end of the experiment, 1 cm^3 of organs has been taken from experimental animals for histological examination. This site has been fixed in 10% normal formalin. Then the tissue has been embedded in paraffin and sections of histological preparations 3-5 microns thick have been prepared and stained with a mixture of hematoxylin + eosin. The obtained preparations have been analyzed under a Leica-1000 DM microscope (Germany), I0x eyepiece, 10x and 40xlens [6]

The results of histological studies have shown that basically their histostructure is comparable with the morphology of control groups of animals. In the stomach, the mucous membrane is well preserved, glandular cells are without any changes. In the small intestine its main elementsare villi and crypts. They are well prominent, villi are finger-shaped, the border of enterocytes is distinguished, the stroma of the villi and the epithelial layer are moderately saturated with lymphocytes, are distinctly distinguished in the enterocytes. In the colon, the crypts are lined with mucous cells, the lumens of the crypts are enlarged and filled with mucoid secretion.

In the liver of experimental animals treated with the medication, no significant changes have been found. In experimental animals at the studied doses, the majority of hepatocytes are in a state of hydropic edema with granular inclusions, and moderately medium-droplet fat inclusions on the periphery. In addition, small foci of cellular infiltration have beendisclosed in the liver parenchyma in some areas. Basically, as usual, the boundaries of the lobules are not distinct in the liver, the hepatocytes are polygonal in shape, their cytoplasm is pink and contains a large, roundish one or two nuclei. In stellate macrophages, small grains of hemosiderin have also been found, as well as in the control. The structure of the various departments of the nephron, renal corpuscles, proximal and distal parts are without any changes. The structure of the capsule and cellular elements of all departments of the nephron indicates their functional viability.

White and red pulp are seen in the spleen; the structure of these elements does not differ significantly from that of control animals. The study of the structural organization of the myocardium is indistinguishable from indicators in the control group, consists of rectangular cardiomyocytes, with a weakly pronounced transverse striation.

The lungs have a characteristic pattern and are represented by numerous dilated alveolar vesicles and atelectasis sites. The interalveolar walls contain numerous blood capillaries, the walls of the bronchi and blood vessels are without any significant changes.

The histology of the thymus is represented by the cortical and brain zones, with signs of age-related involution. The cortical zone is represented by lymphoid cells and trabecular interlayers. Also, the brain area is represented by lymphoid follicles, without clear centers of reproduction.

In this regard, it should be noted that the differences found are a manifestation of the species or age characteristics of animals.

Thus, the results of histological studies allow us to conclude that “Fitin-S” at the studied doses is the optimal medication, its long-term use does not cause noticeable structural destruction or damage and can be recommended for further clinical trials.

Conclusion

Pre-clinical study of the general toxicity of the medication “Fitin-S” has shown that it is referred to class IV of low toxic compounds. The medication “Fitin-S” does not have anaccumulative and local-irritant effect. With repeated intramuscular administration to rats and rabbits, it does not affect the behavior and dynamics of animal weight, does not have a toxic effect on the composition of peripheral blood, kidney and liver function, and also on the pathomorphology of animal organs and tissues. With repeated use, there is a slight slowdown in the blood coagulation process in rabbits at doses of 16 and 32 mg/kg throughout the study period. After 1 month of the recovery period, all these indicators have been changing within the physiological norm. All of the above data allow us to conclude that the medication does not have a toxic effect on the animal organism.

Abstract

The article focuses on the study of hemodynamics of children during the period of induction into anesthesia. The analysis of the study results has been carried out – 80 children aged 3 to 14 years undergone medical procedures on diseases of abdominal cavity and anorectal area. The study results have shown that the combination of sevoflurane and ketamine in small doses has caused an effective analgesic effect with a significant vegetative stabilizing effect providing a stable course of the following stages of anesthesia and postanesthetic period.

Keywords: *Combined anesthesia, induction period, measurements of central hemodynamic, inhalation anesthetics, fentanyl, ketamine.*

Introduction

Induction narcosis is the most essential stage of anesthesia. Mistakes and inaccuracies during the induction narcosis[2] and its complications may become the very reason for the chain of abnormities that entail a negative outcome in the future[7]. It is known that medicines applied during the induction period are not neutral for the organism and might become the reason for serious complications due to hard-hitting medicamental effect of the components[9] of anesthesia on cardiovascular system[6]. Induction period might be accompanied by significant hemodynamic shifts[5]. The most frequent complications of the anesthesia period of children are the disorders of cardiac rhythm and central hemodynamics[11].

The purpose of the work is to study the impact of various types of induction on the condition of central hemodynamics during the surgery on abdominal cavity and anorectal area of children[4].

Materials and Method

The work is based on the analysis of the study results – 80 children aged 3 to 14 years 80. The study has been carried out with children who have undergone surgery because of the diseases of abdominal cavity – 42 children (52,5%) and of anorectal area – 38 children (47,5%).

A complete clinical examination has been held. For the purpose of the objective evaluation of the condition of cardiovascular system a method of echocardiography with the analysis of end-diastolic (EDD) and end-systolic (ESD) dimensions of the left ventricle, R-R interval and ejection time was applied. The study has been carried out using the echocardiograph “Sonoscape”

(China, regnumber cfda 20123231386) of patients on the following stages: prior to surgery (initial), post premedication and post-induction.

Premedication was aimed at eliminating anxiety, preventing nausea and vomiting. Atropine sulfate at a dose of 0.01 mg/kg, diphenhydramine - 0.1 mg/kg, sibazon - 0.25 mg/kg and ketamine - 2.0 mg/kg body weight were prescribed as a part of premedication.

Small doses of ketamine (1 mg/kg) and propofol (1 mg/kg) were administered intravenously to patients of the first group in 30-40 minutes post premedication as well as inhalation of sevoflurane at a dose 2,0 – 3,0 vol%.

Before a skin incision, a fentanyl solution of 3 μg/kg was injected intravenously. The maintenance dose of sevoflurane was 1.5 vol%, the fentanyl dose was 2 μg/kg.

Patients of the second group were exposed to inhalation of isoflurane at a dose 2,0 vol% and intravenous doses of fentanyl of 5 μg/kg and droperidol of 0,4 mg/kg body weight 30-40 minutes post-premedication.

The obtained data has been processed via the set of auxiliary programs Statistica for Windows, Release 5,5 Stat Soft, Inc, with the calculation of arithmetic mean value (M), the average error (m), all digital data has been presented as M±m. The significance of differences was assessed by Student's criterion (t) with a known number of observations (n). The differences were considered significant at $P < 0.05$.

Results

After the premedication patients of the first group has shown an increase in the measurement of the heart rate frequency (HRF) by 6% ($P<0,05$), the tendency to an increase in the measurement of the arterial pressure: systolic arterial pressure (SAP) by 2,3%, diastolic arterial pressure (DAP) by 2,9% (Table.1). During the induction period, propofol and sevoflurane have caused fast and smooth induction, a smooth sleep onset within 30-60 seconds of patients has been registered. While the study period, an insignificant decrease of the heart rate frequency measurement by 4,08% has been noticed compared with similar measurements of the premedication stage. The systolic and diastolic arterial pressure measurements were characterized by the downward tendency respectively by 0,7% and 0,9%.

Table 1. Measurements of the HRF, SAP and DAP at the induction anesthesia period with the use of ketamine, propofol and sevoflurane

Measurements	Study Stages		
	Initial	Premedication	Induction
HRF	108,25±7,46	114,75±8,40*	110,06±6,80
SAP	89±8,20	91,06±9,30	90,43±9,15
DAP	45±7,79	46,31±8,56	45,87±7,50
Sp O2	95,31±0,60	97,56±0,51*	98,25±0,68*

Note: * Reliability of differences in measurements compared to the original ($P < 0,05$).

Discussion

On a premedication stage patient of the second group have shown an increase in the measurement of HRF by 5,5%. SAP measurements - by 3,0%, DAP measurements - by 1,7%. Isoflurane inhalation has caused a slow induction and the solutions of fentanyle and droperidol have been injected intravenously in this connection. After the fentanyle injection, a respiratory depression has been observed, an auxiliary ventilation has been applied and a tracheal intubation has been implemented after the administration of muscle relaxants. Skin cover was warm and had a regular staining whilst the oxygen saturation indicator increased by 3,9%. HRF measurement increased by 2,0%, an insignificant increase in the SAP by 1,2% and DAP by 0,2% compared with similar measurements of the original period has been observed (Table 2).

On the background of the administration of medicines for induction – ketamine, propofol and sevoflurane after the trachea intubation an insignificant change in hemodynamics not negatively affecting a hemodynamic system has been observed. Introduction period of general combined anesthesia with the use of small doses of has been characterized by smooth clinical course.

Table 2. Measurements of the HRF, SAP and DAP at the induction anesthesia period of children with the use of isoflurane, fentanyle and droperidol

Measurements	Study stages		
	Initial	Premedication	Induction
HRF	115±2,38	121,33+ 2,87*	118,93+ 3,93*
SAP	88,40±2,69	91,7±2,87	89,5±4,21
DAP	45,16±2,69	45,92±3,51	45,07±4,32
SpO2	95,38±0,58	97,44±0,6*	99,07±0,73

Note: * Reliability of differences in measurements compared to the original (P<0,05).

When conducting a study of the central hemodynamics measurements of patients of the first group, in the introduction period compared with the similar measurements of the initial period, after the trachea intubation the increase in HRF measurements by 7,6%, CI by 18,5% (P<0,05), some tendency to the increase of SV measurement by 9,3% have been observed. At the same time, a downward tendency to the decrease in the measurements of EF by 5,6% and SPVR by 8,2% has been noted (Table 3).

Table 3. Measurements of central hemodynamics during the anesthesia induction period of children with the use of isoflurane, fentanyle and droperidol (n=40)

Measurements	Initial	Premedication	Induction
EF	70.49±0.85	68.28±1.03	66.55±0.96*
SV	24.59±1.61	22.9±1.31	26.88±1.63
HRF	97.8±2.21	107±2.11*	105.18±1.91*
SPVR	30.29±1.54	32.16±1.77	27.81±1.04**
CI	2.87±0.09	3.02±0.11	3.4±0.1***

Note: * Reliability of differences in measurements compared to the original (P < 0,05).

Table 4 represents the data on the study of central hemodynamics during general anesthesia of children with the use of isoflurane, fentanyle and droperidol. The increase in the measurements of HRF and Specific peripheral vascular resistance.

Table 4. Measurements of central hemodynamics during the anesthesia induction period of children with the use of isoflurane, fentanyle and droperidol (n = 40)

Measurements	Initial	Premedication	Induction
EF	71.96±1.48	71.51±1.17	72.05±1.4
SV	24.87±1.54	23.56±1.31	23.67±1.35
HRF	96.48±2.07	109.15±2.2*	109.9±2.33*
SPVR	29.7±1.41	25.52±1.25*	26.59±1.42
CI	2.81±0.14	3.08±0.15	3.12±0.17

Note: *Reliability of differences in measurements compared to the original (P < 0,05).

In the introduction period of anesthesia after the trachea intubation compared with the premedication stage only a slight tendency to the measurement change has been noted. In comparison with the initial period, only HRF was subjected to a significant change and increased by 13,9%. Only the SV and SPVR measurements had a downward tendency by 4,8% and 10,5% respectively. Subsequent laryngoscopy and intubation do not cause such a pronounced hyperdynamic response as with induction with ketamine and barbiturates. Hypotension was prevented and eliminated by infusion loading.

The results of the existing study show that the combination of sevoflurane with propofol and ketamine in small doses has caused the effective analgesia with a significant vegetative stabilizing effect associated with central suppression of sympatic activity, and has ensured a stable course of subsequent stages of anesthesia and post-anesthesia period. Patients experienced a rapid restoration of the preoperative level of neuropsychic status after surgery.

Conclusions

1. Insignificant changes of the main measurements of central hemodynamics are contingent to the condition of patients during the introduction period, the trachea intubation and the manipulations taken. The vasodilating properties of propofol and sevoflurane suring the introduction narcosis determine a switch hypodynamic reaction of the circulatory system.
2. The evaluation of the clinical course of the introduction period and of the changes of the main measurements of central hemodynamics at conducting the two variants of the combined anesthesia has shown smooth introduction into narcosis and therefore an auxiliary stable course of the subsequent anesthesia stages.
3. Applying small doses of ketamine and propofol coupled with sevoflurane is an optimal method of induction during traumatic and extensive surgery in the abdominal cavity and anorectal area in children.

Comparative Analysis of the Results of Traditional and New Distance Learning Method Among the Master's Degree Students and Physicians in Uzbekistan

Zokhid Abdurakhimov

Senior Researcher, PhD, Public Health, Organization and Management of Health, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Abstract

The rapid changes in medical theory and practice require physicians to undertake continuing medical education. The low level of qualifications of physicians can eventually lead to medical errors. There is a special currency to measure and evaluate the obsolescence of knowledge, the so-called half-life of knowledge.

Materials and Method: Analysis of results and evaluations using various forms of training method on one topic between 2nd year master's degree students (masters) of Tashkent pediatric medical institute and physicians. Training was conducted traditionally (face-to-face form for periods of each time 1 hundred 10 minutes) and distance-based (internet point of-care learning and journal-based continual medical education). The results of tests among 72 masters and 84 physicians were retrospectively analyzed.

Results: According to the study, it was found that the average rating in the group of Masters via traditional method with an "unsatisfactory" evaluation was 2 (4%) while in the group of physicians with the same test the number with an unsatisfactory evaluation was 9 (21%), (which is four times more). The number of Masters who received a satisfactory evaluation was 12 (23%) (18 physicians received the same evaluation, representing 43%). The number of Masters who got a good evaluation was 23 (43%) and only 10 or 24 % of the physicians got the same score (which is twice less than the result of masters) and 16 (30%) Masters received an excellent rating (5 physicians received the same mark or this was 3 times less).

Discussion: More than half of the physicians (being 27 or 64%) responded to the test with an evaluation of "satisfactory" and "unsatisfactory", while only 14 (26% or 2.5 times less) Masters received such marks. Only 15 (35%) physicians received "good" or "excellent" rating, whereas among the masters, this result was 39 (60% or 2 times higher than the responses of physicians). However, among the participant soft the online program unsatisfactory response was not observed. 8 (42%) participants answered satisfactorily, 11 (58%) of the participants responded with good or excellent marks.

Conclusions: Following the results of the analysis, the study showed that the increase in theoretical knowledge has been identified in a larger number of masters. The knowledge gained through traditional teaching or distance (online and journal form of training) learning, seems virtually identical, and the study seems to indicate that they even surpass the traditional method of training.

Keywords: *Medical error, obsolescence, chronic diseases.*

Introduction

The rapid changes in medical theory and practice require physicians to undertake continuing medical education both on the workplaceas well as at home, with additional financial costs associated with accommodation and meals[1]. There are more than 72000 (10000 population-24) physicians in Uzbekistan and Each physician should improve his/her qualification by earning 288 credits within every 5 years. Initially, physicians have to earn 144 credits at the Tashkent Institute of Postgraduate Medical Education (TIPME),

and the other credits can be earned in other short trainings[2]. In the American literature, there is a special currency to measure and evaluate the obsolescence of knowledge, the so-called half-life of knowledge[4]. As a result of obsolescence of knowledge as new information appears, the competence of physicians is reduced by half in a 3-4 years time period[3]. This rapid obsolescence of knowledge dynamics may be relevant to setting educational standards and planning training program accordingly[5].

The purpose of the study: Analysis of results and evaluations using various forms of training method on one topic between 2nd year master's degree students(masters)of Tashkent Pediatric Medical Institute and physicians.

Materials and Method

Materials are the results of the tests obtained among 136 respondents who have undergone training on "Improving method and cost-effectiveness of prevention of several chronic diseases", consisting of a series of 15 questions, and research method are both mathematical as well as statistical.

To achieve the objective, we, together with the Tashkent Pediatric Medical Institute and the Tashkent Institute of Postgraduate Medical Education (TIPME) have developed a training programme on "Improving approaches and cost-effectiveness of prevention of several chronic diseases. Training was conducted traditionally (face to face form for periods of each time 1 hour and 10 minutes) and distance-based (internet point-of-care learning and journal-based CME).

Results

The results of tests among 72 masters and 84 physicians were retrospectively analyzed (Tab. №1).

Traditional teaching method for masters and physicians. Second year Masters have been trained at the department of "Public Health" in 2014. For physicians,the training was conducted at the Institute of Health and Medical Statistics. After training, each participant was given 20 minutes to answer the questions with the following results. A comparative evaluation of results was carried out among the masters of the Russian group before and after training. Before the training, the average number of correct answers was 10,9 (73%), whereas after the training this figure increased to 11,3 (78%). The masters of the Russian group were informed in advance that they would be tested, whereas the masters of the national groups (Uzbeks) were tested immediately after the presentation without warning. According to test results among national groups, the average number of correct answers was 11,3 (or 75%). The average number of correct answers among the practitioner-physicians after the training was significantly lower than those Masters of Russian and national groups and was 8,7 (58%).

Internet point-of-care learning. To explore and introduce new forms of learning we had put our training program "Improving approaches and cost-effectiveness of prevention of several chronic diseases" on to the website of the Medical Association of Uzbekistan (www.avuz.uz). A web application was developed to save the data. Participation in the test tasks,training and testing weredone on a voluntary basis. After registering, participants received access to training program. Thus, 19 masters and physicians were registered and participated on this topic. All data were saved in the database of the website with the consent of the participants, which included the participation date, the amount of time to answer the tests and the percentage of correct answers. At the initial level, the average number of correct answers was 10,6 (70,6%) spending 7,4 minutes on average, while after the training, the average number of correct answers was 11,7 (73%). However, online learning allows reading, printing of educational material and learning in a convenient location for the physician.

Journal-based training. In 2010-2015, more than 1200 physicians participated in journal-based trainings in Uzbekistan, 1021 of whom have been awarded a certificate. Training theme: "Improving method and cost-effectiveness of prevention of several chronic diseases",was published in the "Bulletin of the Medical Association of Uzbekistan." In the journal form of training 42 physicians participated from various regions of Uzbekistan, including (Tab. №2)

Tables 1: Participants of journal-based training.

№	Region	Number of participants
1	Republic of Kazakhstan	1
2	Bukhara region	8
3	Andijan region	7
4	Surkhandarya region	2
5	Tashkent city	3
6	Tashkent Region	3

№	Region	Number of participants
7	Jizzakh region	5
8	Namangan region	2
9	Kashkadarya region	1
10	Samarkand region	7
11	Navoi region	2
12	Syrdarya Region	1
	Total	42

Journal-based learning is not free of charge: and every physician was required to pay 10 euros. All the successful physicians(65% of the test) were given certificates that could be used in the delivery of documents for obtaining a certificate of qualification.

Discussion

Comparative analysis of the results and assessment (Tab. №3). According to the study, it was found that the average rating in the group of Masters via traditional method with an"unsatisfactory" evaluation was2 (4%) while in the group of physicians with the same test the number with an unsatisfactory evaluation was 9 (21%), (which is four times more). The number of Masters who received a satisfactory evaluation was12 (23%) (18 physicians received the same evaluation, representing 43%). The number of Masters who got a good evaluation was 23 (43%) and only 10 or 24 % of the physicians got the same score (which is twice less than the result of masters) and 16(30%) Masters received an excellent rating (5 physicians received the same mark orthis was 3 times less).

More than half of the physicians (being 27or 64%) responded to the test with an evaluation of "satisfactory" and "unsatisfactory", while only 14(26% or 2,5 times less) asters received such marks. Only 15(35%) physicians received "good" or "excellent" rating, whereas among the masters, this result was 39 (60% or 2 times higher than the responses of physicians).

However, among the participants of the online program unsatisfactory response was not observed. 8 (42%) participants answered satisfactorily, 11 (58%) of the participants responded with good or excellent marks.

There were no candidates with unsatisfactory ratings among the participants of the journal-based training, 6 participants (14%) got a satisfactory rating, 36 (86%) of the participants got good or excellent response. Because of the payment for this type of training, we assume that physicians are more motivated to read carefully the training program and can consult with colleagues before completing and submitting test items for review by experts of Tashkent Institute of Postgraduate Medical Education - this may explain the best result answers.

Conclusions

Following the results of the analysis, the study showed that the increase in theoretical knowledge has been identified in a larger number of masters in contrast to the practicing-physicians, although there is no doubt that the physicians are more experienced. The knowledge gained through traditional teaching or distance (online and journal form of training) learning, seems virtually identical, and the study seems to indicate that they even surpass the traditional method of training. These data show that how physicians are trained and their requirements need to be reviewed with an emphasis on the development of distance learning method of training(online and journal-based form) and also experience can be learned from developed countries.

Abstract

Hemiparesis of various severity is a common type of motor disorder resulting from an experience of a stroke. It is motor disorders that lead to the disruption of such categories of activity as the ability to move and self-care, which entails a limited patient mobility. The study has included 35 patients with motor disorders resulting from acute cerebrovascular accidents (CA), and the patients have undergone medical rehabilitation.

Clinical research method (Ashworth and Rivermead scales) and mathematical statistics have helped assess the positive effects of robotic mechanotherapy, which was used in the rehabilitation of stroke patients.

As a result of rehabilitation measures with the use of robotic mechanotherapy, 68.2% of the examined subjects have developed significant strength in the hand, and 45.5% - in the leg ($p<0.005$). In the remaining subjects, no significant improvement in the motor function has been observed, although mobility has improved in all examined patients and the average Rivermead mobility index has been 11.4±2.1 out of 15 ($p <0.001$).

Keywords: *Acute cerebrovascular accident, stroke, paresis, validated scales, Ashworth scale, Rivermead Mobility Index, robotic mechanotherapy, Armeo Power device, Lokomat device.*

Introduction

Although the issue is very evident, as is the need in finding solutions, data provided by the World Health Organization (WHO) suggests that cerebrovascular disorders of various genesis are still a leading mortality and disablement factor. It should be noted that a number of international authors (Sarti C., Rastenyte D., Cepaitis Z., et al., 2000; Howard G., Howard VJ., Katholi C., et al., 2001; National Center for Health Statistics. Health, United States, 2005: With Chartbook on Trends in the Health of Americans[1]. Hyattsville, 2005; Claire L. Allen, 2008; Shinichiro Uchiyama, Noriaki Nakaya, Kyoichi Mizuno, 2009; Benamer H.TS., Grosset D., 2009) consider the stroke issue a global epidemic, which claims lives and threatens the world. The annual 0.2% (2000 new cases per 1,000,000 of people) increase in stroke incidence, as well as the growing mortality during each following year (4,400,000 deaths), high disability rate, low complete recovery rate, impact nations' socioeconomic indicators[2].

According to statistics, in 2017, cardiovascular disorders were the number one cause of death (59.7%), and the most common causes of these were ischemic heart disease, arterial hypertension and their

complications (myocardial infarction, cerebrovascular accidents, etc.) Men aged 30 to 59 are three times more likely to die of infarction and twice more likely to die of a stroke than women[3]. According to some authors, the incidence of strokes in Uzbekistan ranges between 0.9 and 1.4 cases per 1000 people, while mortality in the acute period can reach 35 to 40% (Asadullaev M.M. et al, 2002; Akhmedov O.T. et al., 2002; Gaphurov B.G., Alikulov A.N., 2000)[4].

According to published data, in Belarus the total number of disabilities resulting from cerebrovascular accidents is 6500, and only 10% to 15% of patients get back to work[5].

It is important to provide proper diagnostic of the state of the motor function with a mandatory quantitative assessment of the severity of dysfunctions and disabilities, which can be completed with the help of validated scales and tests[6].

It is motor functions that disrupt such abilities as movement and self-care and limit patients' movement[7].

Recovery of mobility is a paramount goal of the complex rehabilitation system. In medical rehabilitation, the choice of recovery tactics implies an early start, use of individual approaches and integrated method, which, in turn, can help improve patients' mobility[8]. Normalization of pathologically impaired functions is associated with broad incorporation of robotic mechanotherapy into the recovery process. Regaining joint movement with the use of specially designed devices does provide for optimal physical activity even in the most severe cases, when a patient is unable to move independently[9]. An advanced robotic device uses computer programs that regulate workload on an individual basis[10]. A specific thing about the tactics is proportionate exercise load, abduction, adduction, flexion, extension, and rotation [12].

The goal of the study is to evaluate the efficacy of robotic mechanotherapy in the treatment of mobility dysfunctions as part of a rehabilitation program for apoplectic patients.

Materials and Research Method

The study has involved 35 patients with stroke-related motor dysfunction, who underwent medical rehabilitation in the Republican Clinical Hospital of Medical Rehabilitation (the Republic of Belarus, Minsk District).

A group of 23 subjects (66%) have had ischemic CA, 12 subjects (34%) have had hemorrhagic CA. The patients were hospitalized on the 11th to 15th day from the beginning of the condition. All subjects have undergone a rehabilitation program, which includes medicinal therapy, walking training, coordination and equilibrium exercises, physiotherapy (electric stimulation, magnetic and laser therapy, heat therapy, cryo-therapy, massage), and social rehabilitation.

The treatment group (Group 1) has consisted of 20 subjects, including 9 female subjects (45%) and 11 male subjects (55%). Median age has been 56.6±9.6 (Table 1). Apart from the general exercises, robotic mechanotherapy exercises were added to the treatment group's program.

The control group (Group 2) has consisted of 15 patients (8 men and 7 women) aged 53.8±7.8 with similar demographic characteristics, type of stroke and severity of neurologic impairment, and their rehabilitation program has not included robotic mechanotherapy.

Table 1: Sex and age Distribution

Group	Number of subjects			Median age
	Male	Female	Total	
Treatment	11	9	20	56,6±9,6
Control	8	7	15	53,8±7,8
Total	**19**	**16**	**35**	**55,2±8,7**

The Department of Medical Rehabilitation has developed an individual medical rehabilitation program for both treatment and control group based on clinical symptoms and specifics of the main disorder, age and underlying pathologies.

Robotic monotherapy has been carried out with the use of devices intended for functional upper limb therapy (Armeo Power) and lower limb (Lokomat) therapy, manufactured by Hocoma AG, Switzerland. In the groups, the treatment has lasted for 21 to 28 days. Robotic mechanotherapy has been carried out on a daily basis before the afternoon, sessions have lasted 30 to 40 minutes. The procedure has been applied to the lower and upper limbs at a time with an interval of 15 to 20 minutes.

To recover the function of the affected upper limb, an Armeo Power training device has been used for bilateral forearm pronation/supination and wrist flexion/extension[13]. The training has included exercise

for the upper limbs with affected elbow and shoulder joints, which uses the biofeedback principle with the involvement of the wrist's prehensile function and compensation of the forearm's and shoulder's weight[10]. The training would start with minimal possible workload and amplitude of movements with a gradual increase in the intensity and complexity of exercises[12]. For the lower limbs, the Lokomat system has been used, as it consists of robotic walking orthoses, a body mass support system and a running machine [14]. The training would start from a 100% body-weight unloading with a full and complete control of the walking pattern by the Lokomat device.

The training has implied a gradual lowering of the body-weight unloading along with increasing exercise duration, walking speed, hip elevation, and development of an independent walking function. During a session, a patient is suspended on a belt harness. It is possible to adjust the load on the lower limbs depending on the patient's ability to stand, and enables patients to walk with or without assistance. At the early stage, the robot assists in making passive movements with the lower limbs and, as the patient 's motor function recovers, the amount of active movement increases.

Clinical research method (with the use of a modified Ashworth spasticity scale to determine the intensity of paresis and evaluate muscle strength, the Rivermead Mobility Index to evaluate mobility) have been used to evaluate the subjects' neurological status, and they have served as criteria of efficacy of the rehabilitation procedures. The newly obtained results have undergone statistical processing with the use of the applied Statistica 7.0 package (StatSoft Inc., the USA), and the Student's t-test.

The Ashworth Scale has been used to evaluate muscular resistance while performing passive joint movements. The starting position is lying face up, fully relaxed – for measurement of elbow and knee flexion and extension. Next, five consecutive passive elbow and knee joint movements are made over a length of time needed to pronounce the figure 1969 (nine hundred sixty-nine). The exercise helps evaluate the average muscle tone change index. The movement should be made within the range/until pain.

The muscle tone test parameters are:

0 = No increase in muscle tone;

1 = a slight increase minimal tension at the ends of the flexion/extension range of motion;

2 = a slight increase with minimal muscular resistance (tension) less than halfway into the whole range of motion;

3 = a moderate increase throughout the range of motion with no resistance to passive movements;

4 = a significant increase with high resistance to passive movements;

5 = rigid flexion/extension (flexion/extension contracture).

The Rivermead Mobility Index (RMI) is one of the simplest and easiest-to-perform measures of not only a patient's walking, but general mobility as well. The RMI value is the number of points assigned by a question, based on which a physician can answer positively. The RMI value can range from 0 (unable to make any voluntary movements without assistance) to 15 (capable of running a distance of 10 m). The test is usually done for 10 minutes.

To evaluate mobility, different parameters have been used, such as rolling over in bed, moving from lying to sitting, maintaining balance in the sitting position, moving from sitting to standing, standing without support, moving and walking around a room with (if necessary) or without support tools, walking upstairs, walking outside one's living space (on even surfaces), walking around a room without using support tools, picking up objects (see Table 2).

Table 2: RMI criteria

№	Activity	Question
0	Immobile	What kind of movements does a patient make during a day?
1	Rolling over in bed	Can you roll from back to side without help?
2	Moving from lying to sitting	Can you move from lying to sitting on the edge of your bed?
3	Maintaining balance in the sitting position	Can you sit on the edge of your bed without support for 10 seconds?

№	Activity	Question
4	Moving from sitting to standing	Can you get up (from various types of chairs) over less than 15 seconds and stand for 15 seconds (holding on to something with your hands or, if necessary, using a support tool)?
5	Standing without support	Monitoring a patient standing for 10 seconds without support.
6	Moving	Can you get up from your bed and sit down on a chair without assistance?
7	Walking around a room with support (if necessary)	Can you walk 10 m using support tools, but without using someone else's help?
8	Walking upstairs	Can you climb up a stair flight without help?
9	Walking outside one's living space (on even surfaces)	Can you walk outside your home on a sidewalk without help?
10	Walking around a room without using support tools	Can you walk 10 m around your apartment without using a crutch, orthosis or someone else's help?
11	Picking up objects	If you have spilled an object, can you walk 5 m, pick it up and get back?
12	Walking outside one's living space (on uneven surfaces)	Can you walk outside your house without someone else's help on uneven surfaces (grass, gravel, snowdrifts, etc.)?
13	Taking a bath	Can you get into and out of your bathroom (shower room) without supervision and take a bath/shower alone?
14	Walking four steps up and down	Can you walk four steps up and down without holding onto the railing, but using support tools?
15	Running	Can you run 10 m without limping over 4 seconds (brisk walking is allowed)?

Results and Discussion

Before the rehabilitation procedures started, the majority of subjects had moderate and severe mobility deficits. For instance, according to the Modified Ashworth Spasticity scale, in the treatment group (n=20), 31.8% of subjects had moderate or severe hand paresis; 27.3% of the subjects had very severe hand paresis, 9.1% had mild hand paresis. More than half of the group (59.1%) had severe leg paresis, 31.8% had moderate leg paresis, 9.1% were dealing with mild cases. In the control group (n=15), 28.7% of the subjects had moderate hand paresis, 33.4% - severe had paresis, 29.4% - very severe hand paresis; 98.5% of the subjects had mild hand paresis, more than half of the group (62.3%) had severe leg paresis, 29.6% - moderate leg paresis, and 8.1% of the subjects had mild leg paresis (Table 3).

Thanks to the rehabilitation procedures, which have involved robotic mechanotherapy, 68.2% of subjects have gained hand strength ($p<00.5$), 45.5% of the treatment group subjects have gained leg strength; likewise, the control group subjects have shown a 52.7% increase in the hand strength, and 38.6% - in the leg strength (see Table 4).

Table 3: Clinical characteristics of subjects with mobility deficits

Affected area	Type of paresis	Treatment group	Control group
		Incidence (%)	
Hand paresis	Very severe	27.3	29.4
	Severe	31.8	33.4
	Moderate	31.8	28.7
	Mild	9.1	8.5
Leg paresis	Severe	59.1	62.3
	Moderate	31.8	29.6
	Mild	9.1	8.1

Table 4: Follow-up muscular strength and spasticity dynamics according to the Ashworth scale in the treatment and control groups.

Affected area	Treatment group		Control group	
	Points			
	Before treatment	After treatment	Before treatment	After treatment
Hand paresis	3.65±1.01	2.95±1.16*	3.93±0.92	3.4±1.08
Leg paresis	3.4±0.73	2.95±1.07*	3.46±0.72	3.07±0.93

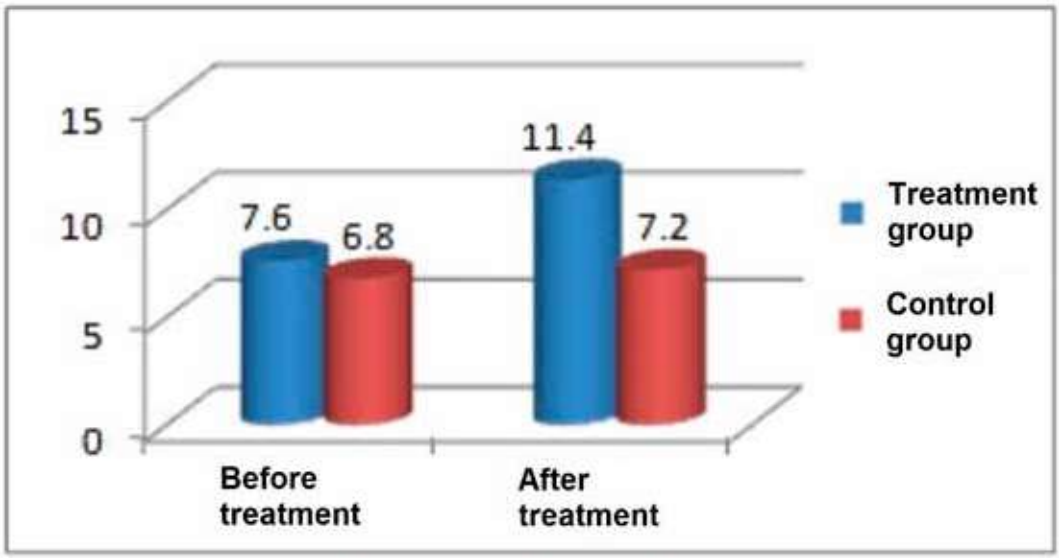

Figure 1: Post-rehabilitation mobility dynamics

The average admission RMI value was 7.6±3.5 in Group 1 and 6.8±3.7 in Group 2 out of 15.

After the rehabilitation procedures, all subjects showed a better mobility, and the improvement was more pronounced in the treatment group: the Rivermead Mobility Index averaged 11.4±2.1 in the treatment group and 7.2±3.2 in the control group out of 15 ($p<0.001$) (Fig.1.). This has been achieved through patients' adaptation to a mobility impairment and development of compensatory and substitutive functions.

The locomotion training with partial body weight unloading with the use of a suspension harness enables free hand movement and more natural walking movement pattern. These devices feature motors, which provide for continuous symmetrical and timeless training sessions.

The dynamics shows a significant spasticity decrease in the treatment group, where subjects have undergone robotic mechanotherapy. A continuous sensor feedback from extensor load receptors, which is observed during this type of walking and hand movement, help to stimulate neuronal networks, which activate muscle locomotion activity patterns and provide for neural plasticity.

The integrated therapy with the use of robots has helped speed up the patients' walking, improved biochemical walking characteristics, reduced muscle tone in the upper and lower limbs in the group of subjects under control dealing with post-stroke hemiparesis during rehabilitation.

Conclusion

The research has made it possible to conclude that the program, which has included robotic mechanotherapy, has been more effective, as it is seen from the higher Ashworth muscle strength indexes in affected limbs, increased Modified Rivermead Mobility Indexes, as well as more a pronounced improvement of impaired functions. Subjects, who have not gone for additional training, have shown minimal improvement according to these characteristics.

Development and Standardization of Dental Plant-Based Preparation in the Republic of Uzbekistan

Aziza A. Djuraeva[1], Viloyat N. Abdullabekova[2]

[1]Senior Lecturer of the Department of Pharmaceutical Chemistry, Tashkent Pharmaceutical Institute, 45, Aibek St., Tashkent, Uzbekistan, 100015, [2]Doctor of Pharmaceutical Sciences, Professor, Tashkent Pharmaceutical Institute, 45, Aibek St., Tashkent, Uzbekistan, 100015

Abstract

Nowadays herbal medicines are widely used in official medical practice in Uzbekistan. At the same time, the most common among both imported and domestic plant-based preparations are liquid dosage forms. The modern stage of application of these medicines is based on the rational use not only of the accumulated experience, but also on the achievements of scientific medicine in the study of the composition and features of biological activity of medicinal plants and isolated from them active compounds. Studies have shown that these drugs contain unique in composition combinations of biologically active substances, providing a wide range of therapeutic and preventive action. To solve the problem developed the composition and obtained on its basis a liquid extract for the treatment of diseases of the oral cavity of the mixture of plants such as chamomile drug, sage drug, St. John's wort, calendula drug in the ratio of raw materials - extraction fluid 1:1, established the most optimal extraction fluid - 70% ethyl alcohol and obtained alcohol extraction.

The resulting liquid extract was conditionally called "Parodonfit" and analyzed according to the requirements of regulatory documentation. Each of the plants has its own quality standard. Qualitative and quantitative analyses of biologically active substances of liquid extract "Parodonfit" with the use of physical and chemical method, such as thin layer chromatography, chromatography spectrophotometry, gas-liquid chromatography was carried out. Biologically active substances in the liquid extract - flavonoids and tannins - were determined during the research. The sum of flavonoids was determined by TLC, where compounds of routine, quercetin, cinarozid were isolated. Qualitative analysis of tannins and determination of heavy metals were conducted by pharmacopoeia method. Quantitative determination of active substances of cinarozid by chromatospectrophotometry was carried out. The tannins in recalculation for tannin - 3,2 % and in recalculation for proanthocyanides - 6,38 % were found out by chemical reactions according to the GD (governing documents). Quality indicators for liquid extract "Parodonfit" have been developed according to the requirements of the normative document: physical and chemical indicators, ethyl alcohol concentration, heavy metals, microbiological purity. The received results have shown perspective and expediency of development of highly effective multicomponent medical products on the basis of medicinal vegetative raw materials.

Keywords: *Plant-based preparation, dentistry, thin layer chromatography, chromatospectrophotometry, wild chamomile, St. John's Wort, calendula and garden sage.*

Introduction

Periodontal disease is one of the most difficult problems of modern dentistry. According to WHO, its level varies from 55% to 98%. In 15-19 years, it's about 55-89 %, in 35-44 years - 65-98 % [1,2]. Wide prevalence and significant «rejuvenation» of this pathology, adverse effect of periodontal infection foci on the body, as well as high level of complications up to complete loss of teeth - all this determines both medical and social significance of this problem. In addition to performing therapeutic and prophylactic dental manipulations, the protocols for the treatment of dental diseases include the prescription of various pharmaceutical preparations, such as antibacterial preparations, non-steroidal anti-

inflammatory preparations, calcium preparations, and preparations for the local therapy of periodontal diseases. Taking into consideration the continuous development of the pharmaceutical industry, the introduction of new drugs, the identification of new aspects of contraindications, side effects of certain drugs, all this requires a dentist to constantly update his knowledge in the field of pharmacotherapy [3].

In connection with this, recently in medicine herbal medicines (plant-based preparation - PBP) have been used more often for treatment of this disease[4], which is primarily due to good tolerability and absence of side effects in the vast majority of cases, as well as the presence of various biologically active substances and trace elements in their composition[5].

Many medications are used to treat diseases of the oral mucous membrane. Their choice depends on the nature of the course of inflammatory process (acute, exacerbation, chronic), the presence of pain, the type of elements of lesion, including soft tissue defect, oral hygiene. In diseases of the mucous membrane of the mouth used various dosage forms: decoction, infusion, infusion, ointment, plant-based paste, plant-based cocktail and their combinations.[6]

The results of the study showed that the range of Drug Products for the prevention and treatment of diseases of the oral cavity there are several types of DF (Dosage Forms) (solid, liquid, soft and gaseous), but the majority of drug products are produced in the form of solid DF. A relatively even distribution of liquid medications by quantity in Uzbekistan and abroad has been revealed. Soft dosage forms are mainly represented among drug products produced abroad.

At the analysis of Dosage Forms in solid aggregate state it has been revealed that among foreign there are three drug products produced in the form of tablets for resorption, while domestic medicinal products are represented by medicinal herbal substances (MHS) and produced in packets and filter - packets.

The analysis of the assortment revealed the presence of only two foreign drug products in the form of sprays.

At the next stage the analysis was carried out with a breakdown of the total assortment of dosage forms of sprays, the results are shown in Fig. 1.

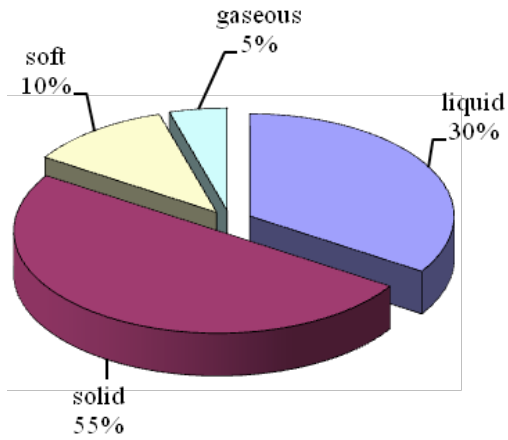

Figure 1: Specific weight of Dosage Forms in the range of drug products registered in the Republic of Uzbekistan, used for the treatment of stomatosis

Carried out marketing analysis of herbal drug products used for prevention and treatment of stomatosis in the pharmaceutical market [7]of the Republic of Uzbekistan, showed the prospects and feasibility of developing highly effective drugs based on local medicinal herbal substances (MHS).[8]

Standardization of multi-component preparations of plant origin is one of the most urgent tasks in modern pharmacy[9]. Determining the authenticity and analysis of the quality of these drugs is a complex procedure that must meet all modern requirements for the standardization[10] of multicomponent drugs. In addition, the growing demand for multicomponent preparations of plant origin used for prevention and treatment of stomatosis makes them potential targets for falsification [12].

Research Objective: Nowadays, studies on the conversion of multi-component mixtures of medicinal plants, which are used in the form of infusions and broths, in the total drugs - extracts are relevant. In obtaining the extracts provides maximum yield of biologically active substances, which increases the pharmacotherapeutic effect. The advantages of liquid extracts and dosage forms on its basis include convenience for use and resistance to storage. In addition, the standardization of active substances allows for control at the stage of production and the accuracy of dosing the finished product, so standardization of liquid extracts and dosage form is no less important.

In order to create medicinal products based on plant raw materials with standard active ingredients and

predictable therapeutic effects, it is necessary to study the relationship between the chemical composition and biological activity. A wide range of biological activity - anti-inflammatory, astringent - has flavonoids and tannins of medicinal plants. The qualitative and quantitative composition of flavonoids and tannins depends on many factors, such as differences in chemotypes and growth conditions of medicinal plants, production and storage technology, etc. In this regard, the need to develop rapid and effective method to determine the qualitative and quantitative composition of flavonoids and tannins, both in plant raw materials, and in phytotherapy based on it is an urgent task.

The article is based on the task of creating a composition for oral cavity treatment by means of such a selection of components that would provide a complex effect of the composition on the affected tissues of the oral cavity, resulting in a high therapeutic effect with simultaneous reduction of negative side effects.

Moreover, the composition of the components is selected in such a way that it represents different groups of biologically active compounds, which, on the one hand, provide a wide range of biological activity (antimicrobial, anti-inflammatory, astringent). Development of new approaches for the standardization of herbal medicines using thin layer chromatography, GLC chromatograph and chromatography spectrophotometry method.

Materials and Method

It is offered a dental product, which includes – wild camomile flowers of the pharmacy, sage leaves, calendula flowers, herb St. John's wort pierced in a ratio of 1:1:1:1.

To develop the technology of obtaining a phytopreparation, initially conducted pharmacognostic studies of raw materials. Wild camomile flowers of the pharmacy, sage leaves, calendula flowers of the medicinal product and the herb of St. John's wort pierced for research were prepared in autumn within the natural range.

We selected the optimal extraction fluid in the following way. We studied 4 extraction fluids: ethyl alcohol with concentrations of 40, 50, 60 and 70%.

Alcohol extraction from plants - liquid extract "Parodonfit" was obtained by repercalation in a battery consisting of three percolators. Repercolation, i.e. repeated (multiple) percolation, allowing the maximum use of the solvent capacity of the extraction fluid, to obtain concentrated extractions with complete exhaustion of the raw materials. The amount of raw material to be loaded into each of the three percolators is calculated. The same amount of raw material is loaded into each percolator. The method of Repercolation is considered to be economically justified for long-term production.

Medicinal plant raw materials are shredded to particles not exceeding 3 mm in size. The shredded raw materials are separated from the dust through a sieve with a hole diameter of 0.25 mm and 30 g are removed. Place the raw material in 3 percolators of 10 g. The first percolator is filled with extraction fluid (70% ethyl alcohol) with an open crane percolator to form a "mirror". The faucet is closed after the extractant displaces the air and left for 2 hours. The displaced liquid is poured into a second percolator. The first percolator is filled with a clean extraction fluid until a "mirror" is formed. After air displacement the first and second percolators are left for 2 hours. From the second percolator poured the amount of extraction in the third percolator, the extraction of the first percolator poured into the second percolator, the first percolator filled with pure extractant until the formation of the "mirror". Three percolators are left for 3 days. From the third percolator is pushed out extraction with a volume of 10 ml. From the second percolator extraction is poured into the third percolator, from the first to the second percolator. The second and third percolators are left for 2 hours. Extraction with the volume of 10 ml is displaced from the third percolator. Pour the extraction from the second percolator into the third percolator and leave for 2 hours. From the third percolator the last extraction of 10 ml is obtained. All portions of the finished product obtained from each percolator are combined, stored and filtered.

The resulting complex product refers to liquid alcohol-containing plant-based preparation. The current regulatory documentation contains general articles on such pharmaceutical forms as "Tincture" and "Extracts", for which the following indicators are mandatory[13]:

- Description
- Authenticity
- Heavy metals
- Alcohol concentration
- Quantitative determination

- Microbiological purity.

Authentication was determined by the following method of analysis: *for qualitative analysis of tannins* we add 1 g of sodium acetate crystals and 10 drops of 1% iron ammonium alum solution to 5 ml of filtrate.

Thequalitative composition of the extract for flavonoids was studied by the TLC test method on "Merck" plates with silica gel COF_{254} for aluminum with the size of 15x10 cm in the system of solvents n-buthanol: acetic acid: water (in a hundred 4:1:2). To detect phenolic compounds of the resulting extract chromatographed ascending method. To identify adsorption zones, 0.05 ml of water-alcohol extract and 0.05 ml of state standard reference sample alcohol solutions of rutin, quercetin and cinaroside were applied to the starting line. Detection of adsorption zones was performed in UV-light at 254 nm length. Three adsorption zones were detected: quercetin (Rf = 0.85); rutin (Rf = 0.55); and cinaroside (Rf = 0.75).

Determining heavy metals to 1 ml of liquid extract add 1 ml of concentrated sulfuric acid, gently burn and calcinate. The resulting residue is processed by heating 5 ml of saturated ammonium acetate solution. Filter through an ashfree filter, wash 5 ml of water and bring the filtrate volume to 200 ml. 10 ml of the obtained solution should pass the test for heavy metals (no more than 0.01% in the preparation). To 10 ml of the resulting solution add 1 ml of diluted acetic acid, 2 drops of sodium sulfide solution and after 1-minute compare with 1 ml of reference solution B, and the same amount of reagents as added to the test solution.

The ethyl alcohol concentration was determined by the developed method with the use of Agilent Technologies "GC 6850 Network GC System" gas chromatograph. Ethyl alcohol concentration in the obtained extract was determined by the developed method using the method of GLC on Agilent Technologies "GC 6850 Network GC System" gas chromatograph.

Chromatography was performed under the following conditions: DB-624 Capillary 30.0m x 250µm x 1.40µm; furnace temperature from 40˚C - 120˚C, duration of analysis-8.0 min, injection 1µl, split 50: 1, injector temperature 120°C; detector temperature 260°C; mobile phase 0.8 ml/min helium (He); flame-ionization detector (FID); air and hydrogen speeds 450 ml/min and 40.0 ml/min.

Preparation of the test solution: Place 10 ml of the test extract with a pipette in a measuring flask with a capacity of 100 ml and bring the volume to the mark with distilled water and stir. The solution is filtered through a 0.45 µm membrane filter.

Preparation of 70.0% RDF ethanol work standard sample solution. To do this, take 66.5 g (precision hanging) of 99% ethyl alcohol and placed in a measuring flask with a capacity of 100 ml, bring the volume to the mark with distilled water and stir. (Solution 1).

10 ml Solution 1 is placed in a measuring flask with a capacity of 100 ml, bring the volume to the mark with distilled water and stir.

Identification of ethyl alcohol on chromatograms of the tested sample is carried out by comparison of retention times of the standard sample. Chromatographs of 1.0 µl of the test solution and ethanol PSO solution shall be alternately taken, obtaining at least 3 chromatograms for each solution.

The reliability of the results of the analysis was checked by determining the suitability of the chromatographic system by: -resolution (R) of ethyl alcohol peaks (not less than 2.0); -association coefficient (T) of ethyl alcohol peaks (not exceeding 2.0); -relative standard deviation (RSD) (not exceeding 2.0%).

The main groups of active substances of the medicinal product "Periodonfit" were quantified. The quantitative content of the sum of flavonoids in terms of cinaroside was determined by chromatospectrophotometry. For this purpose, chromatographic plate "Merck" UF 254 (10 x 15) was divided into 3 strips. On the starting line was applied as a 3 cm strip of 0.05 ml of the extract, on the second strip 0.05 ml of work standardcinaroside solution, the third strip was left free - control. The plate with the applied samples is air-dried for 1 hour and chromatographed upward in a chamber with a pre-saturated mixture of solvents chloroform-methanol-acetic acid (4:2:2) for 30 minutes. When the solvent front passes 7 cm, the plate is removed from the chamber, dried in the air, marked in the UV light (254 nm) zones containing cinaroside at the level of the witness spot. The zone of sorbent containing cinaroside and the zone of control experience, transferred into flasks with lapped corks with a capacity of 50 ml, eat 10 ml of 80% ethyl alcohol and heated in a water bath (60°C) for 30 minutes. With constant stirring the eluate is filtered through the filter. paper and determine the optical density on the SF at a wavelength of 352 nm in the cuvette with a layer thickness of 10 mm.

Preparation of work standart Cinarozid: 0.2 g (so-called) dissolve 80% alcohol in a measuring flask with a capacity of 100 ml (when heated).

Determination of the quantitative content of tannins in the drug: take a pipette 25 ml of the resulting extraction in a conical flask with a capacity of 750 ml, add 500 ml of water, 25 ml of solution of indigosulphonic acid and titrate when continuously stirred with a solution of potassium permanganate (0.02 mol/l) to golden yellow color.

In parallel, a control experiment is conducted.

1 ml of potassium permanganate solution (0.02 mol/l) corresponds to 0.004157 g of tannins in terms of tannins.

Microbiological purity. For the manufacture of high quality and effective plant-based preparation (EPBP) is a prerequisite for quality control (QC) procedure at various stages of the technological process. A special place is occupied by the control of microbiological purity (MBC) of the resulting EPBP.

In accordance with the requirements of the regulatory document definition was carried out in Petri dishes with sterile nutrients: meat - peptone agar - for the quantitative determination of growing colonies, blood agar - to determine hemolytic bacterial strains, yolk and salt agar - to detect pathogenic staphylococcus, Endo - to detect intestinal bacterial groups, Saburo - to excrete fungi. In nutrient media were brought the test drug in different concentrations (1: 2: 4), at least three cups of Petri. All cups with crops were incubated in a thermostat at 37°C. Initial recording of the results was made in 24 hours and 48 hours, the final one - in 5 days. After incubation, the growing colonies were counted and identified.

Results and Discussion

The quality and efficiency of therapeutic action of plant-based preparation directly depends on the method of isolation and receipt of biologically active substances from medicinal plants in the form of extracts. For example, it is known that such traditional method of extraction as decoction, infusion and tincture can allocate about 15-25% of biologically active substances in the medicinal plant. In this case, labile (unstable) biologically active substances are destroyed and the extract significantly loses its medicinal properties. At the same time with these method of allocation of biologically active substances in extracts together with them gets a large enough amount of ballast substances (resinous substances, hydrocarbons, fiber, hairs of plants). These substances, on the one hand, may have a negative effect on the body itself. And it should also be noted that the more used plants in the collection of the extraction, the more pronounced these negative effects, the harder to obtain a quality extract.

Camomile flowers, sage leaves, calendula flowers and St. John's wort herb are pharmacopoeia plants and are of great interest in dentistry as a source of BAS (biologically active substance). Preparations based on these plants are widely used in medicine.

The technical result obtained in the implementation of the invention is expressed in the increase of therapeutic effect with the simultaneous elimination of negative side effects, which ultimately leads to a reduction in the recovery time of patients. Moreover, the composition of the components was chosen in such a way that it represented different groups of biologically active compounds, which, on the one hand, provide a wide range of biological activity (antimicrobial, anti-inflammatory, regenerating, astringent, styptic, capillary strengthening, adaptogenic, immunocorrective action). In this regard, 4 extractants were studied - ethanol with concentrations of 40, 50, 60 and 70% for the liquid extract which includes - chamomile flowers, sage leaves, calendula flowers, St. John's wort herb pierced in the ratio 1:1:1.

The sum of flavonoids was quantified by spectrophotometry. Extraction properties of each object were studied three times; the results were statistically processed and are presented in Table 1.

Table 1. Quantitative determination of the sum of flavonoids in each extract by spectrophotometry.

Extraction fluid	Flavonoid content of extraction, in %
Ethyl alcohol 40%	0.37±0.05
Ethyl alcohol 50%	0.93±0.05
Ethyl alcohol 60%	1.22±0.05
Ethyl alcohol 70%	1.55±0.05

So, as a result of the conducted studies, the most optimal extraction fluid was found - 70% ethyl alcohol and alcohol extraction from a mixture of plants such as chamomile medicinal, sage medicinal, St. John's

wort pierced, calendula medicinal in the ratio of raw materials - extraction fluid 1:1.

The usage of the method of recolonisation instead of maceration allows for more complete extraction of the whole complex of BAS due to a higher concentration gradient, which is created by passing a pure extraction fluid through the raw material. This composition is a biologically active complex compound obtained by mixing components with known therapeutic properties, taken in the ratio providing a given therapeutic effect without negative side effects.

Further research was conducted on qualitative and quantitative indicators of liquid extract in accordance with the requirements of the regulatory document.

The resulting liquid extract is a transparent liquid of brown color, with a pleasant aromatic smell of medicinal herbs and a bitter spicy taste.

At the qualitative analysis of tannins in the liquid extract on the surface of the crystals in the neutral zone of the filtrate black-green coloring appears, which meets the requirements of the ND.

The qualitative composition of the extract for flavonoids was studied by the TLC (thin layer chromatography) method in the system of solvents n-buthanol: acetic acid: water (in a hundred 4:1:2). As a result of the conducted studies 3 adsorption zones were found: quercetin (Rf = 0.85); rutin (Rf = 0.55); cinaroside (Rf = 0.75). The results of TLC analysis of the flavonoid sum are shown in Fig. 2.

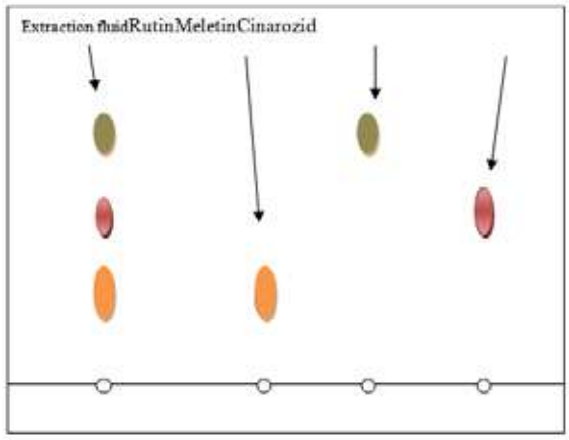

Fig. 2. Chromatogram of liquid extract and alcohol solutions of rutin, meletin and cinarozid as witnesses

When determining the qualitative indices, it was found out that there are no heavy metals in the extract (the color of the test solution is less than that of solution B). Low opalescence is observed.

Ethyl alcohol concentration was determined by the developed method with the use of GC (gas chromatography) method. Identification of ethyl alcohol on chromatograms of the investigated samples was carried out by comparison of retention times of a standard sample. The results are presented in Fig.3-4.

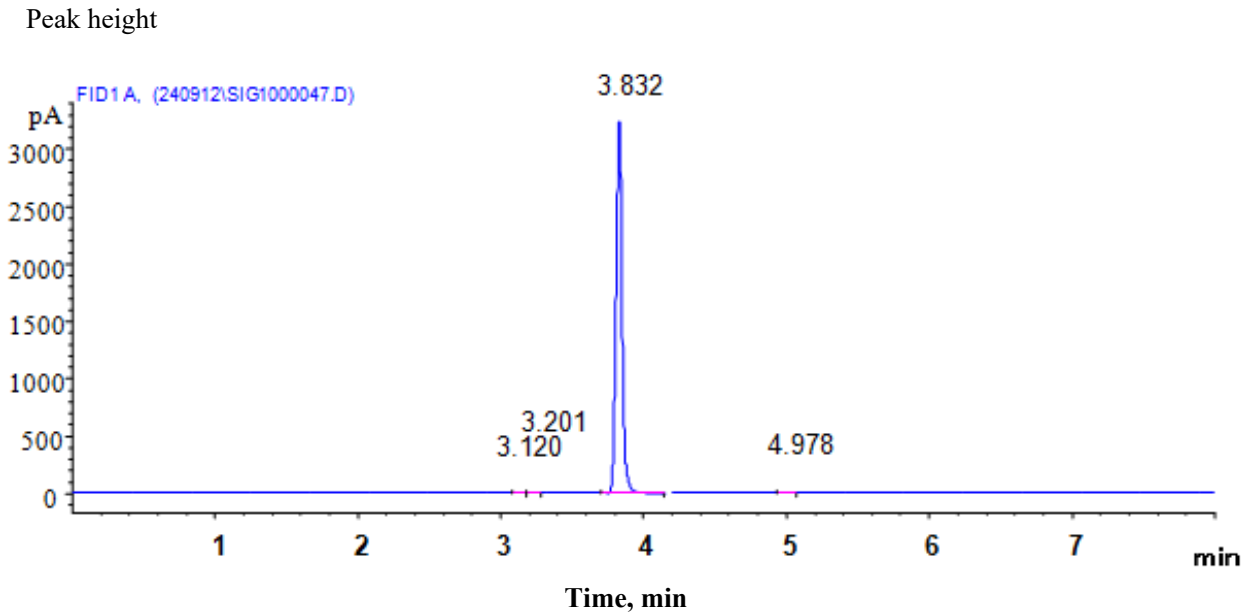

Fig. 3. Chromatogram of standard sample of ethyl alcohol

Peak height

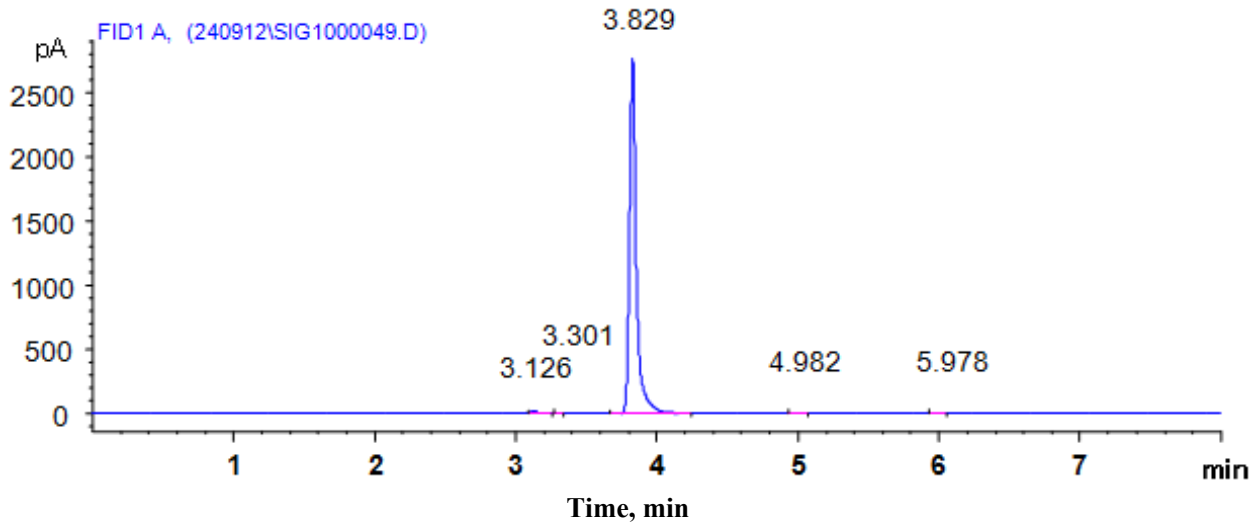

Fig. 4. Chromatogram of "Parodonfit" extract

On the chromatogram the peak with retention time of 3,829 min corresponds to work standard of ethyl alcohol with retention time of 3,832. The concentration of ethyl alcohol in "Parodonfit" extract was calculated by formula

$$X = \frac{H_1 \bullet m_0 \bullet 0 \bullet 100 \bullet P}{H_0 \bullet 100 \bullet 100 \bullet V}$$

H_1-peak height of ethyl alcohol from chromatograms of tested solution; H_0-peak height of ethyl alcohol from chromatograms of ethanol work standard solution; m0 - mass of 96% of ethyl alcohol in grams; V - volume of tested solution used for analyses, in milliliters; P - volume of 70% of ethyl alcohol, for preparation of ethanol work standard solution, in percent.

As a result of the tests carried out it was found out that the quantitative concentration of ethyl alcohol in "Parodonfit" extract was not less than 62.0%.

The quantitative determination of the main groups of active substances in the Parodonfit drug was performed. The quantitative content of the sum of flavonoids in terms of cinarozid was determined by chromatography spectrophotometry to determine the optical density in NF at 352 nm wavelength. The cinarozid concentration of the extract was 0.12%.

Determination of the quantitative content of tannins in the drug was conducted by chemical reactions given in the regulatory document. The concentration of tannins (X) in percent converted to absolute dry raw materials is calculated by the formula:

$$x = \frac{(V - V1) * 0{,}004157 * 250 * 100 * 100}{m * 25 * (100 - W)}$$

Where V - the volume of potassium permanganate solution (0.02 mol/l) spent on titration extraction, in ml;

V1- Volume of potassium permanganate solution (0.02 mol/l) used for titration in control trial, in ml;

0.004157 - amount of tannins corresponding to 1 ml of potassium permanganate solution (0.02 mol/l) (in terms of tannin), in grams;

m - Mass of raw materials in grams;

W - Loss in mass when drying the raw material in percent;

250 - Total extraction volume in ml;

25 - Extraction volume taken for titration, in ml.

The amount of tannins was 3.2 % in terms of tannins and 6.38 % in terms of proanthocyanides.

The research of microbiological purity was conducted in accordance with the requirements of the regulatory document «Method of microbiological control of drugs». A methodology for determining microbial quality was developed.

The results obtained are presented in Table 2.

Table 2: Microbiological control results

Target drug	Selected microorganisms				
	Aerobic Gram-positive bacilli	Staphylococcus	Micrococcus	Escherichia bacteria	Mushrooms
Liquid extract	0	0	0	0	0

Under studying "Microbiological purity" of liquid extract "Periodonfit" the obtained liquid drug corresponds to this index, according to which such drugs should contain no more than $5x10^3$ aerobic bacteria, 10^2 yeast mold fungi in the absence of *Pseudomonas aureginosa, Staphylococcus aureus, Escherichia coli, Salmonella* and no more than 102 other intestinal bacteria. The assessment of quantitative and qualitative composition of the contamination flora did not reveal any deviations from the requirements of SP (State Pharmacopoeia) XI. Quality indicators have been established and will be included in the draft regulatory documents.

Conclusions

1. Based on the data on application of medicinal plants in folk, traditional and scientific medicine, the review of the literature on chemical structure, taking into account a raw-material base it is proved and the optimum composition from four kinds of medicinal vegetative raw materials which is a basis for reception of anti-inflammatory stomatological means is developed.
2. The resource-saving technology was developed by the method of recolation, which consists in the extraction of phytocomposition with alcohol - 70%.
3. Method of standardization of phytocomposition - liquid extract - with the use of chromatographic and spectrophotometric method - TLC and chemical reactions have been developed, the presence of: flavonoids, tannins in liquid extract "Parodonfit" has been established. The phenolic composition of the liquid extract was studied and the following were identified: rutin, quercetin, cinaroside.
4. Tanning materials were studied by quantitative method of analysis calculated on tannin and proanthocyanides.
5. Quality indexes for liquid extract "Parodonfit" according to requirements of normative document are developed: qualitative and physical indexes, ethyl alcohol concentration, heavy metals, microbiological purity.
6. The results obtained can be further used to obtain, standardize and develop a regulatory document for a new combined herbal remedy "Periodonfit" used in dental practice.

Ethical Clearance: No ethical approval is needed.

A Complex of Risk Factors for Developing Dependence on the Combined Abuse of Hashish and Tramadol

Inara Khayredinova[1], Zarifjon Ashurov[2], Indira Giyazitdinova[3], Mark Agranovsky[4]

[1,3]MD, PhD, Department of Psychiatry and Narcology, Tashkent Medical Academy, Farobiy 2, Tashkent, Uzbekistan, 100109, [2]MD, PhD, Associate professor, Head of the Department of Psychiatry and Narcology, Tashkent Medical Academy, Farobiy 2, Tashkent, Uzbekistan, 100109, [4]MD, Professor, Department of Psychiatry and Narcology, Andijan State Medical Institute, Andijan, Uzbekistan

Abstract

Introduction: The study of a set of risk factors for a social-premorbid narcological personality dependent on the combined abuse of hash and tramadol.

Materials and Method: 129 male patients were examined, which were divided into three groups. Group I (main) -41% of patients (n = 53) with a combined abuse of hashish and tramadol, Group II (1 control) -34% of patients (n = 44) with addiction from opiates abusing tramadol without a doctor's prescription, group III (2 control) - 24.8% of patients (n = 32) with a cannabis addiction F12.2. The influence of biological, socio-psychological and personality risk factors on the development of the formation of premorbid-social narcological personality was analyzed. To identify the strength of the relationship between exposure to the factor and the disease, the relative risk (RR) was calculated.

Results: An analysis showed a combination of factors of involvement in psychoactive substances: the presence of a family history of hereditary alcoholism and drug addiction in relatives of -62.3% ($P < 0.001$ and $P < 0.001$), transferred craniocerebral loss of consciousness injuries-39.6% ($P < 0.05$), inferior family-73.6% ($P < 0.01$; $P < 0.01$), single child-50.9% ($P < 0, 05$; $P < 0.05$) or senior - 41.5% ($P < 0.05$), unstable personality type - 50.9% ($p < 0.05$, $p < 0.001$).

Conclusion: The analysis of premorbid-social indicators revealed a relative risk of the formation of a narcological personality and thereby determined a new set of factors for which an algorithm of primary prevention measures was developed.

Keywords: *Concomitant abuse, cannabis, tramadol, risk factors.*

Introduction

According to the latest World Drug Report, in 2017 year approximately 271 million people, or 5.5% of the world's 15–64-year-old population, used drugs, and 35 million people suffer from drug-related disorders. Cannabis continues to be the most widely used drug in the world. A drug use survey showed that 4.7% of the population aged 15–64 years old used prescription opioids for non-medical purposes, with tramadol undoubtedly the most common in terms of opioid abuse. The proportion of patients with codependence is growing.[1] Mental and behavioral disorders caused by the simultaneous use of several psychoactive substances become an extremely relevant and rapidly growing problem in adolescence. Adolescents who use psychoactive substances are a high-risk group for the simultaneous administration of several psychoactive substances, in which use becomes abuse and often addiction. [2]

According to the narcological service of the Ministry of Health of the Republic of Uzbekistan over the past 10 years in the republic there has been a positive trend in the development of the narcological situation by its main indicators. However, the use of pharmaceutical opioids has increased. The Government Decree broadened the lists of prohibited and restricted in circulation narcotic drugs, psychotropic substances and their precursors

(substances used for the manufacture of drugs). In particular, Tramadol was included in list No. 2. [3] Today in Uzbekistan there is a tendency to a combination of abuse of cannabis and tramadol, tramadol and lyrics, tramadol and sedatives. Polydrug abuse is a debatable issue in narcology. Various types of interaction of psychoactive substances with their joint use are described. In foreign and domestic scientific reports, dissertations, the problem of epidemiology, the clinical features of intoxication and withdrawal syndrome, the medical and social consequences of the combined use of psychoactive substances, the aspects related to the study of risk factors, the features of the formation and patterns of development of multidrug are not covered enough.

The risk of formation of addictive behavior is the result of multifactorial interaction, where each of the factors or combination forms a dependence. [4,5] Prerogative risk factors include perinatal pathology, hereditary burden of substance abuse and mental illness, history of craniocerebral trauma, premorbid personality deviations, incomplete family composition, types of education, asocial microenvironment, early onset of use of psychoactive substances.[6,7,8] Separately distinguished as an effective factor is the composition and quality of the social environment.[9] Personality traits are an intermediate phenotype that mediates the development of various psychopathologies, including the development of dependence on psychoactive substances. Psychological trauma, stress at an early age increases the risk of developing a dependence on psychoactive substances.[10,11] Some authors say that for each type of psychoactive substance there are dominant risk factors for the development of addiction.[12] Although most studies have shown a high degree of association between cannabis use and the use of other illicit drugs, the predictors of the transition from cannabis to other illegal drugs remain largely unknown.[13] In the framework of the biopsychosocial model, the formation of a disease requires a combination of three groups of individual factors (domains): biological, personal and social. All domains are important for the onset, development and maintenance of the disease, are closely interrelated and cannot be considered separately.[14]

The study of risk factors for the development of addiction allows for primary prevention, already at the primary link. Knowledge of biopsychosocial factors allows you to choose the right prevention strategy for both primary and secondary.[15]

The aim of our study was to study a set of risk factors for a socially premorbid narcological personality, which is dependent on the combined abuse of hash and tramadol.

Materials and Method

A clinical study was conducted among 129 patients who were treated for drug addiction in the City Narcological Dispensary and the Republican Narcological Center from 2016 to 2018. All male patients, aged 21 to 45 years. The examination was carried out using clinical, psychopathological and anamnestic method with filling in a specially developed patient map, indicating the clinical and dynamic characteristics of the disease, biological, social and individual psychological risk factors. All patients were divided into 3 groups. Group I (the main group) included 41% of patients (n = 53) with a diagnosis of F19.2 - combined abuse of hash and tramadol, group II (control group) -34% of patients (n = 44) with a diagnosis of F11.2, patients with opiate dependence, abusing tramadol without a doctor's prescription in order to achieve euphoria, who did not consume other opiates before taking tramadol. Patients with addiction to opiates who abused tramadol for economic reasons (high cost of psychoactive substances) or other reasons (difficulty in access to psychoactive substances, conflict with the law, and fear of being detained) were excluded. Group III (control) included 24.8% of patients (n = 32) with a diagnosis of hash addiction F12.2. In all three groups, the second stage of the disease was diagnosed. The duration of the disease in the examined ranged from two to five years. Criteria for exclusion from the study were comorbid mental pathology, dependence on other types of psychoactive substances.

The results obtained in the study were evaluated using the statistical program R-studio. In order to establish the statistical significance of differences between groups of qualitative characteristics, we used the contingency table using the Pearson $\chi 2$ criterion. To identify the strength of the relationship between exposure to the factor and the disease, the relative risk (RR) was calculated. If RR = 1, then there is no connection between the factor and the disease. For RR> 1, it shows a direct connection, and for RR <1, reverse connection. Differences were considered statistically significant at $P < 0.05$.

Results

The average age in the three studied groups at the time of admission to the medical institution corresponded to the first period of adulthood - 21-35 years. Patients with a combined dependence on hashish and tramadol occupied a median position of 31.2±1.89 years. A younger age is the prerogative of tramadol dependence - 28.1±1.61 years. Hashish addiction amounted to - 32.0±2.59 years.

When studying the narcological history of patients, it was found that the formation of the syndrome of dependence on combined abuse of hashish and tramadol corresponds to the general principles of the formation of dependence (Table 1).

Table 1: The main clinical and dynamic indicators of the formation of the syndrome of dependence on the combined abuse of hash and tramadol.

Indicator	I group (n=53)		II group (n=44)		III group (n=32)	
	Abs	%	Abs	%	Abs	%
Age of the first intake of hashish (years)	18,2±0,59		15,5±0,59**		16,09±0,60*	
Duration of episodic use (month)	3,69±0,28		2,5±0,19***		3,7±0,31^^^	
Duration of systematic use before withdrawal syndrome (years)	2,47±0,19		2,2±0,18		2,7±0,26	
Average dose of psychoactive substances consumed per day	1-2 cigarettes - 5-6 tramadol tablets		20-25 Tablets of tramadol		2 cigarettes	

Note: * - Differences regarding the data of group I are significant (* - P <0.05, *** - P <0.001); ^ - differences relative to the data of group II are significant (^^^ - P <0.001).

Discussion

The formation of dependence on the combined abuse of hash and tramadol began with the consumption of cannabinoids and the subsequent accession of opioids, in particular tramadol. They began to use them earlier by about 18-22 months compared with the start of the use of tramadol. The duration of episodic administration depended on the prevailing effect in the state of intoxication of the first hash samples. If the first samples were characterized by a subjectively pleasant experience of euphoria, then the duration of episodic administration did not exceed 3 months. With the development of unpleasant sensations associated with general intoxication disorders, the episodic stage increased on average to 4 months. The episodic stage was of a group nature with the transition to a systematic reception in solitude. The prevailing motives for the transition to polinarcotism were ataractic - 39.6% and submissive - 22.6%. Not worn in character.

Biological Factors: When comparing biological factors in the main group and control groups, a number of statistically significant differences were revealed. The presence of alcoholism and drug addiction among relatives was significantly more common in the main group - 62.3% (P <0.001 and P <0.001), which is an important risk factor for the development of dependence on psychoactive substances. The quantitative characteristic of hereditary burden-degree, [16] which was analyzed by the number of relatives with addiction, determined a "high" degree of hereditary burden in the group with combined abuse of 35.8% (P <0.01 and P <0.01), for no indicator of an "average" degree of hereditary burden in the studied groups revealed significant differences (P> 0.05). The prevalence of traumatic brain injury with loss of consciousness in the main group (39.6%) than in the control groups (P <0.05), which can play the role of a pathoplastic factor, is noteworthy. In pathologies from other systems, no differences were found (P> 0.05).

Socio-psychological factors: It all starts with the family, a small social group that performs a set of functions, where such functions as emotional, educational and spiritual and moral often fall out. The vast majority of the studied in group I - 73.6% (P <0.001; P <0.001) were brought up in single-parent families. Guardianship was not a significant factor among the subjects (P> 0.05).

Table 2: The frequency of occurrence of clinical and biological risk factors for the formation of a narcological personality in the studied groups

Clinical and biological risk factors		I Group(n=53)		II group (n=44)		III group (n=32)		R_1	R_2
		Abs.	%	Abs.	%	Abs.	%		
One parent's alcoholism		17	32,1	16	36,4	12	37,5	0,88	0,86

HIV infection		2	3,8	3	6,8	0	0	0,55	

Note: * - Differences relative to group II data are significant (* - P <0.05, ** - P <0.01, *** - P <0.001); * - differences regarding group III data are significant (^ - P <0.05, ^^ - P <0.01, ^^^ - P <0.001)

Intra-family relations give an important role in the development of a person who is prone to drug addiction in the future. Intra-family relations are the first instance of interaction with society. When studying the role of the family (Table 3), it was found that the predominant type of upbringing in the first group was the dominant hyperprotection - 60.3% (P <0.001; P <0.001), in the second group, the concurrent hyperprotection was 38.6% (P <0, 05), and in group III, hypoprotection is 43.7% (P <0.01). The vast majority of all studied (52.7%) noted an unfavorable psychological climate in the family, with a lack of understanding of each other. Family relationships could be affected by the birth order of the child in the family. So, those examined in the main group were more often the only sons - 50.9% (P <0.05; P <0.05) or the eldest in the family - 41.5% (P <0.05), and for groups I and II it was common to be the middle or youngest child - 52.3% (P <0.001) and 53.1% (P <0.001).

Table 3: The role of the family in the development of the pre-narcotic personality of the studied groups

Family Relationship Factors		I group (n=53)		II group (n=44)		III group (n=32)		R_1	R_2
		Abs	%	Abs.	%	Abs.	%

Note: * - Differences regarding the data of control group 11.2 are significant (* - P <0.05, *** - P <0.001); ^ - differences regarding the data of the control group 12.2 are significant (^ - P <0.05, ^^ - P <0.01, ^^^ - P <0.001)

The data suggest that the microsocial conditions considered could influence the formation of the pre-narotic personality.

The result of the study of the level of education among patients did not significantly differ (p> 0.05) (Table 4). A characteristic field of activity was revealed for the main group, which is represented by trade and sales of 43.4% (P <0.05) and for group II, marketing and advertising in 36.4% (P <0.01), and characteristic for group III labor activity is not identified.

Table 4: Distribution of subjects by level of education and labor activities in the study groups

Figures		I group (n=53)		II group (n=44)		III group (n=32)		R_1	R_2
		Abs	%	Abs.	%	Abs.	%		
Level of education	Secondary education	20	37,7	21	47,7	12	37,5	0,79	0,91
	Specialized secondary education	25	47,2	15	34,1	13	40,6	1,38	1,07

Note: * - Differences relative to group II data are significant (* - P <0.05, ** - P <0.01); ^ - differences relative to group III data are insignificant (P> 0.05)

When studying family status, it was determined that patients with cannabis addiction were significantly more likely to be divorced - 37.5% (P <0.05).

When studying personality factors, the personality type was considered (Table 5). Patients with a combined dependence of 50.9% (p <0.05, p <0.001) were characterized by an unstable type, with a pronounced craving for entertainment and with the desire to remain without mother's control, with a tramadol dependence - hysterical 22.7% (P <0, 05), and for hash-epileptoid personality type - 31.5% (p <0.01).

Table 5: The distribution of subjects by type of personality

Personality type	I group (n=53)		II group (n=44)		III group (n=32)		R_1	R_2
	abs	%	abs	%	abs	%		
Asthenic	1	1,9	0	0	3	9,4	1,66	0,20

Conclusion

A correlation analysis of the influence of risk factors for initiation of combined abuse of hashish and tramadol, which lead to the formation of a socially premorbid narcological personality among the studied groups, allows us to conclude that patients with a combined pathology of the cannabinoid group and tramadol have a large history of hereditary burden of alcoholism and drug addiction in relatives with a "high" degree, the presence of hereditary burden in parents does not affect the formation of drug addiction oh personality. Craniocerebral trauma with loss of consciousness is directly related to poly-narcotism. Addiction syndrome was consistent with the general principles of addiction, but they started using cannabis later than other patients. The analysis showed that excessive control of parents over their attempts to do something, limitation of activity, independence, abuse of fault, and not an explanation lead to psychological strangulation. Moreover, the children were the eldest or only child. The dominant hyperprotection was explained by the family climate and family inferiority, which led to the development of an unstable personality type in patients with combined dependence. All these factors are interrelated and thereby create a complex of risk factors predisposing to the formation of a combined dependence on the cannabinoid group and tramadol.

The selected complex of risk factors allows us to develop an algorithm for primary prevention of identifying and deactivating risk factors, on the principle of the relationship between teachers of an educational institution, general practitioners and a narcological dispensary, law enforcement agencies, neighborhood gatherings and youth movements.

[2]Professor, Head of the Department of Biotechnology, Tashkent Pharmaceutical Institute, Tashkent, Uzbekistan

Abstract

Silver nanoparticles were synthesized by the method of "Green Synthesis" using extracts of Scutellaria Iscandaria L. The "Green" pathway for the synthesis of silver nanoparticles has been described using an aqueous extract of the plant Common Skullcap as a reducing and stabilizing agent. A dry powder of silver nanoparticles was obtained from the Synthesized Suspension. The role of Luteolin flavonoid contained in Scutellaria Iscandaria L. extract in the synthesis of silver nanoparticles as a reducing and stabilizing agent is shown, the possible mechanism of nanoparticle formation is given. The synthesized silver nanoparticles have been studied by infrared spectroscopy, mass spectroscopy (ICP-MS), and high-performance liquid chromatography (HPLC). The size and shape of the obtained nanoparticles were characterized by the Atomic Force Microscopy (AFM) method. The antimicrobial activity of dry powder and aqueous suspension with silver nanoparticles was also studied at the Strains Test: St.aureusATCC 25923, B.subtilis ATCC 6633, Candida alb. 885-653.

Introduction

Over the last two decades, there has been a significant growth in research on the properties of nanoscale particles and various nanomaterials, which is associated with a wide range of opportunities for their practical application[1]. Applied developments in this direction abroad are being successfully introduced into production by enterprises in the nanoindustry; there is reason to believe [2] that further progress in this direction will make it possible to successfully solve many problems (energy supply, ecology, raising living standards, fighting epidemics and reducing mortality from various diseases, etc.) that arise at the present stage of development of human civilization.

Silver nanoparticles destroy the cell walls of bacteria[4], causing their immediate death from physical destruction rather than from toxin poisoning. Bacteria break down and die, and nanoparticles are able to function further.[5] This way of destroying bacteria leaves them unable to adapt, develop a protective mechanism and pass it on to future generations[3]. The undoubted advantage of nanoparticles over silver ions is that the surface coating of nanoparticles is protective on the one hand and can act as a platform for the transfer of various active substances on the other[6].

Nowadays, with the development of nanotechnologies, interest in silver as an antibacterial and bactericidal agent has increased greatly[7]. Nanotechnology has made it possible to reduce the cost of silver-based drugs and make them more affordable in the treatment of many infectious diseases. Among more than 800 items of consumer nano-goods, the greatest demand in the world is for products containing silver nanoparticles[8].

To date, a new method for obtaining nanoparticles of metals is considered the method of "green synthesis"[9].

The approach based on the method of "Green Synthesis" is non-toxic, environmentally friendly and economically efficient in comparison with other method, as in the method vegetable extracts are used as reducing agents and stabilizers of nanoparticles[10] .

The main advantage of plant-based biological systems[11] for the production of nanoparticles is the biological safety of the process and the possibility of obtaining[12] the necessary volume of production without additional costs[13].

The most frequently used method for obtaining metal nanoparticles in aqueous solutions are those based on the reduction of metal ions in the solution under conditions conducive to the formation of nanoparticles. The method differ mainly in the type of reducer and stabilizer (a substance that helps to preserve nanoparticles in solution in nanosize state). Nanoparticles can be synthesised by chemical reduction - with the use of chemical reducers and stabilisers (pure chemical synthesis) or with the use of current or radiation sources providing reduction by hydrated electron and other reducing particles (photochemical, radiation-chemical and electrochemical synthesis) and biological reduction - with the use of water media containing biological reducers and stabilisers (biological or "green" synthesis). In the latter case, water extracts from various biological objects (green plants, fungi, bacteria, etc.) are used.

To create safe medicines or materials containing silver nanoparticles, it is necessary to obtain aqueous solutions of such nanoparticles, which have high antimicrobial activity and at the same time low enough toxicity for the human body. To solve this problem, over the past 10-15 years, studies have been conducted on the action of the same solution of nanoparticles on bacterial cultures and normal culture cells. Unfortunately, as far as we know, such parallel research is very few, which does not allow us to draw an unambiguous conclusion about the possibility of creating appropriate drugs.

From the literature it is known that the search for new effective means to combat cancer has shown, in particular, that, in addition to antimicrobial activity, silver nanoparticles also have cytotoxicity for various types of malignant cells. Such data have been obtained for aqueous solutions of nanoparticles in studies of their action on the viability and functional activity of various cell cultures [14]. This suggests that solutions of these nanoparticles can be used to create drugs for oncology that are sufficiently effective and at the same time do not cause such serious side effects as those currently used in chemotherapy. But even in this case, it is necessary to obtain solutions of nanoparticles, which show, in the same concentration, high toxicity for malignant cells of this type and low toxicity for normal cells of the organ or tissue concerned.

To date, it has been established that the action of silver nanoparticles on cultured cells of both bacteria and mammals is significantly dependent on the way the nanoparticles are produced. So, for the development of both antimicrobial and antitumor drugs based on silver nanoparticles, the actual task is to create a method for obtaining aqueous solutions of these nanoparticles, ensuring their high efficiency as an active component in drugs and at the same time low toxicity to the human body.

It is known that formation of silver nanoparticles occurs at the expense of various biologically active substances that are in medicinal plant raw materials. In particular, plant flavonoids may include metal ions in the chelating complex and restore them. Flavonoids contain various functional groups that can cause the formation of nanoparticles. On the territory of Uzbekistan there is a sufficient number of medicinal plants rich in flavonoids, in particular Scutellaria IscandariaL. The -OH groups inherent in flavonoids may be responsible both for the reduction of silver ions to nanoparticles and for their role as stabilizers[15].

In this regard, today it is relevant to study the possibility of biosynthesis of metal nanoparticles, including silver, using domestic plant raw materials and justification of the possibility of formation of nanometals by modern physical and chemical method.

Some flavonoids have the ability to chelate metal ions through their carbonyl groups or π-electrons, the presence of such mechanisms may explain the ability of flavonoids to adsorb on the surface of the emerging nanoparticle. This means that they take part in the initiation stages of nanoparticle formation (nucleation) and further aggregation in addition to the bioremediation stage. In addition, isolated flavonoids and flavonoid glycosides have the ability to induce formation of metallic nanoparticles.

Among the great diversity of flavonoids containing plants growing on the territory of Uzbekistan, special attention is drawn to Scutellaria Iscandaria L. from

Labiatae (ScutellariaLamiaceae), which along with various flavonoid compounds is rich in other biological active substances such as glycosides, essential oils, organic acids, macro and micro elements, tannins, etc.[16].

"Green synthesis" method, as opposed to chemical synthesis, are cheaper. They allow nanoparticles to be produced[19] in unlimited quantities without significant energy costs[17], as they are considered cost-effective, and are also non-toxic. Biological method are environmentally safe as they do not use toxic compounds[18]. According to many authors[21], a variety of plant metabolites including terpenoids, flavonoids, polyphenols, sugars, alkaloids, phenolic acids and proteins are transferred to water extracts. These biologically active substances contain the hydroxo and aldehyde groups responsible for the reduction of silver ions, and the carboxylic group responsible for stabilizing the resulting nanoparticles.

A number of silver nanoparticles obtained in this way exhibit antibacterial and fungicidal properties, which makes them promising for use in new medical and cosmetological preparations. Antibacterial properties of silver nanoparticles depend on their size: the smaller the particle, the stronger is the bactericidal effect, as smaller nanoparticles have a larger surface area, which provides better interaction with the bacteria.

Silver nanosuspensions are in demand in various industries. Taking into account that the production of silver nanosuspension is mass-produced, it becomes clear that their production must be rational, efficient and these products must meet high quality and safety requirements. For example, in the production of pharmaceuticals or cosmetics with silver nanoparticles, it is more efficient to produce a dry powder of silver nanoparticles, where the exact quantity of silver nanoparticles can be calculated. Thus, dry silver nano-silver powder is more efficient than a suspension of silver nanoparticles.

In connection with the studied data, we find it interesting to study the formation of silver by the method of "green synthesis" using Scutellaria Iscandaria L. and study their antibacterial properties.

Research objective is to obtain an aqueous suspension and dry substance with silver nanoparticles by the method of "Green Synthesis" using a plant of the genus Common Skullcap, as well as the study of their physical, chemical and antimicrobial properties.

Materials and Method

The above-ground part of Scutellaria Iscandaria L. collected in July in the Pontifical district of Namangan region of the Republic of Uzbekistan was used as plant raw material, while the silver ion source was 0.01 M nitrate.

Production of silver nanoparticles was carried out by "green synthesis" method.

Extract Obtaining: Water extraction of dried grass was used as a regenerating agent. For this purpose, 1 kg of shredded raw material was placed in the extractor, 10l of purified water was poured, and then left to swell for 24 hours and received the first drain. Then we added 10 liters of purified water and got the first drain. Both drains were combined and filtered. The received suspension was stored in a refrigerator at temperature 20°C[22].

Silver Nitrate Preparation: To produce 0.01 m of silver nitrate, 80 l of distilled water was added to 136 g of silver nitrate powder. Thoroughly stirred until completely dissolved.

Phytosynthesis of Silver Nanoparticles: For the phytosynthesis of silver nanoparticles, a solution of silver nitrate ($1*10^{-3}$ mol/l) in a ratio of 1:4 was added to the resulting extract. Nanoparticles were synthesized at room temperature until light changes. The pH value of the solution was 5.5.

Production of dry substance with silver nanoparticles: To obtain a dry powder of silver nanoparticles, the liquid extract was first converted into a dense form using a rotary evaporator, thus obtaining 5 liters of the dense extract. Dry extract powder with silver nanoparticle from a dense suspension was obtained by means of Lyophilic drying.

Quantitative determination of the content of micro- and macro-elements in the dry substance by the method of ICP-MS.

By results of studying the elemental composition of dry substance of silver nanoparticles by method ICP-MC it is possible to make calculation of silver for carrying out physico-chemical, microbiological analyses.

The method of impurity(Li, Be, Sc, Cr, Mn, Co, Ni, Cu, Zn, Ga, As, Se, Rb, Sr, Y, Nb, Mo, Rh, Ag, Pd, Cd, Sn, Sb, Te, Cs, Ba, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Hf, Ta, W, Re, Ir, Pt, Au, Tl, Pb, Bi,

Th и U) elements in soils, Soils and bottom sediments are based on a highly sensitive multi-element analysis method - mass spectra with inductively coupled plasma (ICP-MS).

IR-spectroscopy research: IR spectra of the initial extract of Scutellaria Iscandaria L. and the slurry after phytosynthesis were recorded on an IR spectrophotometer (Cary 630 Ftir Agilent Technologies USA) in the frequency range of 4000-400 cm^{-1} (resolution 4 cm^{-1}, number of scans of the sample 50). A certain amount of solution was applied to the KRS substrate, dried for about 5 minutes and the spectrum was recorded.

Study of identification and quantitative determination of flavonoid content: The identification and quantification of flavonoids in Scutellaria Iscandaria L. was studied by HPLC with photometric detection on Agilent 1100. Luteoline, Apigenin, Rutin, Quercetin (ICC lnc, USA Indofine) standards were used. For the preparation of a standard sample with a concentration of 0.05 mg/cm^3, 5 mg standard is placed in a measuring flask with a capacity of 100 cm^3, bring the volume to the mark with methanol. To prepare the sample for the suspension with silver nanoparticles add 2 ml of hydrochloric acid and heated in a water bath with a reverse refrigerator for 1 hour 30 minutes. The solution is quantitatively transferred into a measuring flask for 100 cm^3 and brought to the mark 70% ethanol. Then the flask is placed for 5 minutes in an ultrasonic bath.

Further, the sample for HPLC analysis is filtered through a membrane filter and used for analysis. Conditions for chromatographic analysis: column: 5 µm, 250×4.6 (e.g. Agilent 5 µm C18(2)); mobile phase: acetonitrile - 0.1% trifluoroacetic acid solution pH 2.6 (40:60); mobile phase rate: 1.0 cm^3/min; Column Temperature: 30^0C; Detection: UV, λ= 254 nm. Volume of Introduced Sample: 10 mm^3.

The content of the indicator components is calculated according to a graduation chart or a formula:

$X = C \times S1 \times V\ S2 \times m$,

C — concentration of the corresponding standard solution, mg/cm^3;

S1 – the area of the peak determined by the component in the analysed sample;

S2 — area of the peak determined by the component in the standard sample;

V — is the total dilution volume of the sample, cm^3;

m — hinge mass, gr.

AFM (Atomic force microscopy) study of silver nanoparticles: Method - atomic force microscopy (AFM) to visualize the resulting nanoparticles. The procedure for preparing samples for atomic force microscopy consists in their immobilization on an even substrate. The substrate material can be varied in a wide range depending on the tasks at hand. Traditionally atomic-smooth substrates made of mica, graphite and other layered materials as well as various glasses, polymeric materials and metal surfaces are used as substrates.

Study of antimicrobial activity by microbiological method: The antimicrobial activity of silver nanoparticles was determined[23] by the Diffusion method in Agar and serial dilutions on solid nutrient media[24].

Diffusion in agar on a dense medium (nutrient medium) by comparing the size of the growth depression zones of test microbes.

The following strains were selected: St. aureus ATCC 25923, B.subtilisATCC 6633, Candida alb. 885-653.

Nutrient media: Wednesday No.1, Wednesday No.2.

Nutrient media were prepared in accordance with the manufacturer's instructions.

Autoclaving - 1/atm (121°C) for 15 minutes.

Inoculum Preparation: Neglected daily culture St. Aureus, B. subtilis, Candida alb. grown in a densely nutritious environment. Microbial suspension was prepared by suspending isolated colonies from a 24-hour culture to a standard turbidity of 0.5 McFarland.

Solution Preparation:

Working Solutions:

Tested solution #1: Dry powder with silver nanoparticles obtained by green synthesis method using aqueous extract of common skullcap.

Distilled water was used as a solvent and diluent.

All solutions were applied 100 µl each in wells with one cup of Petri. Then they were kept at room temperature for 1-2 hours.

The cups were incubated in a thermostat at 36 (±1) C^0 for 18-24 hours. After incubation the growth delay zones were measured to the accuracy of 1 mm with the HiAntibiotic Zone Scale CPW 297. The results were taken into account by changing the growth delay zones of microbes around the well (including the diameter of the well itself).

Results

During our Green Synthesis studies, we observed that the color of the observed suspensions was changing. During 1 hour to 4 hours the color of the solution changed from yellow - brown to dark brown light. The change in color indicates an increase in the concentration of silver nanoparticles, as well as an increase in particle size. The liquid extract was then thickened to a thicker form using a rotary evaporator. A 5-liter thick suspension was obtained. Then it was dried by sublimation. From 1 kg of raw material 75 g of dry substance with silver nanoparticles was obtained. Dry fine amorphous powder is dark brown, hygroscopic, slightly crumbling, the smell is weak and peculiar.

The elemental composition of dry substance was studied quantitatively. In particular, the amount of silver in the studied samples was 2500 ppm (2500 mg/kg), which is - 0.25% .

It is known that silver deposition in concentrations of 10-20 µg/ml causes reduction of tumor necrosis factor, interleukin-1, interleukin-6, and at concentration of nanoparticles at the level of 100 µg/ml 50% survival rate of A549 lung cancer cells is achieved. According to EPA (USA) recommendations, the daily permissible dose of silver (RfD) that does not cause cell necrosis is 5 µg per 1 kg of body weight per day.

IR spectroscopy study of Scutellaria Iscandaria L. extracts and extract suspensions with formed silver nanoparticles are presented in Fig.1 and 2.

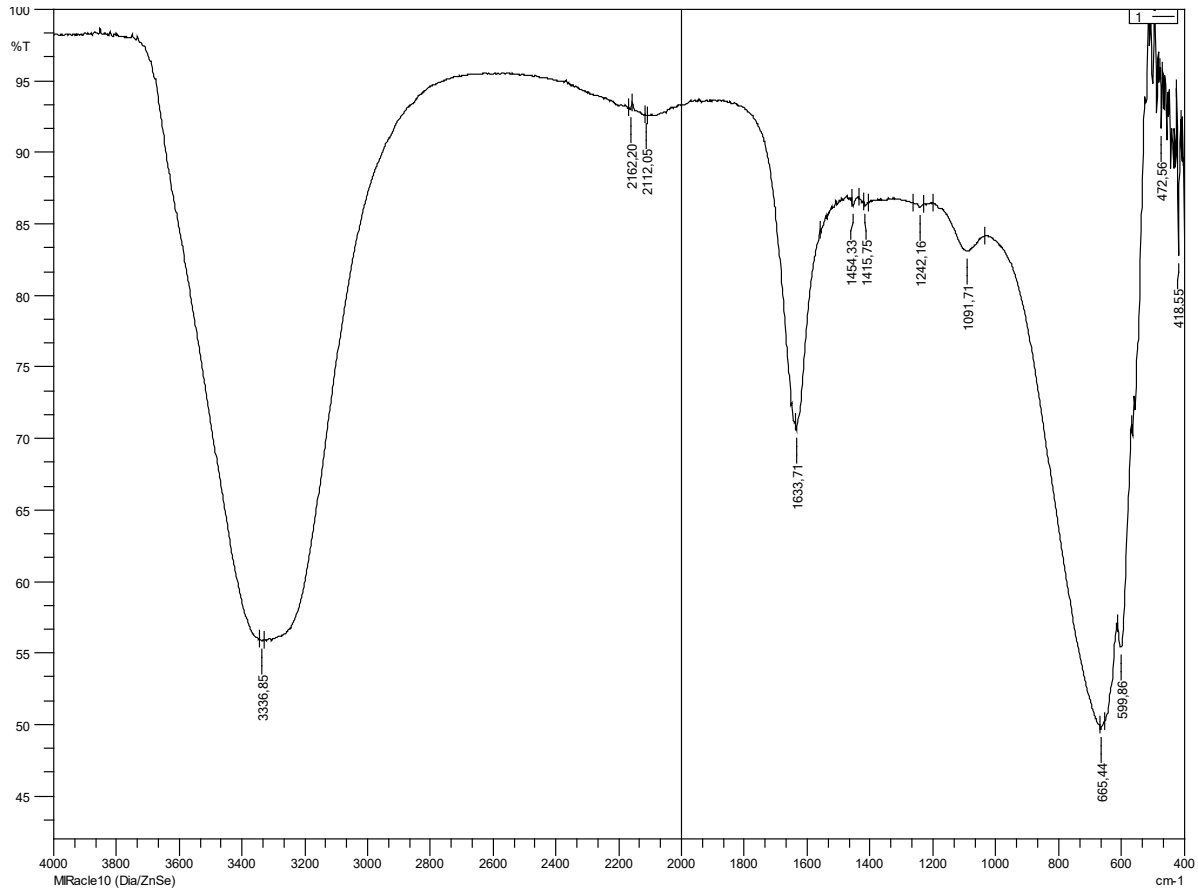

Fig. 1. IR absorption spectrum of Scutellaria Iscandaria L. extract.

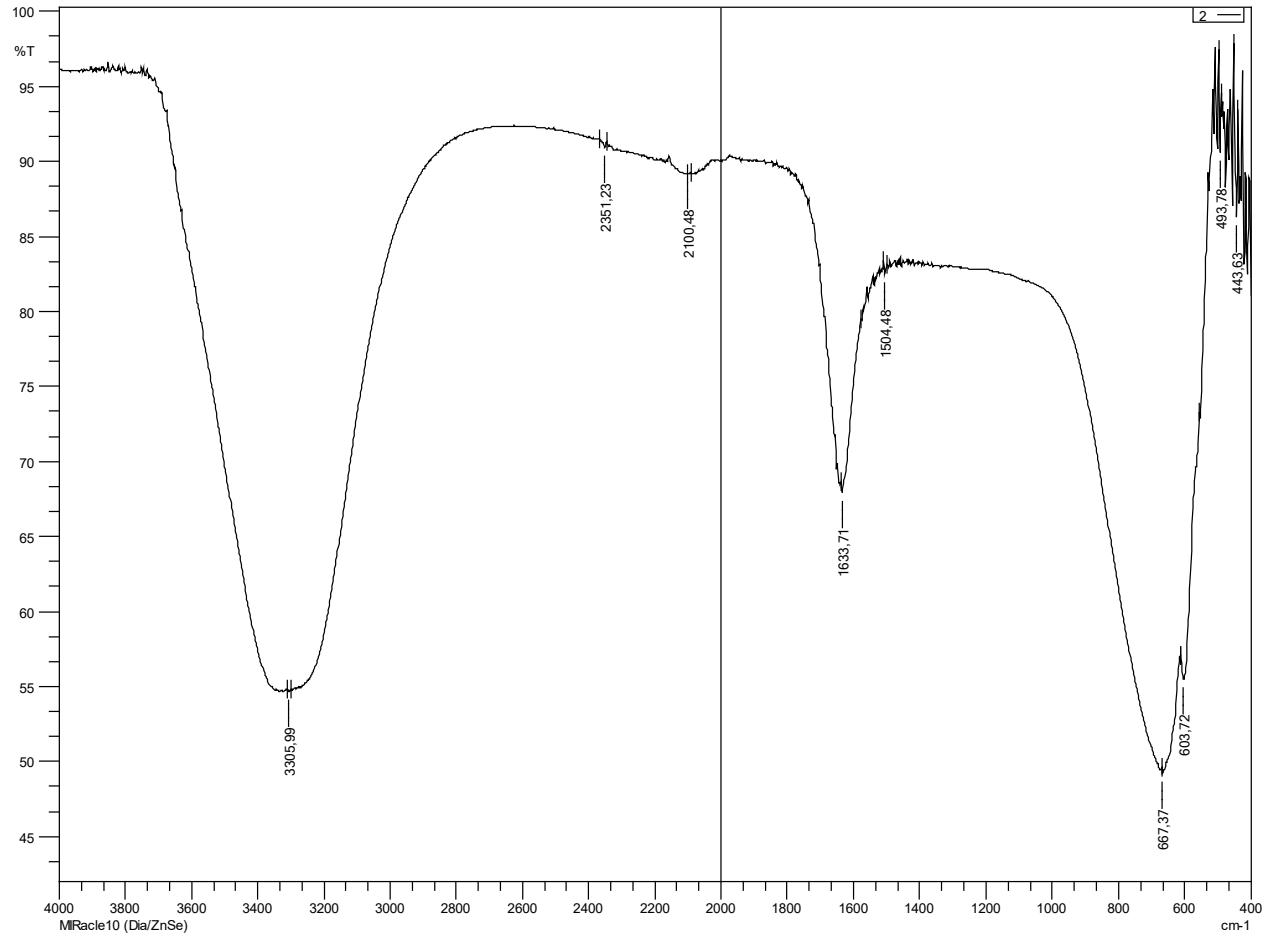

Fig 2. IR spectrum of silver nanoparticles absorption using Scutellaria Iscandaria L. extract.

In the presented infrared spectra, the following characteristic peaks in the absorption area can be distinguished: 3336-3305 cm^{-1}, 2112-2100 cm^{-1}, 1633 cm^{-1}, 1454-1504 cm^{-1}, 1091 cm^{-1}, 400-667 cm^{-1}. It is known that these peaks are connected with valence oscillations of hydroxyl groups in alcohols or phenolic compounds, functional groups C-O of phenol, C-H of aromatic ring.

Removed IR spectra (Fig.1, 2) showed the fluctuations of the temple ring at 1633 cm^{-1}. In the spectrum of the extracts under study there is a wide absorption band in the region of 3336 cm-1, which refers to the valence oscillations of OH-groups in alcohols and phenolic compounds.

After the interaction of $AgNO_3$ solution with Scutellaria Iscandaria L. extract, instead of the band at 3336 cm^{-1}, there is a band at 3305 cm^{-1}, which suggests that hydroxyl groups of phenolic compounds that are part of the extract take part in the restoration of silver ions and formation of nanoparticles.

Absorption bands at 1415 and 1454 cm^{-1} refer to the valence vibrations of the benzene ring at low intensity. Absorption bands in the area of 1242 cm^{-1} belong to the valence oscillations of C-O phenol, while absorption bands in the area of 665 cm^{-1} characterize the deformation oscillations of C-H of the aromatic ring. Taking into account that Scutellaria Iscandaria L., contains flavonoid compounds, which participate in formation of silver nanoparticles, we have carried out a comparative chromatographic study of water extraction of Scutellaria Iscandaria L. and suspensions with silver nanoparticles.

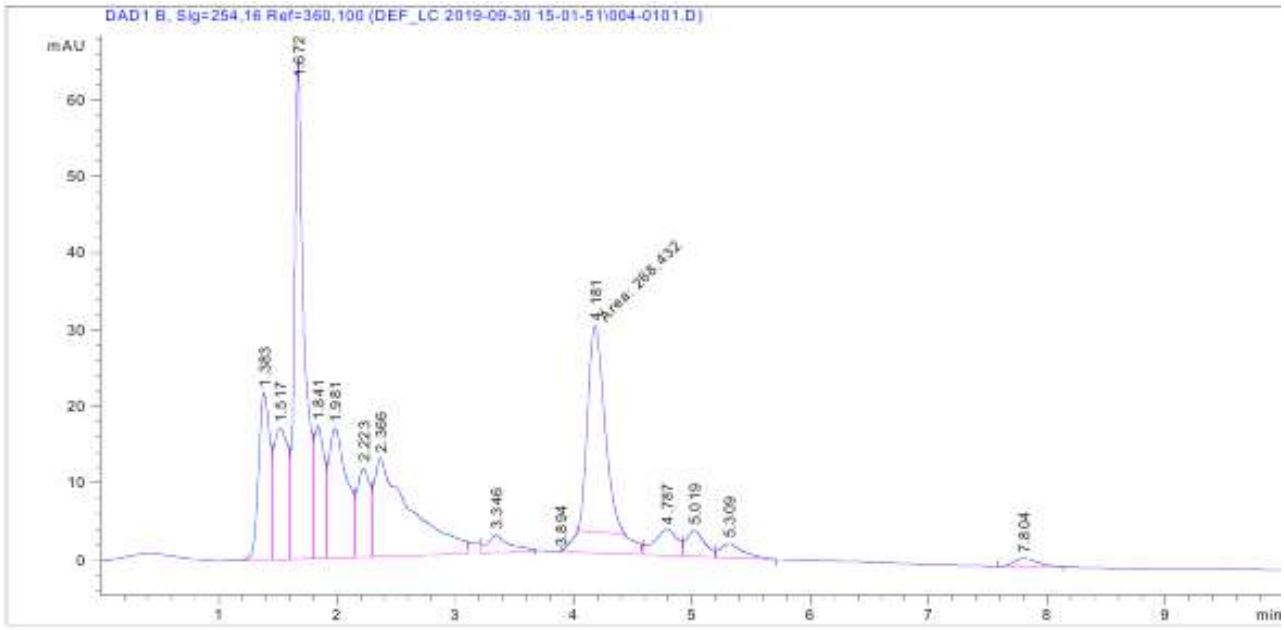

Fig. 3. Luteolin chromatogram.

To begin with, chromatograms of Lutheonine standards were taken (Fig. 3).

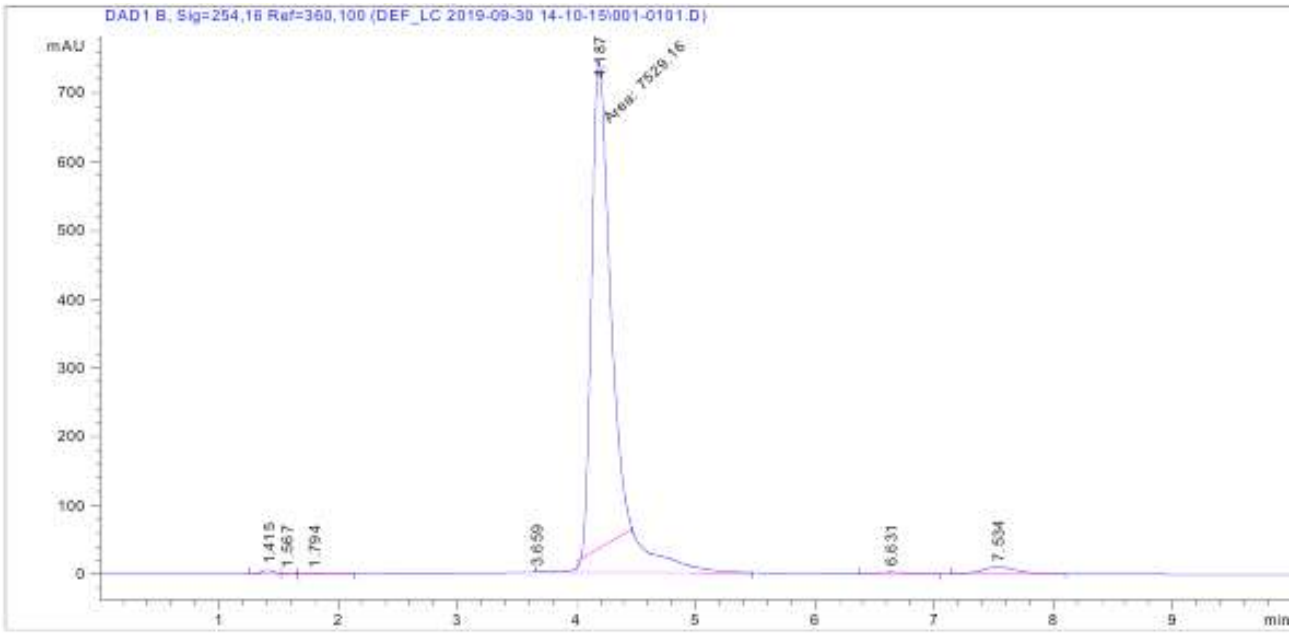

Fig. 4. Water extraction chromatogram of Scutellaria Iscandaria L. (Determination of flavonoids: Luteolina).

The chromatogram shows that the peak holding time for the Luteolin standard is 4.1 minutes.

Further, the water chromatogram of Scutellaria Iscandaria L. was taken. As can be seen from the picture below, the chromatogram also shows peaks in the area of 254 nm, whose retention time (min) characterizes the presence of only Luteolin - 4.1 minutes.

According to the results of the analysis, the content of Luteolin in the samples of Scutellaria Iscandaria L. extract is - 0.0062 mg/g (fig.), and in the suspension with formation of silver nanoparticles - 0.0039 mg/g (fig.).

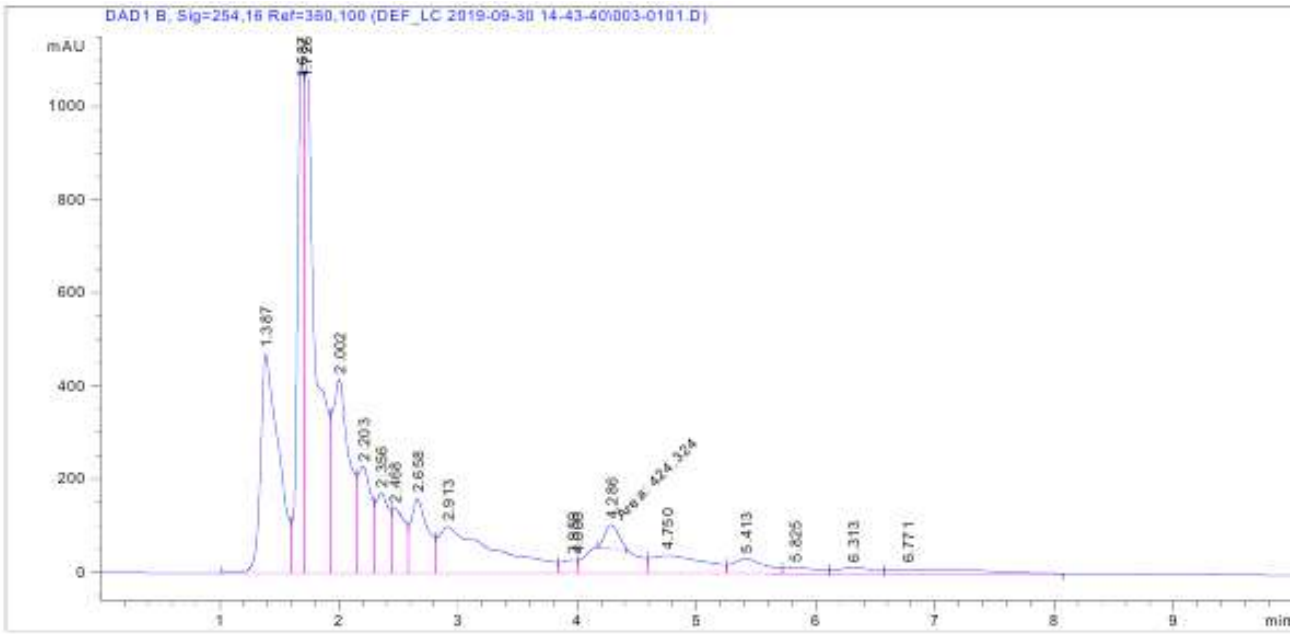

Fig. 5: HPLC - water extraction chromatogram of Scutellaria Iscandaria L. with silver nanoparticles.

Table 1: The generalized results of chromatographic analysis are presented.

Standard Names	Contents of Scutellaria Iscandaria L. water recovery standards.	Contents of Scutellaria Iscandaria L. water extraction standards with silver nanoparticles.
Concentration of mg/g		
Luteolin	0,0062	0,0039

As can be seen from the data presented, the flavonoids contained in Scutellaria Iscandaria L are actively involved in the formation of silver nanoparticles[25].

As is known from literature data[26], the rich phytochemical composition of the extracts used suggests its complex action, for example, as a reducing, stabilizing agent. The mechanism of nanoparticles formation consists mainly of three stages: ion recovery, clustering, and further growth of nanoparticles. Features of each stage depend on the nature of the reducing agent, its concentration, pH, $AgNO_3$: concentration of the reducing agent. The -ON groups present in flavonoids such as luteolin are responsible for the reduction and play the role of stabilizers, therefore, the resulting suspension with nanoparticles can be stored as colloids.

As is known from the literature, the rich phytochemical composition of the extracts used suggests its complex action, for example, as a restorative and stabilizing agent. There is no corresponding literature explaining the mechanism of flavonoid recovery and stabilization of silver nanoparticles. The mechanism of formation of nanoparticles consists mainly of three stages: restoration of ions, clusterization and further growth of nanoparticles. Features of each stage depend on the nature of the reducing agent, its concentration, pH and concentration of the reducing agent. According to some researchers, the -OH groups present in flavonoids, such as Luteolina, may be responsible for the recovery and play the role of stabilizers, so the resulting suspension with nanoparticles can be stored in the form of colloids.

Luteoline reacts with Ag+ as acid through the most reactive hydroxyl groups attached to the carbon atoms of the aromatic ring, which can restore silver ions to nanoparticles and provide stability against agglomeration (Fig. 6).

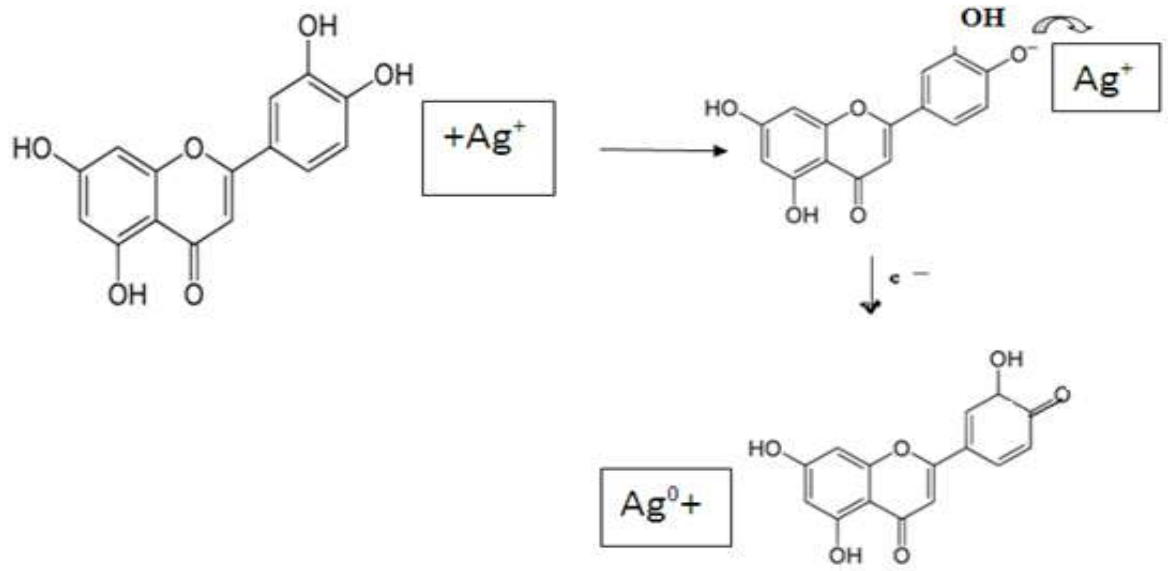

Fig. 6. Approximate mechanism of silver ions reduction to silver nanoparticles by the Luteolin molecule.

From this we can conclude that the formation of silver nanoparticles was due to all flavonoids inherent in the extract of Scutellaria Iscandaria L.

Further, we studied the size and shape of the formed silver nanoparticles by Atomic Force Microscopy.

According to microscopic studies, the morphological characteristics (shape, size, structures) of silver nanoparticles were studied. In particular, the size of silver nanoparticles derived from extracts of medicinal plants Scutellaria Iscandaria L. was 45.7 nm (25% of the total number of particles) with a basic fraction (81%) ranging from 36.6 nm to 64 nm.

Determination of the antimicrobial activity of the preparation by serial dilution makes it possible to determine more precisely the minimum concentration of the preparation that inhibits bacterial growth[27].

The bacteriostatic dose was considered to be the concentration of the preparation, which inhibited the growth of the culture of the test strain, and the bactericidal amount of the preparation, which completely inhibited the growth of microbes. Sensitivity of microorganisms was estimated by a unified method: group 1 was considered highly sensitive, group 2 - sensitive, and group 3 - stable.

Stable - the strain is not suppressed at the concentrations of the drug created in organs and tissues at recommended dosing modes.

Absence of the zone of microbial growth delay around the well indicates that the experimental strain is not sensitive to this experimental drug [28], at a zone with diameter up to 10 mm the strain is considered to be insensitive. In standard conditions of experience by the size of zones formed by preparations, it is possible to judge about the degree of sensitivity of the investigated microorganism.

Based on the results of ICP-MS, the amount of silver was determined to be 0.25%, from these data for analysis of antimicrobial activity in terms of dosage was taken dry powder of silver nanoparticles in 3 different concentrations. 1-0,5%; 2-0,25%; 3-0,125%.

The results of the evaluation of sensitivity and inhibition diameters of growth zones of silver nanoparticles were carried out in Table 2.

Table 2

No	Test strains	Test Results Diameters of microbial growth inhibition zones
1	Staphylococcus aureus ATCC 25923	25-32 mm
2	Bacillus subtilis ATCC 6633	36-40 mm
3	Candida albicans ATCC 885-653	30-38 mm

The results of the conducted studies (Table 2) showed that the greatest efficiency of the studied sample

was observed in relation to Bacillus subtilis ATCC 6633- the diameter of the inhibition zone was 36-40 mm and Candida albicans ATCC 885-653 - the diameter of the inhibition zone was 30-38 mm, also Staphylococcus aureus ATCC 25923 - the diameter of the inhibition zone was 25-32 mm.

Silver has a wide range of antibacterial activity, including antibiotic-resistant gram-positive and gram-negative strains. There is a direct correlation between silver's concentration, particle size and its antimicrobial action. The higher the concentration and smaller the particle size, the more effective silver is at inhibiting bacterial growth. The treatment of infection caused by microorganisms in this category is usually effective when tested preparations are used in recommended doses. The sensitive ones were Staphylococcus aureus, Candida albicans with a growth delay zone around wells, which was 30-40 mm. Category-induced infection treatment may be effective when the test subject is administered at elevated doses or when the focus of infection is localized in those organs or tissues in which elevated drug concentrations are created due to physiological features. In addition, after observing the results, we kept the cups in the thermostat for another 1 week and observed microbial growth. During 1 week no microorganism growth was found in the culture.

Wasteless Technology: On the basis of the above data, water was vaporized in the process of obtaining a thick extract. As silver nanoparticles are considered to be small metal particles, they were not only in the dense suspension but also in the water part. On this basis, we found it interesting to study the antimicrobial activity of the evaporated water part.

First, we studied the amount of silver in water using the ICP-MS method. The amount of silver in the tested samples was 0.023 mg/l.

Table 3

No	Test strains	Test results Diameters of microbial growth inhibition zones
1	Staphylococcus aureus ATCC 25923	-
2	Bacillus subtilis ATCC 6633	36-38-40 mm
3	Candida albicans ATCC 885-653	-

During the antimicrobial activity study, water with nano-silver was also taken at 3 x concentrations.

The results of the sensitivity and inhibition diameters of microbial growth zones of water with silver nanoparticles are given in Table -3.

No activity was detected on Staphylococcus aureus and Candida albicans during the studies. The absence of a microbial growth delay zone around the well indicates that the test strain is not sensitive to this test drug. Only Bacillus subtilis ATCC 6633 was considered sensitive, with a growth inhibition zone diameter of 36-38-40 mm.

Conclusions

For the first time, a dry substance of silver nanoparticles was obtained by the "Green Synthesis" method using an extract from a plant of the Common Skullcap. The role of Luteolin flavonoid contained in Scutellaria Iscandaria L. extract in the synthesis of silver nanoparticles as a reducing and stabilizing agent is shown, the possible mechanism of nanoparticle formation is given. Synthesized silver nanoparticles have been studied by IR-spectroscopy, Mass Spectrometry (ICP-MS), High Performance Liquid Chromatography (HPLC). The size and shape of the obtained nanoparticles were characterized by the Atomic Force Microscopy (AFM) method. Their antimicrobial activity was also studied on the test strains: St.aureusATCC 25923, B.subtilis ATCC 6633, Candida alb. 885-653.

IR spectroscopy data suggest that hydroxyl groups of phenolic compounds in the extract take part in the reduction of silver ions and the formation of nanoparticles.

It follows that the Scutellaria Iscandaria L. extract contains flavonoids that participate in the formation of nanoparticles. We have investigated the role of flavonoids, in particular, Luteolin method of HPLC, contained in the extract of Scutellaria Iscandaria L. in the reduction of silver ions in the solution with the formation of silver nanoparticles.

It was found that Luteolin is also actively involved in the restoration of silver nanoparticles, so its content in the biosynthesis process is reduced by half. The formation of silver nanoparticles is confirmed by the appearance of the color of the resulting ash, as well as the results of atomic force microscopy, which allowed to obtain an image of silver nanoparticles. The AFM image allowed us to establish that silver nanoparticles obtained using Scutellaria Iscandaria L. extract have a size of 45.7 nm (25% of the total number of particles)

with a basic fraction spread (81%) of 36.6 nm to 64 nm. Consequently, Scutellaria Iscandaria L. may be a promising raw material for the synthesis of silver nanoparticles.

Silver nanoparticles obtained with the use of Common Skullcap extracts have been shown to exhibit strong antimicrobial activity; they have bactericidal effect on Bacillus subtilis, Staphylococcus aureus, Candida alb.

Based on previous data, it can be concluded that the silver nanoparticles obtained with the use of Common Skullcap extract can be used to treat inflammatory processes. The results of the study confirmed that the bactericidal dose of the drug was higher than the bacteriostatic dose.

Comparative data on the antimicrobial activity of silver nanoparticles powder and water with silver nanoparticles allow concluding that not only the concentration of nanoparticles, but also the biological active substances contained in the dry powder with silver nanoparticles play a major role.

Later, when planning the production of dry substance with silver nanoparticles, we can use the water obtained in the process of evaporation to obtain a thick extract in various areas, such as in cosmetology, meal grass for addition to feed, because in the process of extraction was not used organic substances. On this basis, we can conclude that the selected technology for the phytosynthesis of nanoparticles will relate to the wasteless technology.

Abstract

The modern concept of the diagnosis of peripheral artery disease is one of the urgent problems of modern medicine. Peripheral Artery Disease (PAD) is a pathology characterized by the formation of plaques in the peripheral arteries. As reported at the Scientific Session soft the American Heart Association in 2007, the prevalence of asymptomatic PAD in adults in the United States was constantly increasing, and now it is found in almost 5% of adults aged 40 years and older. In addition, PAD is an indicator of the condition of the arteries and its presence is associated with an increased risk of heart attack and stroke.

Keywords: *Vascular ultrasonography, dopplerography, peripheral artery disease, ultrasound duplex studies, ABI.*

Introduction

Prevention issues as a strategic direction of healthcare development in Uzbekistan are contained in all state legislative acts of recent years[1]. However, many of the necessary projects have not been properly implemented in everyday practice, including a strategy aimed at preventing chronic lower limb ischemia[2]. One of the reasons for the high mortality rate is the lack of effective primary prevention measures that ensure the timely identification and correction of risk factors for the development of pathology[4].

Unfortunately, today there is very little accurate data on the epidemiology of obliterating diseases of the arteries of the lower extremities. Information on the results of published studies on this issue is fragmentary and contradictory, which does not give a complete picture of the prevalence of this process in different regions, among different age and ethnic groups, the dynamics and outcomes of these diseases. According to published data, the prevalence of obliterating diseases of the arteries of the lower extremities in the countries of Europe and America is 2.1-20.7%, and this pathology is extremely rare in the indigenous peoples of Asia. Great importance is attached to the study of the prevalence, risk factors, and clinical features of these diseases among various ethnic groups. There are only a few short reports on the prevalence of obliterating diseases of the lower limb arteries among indigenous peoples[3].

The aim of the study. The study of the prevalence of peripheral arterial disease among residents of the Khorezm region aged 45-90 years and the development of an optimal model for its ultrasound diagnosis for general practitioners.

The degree of influence of unmodifiable and modifiable risk factors, as well as their combinations, in the occurrence of arterial pathology of the lower

extremities in this contingent is studied, taking into account the identified regional characteristics.

An objective picture of the prevalence of stenosing atherosclerosis of the arteries and hemodynamic disorders of the lower extremities in this population is obtained.

For the first time, an analysis of the information content of non-invasive diagnostic method in patients with PAD was carried out. The criteria for stenotic lesions of the arteries according to the values of the ankle-brachial index

Materials and Method

Among the examined 487 (87.0%) patients, no PAD was detected, and 73 (13.0%) patients were diagnosed with PAD. Arterial events were noted in the lower extremities in 38 (6.8%) patients. The proportion of patients with average SBP at the ankle level of 300 mm in different areas was generally the same (22 (30.1%) patients in the city of Urgench, 6 (8.2%) of them in the Urgench district, 3 (4.1%) patients in Hankha, 4 (5, 5%) patients in Bagat, 4 (5.5%) patients in Khazarasp, 7 (9.6%) patients in Yangarik, 6 (8.2%) patients in Khiva, 10 (13.7%) patients in Kushkupir, 2 (2.8%) patients in Shavat, 3 (4.1%) patients in Yangibazar, 6 (8.2%) patients in Gurlen).

The average ABI was 0.92+ 0.23 and was less than 0.9 in 13.0% of patients. The average ABI decreased with age; in elderly patients, the ABI was 0.96 + 0.18 versus 0.86 + 0.25 in senile patients. In addition, approximately twice as many elderly and senile patients of 63 (14.7%) patients had an ABI of less than 0.9 compared with middle-aged patients 10 (7.6%). When analyzing the ABI taking into account the type of patients, the ABI was less than 0.9 in 16 (22.0%) patients with coronary heart disease (mean value of the ABI 0.91+ 0.24), in 15 (21.0%) patients with cerebrovascular disease (the average value of the ABI is 0.91+ 0.23), in 6 (8.0%) patients with multiple vascular pathology (the average value of the ABI is 0.87+ 0.25) and in 36 (49.0%) patients with only cardiovascular risk factors (average LPI 0.94+ 0.22). When taking into account the living area of the Khorezm region, the ABI is less than 0.9 in: 22 (30.1%) patients in the city of Urgench, 6 (8.2%) of them in the Urgench district, 3 (4.1%) in Hankha, 4 (5.5%) in Bagat, 4 (5.5%) in Khazarasp, 7 (9.6%) in Yangarik, 6 (8.2%) in Khiva, 10 (13.7%) in Kushkupir, 2 (2.8%) in Shavat, 3 (4.1%) in Yangibazar, 6 (8.2%) in Gurlen.

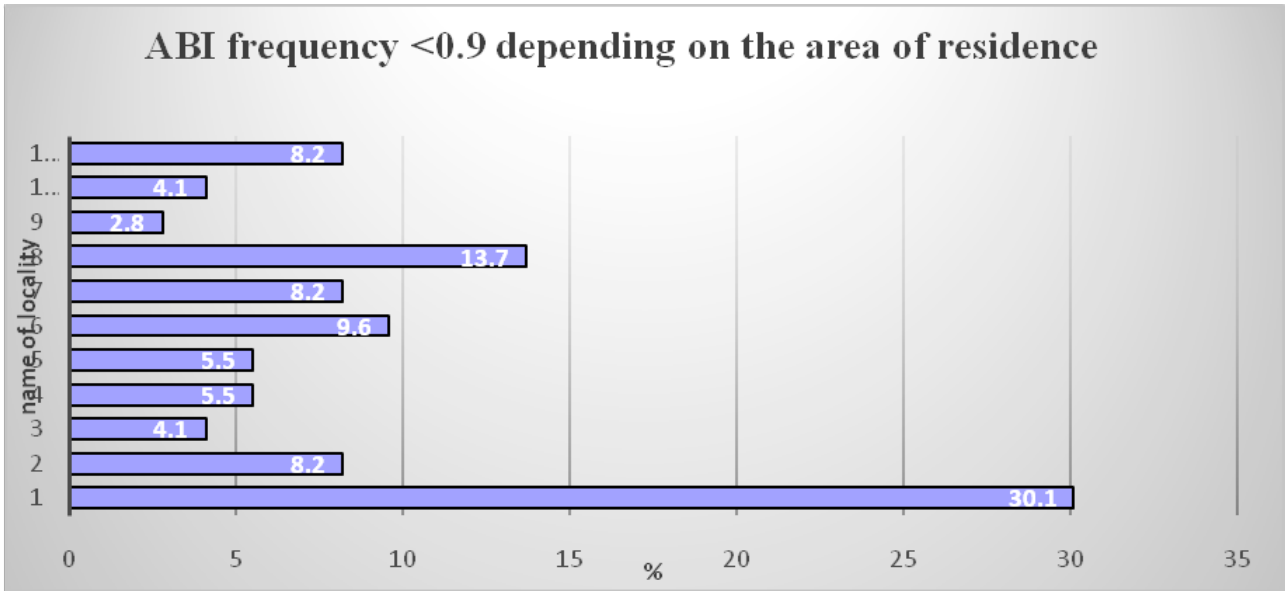

Figure 1. ABI frequency <0.9 depending on the area of residence

The prevalence of ABI values of 1.3 among patients with and without diabetes did not differ significantly and amounted to 3.0 versus 2.2% between the two groups.

Table 1: The indicators of the ankle-brachial index in groups

ABI values	Total (n-560)	Coronary (n-149)	Cerebrovascular (n-111)	Multivascular (n-39)	Only RF(n-261)
Average (M±SD)	0,92 ±0,23	0,91±0,24	0,91±0,23	0,87±0,25	0,94± 0,22
0,5	6 (1,1%)	1 (0,7%)	1 (0,9%)	1 (2,6%)	3(1,2%)
0,5-0,7	26 (4,6%)	5 (3,4%)	6 (5,4%)	3 (7,7%)	12 (4,6%)
0,7-0,9	41(7,3%)	10(6,7%)	8(7,2%)	2 (5,1%)	21 (8,0%)
0,9-1,1	300(53,6%)	78(52,3%)	57(51,4%)	20(51,3%)	145(55,6%)
1,1-1,3	128(22,9%)	35(23,5%)	25(22,5%)	9 (23,0%)	59 (22,6%)
More 1,3	59 (10,5%)	20(13,4%)	14(12,6%)	4 (10,3%)	21 (8,0%)

The determination of the ankle-brachial index led to a noticeable change in the distribution of patient types.

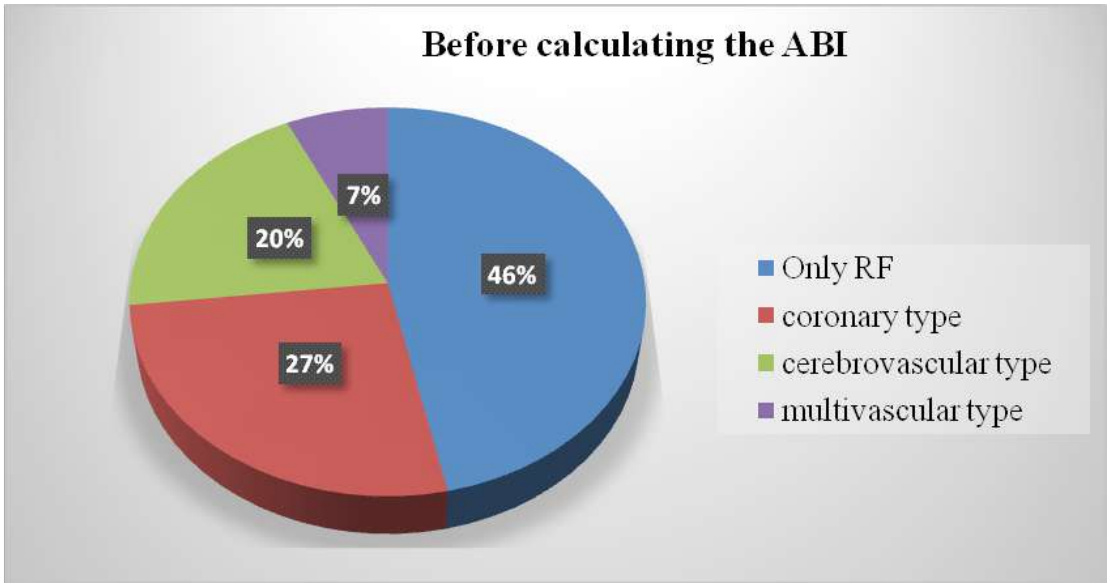

Figure 2. Patient distribution before calculating the ankle-brachial index in peripheral artery disease

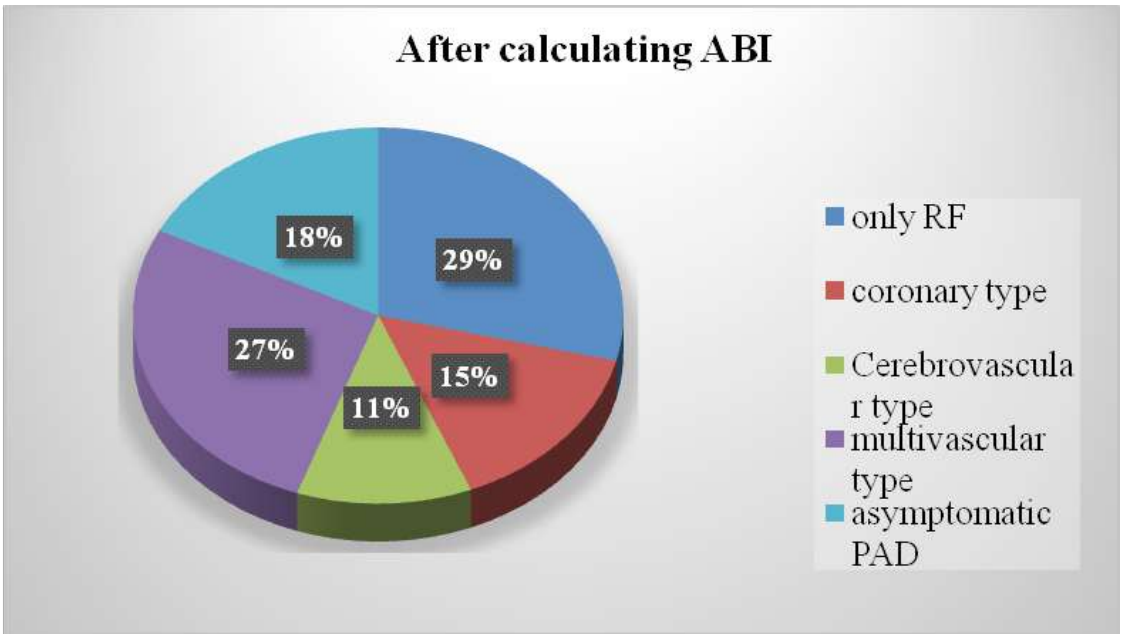

Figure 3. Patient distribution after calculating the ankle-brachial index for peripheral artery disease

Results

When enrolled in the study, patients with high risk and asymptomatic PAD were divided into four groups: patients with [1] documented coronary artery disease, [2] documented cerebrovascular disease, [3] documented multivascular disease (both coronary and cerebrovascular disease) and [4] the presence of at least one cardiovascular risk factor without ischemic or cerebrovascular disease. After evaluating the ankle-brachial index, coronary patients with PAD and cerebrovascular patients with PAD were counted as patients with multiple vascular lesions. Almost (38%) of the examined individuals, initially rated as having only RF, had PAD (36 (49.3%) of the total). The percentage of patients with multiple vascular lesions, which initially was 19 (3.4%), increased to 39 (7%) after measuring the ABI.

Widespread RF PADs include obesity, dyslipidemia, arterial hypertension, diabetes mellitus, smoking, and increased age.

BMI of patients ranged from 17.1 to 48.6 with an average of 26.9 kg / m² + 4.5% kg / m². 1.4% of the subjects were overweight, 1.5%[8] were of normal weight, 40.7% were obese, 19.6% were obese 1 st, 5.1% were obese 2 st, and 0.8% had obesity 3 tbsp. Only 32.6% of participants had normal BMI. and 66.2% were at least overweight. 33.5% of patients with PAD suffered from obesity, which is less than the proportion of people with obesity in patients with irreplaceable LPI (44.4%). Patients with a BMI of at least 30 (class I obesity) accounted for 40% of patients with PAD and 21.0% in patients without PAD (which roughly corresponds to the proportion in the average population). A significant relationship between BMI and PAD was revealed.

Discussion

Overall, 25.4% of participants suffered from diabetes (25.0% of women and 25.6% of men). The average disease duration was 12.1 + 10.1 years. 45% of all diabetics had PAD, compared with 26.4% of non-diabetic patients, and significantly more diabetics than non-diabetics with PAD. Overall, 33.5% of patients with PAD had diabetes mellitus. Of all diabetics, 44.4% had a history of myocardial infarction and 86.4% had arterial hypertension.

In addition to history, dyslipidemia was determined by laboratory determination of LDL (low density lipids), HDL (high density lipids), triglycerides and total cholesterol (HDL <1 mmol / L, LDL> 4.2 mmol / dL), triglycerides> 2 3 mmol / L (150 mg / dl) and total cholesterol> 6.2 mmol / L (240 mg / dl). 21 (37.8%) patients with high cholesterol had PAD, 20.3% of those without high cholesterol suffered from PAD. 5.3% of patients had high LDL levels. Of all patients with hyperlipidemia, 35.4% had PAD, 46.0% had myocardial infarction, and 88.0% had arterial hypertension.

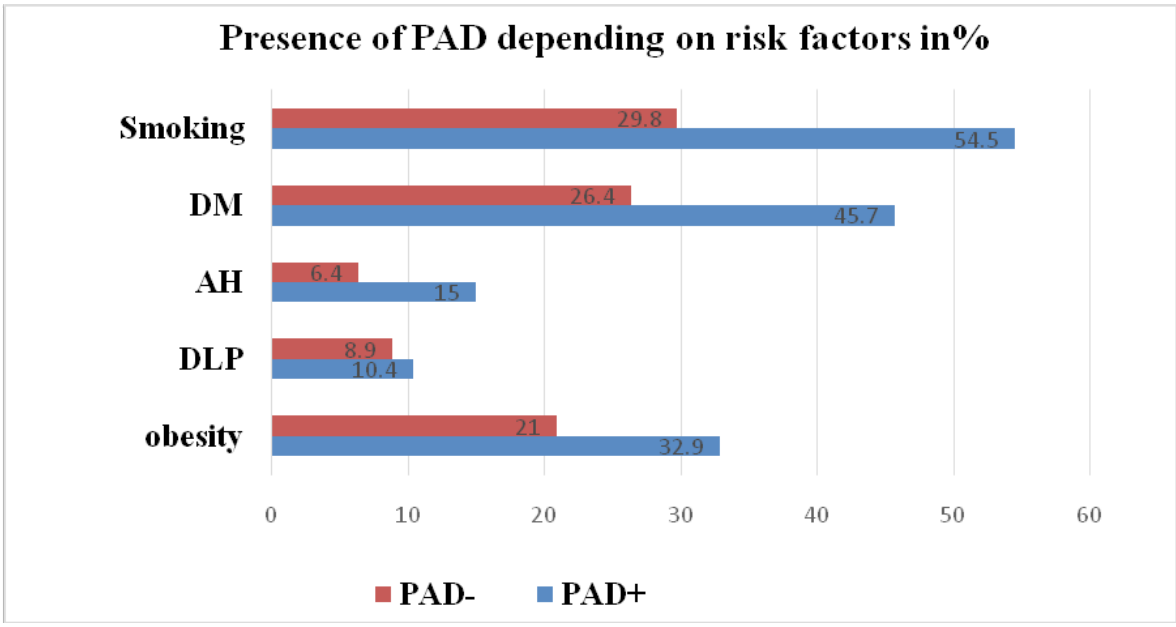

Figure 4. The presence of PAD for various cardiovascular risk factors: obesity, dyslipidemia, arterial hypertension, diabetes mellitus, smoking

Overall, 83.9% of all patients had hypertension. 34.0% of patients with arterial hypertension also had pathological ABI. 82.9% of patients with pathological ABI had arterial hypertension. 4.3% of the subjects were smokers (2.6% of women and 5.3% of men). Significant relationships have been identified between PAD and smoking. 29.8% of patients who never smoked had PAD, compared with 37.7% of former smokers and 54.5% of smokers (43.1%) ($p < 0.05$).

10 (7.6%) of patients under the age of 60 suffered from PAD. 44 (13.7%) patients out of 320 elderly patients had PAD. Over 75 years old, 19 (17.6%) of 108 patients suffered from PAD. Thus, there is a correlation of age with the presence of PAD.

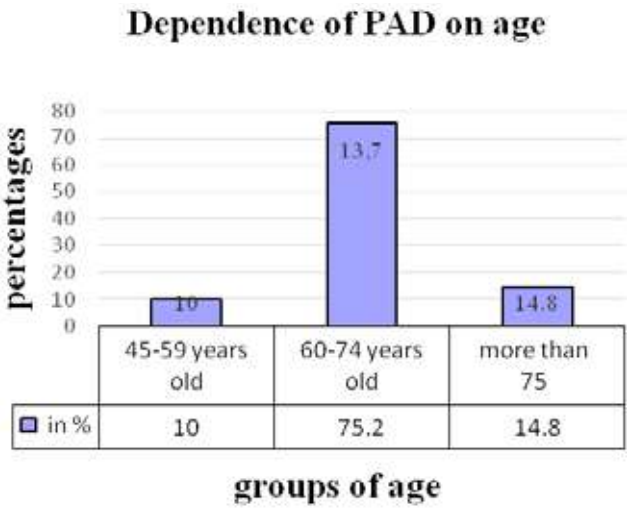

Figure 5. Frequency of PAD depending on age

Table 2: Distribution of the number of risk factors

The number of risk factors	Absolute number	%
0+1	128 (29 + 99)	25,20
2	299	58,86
3	132	25,98
4	18	3,54

Traditional risk factors were analyzed: hyperlipidemia, elderly and senile age, arterial hypertension, smoking and diabetes mellitus. The number of RFs for each patient was calculated. The distribution is shown in table.

Since only 26 patients had one risk factor. 117 patients had 2 RFs, 85 patients had 3 RFs, and 6 patients had 4 RFs. A correlation was found between the number of RFs and the presence of PAD. 11.1% of patients with 1 risk factor or without it had PAD. 50% of patients with two risk factors suffered from PAD. Patients with 3 risk factors had a PAD probability of 36.3%. 2.6% of patients with four risk factors had PAD.

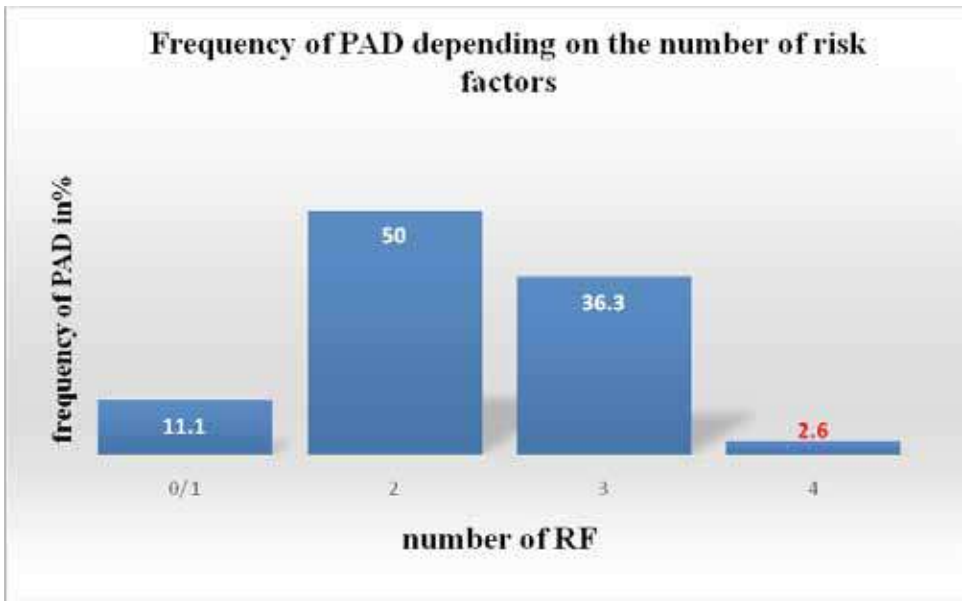

Figure 6. The frequency of PAD depending on the number of RF

Other possible RFs included the presence of first-line relatives with PAD. 13.4% of patients had a hereditary burden.

Among the concomitant diseases of PAD, other diseases of the cardiovascular and cerebral system (MI, IS, TIA) were analyzed. Among patients who had myocardial infarction, 39% had PAD or asymptomatic elevated ABI, compared with 31% of patients who did not have myocardial infarction. 45.1% of patients with PAD had a history of myocardial infarction. 36.4% had MI, in the absence of PAD. In 42.9% of patients with the condition after IS / TIA, PAD was diagnosed, compared with 32.6% of patients without cerebrovascular disease. In patients who complained of angina pectoris, 36.8% of cases had PAD. Significant correlation of selected concomitant diseases with PAD was not observed.

Conclusion

The results can be used in the work of medical expert commissions. The baseline examination should include a medical history, examination, palpation and auscultation, as well as a measurement of the ankle-brachial index.

The necessity of compulsory use of the ankle-brachial index (ABI) for the diagnosis of asymptomatic lesions of the arteries of the lower extremities in a screening examination of the elderly and senile, as well as people with high cardiovascular risk, has been proved.

The developed criteria for the values of the ankle-brachial index make it possible to diagnose lesions in the arteries of the lower extremities and to predict violations in the main arteries of the head and heart

Given the high diagnostic accuracy in assessing arterial disease of the lower extremities, color Doppler mapping of arteries is sufficient for decision-making in the treatment of these patients and may reduce the number of diagnostic angiographies. The method allows to assess the degree of damage, to clarify the topical diagnosis of PAD and to give an objective assessment of the functional state of the limbs, which can be effectively used in planning and monitoring treatment.

Abstract

This article presents topical issues devoted to the study and prospects for the development of enzyme preparations in modern pharmaceutical practice in the Republic of Uzbekistan. In the context of existing resources, the rational use of high-quality, effective, safe medicines and the creation of new ones by combining local raw materials with an innovative approach is a priority. The expediency of combinations of drugs useful for medical practice for effort or combination of effects is noted.

In medicine, nonsteroidal anti-inflammatory drugs (NSAIDs) are commonly used to treat rheumatoid arthritis and other inflammatory diseases. NSAIDs are the basic drugs in the pharmacotherapy of many chronic, acute diseases, normalizing biochemical parameters and the functional state of blood cells. These drugs are taken over-the-counter and for a long time, and therefore resolving issues, related to the safety of their use, the search for a combination is relevant. Currently, domestic developments of NSAIDs (fensulkal, blizketazin) are being carried out by combining enzymes (to enhance the effect) and in justified rectal and transfermal medicinal forms. Many diseases are associated with impaired secondary enzyme deficiency. Clinical studies confirm the high effectiveness of the combination of NSAIDs with enzyme preparations. The classification of proteolytic enzymes, the importance, scale and resources of the prevalence of plant enzymes in the Republic are presented. Of particular interest is the papaya (melon tree). Papain and chymopapain are latex enzymes of the fruits of the melon tree.

Keywords: *NSAID's, enzymes, enzyme preparations, pharmacy.*

Introduction

Currently, the most topical issues of rational use of drugs is the ability to assess the effectiveness, safety and quality, in circulation of medicines throughout their "life cycle": from the development, quality criterion before registration studies, the procedure of examination before going into wide clinical practice and the period of stay in the pharmaceutical market. In the XXI century medicine came with a powerful arsenal of drugs. Global pharmaceutical industry generates tens of thousands of medical products.[1]

The problem of drug provision, rational and safe pharmacotherapy has now become one of the most urgent tasks of the clinicians and pharmacists[2,]. This is due, on the one hand, with the ever increasing market of medicines (drugs) and the volume of scientific information[3], on the other - with the need to determine the most popular groups and classes of drugs.[4]

In the context of existing health care resources rational use of high-quality, efficient, safe medicines and the creation of new combination of using local raw materials with an innovative approach is a priority.

This requires the introduction of optimal evidence-based approaches that receive the greatest benefit and cost-effective to carry out, rational, effective and safe therapy combination drugs. [5]

Quality drugs - the basis of the safe treatment of patients. It is known that safety of drugs characterized by the absence of adverse reactions when it is used, and the efficiency – by the level of pharmacotherapeutic effect achieved by using the minimum dose of the active ingredients.

Adverse drug reactions (ADR) are a major problem of pharmacotherapy. The problem of safety conducted drug therapy involves the collection of information about their occurrence. Information about all the side effects of drugs used for more in-depth study of the causes of severe drug complications and their prevention measures. However, in recent years, along with the improvement of the work on timely notification of any cases ADR, remains unresolved the question of creating the conditions for a more complete account of all of these reactions. According to the International Center for the monitoring of adverse reactions to the WHO (Uppsala, September 2006, the Republic of Uzbekistan entered), it is considered that 2-3% of the general population of people suffering from the side reactions of drugs. [5, 6.]

The development of modern scientific and practical directions allows individualized drug selection, dosing regimens taking into account features.

The possibilities of modern clinical pharmacology study of drugs opens promising directions and have a great future.

These features and method should be actively used in the expert evaluation of the efficacy and safety of drugs. Questions of the rational, and hence effective, quality and safe pharmacotherapy are gone far beyond the medical community; they rightly belong to the most important strategic tasks of the day, a full program of import substitution drugs.

This is the basis of creating and entering the pharmaceutical market in the broad appeal of highly effective drugs.

In medical practice, often use multiple drugs simultaneously. Thus, they can interact with each other by changing the severity and nature of the main effect, its duration (prolongation), and the effort or weaken side and toxic effects.

Combined differences drugs are often used to enhance or combination of effects, i.e., appropriate combinations useful for medical practice.

The pharmacological interaction related by the fact that one substance alters the pharmacokinetics or pharmacodynamics of other component of the mixture. Furthermore, it is possible chemical and physical-chemical interaction of the substances in their joint application. [7]

In medicine, for the treatment of rheumatic, arthritic and other inflammatory diseases are widely used non-steroidal anti-inflammatory drugs (NSAID). NSAID are the basic drugs in the pharmacotherapy of many chronic, acute illnesses, normalize the biochemical parameters and functional status of the blood cells and connective tissue. More than thirty million people worldwide take NSAID on a daily basis, and 40% of patients older than 60 years and about 20% of hospitalized patients. [8]

However, their long-term use in effective doses is often difficult because of the frequent complications. Strategically important question remains to use the well-known and affordable drugs, adjusting the therapeutic dose, dosage form, or by combining with the possibility of obtaining synergy among them, reducing their toxicity, increasing safety and to introduce in the domestic pharmaceutical practice.

In a variety of publications of domestic and foreign scientists pay attention to the fact that 30% of men and 50% of women taking the recipe less form of NSAID and 60% of patients taking the drug without consulting a doctor.

Among NSAID ibuprofen, due to the relatively low toxicity, has been widely used in pediatric and geriatric medicine. Low toxicity of ibuprofen is proportional to its therapeutic efficacy. Relevance of research on the combination of a rectal and transdermal dosage forms is the need to increase the therapeutic efficacy of ibuprofen and its security application. [9]

The feasibility of using enzymes is associated with their ability to enhance, accelerate the therapeutic effect in various diseases in clinical practice. They act as a catalyst for biochemical processes, stimulate metabolism. Many scientists, as well as Uzbeks, devoted their work to the study and introduction of papaya into domestic practice.

Another important representative of proteases (animal or microbial) is serratiopeptidase, which is called the "silkworm enzyme", because it is produced from Serration bacteria found in the intestines of silkworms. Serratiopeptidaseis a proteolytic enzyme for the treatment of inflammation, and reduces the intensity of inflammation due to the hydrolysis of biologically active substances. Widely used in Japan, USA, Germany, Italy.

Thus, it is shown that drugs, which are natural physiologically active protein compounds (enzymes) have gained a worthy place among the means of practical medicine. Actual aspects of marketing research of drugs containing enzymes and presented on the pharmaceutical market of the Republic of Uzbekistan (RUz) have been carried out. The data for 2017, 2018 and 2019 were studied on the market of the Republic of Uzbekistan dominated by drugs containing enzymes of imported production (73%), and especially of animal origin (80%). The data presented in the State Register of Medicines by country (foreign, CIS, domestic) as well as by drug companies and pharmacotherapeutic groups are presented. The main types of dosage forms are coated tablets (53.13%). It is noted that the use of local raw materials containing enzymes with an innovative approach by combining drugs in rational dosage forms of quality control is a government priority in the development of the domestic pharmaceutical industry.

Materials and Method

The search for new classes of chemical compounds that are promising for targeted synthesis of anti-inflammatory, antimicrobial agents will reduce the financial costs of the development of new antimicrobial agents.

In the Uzbek scientific research chemical and pharmaceutical Institute named after A. Sultanov synthesized new biologically active drug-fensulkal, which is a bisulfite derivative of phenylglyoxylic acid, and benzoketazone.

Fensulkal characterized moderate toxicity and has pronounced anti-inflammatory and anti-microbial properties, which in total is very important for pathogenetically oriented treatment of many gynecological diseases. Results patent studies showed that the potassium salt of sodium bisulfite phenylglyoxylic acid derivative is a novel, previously non-synthesized and non-described compound (patent RUz IAP №02245/ 04.10.02). [10]

Today fensulkal used in the form of tablets (0.1g active substance TPA42 Uz- 0663-2003 and ointments (0.5% and 3% PAE 42 Uz-0187-2007).

Also benzketozon (thiosemicarbazone) NSAID recommended for rheumatic diseases (3%) ointment and combined gel.[11]

Currently under operation of the development combining with enzymes and antiallergic means in reasonable rational medicinal forms.

Many diseases (if not most) are associated with a violation of the qualitative and quantitative composition of enzymes in the body, the occurrence of secondary enzyme deficiency. When conducting pharmacotherapy, special attention must be paid to those drugs that have active metabolites formed during biotransformation. There are drugs that are initially inactive, and only as a result of biotransformation from them is active metabolites formed that determine the pharmacodynamic effects (Fig. 1)[12].

Prodrugs and their Active Metabolites: The Role of Cytochrome P-450 Isoenzymes:

Spironolactone	CYP 3A4	Canrenone
Clopidogrel	CYP 2C19	2-oxo clopidogrel
Enalapril	Carboxyesterase	Enalaprilate
Azathioprine	Xanthine oxidase	Mercaptopurine
Primidone	CYP 3A4	Phenobarbital
Tamoxifen	CYP 2D6	Endoxifene
Losartan	CYP 2C9	E-3174

Fig. 1. Examples of prodrugs, active metabolites, which are formed with the participation of biotransformation enzymes.

Results

The most common reason that inflammation does not proceed as necessary for a full and quick recovery is a violation of catabolic processes (destruction) and the release of the focus of inflammation from destroyed tissues, which again is caused by an imbalance in the work of enzymes. If these processes are improved, the damage zone will decrease and will be better prepared for the beginning of the recovery phase of inflammation with high chances of a more favorable outcome.

This fact has led us to the idea of the need to introduce enzymes into the body from the outside by combining drugs.

A lot of importance is the fact that with NSAIDs and antibacterial agents and enzymes (serratiopeptidase) working senergically helps to enhance their positive effects.[12]

Clinical studies confirm the high effectiveness of the combination of antibacterial agents and enzyme preparations in most acute and chronic inflammatory infections. With the simultaneous administration of antibacterial drugs in combination with proteolytic enzymes, the effectiveness of treatment increases, while the side effects of antibacterial agents, as well as the risk of complications, including intestinal dysbiosis, are reduced. Examples are diseases such as sinusitis, bronchitis, cystopyelitis, adnexitis, prostatitis, etc.

In the same way that serratiopeptidase potentiates the action of antibiotics; it potentiates the action of non-steroidal and steroidal anti-inflammatory drugs and therefore is often prescribed in combination with them or as a continuation of treatment after a short course of non-steroidal anti-inflammatory drugs according to all their indications.[13]

The use of enzymes (proteolytic enzymes) in the treatment of various diseases has its own history. Since ancient times, in the treatment of purulent wounds, abscesses and other purulent diseases of soft tissues, they used pumpkin juice, applied the pulp of papaya or green pineapple. Since all these plants contain a large number of enzymes, they contributed to more rapid cleansing and healing of wounds.

Enzymes are substances that are present in the tissues and cells of all living organisms and are able to accelerate the chemical reactions that occur in them many times. Enzymes can be simple proteins, built entirely from polypeptide chains and decomposed by hydrolysis only into amino acids. Simple proteins are hydrolytic enzymes (e.g., proteases, lipases, and ribonuclease) that perform their function in the absence of coenzyme. In most cases, enzymes are complex proteins. Complex proteins (holoenzymes) contain, along with the protein part (apoenzyme), a non-protein component (coenzyme or prosthetic group) (Fig. 2).

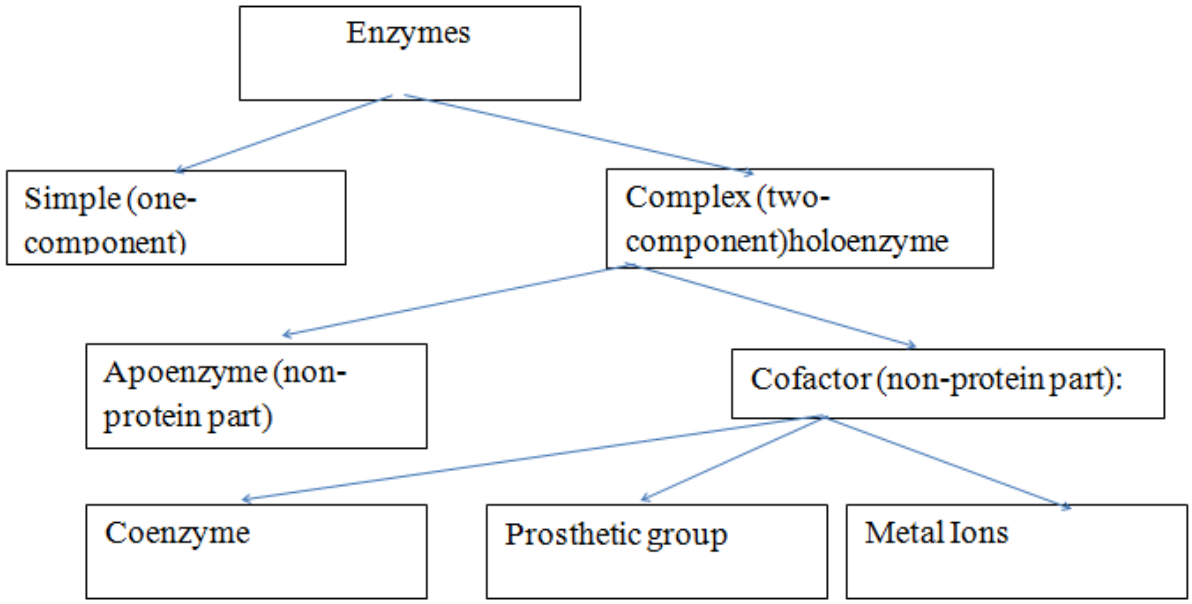

Fig. 2 Nomenclature of enzymes.

A substance whose chemical transformation catalyzes an enzyme is called a substrate.

Classification and nomenclature of enzymes: In 1961, the International Union of Biochemistry and Molecular Biology developed a systematic nomenclature, according to which all enzymes are divided into 6 main classes, depending on the type of catalyzed chemical reaction.

Each enzyme has a common working name, and a systematic one, used to uniquely identify the enzyme.

Working names are formed from combining the name of the substrate, the type of reaction and the end of "-ase". For example: lactate + dehydrogenation + ase = lactate dehydrogenase. The systematic name of the enzyme is formed as follows: name of substrates: name of the type of chemical transformation + ase. The same lactate dehydrogenase will have the systematic name "l-lactate: over + oxidoreductase".

Each of the six classes of enzymes has its own serial number, strictly assigned to it. [14]

In 2009, global sales of enzymes and enzyme preparations amounted to 440 million euros, including enzymes produced using traditional (classic) producer strains of 180 million euros (41% of total sales) homologous to GMM 1-2 safety classes - 132 million euros (30% of total sales). The sales of enzymes from heterologous GMMs of safety class 3 amounted to 128 million euros (29% of total sales in the global food market).[15]

Discussion

The production of enzyme preparations is one of the most large-scale and dynamically developing branches of biotechnology. Large volumes of production and a wide range of enzyme preparations are due to their demand in various industries, medicine, and scientific research.

According to the current classification, about 2,000 enzymes have been identified. The industry produces about 250 types of enzyme preparations. At the same time, about 99% are accounted for by 18 enzyme preparations.[16,17]

Sources of enzyme preparations.

Of all the existing natural sources of enzymes, microorganisms, some plants or individual organs of plants and animals that can accumulate significant amounts of enzymes are of practical interest for large-scale production of enzyme preparations.

Plant raw materials. The source of enzymes can be sprouted cereal grain, which can be used directly as a technical enzyme preparation or feedstock to obtain purified preparations. As a raw material for proteinases use the latex of melon tree and ficus, green juice of pineapple, papain, bromelain, ficin papaya, pineapple, figs.

The technology for the production of enzyme preparations from plant and animal raw materials includes two main stages: collecting enzyme-containing raw materials; isolation and purification of the target product.[18]

Proteolytic enzyme. These enzymes catalyze the hydrolysis of the peptide bond in the molecules of proteins and peptides.

Previously, proteolytic enzymes were classified into proteinases that break down proteins into polypeptides, and peptidases that hydrolyze polypeptides to amino acids. According to modern classification, proteases are divided into endo- and exopeptidases. The former can hydrolyze deep peptide bonds and break down proteins. In turn, endopeptidases, depending on the structure of the active center, are divided into serine, thiol, acid (carboxyl) and metalloproteinases. Exopeptidases can cleave terminal amino acids. In this regard, exopeptidases are divided into:[18,19]

- Aminopeptidases catalyzing the cleavage of N-terminal amino acids;
- Carboxypeptidases catalyzing the cleavage of C-terminal amino acids;
- Dipeptidases exhibiting specificity for dipeptide substrates.

Proteases are widely used in agriculture, food industry, and medicine.

Proteases of technological importance are divided into plant, animal and microbial.

Plant proteases. Papain and chymopapain are latex enzymes of the fruits of the melon tree. They belong to the group of thiol proteinases, activated by reduced glutathione and cysteine.

Ficin and bromelain. The first is obtained from figs, the second - from pineapple juice. These enzymes belong to thiol proteases. Both enzymes have similarities in properties and use with papain. They are also used to remove protein turbidity in beer and to soften meat.

Proteases of animal origin. They have a huge role in digestion processes.

Trypsin is a serine proteinase secreted by the pancreas, which is used as a crude pancreatin in the food industry for the production of hydrolysates.

It hydrolyzes peptide bonds formed by arginine and lysine.Trypsin is secreted by the pancreas as an inactive trypsinogen precursor and is activated by another enzyme.

Chymotrypsin - is secreted by the pancreas into the small intestine in the form of inactive chymotrypsinogen. It is activated by trypsin; wherein two dipeptides are cleaved off.

Hydrolyzes peptide bonds formed by tyrosine, tryptophan, phenylalanine. [20]

Pepsin - is produced by the gastric mucosa in the form of pepsinogen, which turns into active pepsin under the influence of HCl or by cleavage of one peptide bond.

Pepsin is part of the drug, tonic agents, chewing gum.

Microbial proteases. Fungal and bacterial proteases exhibit trypsin-like, pepsin-like, thiol-like, and other actions. There are enzymes with optimum in acidic, neutral and alkaline environments.

The feasibility of using proteolytic enzymes is systematically associated with their ability in clinical practice to enhance, accelerate the therapeutic effect in various diseases, affecting their introduction to the general patterns of their development, inflammation activity in patients with rheumatoid arthritis, ulcerative colitis, etc. Currently, proteolytic enzymes are effectively used to reduce the inflammatory process. [20]

Proteolytic enzymes do not belong to anti-inflammatory drugs of direct action. They act as a catalyst for biochemical processes, triggering or accelerating biochemical reactions in the inflammation zone, where there is a local deficiency of their own proteolytic enzymes, in which the duration of inflammation increases and recovery is delayed. Visher T.L et. al., 1976

Proteolytic enzymes (PE - catalyze the hydrolysis of the peptide bond in the molecules of proteins and peptides) provide reliable relief of inflammation as a result of pronounced fibrinolytic activity and exert an effect through anti-inflammatory, immunomodulating, antiaggregant, fibrinolytic, decongestant, and analgesic effects (Klein G. et al. 1999). .

Depending on the purpose of the application, certain requirements are imposed on the enzyme preparations with respect to the composition of the enzymes, the optimal conditions for their action, the degree of their purification, which is especially important for microbial preparations that require chemical, microbiological and toxicological control, the use of excipients, cost, etc. [14]

The search and implementation in medical practice of new highly effective enzyme preparations of plant origin is of certain interest. [21]

One of the properties of enzyme preparations is the ability to potentiate and facilitate the action of other drugs, as well as reduce their side effects.

The ability of enzymes to increase the concentration of antibacterial agents in the blood, to facilitate their penetration into the tissues and thereby increase the effectiveness of therapy is well known (Koyama A. et al., 1986; Selan L. et al., 1993).

World medicine limits the use of antibiotics. Scientists believe that in the future, antibiotics can be replaced by super-antibodies, for which the cell wall will not be an obstacle, will be able to penetrate into the cells and destroy pathogenic bacteria, viruses and toxins. They are testing antibody modification technology that allows them to freely enter cells and leave them [22, 23.]

In the modern world, much attention is paid to the use of biologically active herbal preparations in medical practice.

A typical representative of plant proteases is papain and chymopapain, and belongs to the group of thiol proteases.

Papain is a monothiol cysteine endoprotease.[16] By the nature of the enzymatic action, it is called “plant pepsin.” But, unlike pepsin, papain is active not only in acidic, but also in neutral and alkaline media (pH range 3–12, optimum pH 5). It retains activity over a wide temperature range. [22]

The papain catalytic center contains a dithioacyl group. [15,]

Papain also has anti-inflammatory properties. Without acting directly on the focus of inflammation, papain stimulates metabolism, which affects the acceleration of the regeneration of inflamed tissues[18]. Papain increases blood flow and destroys toxic substances in the focus of inflammation[24,]. In addition, papain destroys toxins released by many pathogens, participates in the synthesis of arginine[25], an amino acid

that stimulates growth hormone, which in turn is very important for the regeneration of liver cells[26,]. Papain also accelerates the healing of wounds, trophic ulcers and pressure sores. [27]

Exopeptidases having the ability to cleave terminal amino acids have already been indicated that proteolytic enzymes catalyze the hydrolysis of the peptide bond of proteins and peptides.

Papaya breaks down proteins into polypeptides and amino acids, and hydrolyzes any peptide bonds.

The homeland of the melon tree is Central and South America. It is cultivated in all tropical countries of the world as a fruit tree.

Uzbekistan has all the climatic conditions to cultivate a melon tree (papaya), the fruits of which can be used as raw materials for enzyme preparations, and the aerial part for obtaining effective medicines. A lot of works have been devoted to the phytochemical and proteolytic study of papaya growing in Uzbekistan (Aziizov I.K., Rakhimov M.R., Musaeva N.A. 2000) [27]

As a result, the substance and injection drug were approved for medical use in Uzbekistan. (2000)As a result of the study, useful amino acids were identified and the anti-inflammatory effect of the papaya substance was revealed, as well as the anti-inflammatory and immunostimulating activity of the tincture of the aboveground part of the domestic papaya.

The leaves contain free and bound phenolic compounds, tannins, organic acids, steroid and triterpene saponins, flavonoids, lipids, coumarins, glucose, alkaloids used in the treatment of tuberculosis and having choleretic and diuretic properties.

In Peru, papaya leaves are famous as an indispensable tool for healing wounds. Recently, papaya made a sensation in the medical world: Indian scientists have discovered that the cortex of a melon tree contains a substance that is 250 times more effective in inhibiting the growth of cancer cells than the most modern and advanced drugs. Research is underway (bark has never been used in medicine before), if contraindications are not identified, papaya will give the world an effective cure for a terrible disease.[23,24]

Papain is used in medicine: ophthalmology, neurosurgery, neuropathology, gastroenterology, urology.

Properties: It is capable of breaking down proteins of polypeptides and amino acids, acting on any peptide bonds (except for bonds of preline, glutamic acid of a dislocated carboxyl group), breaking down proteins deeper than most enzymes of animal and bacterial origin, and dissolving dead cells.

It has: proteolytic, anti-inflammatory, anticoagulant, dehydration, analgesic, bactericidal, hemolytic properties. Another important representative of proteases (animal or microbial) is serratiopeptidase. Serratiopeptidase is an enzyme for the treatment of inflammation. Serratiopeptidase is a proteolytic enzyme (that is, it is used by the body to break down proteins to amino acids), which is sometimes called the “silkworm enzyme” because it is produced from Serration bacteria found in the intestines of the silkworm. This enzyme is responsible for the splitting of the silkworm cocoon. [28]

One of the most widely used proteolytic enzymes in the treatment of inflammatory diseases in Japan, Germany, Italy, the USA for more than 40 years is serratiopeptidase. It is present in all living systems, but was first discovered in the body of a silkworm, which uses it to dissolve a cocoon when a butterfly appears[20]. Doctors have long appreciated the anti-inflammatory and analgesic properties of this natural substance and have successfully used it as an alternative to anti-inflammatory drugs[28]. Serratiopeptidase has proven itself in the treatment of post-traumatic and postoperative edema, as well as the relief of pain and inflammation in rheumatic diseases (Esch P.M. et al., 1989; Panagariya A. et al., 1999).[29]

Over the years, serratiopeptidase (an enzyme of animal origin) has been shown to be effective in sports injuries, sprains and ruptures of the ligaments, fractures and dislocations, postoperative edema, the risk of transplant rejection, and cavity surgery, not only to improve healing processes, but also to prevent postoperative adhesions, for the treatment of ENT pathology and inflammatory lung diseases - not only with the aim of resolving inflammation as soon as possible, but also giving dynamic properties to the mucociliary system of transport thanks to the action thins mucus. Also, it increases the effectiveness of the treatment of acute inflammatory dermatoses. The drug reduces breast edema and is indispensable for mastitis in breast-feeding thanks to not only high efficiency, but also safety.

Serrata has a direct effect on the pathogenetic mechanisms of these diseases and contributes to their cure due to the fact that:

- Reduces the intensity of inflammation due to the hydrolysis of biologically active substances - inflammatory mediators (bradykinin, histamine, serotonin, etc.), a decrease in the dilatation of capillaries and the regulation of their permeability;
- Working synergistically with non-steroidal anti-inflammatory drugs and antibacterial agents, enhances their positive effect. [15, 29]

The authors of studied the interaction of local and general reactions of the body in patients with traumatic osteomyelitis of the lower jaw of the fermentative drug "Serrata[17]".

It should also be noted that many take with chronic inflammatory pathologies, which means for a long period (key enzyme No. 41 of October 20, 2008. Weekly "Drugstore").[20-23]

However, many studies of this substance were poorly structured and did not include control groups. Further research will shed light on the ability of serratiopeptidases to treat these and other conditions.

A prospective study of the effects of serratiopeptidase (Aniflazim) on postoperative edema and pain was carried out with the participation of three randomized groups of patients. Sixty-six patients participating in this study received surgical treatment due to rupture of the lateral ligament of the knee joint.

In addition to reducing swelling, subjects also noted a decrease in pain.

According to BioMed Research International, for 2017, serratiopeptidase reduces swelling by reducing the amount of fluid in the tissues, thinning it and facilitating outflow. In addition, the enzymatic activity of this drug dissolves the dead tissue surrounding the damaged area, which helps to speed up the healing process.

Serratiopeptidase was noted to be superior to placebo in reducing pain, swelling, and chest tightening. A moderate to noticeable improvement was observed in 85.7% of patients receiving the supplement, while among the placebo group; only 60% of the subjects experienced a similar improvement. A "noticeable" improvement was found in 22.9% of patients receiving treatment, compared with 2.9% of the placebo group.[30]

It helps relieve symptoms of superficial vein thrombophlebitis. [21]

Italian researchers have compared the efficacy of serratiopeptidase and seaprose S in the treatment of inflammatory vein disease. Both treatments have been found to effectively reduce pain and alleviate the symptoms of thrombophlebitis.

In most studies, serratiopeptidase was used in a dosage of 10 to 60 mg. However, additional studies are still required to determine the optimal dose.

Also, judging by the available research data, this enzyme is an effective tool to reduce swelling after surgery and can be an alternative to conservative measures, such as the use of ice.[31, 32]

One of the properties of enzyme preparations is the ability to potentiate and facilitate the action of other drugs, as well as reduce their side effects. The ability of enzymes to increase the concentration of antibacterial agents in the blood, to facilitate their penetration into tissues and thereby increase the effectiveness of therapy. (Koyama A. ct al, 1986, Senan L.et al., 1993)

Most enzyme preparations are available in the form of dragees or tablets in enteric coatings, which protects the enzymes from being released in the stomach and destroyed by hydrochloric acid of gastric juice. The size of most tablets or dragees is 10 mm or more. Nevertheless, it is known that solid particles with a diameter of not more than 2 mm with an optimal size of 1.4 mm can be evacuated from the stomach at the same time as food[21.]

If the tablet or dragee is in the stomach for a long time, the enteric coating is destroyed, and the enzymes inside are inactivated. However, proteoastic enzymes are used in suppositories in gynecology. (Longidase).

Suppositories are also used for the registration of the Ruhr University G. Bohuli, Germany.

Thus, we see that drugs, which are natural physiologically active protein compounds (enzymes, their inhibitors and activators, hormones), have found their rightful place among the means of practical medicine. Unfortunately, the daily clinical use of enzymes is limited by both economic factors - their high cost and low availability, and their rapid inactivation under the conditions of the body, and various adverse reactions caused by or as foreign proteins (antigenicity,

allergenicity, toxicity, etc.). Significant number of these obstacles can be eliminated through the use of enzymes in a stable, immobilized form, especially since the efforts of engineering enzymes today operated by a significant number of method of covalent and non-covalent fixation of enzymes on insoluble and soluble carriers of diverse nature.

Modern medicine is increasingly using highly purified preparations of physiological active substances (PAS) of a protein nature in various fields of clinical medicine as promising drugs for medical treatment due to their extremely high activity and specificity. [33, 34]

We have given relevant aspects of the marketing research of drugs containing enzymes on the pharmaceutical market of the Republic of Uzbekistan. The results obtained indicate the feasibility of further marketing research of the nomenclature of drugs to assess the prospects of creating and introducing new domestic drugs containing enzymes.

A content analysis of drugs containing enzymes presented on the pharmaceutical market of the Republic of Uzbekistan and included in the State Register of Medicines of the Republic of Uzbekistan was carried out.

In the process of conducting a content analysis, as an object of study, we studied the data on the registration of drugs of enzyme origin based on the materials of the "State Register of Medicines and Medical Devices" for the period 2017, 2018 through the first half of 2019, and a list of essential drugs.[36, 37]

Content analysis is a formalized method for studying textual graphic information, which consists in translating the studied information into quantitative indicators and its static processing. In our studies, we developed and used a scheme for conducting content analysis.[35]

Currently, 63 trade names of pharmaceutical preparations containing enzymes are registered in the Republic of Uzbekistan, taking into account various forms, dosages and packaging. The pharmaceutical market of the Republic of Uzbekistan is mainly dominated by drugs containing imported enzymes (73%).

In accordance with the State Register of Medicines, we conducted an analysis of the nomenclature of drugs containing enzymes of origin. Currently, enzymes of animal origin prevail (80%), (tab. 1).

Also, all drugs containing enzymes can be divided into pharmacotherapeutic groups: proteolytic agents (for external and internal use), digestive enzyme preparations, immunomodulating agents, enzyme preparations (systemic effects), multivitamin preparations and other drugs. The largest number of trade names of drugs containing enzymes is noted in the pharmacotherapeutic group "enzyme preparations" (54.5%), Fig. 3.

Table 1. Analysis nomenclature medicaments containing enzymes origin.

№	By origin	2017 y.		2018 y.		2019 y.	
		Amount	%	Amount	%	Amount	%
1.	Plant	5	7.94%	7	10.94%	8	12.12%
3.	Microbial synthesis	5	7.94%	6	9.37%	6	9.09%
2.	Animal	53	84.12%	51	79.69%	52	78.78%

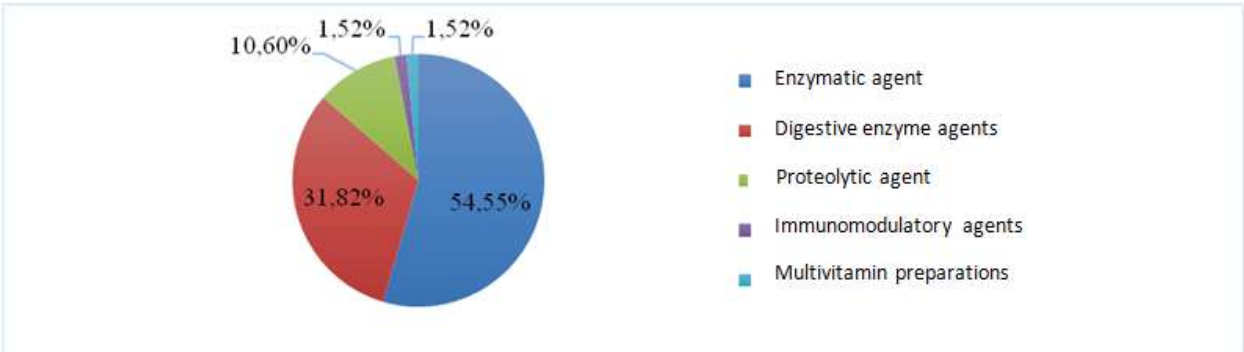

Figure 3. Distribution of trade names of drugs containing enzymes by pharmacotherapeutic groups.

A content analysis of enzyme drugs by type of dosage form was also carried out.

In the course of the analysis of the market for drugs containing enzymes, it was found that the main form of the dosage form for this group are coated tablets (53.13%).It can be concluded that a structured content analysis of enzyme drugs was carried out by comparing quantitative and qualitative characteristics according to the criteria: pharmacotherapeutic group, origin of the assortment of non-CIS countries, CIS countries and the Republic of Uzbekistan.

A relatively large number of enzyme preparations of foreign production were identified (73%), of which drugs imported from the CIS countries (24%), from foreign countries (49%), and domestic (25%) and (27%) for the period 2017- 2019, which suggests the relevance of replacing imported drugs with drugs of local origin obtained on the basis of substances of local raw materials. Moreover, Uzbekistan is rich in raw materials for the production of enzymes of plant and animal origin. Also relevant is the issue of obtaining drugs using local raw materials with an innovative approach, combining PAS to improve absorption and obtain a synergistic effect and reasonable selection of a rational dosage form.

Conclusion

The issue of strategic importance remains the use of well-known and affordable drugs in various combinations in various dosage forms, taking into account the possibility of obtaining the synergistic effect of their action, thereby reducing toxicity, increasing safety and introducing them into domestic pharmaceutical practice.

Moreover, the main emphasis is on those types of products, the introduction of which into production does not require large expenditures, time and money, and will reduce future consumption in their imports. The use of local raw materials with an innovative approach by combining drugs in rational dosage forms of quality control, standardization is an urgent and priority task of the government in the development of the domestic pharmaceutical industry.

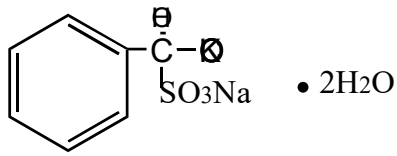
Abstract

According to the World Health Organization (WHO), non-steroidal anti-inflammatory drugs (NSAIDs) are effective in treating pathologies accompanied by inflammatory and painful processes of various etiologies. More than thirty million people in the world receive NSAIDs daily, with 40% of these patients over 60 years of age, and about 20% of inpatients.



The development vector of pharmaceutical industry in the years of independence is aimed at developing and introducing import substitution drugs produced in our country.

Keywords: *Fensulkal, method, determination, chromatography.*

Introduction

In the Republic of Uzbekistan, special attention is paid to the development of pharmaceutical industry and providing the population with domestically produced products. In this regard, expanding the range of antimicrobial and anti-inflammatory drugs, using domestic resources, is a priority in the development of science and technology in the direction of modernization of production and technology to introduce domestic developments of drugs and medical products. A number of government resolutions are aimed at supporting domestic manufacturers producing pharmaceuticals, so in the production of domestic medicines equally, preference is given to drugs developed from raw materials of plant and synthetic origin. As well as standardization and quality control of medicinal products plays a crucial role in providing the population with effective and safe medicines[1].

The Uzbek Scientific Research Institute of Chemistry and Pharmaceutics named after A. Sultanov synthesized a new biologically active drug - fensulkal, which is a bisulphite derivative of phenyl glyoxylic acid. The results of patent studies have shown that potassium salt of sodium bisulphite derivative of phenyl glyoxylic acid (fensulkal) is a new, previously not synthesized and not described compound [7].

The substance is characterized by moderate toxicity and has strong anti-inflammatory and antimicrobial properties, which together is very important for pathogenetic treatment of many gynecological diseases[2]. Scientists of Tashkent Pharmaceutical Institute together with the above mentioned institute are working on creation of pharmaceutical forms and development of effective method of analysis[3].

Standardization and quality control of medicinal products plays an important role in providing the population with effective and safe medicines[4]. Nevertheless, along with the search for new medicinal products it is necessary to solve the issues of

development of method for their analysis[5],. Fensulkal in substances is quantitatively determined by several method such as chromatography spectrophotometry, spectrophotometry, HPLC[6]. Comparative analysis of the method for quantitative analysis of fensulkal in a substance is relevant as a result of the selection of a more valid one for the purpose of introducing into the quantitative analysis method the first time combined preparations containing this PAI (pharmaceutical active ingredient) are obtained[7].

Research Objective: Comparative analysis of the spectrophotometric, chromato-spectrophotometric and high-performance liquid chromatography (HPLC) method for quantitative determination of fensulkal in PAI.

The research subjects were samples of production batches of fensulkal (PS 42 Uz-0185 - 2017).

"Silufol UV-254" (Czech Republic) plates were used for thin layer chromatography (TCH) and chromatography spectrophotometric method. Various organic solvents were used as a mobile phase (MP): chloroform, acetone, ethyl acetate, hexane, etc. in different variations and ratios [5,6,7]. In work they used liquid chromatograph "Agilent Technologies 1100 series" with software "Chemstation A.09.0" with four-channel gradient pump, degasser and spectrophotometric detector. Acetonitrile, methanol as well as 1% acetic acid solution and buffer solutions with different pH values were used as organic solvents. The optical density of the investigated solution (0.001% fensulkal solution) was measured at a layer thickness of 10 mm in the range of wavelengths from 200 to 400 nm relative to the working standard (WS) of fensulkal. Purified water was used as a comparison solution. The quantification of the active substance was calculated using a formula:

$$X(\%) = \frac{D_1 * C * V_p^1 * V_p^2 * 100}{D_0 * a * V_{ali}^1} \quad (1)$$

Where, D_1 - the value of optical density of fensulkal in the test solution; D_0 - the value of optical density of working sample (WS) of fensulkal; C- the concentration of the preparation in 1 ml of standard solution g/ml; a- the quantity of the test substance; $V_p^1 * V_p^2$ – the volumes of dilution of the quantity; V^l_{ali} - the volume of aliquot part.

The aqueous solution of fensulkal has a maximum absorption at a wavelength of 252±2nm. The spectrum of absorption of fensulkal is shown in Fig. 1,2.

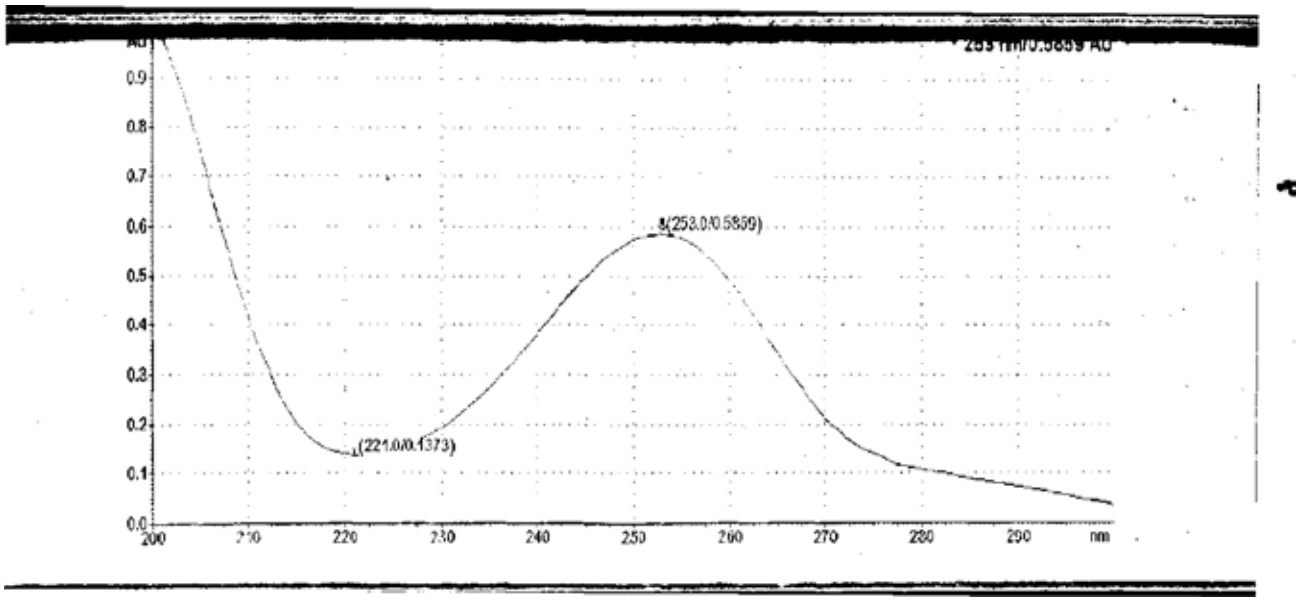


Fig. 1. UV spectrum of WS fensulkal

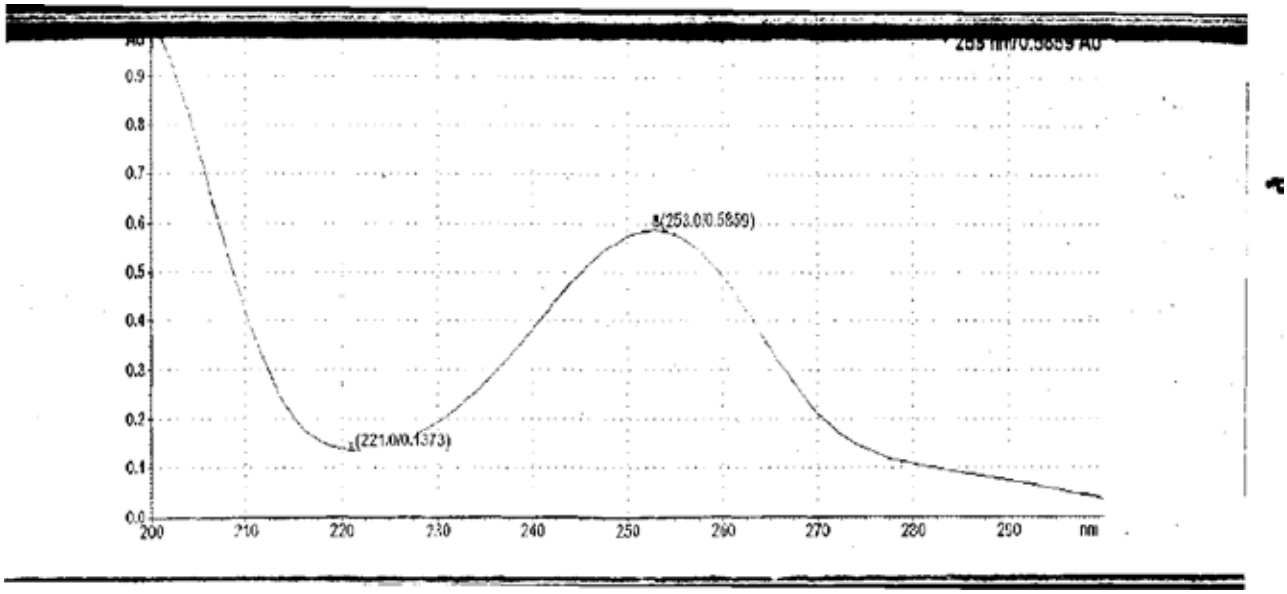

Fig. 2. UV spectrum of the test sample of fensulkal

The received data of quantitative determination of fensulkal in PAI by spectrophotometric method are given in Table 1.

Table 1: Results of the analysis of the quantitative determination of fensulkal in PAI by UV spectrophotometry

No.	Quantity of fensulkal, gr	X, %	Metrological properties
Fensulkal			
1	0,0250	98,90	X_{av}= 99,0 f =4; t(P;f)=2,78; S^2=0,078; S=0,837; ΔX_{cp}= 0,99; ε_{av}= 0,9%
2	0,0249	98,95	
3	0,0249	98,95	
4	0,0250	99,10	
5	0,0251	99,10	

Table 1 shows that the relative error of the method was 0.9%, which also confirms the accuracy of the results obtained within the method.

For the chromatography spectrophotometric determination of 0.2 g of fensulkal was placed in a measuring flask with a capacity of 100 ml and diluted with water to the mark. Then a 0.05 ml water solution of the test sample was applied to the starting line of the "Silufol-UV_{254}"chromatographic plate using a calibration capillary. At the same time, a standard sample of 0.01 ml of witness substance containing 1.0 mg of fensulkal was chromatographed. The plate was chromatographed and after the mobile phase reached the front line, the plate was dried at room temperature. The adsorption zones were detected in UV-light at λ = 254 nm. For quantitative determination of the localization zone, the adsorption zones were eluated, transferred to a paper filter and 100 ml of fensulkal was washed with purified water. Optical density of the obtained eluates was measured on spectrophotometer "Agilent 8453E" at 252 nm. The quantitative content of fensulkal was calculated using the following formula 1.

Preparation of WS solution of fensulkal: About 0.025 g (precise quantity) of fensulkal (VFS 42 Uz-0185-2007) is placed in a measuring flask with a capacity of 50 ml, add 20 ml of a mixture of purified water with methanol, shake to dissolution, bring the volume of the solution to the mark and stir. Place 1 ml of the resulting solution in a measuring flask with a capacity of 50 ml and bring the volume of solution with purified water to the mark. The solution is used freshly prepared. The resulting solutions are filtered through

a filter "Millipor" with a pore size of 0.45 µm. 20 µl of the obtained solutions are injected into the injector of the chromatograph and analyzed under the above conditions, receiving at least 5 chromatograms. The content of fensulkal, in % is calculated by formula (2):

$$\tilde{O}(\%) = \frac{S_1 * a_0 * 2 * P}{S_0 * \grave{a}_1} \quad (2)$$

Where, S_1 - the area of peak fensulkal on a chromatogram of a test solution; S_0- the area of peak fensulkal on a chromatogram WS of fensulkal; a_0– quantity of WS Fensulkal, gr; P – Fensulkal content in WS, %.Content of $C_8H_{10}O_8SNaK$ (fensulkal) should be not less than 98,5 %. The obtained results are presented in Table 2.

Table 2: Results of quantitative determination of fensulkal by chromatography spectrophotometric method

No.	Quantity of Fensulkal, gr	$X_{\%}$	Metrological properties
1	0,2001	98,7	X_{av} = 99,16%; f = 4; t(P;f) = 2,78; S^2 = 0,31; S = 0,51; ΔX_{av} = 0,69; ε_{av} = 1,9%
2	0,2000	99,0	
3	0,2004	99,2	
4	0,2000	99,3	
5	0,2001	99,6	

The data presented in Table 2 confirm the accuracy ($\varepsilon_{average}$=1.9%) of the results obtained and the reproducibility of the developed method for determination of the quantitative content of fensulkal.

HPLC analysis was performed on a liquid chromatograph by "Agilent Technologies" with a column 150 mm long, 3.0 mm in diameter, filled with Zorbax Eclipse XDB C-18 sorbent with a particle size of 5 µm, equipped with a UV detector with a variable wavelength (254 nm) and an isocratic pump. The data were processed using the "ChemStation" software. The relative standard deviation of the peak areas of the received chromatograms should not exceed 2.0% (Fig.3).

As a mobile phase several systems of organic solvents in different ratios were used.

In terms of retention time and symmetry of peaks we have chosen the following conditions for chromatography:

- 150x3.0 mm analytical column filled with Zorbax Eslipse XDBC18 sorbent with 3.5 µm particle size;
- Column temperature - indoor;
- Detection - 254 nm;
- Mobile phase degassed and filtered mixture of methanol and water in ratio (25:75);
- Injector loop volume - 20 µl;
- Flow rate - 0.6 ml/min.

The Fensulkal separation factor (K`) was 0.86, the number of theoretical plates was more than 2250 and the asymmetry factor did not exceed 1.1. The results of the quantitative determination are presented in Table 3.

Table 3: Results of the quantitative determination of fensulkal by HPLC method

No.	Quantity of Fensulkal, gr	$X_{\%}$	Metrological properties
1	0,0510	98,1	X_{av} = 99,08%; f = 4; t(P;f) = 2,78; S^2 = 0,42; S = 0,64; ΔX_{av} = 0,8; ε_{av} = 1,5%
2	0,0509	99,2	
3	0,0520	99,0	
4	0,0510	99,8	
5	0,0501	99,3	

The data presented in Table 3 confirm the accuracy (ε_{av}=1.5%) of the results obtained and the reproducibility of the developed method for determination of the quantitative content of fensulkal.

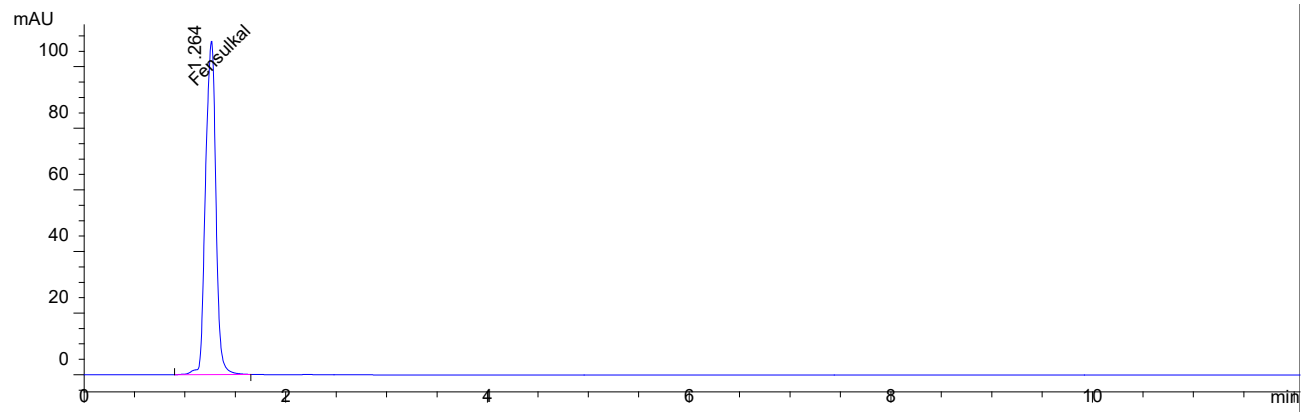

Fig. 3. Chromatogram of WS fensulkal

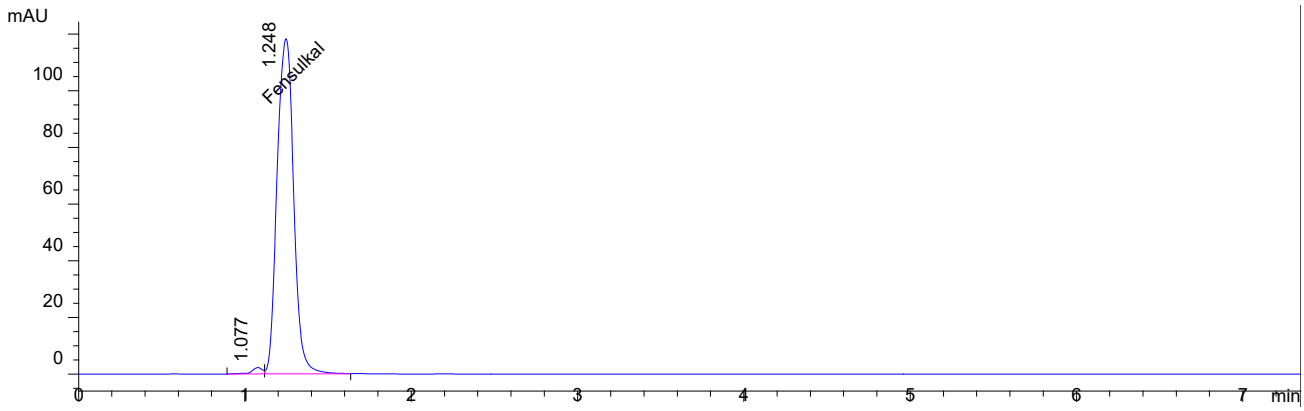

Fig. 4. Chromatogram of the test sample of fensulkal

From the above chromatograms (Fig. 3,4) we can see that at column temperature 20^0C the retention time of fensulkal is 1.248 min. The results of quantitative determination are presented in Table 3.

Since the HPLC method of determining the quantitative content of fensulkal is accurate enough to validate this method on several indicators.

Linearity was assessed by the response of the analytical instrumentation, and model solutions of different concentrations were prepared, corresponding to a range from 25% to 100% of the range specified in the respective technique. These solutions were analyzed on the "Agilent Technologies" liquid chromatograph under the conditions specified above. The results obtained indicate that the best range of linearity is observed in the range of concentrations of the preparation from 0.001 mg/ml to 0.3 mg/ml (Table 4, Fig. 5).

Table 4: Dependence of areas of chromatographic peaks on solution concentration (Linearity)

Solution concentration, mg/ml	Chromatographic peaks area
0,001	51,27
0,10	3649,44
0,15	7350,09
0,20	11039,68
0,30	14765,40
Correlation coefficient	0.999422
Standard deviation	1315.841881
Linear Angular Coefficient	7.01688E-06

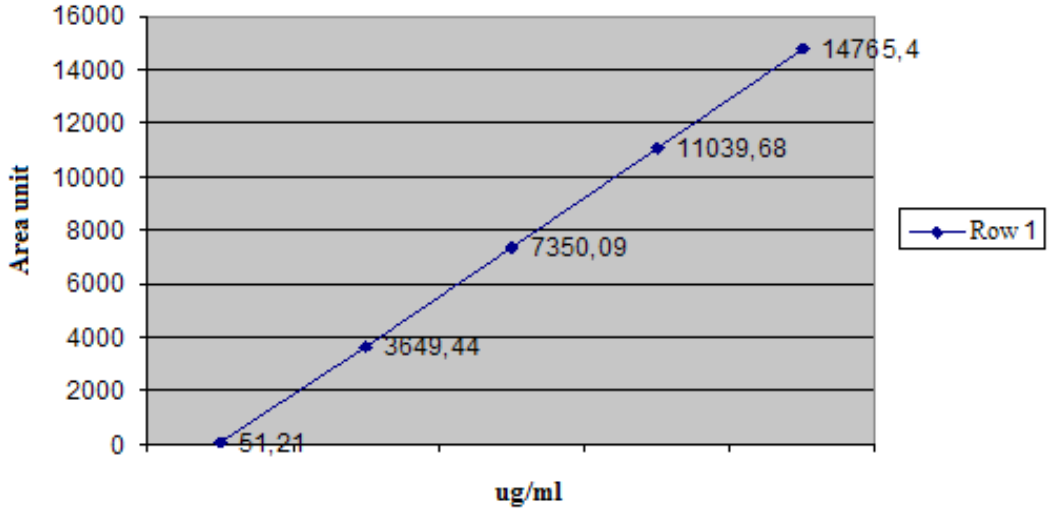

Fig. 5. Fensulkal Linearity Graph

Correctness of the technique was determined by three times determination of 7 analytical concentrations of the substance under study (Table 5). The quantitative content of fensulkal was calculated by the above formula.

Table 5: Evaluation of the correctness of the developed HPLC methodology of the fensulkal

Number of active component from declared, %	Quantity of fensulkal, gr	Found, gr	Regeneration, %
70	0,0350	0,0348	99,4
80	0,0401	0,0398	99,2
90	0,0451	0,0446	98,8
100	0,0502	0,0497	99,0
110	0,0551	0,0547	99,2
120	0,0601	0,0595	99,0
130	0,0650	0,0647	99,5
Average regeneration rate			99,15

From the results in the table we can see that the average regeneration rate is 99.15%, which indicates the correctness of the technique. So, we have developed a new method of separation, detection and determination of the quantitative content of the substance fensulkal by HPLC. The validation of the technique has been carried out; such parameters as sensitivity, linearity, accuracy, reproducibility, selectivity and correctness have been established.

Similarity (e.g. the same spectrophotometer, the same laboratory assistant, the same day, identical reagents) was shown by analyzing 6 prepared samples at 100% concentration of the pharmaceutical substance in the solution under study. The results were evaluated and calculated by calculating the mean value, standard deviation, coefficient of variation and confidence interval. The number of tests required for routine control of each sample was established in the specification depending on a certain coefficient of variation and boundaries of the norm. With the help of intermediate precision it was shown that the analytical technique ensures the obtaining of consistent results regardless of changes in external circumstances provided the homogeneity of the sample under study. All conditions for the laboratory have been taken into account in the validation process. Typical variables were variability, staff, day of analysis and instrument.

Conclusion

Method have been developed to control the quality of fensulkal in substances using UV-, chromatography spectrophotometric, and HPLC method of analysis, the

relative error of which was 0.9 percent for the UV-, chromatography spectrophotometric method; 1.9 percent for the chromatography method; and 1.5 percent for the HPLC method. The developed method are included in the pharmacopoeia article of fensulkal and can be used for quality control not only of fensulkal in PAI, but also in medicinal forms with its content.

Abstract

Hypertension is a disease whose main symptom is an increase in blood pressure due to neuro-functional disorders of vascular tone. Hypertension affects men and women equally. The disease usually begins after the age of 40. This is a very common pathology. It is called the disease of the fall of life, although in recent decades hypertension has become much younger.

Capsule,substance, extract, calcium Hypertension is one of the causes of disability and mortality in patients with disorders of the cardiovascular system.

One of the causes of hypertension is prolonged and frequent neuropsychological stress, prolonged stress. Hypertension very often occurs in people whose work is associated with constant emotional stress. People who have suffered a concussion often suffer from it.

The paper presents the results of the development of the optimal composition and hard gelatin capsules based on the dry extract of Jujube fruit - Ziziphusjujuba (jujube, jilanjija). The formulation and technology of the single - source pharmaceutical product in the form of capsules "Yuyuzin" with antihypotensive activity was developed. As excipients used MCC, Aerosil, calcium stearate.

Keywords: *Technology, excipients, substance, capsule, antihypotensive activity.*

Introduction

More than 1 billion people on earth suffer from arterial hypertension (AH). AH remains the most common disease of the cardiovascular system in many countries. It has been diagnosed in 30% of adult population in developed countries, and it has reached 44% among men of working age, and it has reached 55-60% among people over 60 years of age. AH is the most common reason for medical appointment and administration of medications [1].

AH is also a leading cause of cardiovascular morbidity and mortality. It has been established that the risk of Myocardial Infarction increases with an increase in blood pressure (BP). Acute cerebrovascular accident In 95% of cases, 94% of Myocardial Infarction in women and 75% in men occur against the background of hypertension. Studies show that about 75% of elderly patients with heart failure have a background of AH. It is also the most common cause of atrial fibrillation, which occurs among other permanent forms of arrhythmias. In general, the incidence of hypertension in patients with cardiovascular pathology is 96%, and only 4% of patients do not have this background disease[2].

One of the most important tasks of modern pharmaceutical technology is the development of dosage forms boosting to enhance the bioavailability of drugs and reduce side effects. This is achieved in various ways, among which the usage of special excipients

and technological method can be distinguished. Of the greatest interest from oral dosage forms are capsules, due to a number of advantages and positive characteristics: accuracy and uniformity of dosage, corrective ability, high bioavailability, stability, aesthetics.

Currently, much attention is paid to the search for new antihypotensive medications based on local drug raw materials. One of such unique plants growing in Uzbekistan is Jujube - *Ziziphinsjujube* (jujube, jilanjija). Jujube fruits have been used as a hypotensive agent in traditional medicine [3]. The technology for obtaining a dry extract of Jujube fruits, based on Jujube fruits with a hypotensive effect, was developed at UzKFITI[4].

Objective: Formulation development and technology of the single - source pharmaceutical product in the form of capsules "Yuyuzin"

As you know, the technology of solid dosage forms of herbal preparations has its own characteristics, associated with the physicochemical properties of the starting substances, which must be taken into account when choosing excipients when establishing the regime of production operations.

The initial stage in the development of the technology for producing solid dosage forms of drugs is the study of the structural, mechanical and technological properties of active substances, depending on which the pressed material can behave differently. According to the indicators of the technological properties of the substance, it is possible to predict the types and quantities of necessary auxiliary substances, as well as the progress of the process [5].

The Jujube fruits substance we have been studying is a product of plant origin, which has a variety of physical and mechanical properties and absorbability. Absorbability plays an important role in the technology of solid dosage forms (TDLF) containing plant extract It affects the technological properties of the substance, such as fluidity, bulk, compressibility, elasticity, viscosity, ductility, which determine a number of technological parameters, such as the rate of granules formation, pressure, speed of pressing.

Our studies showed that the substance has non-positive technological parameters (Table 1).

In order to scientifically substantiate the type and amount of excipients introduced into the capsule composition and the optimal encapsulation method, the physicochemical and technological properties of the dry extract of Jujube fruits have been studied according to the method described in the literature. The results of the experiments are presented in table 1.

Table 1: The results of the study of the technological properties of dry extract of Jujube fruits

№	Test characteristic	UM	Results
1	**Grain particle size**	μm,%	
	+500		0.4
	-500 +300		5.8
	-300 +200		37.4
	-200 +150		49.3
	-150 +100		6.3
	-100		0.8
2	Friability	μm,%	no
3	Angle of repose	degree	42
4	Bulk volume	g / ml	0.66
5	Residual humidity	%	5

As can be seen from table 1, the examined dry extract as a whole does not have satisfactory technological characteristics for the production of encapsulated dosage forms, which requires the introduction of excipients into the capsule composition.

It is necessary to choose an optimal particle size distribution for the development of a dosage form of the drug in the form of capsules.

Analysis of the dry extract showed that it contains about 5% moisture, i.e. dry Jujube fruit extract is a hygroscopic substance.

Preliminary pharmacological studies to determine the specific hypotensive activity of the dry extract of Jujube fruits showed that the optimal single dose is 0.35 g.

As a result of studying the properties of the dry extract, it was found that it is a brown powder with sweet astringent taste and distinct smell.

The following are the results of the development of the technology for producing an encapsulated dosage form of the dry extract of Jujube fruits. In addition to pharmacologically active substance, auxiliary ingredients that must be biologically indifferent are introduced into the composition of the mass for filling capsules in order to give it necessary technological characteristics, as well as to set, if necessary, biopharmaceutical properties[6].

Considering the above factors, various excipients has been used to obtain the capsules of the Yuyuzin preparation. Fillers or diluents are most often used. They give the mixture for filling capsules the necessary optimal volume. For these purposes, in the manufacture of medicine in the form of hard capsules, milk sugar, microcrystalline cellulose (MCC), dibasic calcium phosphate, crospovidone and other substances are used that allow to adjust bulk density and give the filler necessary flowability, and MCC, in addition, allows to slow down the absorption process, which is important for the prolonged action of the drug. Tamped powders break up 2 times longer than freely filled ones, but the difference becomes insignificant with the introduction of disintegrants. Aerosil, talc, calcium carbonate are used In this quality. Calcium or magnesium stearate, etc. are commonly used to impart friability. MCC, aerosil-200, potato starch, lactose anhydride, crospovidone, calcium stearate in various proportions were tested as auxiliary substances.

Subsequently, each batch was individually moistened with 96% ethanol, 2%, 5%, starch paste, MC gel, Na-CMC, MCC, Aerosil, starch, lactose, crospovidone, calcium stearate to form the optimal wet substance. The data are shown in table 2.[7]

As can be seen from table 2, we tested MCC, aerosil, lactose anhydride, crospovidone, calcium stearate in various ratios as auxiliary substances. Based on the results, the capsule mass had been prepared in 8 different formulations and the influence of excipients on the technological properties of the substance was determined (table 3).

Table 2: The composition of the components of the capsules Yuyuzin

Composition, g	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**

Residual humidity %	5	3.5	4.8	5.5	3.1	4.5	5	4.1

The analysis of the physicochemical properties of the capsules was carried out in accordance with the requirements of National Pharmacopeia, vol. XI. The results of the analysis showed that of the 8 investigated compounds, the most satisfactory results were obtained for compounds 2 and 5. However, taking into account the presence of the production of excipients in the Republic of Uzbekistan, composition 5 has been selected as the most suitable in the future for organizing the production of Yuyuzin capsules.

To obtain Yuyuzin capsules of 0.35 g each, to 37.2 g of the crushed dry extract of Jujube fruit, 9.0 g of MCC, 0.53 g of calcium stearate, 1.06 g of Aerosil are added and the mixture passes through a sieve with a hole size of 0.25 mm. Then the resulting mass in the amount of 47.7 g is moistened with 10 ml of 96% ethyl alcohol and repassed through a sieve with a hole size of 0.63 mm. The obtained granules are dried at a temperature of 45 + 5 ° C for 30-45 min to the optimal residual humidity.

The dried mass in the amount of 45.1 g is sieved through a sieve and the finished granules are transferred to the stage of filling capsules. 0.45 g "0" gelatin capsules are filled on a capsule filling machine from Pharma-ChemIndustris (India). 100 pcs capsules received.

The resulting Yuyuzin capsules of 0.45 g are packed in 30 or 60 pcs in bottle.

Adaptive Capabilities of Underweight Newborns and Development Features in their First Year of Life

Kh. Akramova[1], A. Djalilov[2]

[1]PhD, Teaching Assistant, Department of Hospital Pediatrics No.1 on the Basis of Alternative Medicine, Tashkent Pediatric Medical Institute, 223 Bogishamol Str., Yunusabad District, Tashkent, Uzbekistan, [2]PhD, Docent, Vice-rector for Medical Care, Tashkent Pediatric Medical Institute, 223 Bogishamol Str., Yunusabad District, Tashkent, Uzbekistan

Abstract

Introduction: The issue of caring underweight infants is vital today because of the relatively high mortality rate. The perinatal death in full-term babies born with low birth weight is 3–8 times higher than in children with normal weight and takes the second place in the structure of perinatal mortality after prematurity. Moreover, the lack of a well-established concept for the management of such children in the first year of life in the literature, make us to conduct additional studies in this sphere. In order to evaluate the adaptive capabilities of children and monitor their physical development, growth curves and development of children checked according to WHO standards.

Method: 281 newborns and 272 mothers were examined. Newborns were divided into 2 groups: group 1-83 premature infants with low body weight; group 2-103 full-term newborns with low body weight. The control group consisted of 95 full-term newborns. Quantitative determination of human placental growth factor (PlGF) was performed based on the enzyme-linked immunosorbent assay. Correlation analysis and statistical processing of the gained data were calculated on MS Excel - XP software and statistical analysis of the results was carried out using method of variation statistics.

Results. 83 mothers had babies born prematurely with low body weight relative to gestational age (group 1); in 102 mothers - full-term, but with low body weight (group 2). The control group consisted of 87 women whose newborns were born on time (38.4 ± 6.3 weeks) and body weight corresponded to gestational age. A high risk of birth with low body weight in pregnant women was observed with signs of fetal growth retardation by ultrasound examination (OR = 11.58), with anemia (OR = 8.17), other malnutrition (OR = 5.75), placental insufficiency (OR = 5.46). Signs of perinatal cerebral hypoxic-ischemia of the 2nd degree were noted in groups 1 and 2, respectively, in 73.5% and 66.0% of children.

Conclusion: Pregnant women who have proteinuria and preeclampsia are 3 times more likely to have babies with low body weight compared to pregnant women with normal renal function and blood pressure. Underweight preterm infants are born in severe asphyxia, with a severe degree of RDS, severe disorders of the central nervous system; they require primary resuscitation measures more often, longer antibacterial therapy.

Keywords: *Premature infants, intrauterine growth retardation, adaptation, neurological disorders, placental growth factor, neurospecific protein S100b.*

Introduction

According to the World Health Organization (WHO), the problem of nursing for underweight babies is still actual due to the relatively high mortality rate. Out of 2.7 million dead newborns, 60-80% are premature and/or low birth weight infants (United Nations, 2015; and UNICEF, 2014)[11]. The perinatal mortality of full-term babies who born with low birth weight is 3–8

times higher than in children with normal weight and takes the second place in the structure of perinatal losses after prematurity (Galinsky et al, 2018; and Plomgaard et al, 2017)[7,10]. Premature babies die 30-35 times more often than babies born on time, and perinatal mortality in premature pregnancies is 30-40 times higher than in urgent births. Among children born with low body weight, the proportion of healthy ones do not exceed 10-25%, and the percentage of severe neurological abnormalities (childhood disabilities - cerebral palsy, blindness, deafness, mental retardation) varies from 12 to 32%. In 32.5% of children born with low weight, deviations in physical development persist even by the age of 1 year (Barkun et al, 2013;)[2].

Conflicting thoughts are available in the literature for infants born with low birth weight. Some authors claim a decrease in the number of children with disabilities, while others say that the number of children in this category is not decreasing today (Kometova et al, 2017; Pisani & Spagnoli, 2016; and Wojtczak-Soska & Lelonek, 2010)[9]. In this regard, the problem of studying the clinical and biochemical characteristics of the adaptation of underweight newborns and the optimization of the tactics of medical care for this category of children is extremely important and represents both scientific and practical significance (Lebedeva et al, 2015; and Wojtczak-Soska & Lelonek, 2010)[4,14].

The current approaches to assessing the severity of a condition are based on a diagnosis, risk factors for the therapy used, and changes in the physiological functions of the newborn's organism[1]. However, the true condition of the patient is determined only by the last of the listed factors. This is the reason for the active search for new markers that have diagnostic and prognostic value in the development of the pathological process (Akramova,; and Variane et al, 2017)[2,13].

In this regard, recently special attention has been paid to the determination of neurospecific proteins, neurotrophic and growth factors in the blood serum of newborns from the first days of life[5]. Significant changes in the levels of the above factors in blood serum can be detected much earlier than structural disorders that can be detected by modern method of neuroimaging (Breatnach et al, 2016; Laptook, 2016; and UNICEF, 2014)[6,12].

The lack of a unified concept for the management of such children in the first year of life, necessitate additional studies in this area aimed at optimizing the care of children born with low body weight and reducing the incidence and mortality of children in this category (Akhmedova, 2016).[3]

The aim of our study was to evaluate the prognostic significance of anamnestic factors and biochemical markers in the birth of underweight newborns, as well as to establish the features of their development in the first year of life (Laptook, 2016)[8].

Material and Method

Study Population: Taking into account the goals and objectives of the study, the research was carried out in the City Perinatal Center of Tashkent, Republican Specialized Scientific-Practical Medical Centre of Pediatrics, and the family polyclinics of 44, 45, 46, 47 in Tashkent. Overall, 281 newborns and 272 mothers were examined (18 of the examined newborns were twins). Newborns were divided into 2 groups: group 1 - 83 premature infants with low body weight relative to gestational age; group 2 - 103 full-term newborns with low body weight relative to gestational age. The control group consisted of 95 full-term newborns (38.4 ± 6.3 weeks), whose body weight corresponded to gestational age. Follow-up observation was carried out on 72 lightweight newborns regarding gestational age in the first year of life.

Laboratory Tests: Quantitative determination of human placental growth factor (PlGF) was carried out based on the enzyme-linked immunosorbent assay "Quantikine Human" (USA) of the solid-phase method in the blood serum of mothers and their newborns. Using ELISA, S100b protein was determined in the blood serum of 89 newborns, among them 40 full-term newborns were with normal body weight and 49 newborns with low body weight. S100b protein content was determined by enzyme-linked immunosorbent assay using serum reagents "CanAg" (Sweden).

Anthropometric assessments: To assess the adaptive capabilities of the body in children and monitor their physical development, growth curves and development of children were observed according to WHO standards. Anthropometric data: indicators of body weight, body length, BMI (body mass index - kg/m^2), as well as age-related achievements of the stages of motor development were plotted on curves and evaluated according to the recommended WHO growth and development standards (2006).

Medical care for underweight newborns and its evaluation: Evaluation of the effectiveness of the proposed medical care for children with low birth weight was carried out according to the results of observation and research in 72 children up to the age of one. Everyone was recommended the rules and stages of conducting underweight children in the first year of their life. During the study, the examined children were divided into 2 groups: the first group consisted of 49 children who underwent medical care in accordance with the proposed recommendations in full; the second group consisted of 23 children who received the recommendations in part because of non-compliance with the recommendations on the part of their parents (moving to another place of residence, mother's studies at a university, etc.).

Recommendations for caring for underweight children in a maternity complex were as follows: joint stay with the mother; prevention of hypothermia; ensuring the proper organization of breastfeeding; if necessary, resuscitation and treatment of newborns according to the approved clinical guidelines.

Recommendations for the care of underweight children in a clinic with our additions were as follows: exclusively breastfeeding in the first 6 months of life, the longest possible preservation of breastfeeding until reaching 2 years of age; monitoring the implementation of the daily regimen and nutrition; increase immunity through regular hardening (walks, water procedures, general massage); prevention of rickets, hypovitaminosis A and iron deficiency anemia; carrying out preventive vaccinations according to an individual schedule, monthly monitoring and evaluation of the growth and physical development of children, and, if necessary, more often against the background of correction of revealed violations. The first patronage to underweight children the day after discharge from the maternity hospital or hospital (wards of the first and second stages of nursing), since such children give higher rates of morbidity and infant mortality. Then, in the first month, an examination by a general practitioner (GP) or pediatrician once a week, from 1 to 6 months - 1 time in 2 weeks, 6-12 months - 1 time per month, according to indications - more often; examination of the child at home - in the first 3-4 months during periods of epidemic of infectious diseases. At each examination, it is necessary to conduct anthropometric measurements with an assessment of the dynamics of body weight, body length and BMI. Examination of narrow specialists: an orthopedist - every month for the first 3 months, then once a quarter; ophthalmologist and otorhinolaryngologist - at the 1st month of life, repeatedly at least 2-3 times a year (1 time per quarter); neuropathologist - 1 time in 3 months in the first year of life.

Statistical Analysis: To carry out correlation analysis and statistical processing of the obtained results, the MS Excel - XP programs were used. Statistical analysis of the results was carried out using method of variation statistics.

Results

The results of the anamnesis and clinical observation of 272 mothers in a hospital are presented, of which 83 mothers had babies born prematurely with low body weight relative to gestational age (group 1); in 102 mothers - full-term, but with low body weight (group 2). The control group consisted of 87 women whose newborns were born on time (38.4 ± 6.3 weeks) and body weight corresponded to gestational age.

It was found that a burdened obstetric and gynecological anamnesis and a complicated course of pregnancy and childbirth (pathological preliminary period, primary and secondary weakness, premature detachment of a normally located placenta) in mothers of children with low body weight of two groups relative to the control ($p < 0.05$).

Table 1: Assessment of risk factors for birth of low birth weight infants depending on the course of pregnancy

Risk factors	Attribute risk	Coefficient of relevant risk
USI data (chorion thickness)	0,91	11,58
Anemia	0,88	8,17
Malnutrition	0,84	5,75
Multiple pregnancy	0,82	5,58
Placental failure	0,81	5,46
Proteinuria	0,79	4,86
Arterial hypertension	0,77	4,41
Infection	0,76	4,23
The risk of abortion	0,76	4,23
Preeclampsia	0,64	3,28

As can be seen from table 1, a high relative risk of giving birth to children with low body weight in pregnant women was observed with signs of fetal growth retardation by ultrasound examination (ultrasound)

(chorion thickness) (OR = 11.58), with anemia (OR = 8.17), other malnutrition (OR = 5.75), placental insufficiency (OR = 5.46).

The risk ratio for manifestations of proteinuria and preeclampsia ranged from 4.86 to 3.28, indicating a direct relationship between these conditions and the severity of their influence. In pregnant women who had the above complications, children were born 3 times more likely to be born with low body weight relative to gestational age compared to pregnant women with normal functional state of the kidneys and blood pressure.

The analysis of risk factors for the birth of children with low body weight confirmed the multifactorial nature of their occurrence. Thus, the risk of having a baby with a small body weight varies widely and largely depends on the risk factors that caused them, the criteria that form the basis of its calculation.

A comparative analysis of the peculiarities of adaptation of the body of newborns showed that when children were admitted to the pathology department, the age of the children in groups 1 and 2 did not differ and amounted to 4.9 ± 0.6 and 4.6 ± 0.6 days, respectively. Indicators of physical development of the studied children at birth are presented.

There is no doubt that in the neonatal period, the physical development of newborns with low body weight significantly differs from full-term infants at a high level of statistical significance ($p < 0.001$). When assessing the condition at birth, it was found that all children of the 1st group were born in serious condition, the 2nd group - in most cases (66.0%) of moderate severity, and in the control group - in satisfactory.

The Apgar score at 1 and 5 minutes of life (Table 3) was significantly lower in infants born with low birth weight compared with full-term infants ($p < 0.001$). in the second group, the Apgar score was higher, but unreliable.

Table 2: Apgar score for 1st and 5th minutes of life in low birth weight infants

Apgar score	Group 1 (n=83)	Group 2 (n=103)	Control group (n=95)
At the 1st minute	3,6±0,2 ***^^	5,7±0,2**	7,8 ± 0,1
At the 2nd minute	5,1±0,2 ***^	6,3±0,2*	8,9 ± 0,1

Note: * Reliability of the data for the control group (* -p <0.05; ** - p <0.01; *** - p <0.001); ^ - data reliability between the 1st and 2nd group (^ -p <0.05; ^^ - p <0.001)

Table 3: Diseases of newborns with low body weight

Disease	Group 1 (n=83)		Group 2 (n=103)	
	Abs.	%	Abs.	%
Respiratory distress syndrome (RDS)	78	94,0±2,6	69	67,0±4,6

Intraventricular hemorrhage 3rd stage	6	7,2±2,8	3	2,9±1,7
Periventricular leukomalacia	10	12,0±3,6	7	6,8±2,5
Anemia	72	86,8±3,7	52	50,5±4,9*
Jaundice	70	84,3±4,0	85	82,5±3,7

Note: The reliability of the data between group 1 and 2 (* - p <0.05; ** - p <0.001)

Signs of perinatal hypoxic-ischemic brain damage of the 2nd degree were recorded in groups 1 and 2, respectively, in 73.5% and 66.0% of children, degree 3 - 2.2 times more in premature infants. Grade 3 intraventricular hemorrhage (IVH) was diagnosed 2.5 times more often in premature infants than in full-term infants with low body weight (7.2% and 2.9%, respectively). Periventricular leukomalacia (PVL) was also significantly more often observed in premature infants than in full-term babies with low body weight ($p < 0.05$) (Table 4).

In all newborns, jaundice was conjugative in nature. Newborn children of groups 1 and 2 had a longer icteric period than newborns of the control group. There were no significant differences in the characteristics of icteric syndrome in newborns with low body weight. Jaundice in preterm infants was observed in 84.3% of cases and in 82.5% of cases in newborns of group 2. Severe anemia at birth prevailed in group 1 infants ($p < 0.01$). The high frequency of diseases of the nervous and respiratory systems (RDS, cerebral ischemia) in underweight children is due to the more pronounced immaturity of these systems at the time of birth. RDS was registered in 94.0% of children of the 1st group and in 67.0% of newborns of the 2nd group.

In the assessment of the length of infants with low body weight in the hospital, it was found that statistically significantly longer children from group 1 spent both in intensive care (19.3 ± 2.4 days, $p<0.05$) and in the neonatal pathology department (41,4 ± 1.9 days, $p<0.001$).

Among the syndromes of central nervous system damage in underweight preterm infants, the syndrome of oppression associated with exposure to hypoxic factors and muscle hypotension predominated, and in children of the 2nd group, vegeto-visceral disorders and muscle hypertonicity (Table 5).

Table 4: Syndromes of posthypoxic damage to the central nervous system (CNS) in newborns with low body weight

Diseases	Group 1 (n=83)		Group 2 (n=103)		Control group (n=95)

Table 5: S100b in preterm low birth weight infants depending on the severity of asphyxiation

Duration of Observation	1st Subgroup	2nd Subgroup	Control Group
At the birth	2571,8±55,5*	1428,7±56,1*	571,5±56,9
On the 2-3 days of birth	3886,4±51,2*^	2714,5±49,5*^	574,2±46,3

Note: * Data reliability in relation to the control group (* - $p < 0.001$); ^ - reliability of data in relation to indicators at birth and on the 2nd-3rd day of life (^ - $p < 0.001$)

Motor activity was reduced in 1 group in 56 newborns (67.5%), and in the second - in 36 (35.0%) newborns. Muscle tone was changed in all children with low body weight, with muscle hypotension occurring in most children of the 1st group (67.5%), and in the 2nd group - hypertension (43.7%). All newborns with low

body weight showed hyporeflexia and rapid exhaustion of unconditioned reflexes.

In newborns of the control group, disorders of the central nervous system were observed in 20.0% of newborns, with increased prevailing neuro-reflex excitability (6.3%) and muscular dystonia in the form of hypertonicity (4.2%).

In 33 (39.8%) premature infants with low body weight relative to gestational age, a syndrome of vegetovisceral disorders was revealed, in full-term infants with low body weight this percentage was 36.9%. It was manifested by a violation of microcirculation, thermoregulation and motility of the gastrointestinal tract. Equally often, microcirculation disturbances (marbling of the skin, pallor, acrocyanosis) and thermoregulation disorders were observed, which required the need for newborns to be in the couveuse. Violations of the motility of the gastrointestinal tract in the form of regurgitation and constipation were 2 times more often observed in premature infants than in children of the control group. In preterm infants with low body weight, inhibition syndrome was 2.2 times more common than increased neuro-reflex irritability syndrome, and in full-term infants with low birth weight - 1.3 times. The revealed syndromes of posthypoxic damage to the central nervous system during the observation process were characterized by a periodic change in the phases of cerebral activity.

The level of S100b depended on the gestational age - the highest rates at birth were recorded in newborns born at 28-30 weeks of gestation (811.2 ± 46.9, $p < 0.05$). In this group of newborns, an increase in the level of S100b was also observed for 2-3 days (1075.6 ± 31.8 ng / l, $p < 0.01$), while in full-term infants the level of S100b did not significantly differ from the indicator at birth (Figure. 1).

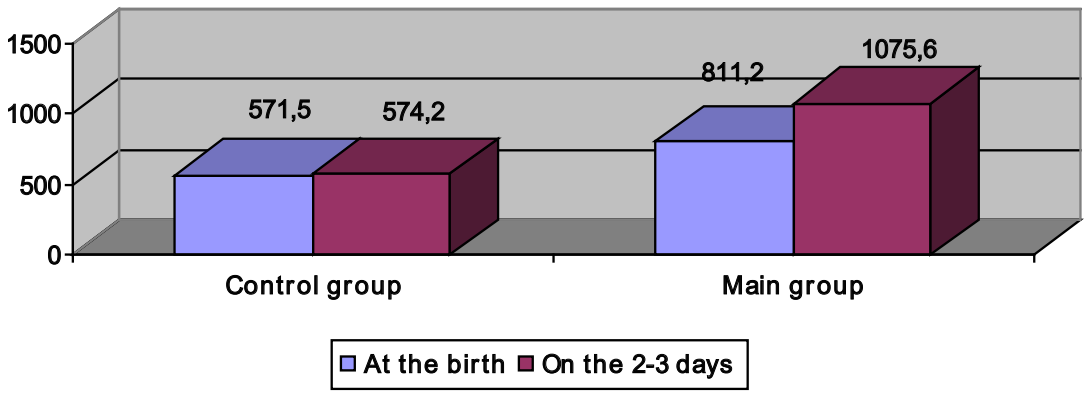

Figure 1: S100b in newborns at the 2nd-3rd days of life

In children born in severe asphyxia (37 newborns), on the first day, the serum concentration of S100b protein was significantly higher than standard values (4-5 times) and averaged 2571.8 ± 55.5 ng/l, whereas Compared with newborns with an Apgar score of 5–7 points, an increase in S100b level was observed by a factor of 2–3.

Among the newborns, 2nd subgroups with an Apgar score of 5-7 points (38 newborns) showed an increase in S100b content by a factor of 2–3 compared with the control group (25 full-term infants) and averaged 1428.7 ± 56.1 ng/l (tab. 6).

Correlation analysis in the compared groups of newborns revealed a pronounced inverse relationship between the level of S100b in the blood serum of newborns and the severity of asphyxiation at birth, characterized by Apgar score at 1 minute: the lower Apgar score, the higher the serum S100b protein level ($r = -0.756$; $P < 0.01$). It should be borne in mind that on the first day of life, an increase in serum concentration of S100b in newborns with brain hypoxia is probably due to the neuroprotective effect of this protein, however, an increase in concentration on the first day should not exceed a 3-fold increase compared with the upper limit of normal. Exceeding the concentration of S100b in blood serum by 4 or more times on the first day is usually an unfavorable prognostic sign, indicating destructive changes in brain cells, and indicates the

possible formation of severe structural brain disorders within 10-14 days.

An analysis of the level of human PlGF in the blood serum of mothers of the main and control groups revealed that in the main group the level of PLGF was significantly lower ($p < 0.01$) than in the control group (84.3 ± 13.4 and 275.0 ± 26, respectively 5 pg / ml) (Figure. 2).

This fact may indicate a disorder of the processes of invasion of chorionic villi and the formation of insufficiency of the second wave of trophoblast invasion in conditions of a low level of PlGF.

In the study of PlGF in umbilical cord blood in premature infants with low body weight (28 children), we found that this indicator was significantly reduced compared to the control group (20 children) 2.5 times and 1.6 times compared with the group full-term infants with low body weight relative to gestational age (27 children) (Figure. 3).

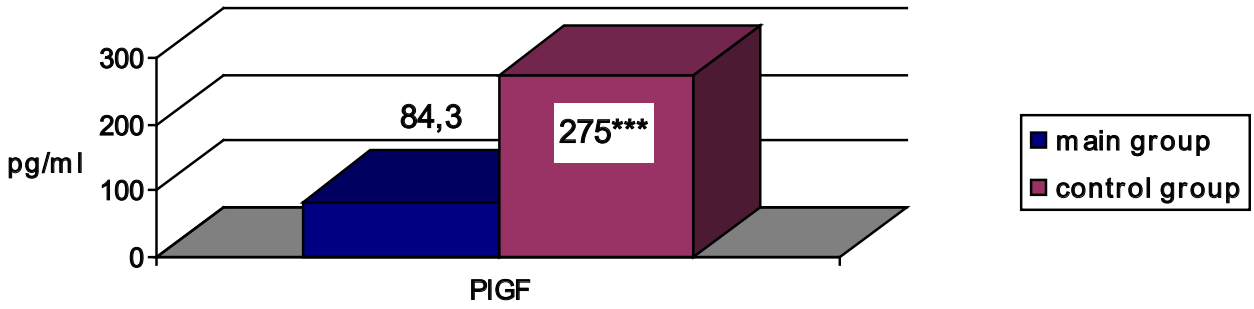

Figure. 2. Indicators of PlGF in a comparative aspect in mothers

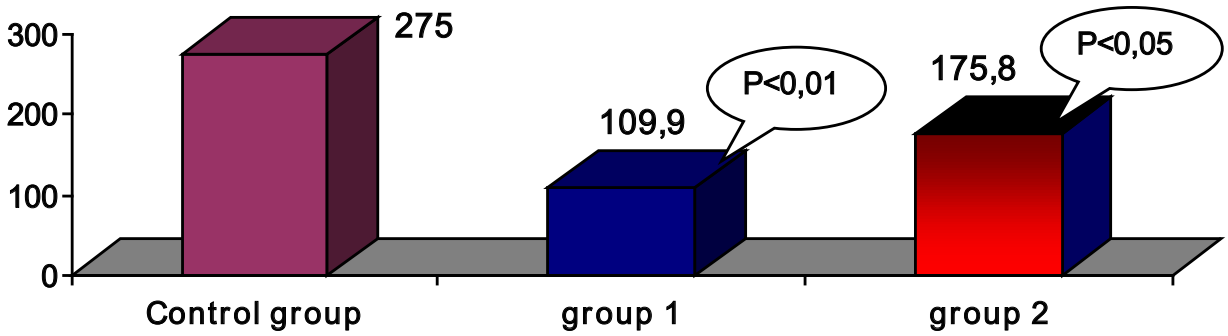

Figure 3: PlGF in newborns

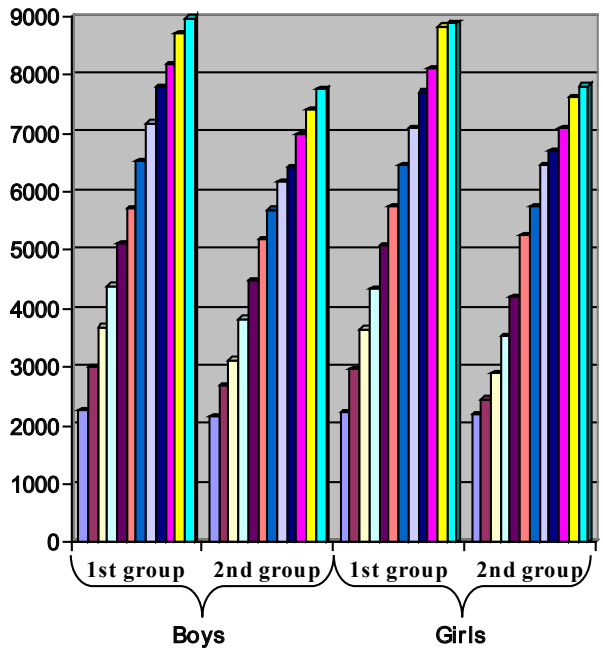
The decrease in PlGF indicators correlates with the formation of low body weight ($r = + 0.49$, $p < 0.05$), and also has a direct correlation with the state of health of premature infants with low body weight relative to gestational age ($r = + 0.51$, $p < 0.05$).

On the 4th day of life, in order to clarify the state of the central nervous system and identify distant neurological disorders, neurosonography was performed. It was revealed that newborns without neurological impairment, by the age of 6 days, are safe in relation to the formation and development of the central nervous system, they can conditionally be considered healthy children. Cerebral ischemia of the first degree, obviously, was due to a hypoxic lesion of the central nervous system transferred in the prenatal period. She was characterized by minor neurological symptoms and the absence of significant changes in the parameters of neurosonography.

When studying the relationship between the level of PlGF in mothers and the level of S100b in their newborns in the formation of low fetal body mass, a strong inverse correlation relationship was established ($r = -0.875$, $p < 0.001$), with a decrease in the level of PlGF, a significant increase in S100b was noted ($p < 0.05$)

During the study, children were divided into 2 groups: the first group consisted of 49 children who received full medical care in accordance with the proposed recommendations; the second group consisted of 23 children who received the recommendations in part because of non-compliance with the recommendations on the part of their parents (moving to another place of residence, mother's studies at a university, etc.).



The analysis showed that the proposed methodology for the management of this category of children contributes to the leveling of disorders in neurological status.

As can be seen from the data presented in table 7, the recovery of tendon and unconditioned reflexes occurred in a larger percentage of children of group 1 ($p < 0.05$) compared with children of group 2. The proposed method gave a more pronounced effect in the restoration of motor and sensory functions, accompanied by an improvement in muscle tone, which is associated with the stimulation of reparative processes of the central nervous system in children who received full medical care.

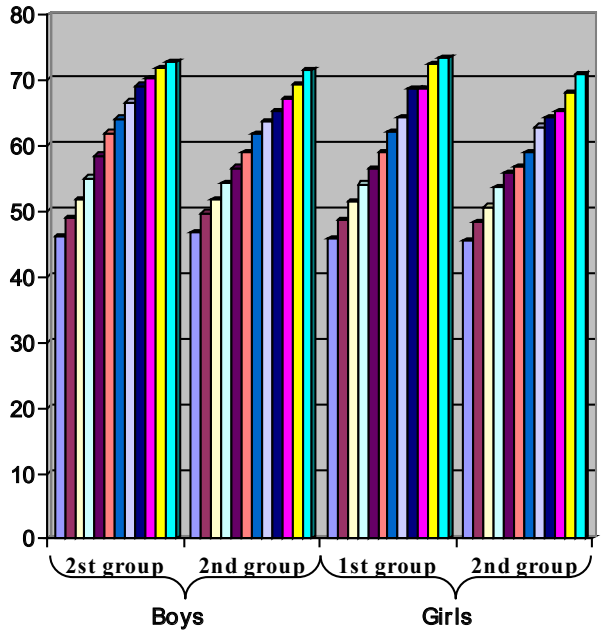


Table 6: The comparative effectiveness of the medical care for children in their first year of life

Values	Group 1, n=49		Group 2, n=23		P
	Abs.	%	Abs.	%	
Normalization of tendon reflexes	29	59,3	8	48,4	<0,05
Normalization of unconditioned reflexes	47	96,3	13	74,2	<0,05
The level of motor activity	33	66,7	9	54,8	<0,05
Muscle tone improvement	47	96,3	13	64,5	<0,01
Improving turgor tissues	45	92,6	12	54,8	<0,01
Body weight gain	47	96,3	13	71	<0,01

When assessing the physical development of the examined children every month during the first year of life, a statistically significant difference was revealed between the groups of underweight children ($p < 0.05$-0.01) (Figure 4).

Body weight to age

Body length to age

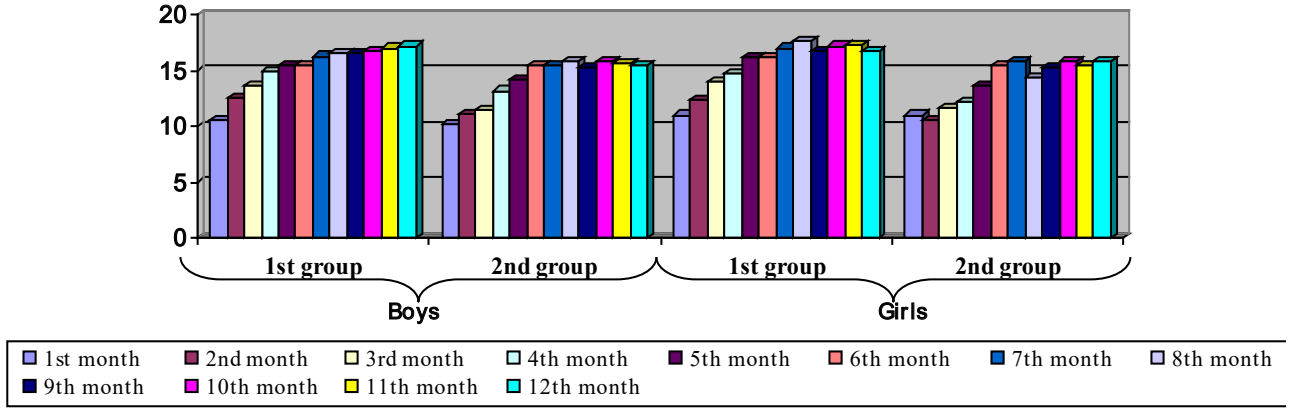

Figure 4. Dynamics of anthropometric data in underweight children in the studied groups

Children of group 2 at all periods of observation, body weight and BMI were less than children who fully complied with the proposed recommendations ($p < 0.05$). Particularly pronounced lags in physical development were noted in children in group 2 at the age of 6 to 12 months.

One of the indicators indicating the nutritional status of a child is BMI. As can be seen, in children of the 2nd group in all age periods there is a significant decrease in BMI, more pronounced after 6 months of life. Children with indicators below two standard deviations are regarded as having reduced weight and a moderate degree of protein-energy malnutrition (PEM). In children of the 2nd group at the age of 12 months, the indicators of weight, body length, and BMI were in the interval "(-1CO) - (-2CO)". These mass indicators do not correspond to the norm, but tend to normalize.

Monitoring of anthropometric measurements in children of group 1 in the first 6 months showed that at birth, the average body mass and body length correspond to -3CO, BMI - within -3CO and -2CO; from 2 months, the dynamics of increase in body weight increases and is in the range of -3CO - -2CO, while the rate of increase in body length lags behind over the next months and corresponds to values below the -2CO curve, due to this, BMI increases. So, in 2 months, BMI corresponds to values lying in the range -2CO - -1CO; at 3 months - -1CO, at 4 and 5 months - from -1CO to the median, i.e. according to this indicator, they correspond to standard values, at 12 months - the median. This dynamics is typical for boys and girls. These results indicate that low birth weight in the first 3-6 months causes a violation of the harmonious development of the baby with normalization by 12 months (Figure. 4). It should be noted that in the 2nd group, 56.3% of children showed a lag in physical development, while in the 1st group this percentage was 22.2%.

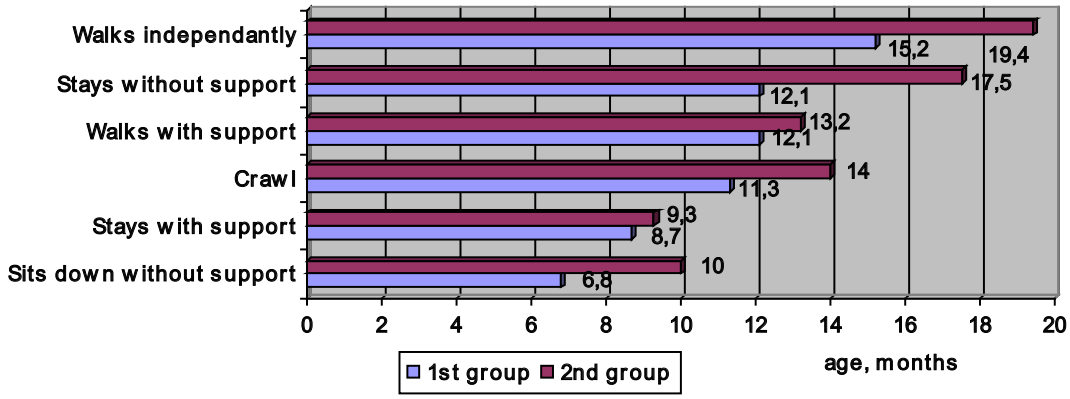

Figure 5: Indicators of motor development of children born with low weight

The characteristic features of the motor development of underweight children who have not received medical recommendations in full and the lag in motor development are presented in Figure. 5. So, all skills that are an indicator of motor development of children were later developed in children of this contingent, especially skills such as "sitting without support" (10.0 ± 0.85, p <0.05), "standing alone" (17, 5 ± 0.8, p <0.01) and "walks independently" (19.4 ± 0.9, p <0.01)[4].

As it is all-known factor that, children born with low body weight are the maximum risk group for the formation of severe pathology leading to disability, and they are prescribed a huge number of drugs and manipulations, which often lead not to an improvement in condition, but to a breakdown of natural compensation. When studying the incidence of children differentially depending on management method, it was found that children who received the introduced care (group 1) were much less likely to have acute respiratory infections - 8.4 ± 1.3 times versus 14.6 ± 1.3% times (p<0,01). The duration of the disease in the first year of life was significantly less, almost twice, in the 1st group of children: respectively, 51.6 ± 2.4 versus 91.3 ± 2.4 days in the 2nd group (p <0.01). The duration of treatment was also shorter when using the introduced management of underweight children. The frequency of pneumonia and bronchitis in the 1st group was 1.6 ± 0.19 times, in the 2nd group - 2.3 ± 0.1 times; the duration of the disease in group 1 was 13.7 ± 1.6 days, in group 2 - 21.9 ± 2.3 days. The duration of pneumonia treatment in group 1 was less (13.3 ± 1.7 days) than in group 2 (19.8 ± 2.8 days).

Significantly less frequently diarrhea was observed in children of the 1st group (1.6 ± 0.2 times), in children of the 2nd group the frequency was 2.7 ± 0.3 times (p <0.05). The duration of the disease and the need for prolonged treatment was less in group 1. The frequency of rickets in children of the 1st group was more than 2 times less and amounted to 5.3 ± 1.2, in the 2nd group - 11.0 ± 0.8 (p <0.001). The duration of signs of rickets was also 2 times less in group 1 - 160.0 ± 3.2 versus 324.6 ± 2.9 days (p <0.001), which indicates a significant proportion of the influence of the principles of management of underweight children during the first year of life. The frequency of anemia in underweight children was also different depending on the principles of their management. It was revealed that in the 1st group the incidence rate of anemia was almost twice lower than in the 2nd group and amounted to 4.2 ± 1.3% versus 7.6 ± 1.6%.

Discussion

In general, a significant decrease in the frequency of diseases among children of group 1 was established compared with children of group 2 (18.5% versus 34.4%, respectively, p <0.01). According to the dynamic observation, the frequency of visits to SP and SVP for diseases (diarrhea, bronchopneumonia, acute respiratory viral infections, otitis media) decreased by 1.8 times, the frequency of hospitalizations decreased. At the same time, in the 2nd group, the frequency of hospital admissions to the hospital ranged from 5 to 6 times a year, while in the 1st group - on average 2 times a year.

Thus, in a differentiated study of the effectiveness of the proposed method for caring for underweight children, it was found that children who received incomplete recommendations lagged behind physical and motor development, and were also more likely to suffer from diseases such as acute respiratory infections, pneumonia, diarrhea, rickets, and anemia.

Based on the data obtained, it can be concluded that for the prevention of birth of low birthweight infants, it is necessary to improve the quality of antenatal care for pregnant women with the correction and treatment of identified disorders and diseases, taking into account the identified prognostic factors; in order to ensure normal development and reduce the incidence of diseases in children born with low birth weight relative to the gestational age, it is necessary to provide care and follow up for them during the first year of life in accordance with additional recommendations on tactics of managing underweight children with adherence to modern WHO/ UNICEF technologies.

A high relative risk of giving birth to underweight infants in pregnant women is a delay in fetal development according to ultrasound (chorion thickness) (OR = 11.58), with anemia (OR = 8.17), and placental insufficiency (OR = 5.46). For low birth weight infants, especially premature infants, low adaptive capabilities of the body are characteristic. Underweight preterm infants are born in severe asphyxia (3-4 points on the Apgar scale), with a severe degree of RDS, severe disorders of the central nervous system; they require primary resuscitation measures 1.7 times more often, longer antibacterial measures (3-4 courses - 1.4 times more often, 5 or more - 2 times more often) and respiratory therapy.

The excess on the first day of the concentration of S100b in blood serum by 4 or more times is an

unfavorable prognostic sign for the formation of severe structural disorders of the brain, as evidenced by neurosonography indicators - signs of intraventricular hemorrhage, PVL and ischemic manifestations.

A low level of PlGF (below 100 pg/ml) in the blood serum of mothers indicates a high risk of intrauterine growth retardation and the birth of underweight newborns, which is confirmed by the correlation between the mother's PlGF level and newborn body weight. The adaptation and development of diseases of premature infants with low body weight relative to gestational age is also directly affected by the low level of PlGF in the blood serum of the child himself.

Neurospecific protein S100b in newborns and placental growth factor PlGF in mothers and newborns are biochemical markers of the birth of low birth weight infants, their adaptation disorders with the development of diseases of the central nervous system and other systems

Conclusion

The risk ratio for pregnant women with proteinuria and preeclampsia varies from 4.86 to 3.28, which indicates a direct relationship between these conditions and the severity of their effect. Pregnant women who have the above complications are 3 times more likely to have babies with low body weight relative to gestational age compared to pregnant women with normal renal function and blood pressure. Care and observation during the 1st year of life, according to additional recommendations on tactics of conducting underweight children with observance of modern technologies. WHO/UNICEF helps to improve central nervous system disorders (normalization of tendon and unconditioned reflexes, physical activity), physical and motor development, as well as reduction 1.9 times the incidence rate among children of this contingent.

Acknowledgements: We are grateful to the staff members of City Perinatal Center of Tashkent, Republican Specialized Scientific-Practical Medical Centre of Pediatrics, and the family polyclinics of 44, 45, 46, 47 in Tashkent for the cooperation and support in our research. The parents of the participants kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from all participants' parents of the research for publication of this paper and any accompanying information related to this study. A copy of the written consent is available for review by the authors.

Conflict of Interest: The authors declare that they have no competing interests.

Abstract

Introduction: Nutritional issues in children are associated with a complex of factors. Early assistance to the child is feasible with the on time detection of developing deviations in the health, growth and development. The actual tasks were to determine the level of growth and development of children in the regions of the Republic of Uzbekistan, assess the effectiveness of programs implemented in the country to improve nutrition and prevent micronutrient deficiency based on the application of new standards for the growth and development of children, as well as develop relevant proposals and recommendations.

Materials and Method: 3969 children under 5 years old living in 6 regions of Uzbekistan were observed. In order to monitor the growth and development of children, anthropometric measurements were carried out in the following periods: the first measurements - at birth, the second and third - at the age of 15 days and 1 month, then monthly until the expiration of 12 months, 1 time in 3 months - between 12 and 36 months, every 6 months - between 36 and 60 months and then annually. An immunological study was conducted as well for children with malnutrition.

Results: The percentage of BF in the city of Tashkent was 78.6%, Tashkent region - 66.4%, Khorezm region - 67.3%, Fergana region - 85.7%, Bukhara region - 72.2% and the Republic of Karakalpakstan - 89.0 % Based on those results, it can be stated that in the region where the percentage of IHV was lower (Tashkent and Khorezm regions), the percentage of children with low body weight is greater. By the end of 2012 and the beginning of 2013, the percentage of children of the first 6 months of life with reduced weight decreased in all regions. The dynamics of reduced weight by the end of 2012 among children aged 6-12 months was positive

Conclusion: Anthropometric indicators in children of the first 5 years of life, regardless of gender, in almost all studied regions in terms of body weight and body length/height in most cases were same level. In children under 5 years old, low body weight relative to age prevailed among the forms of impaired physical development and nutrition in all regions.

Keywords: *Malnutrition, growth and development impairment, children, socio-economic regions, Uzbekistan.*

Introduction

Taking into account the importance of normal growth as an overall indicator of health status, the World Health Organization (WHO) has developed standards for the growth and development of children[1]. These standards allow us to show how children should grow, to monitor

their growth and development with the adoption and conduct of timely preventive measures (Bogomolova, 2015; Khodzhieva et al, 2016 and *Growth reference 5-19 years. BMI-for-age*, 2007)[17].

Children's health and development are highly dependent on nutrition and the environment. The nutritional problems of children, in turn, are determined by a complex of factors, among which the well-being of the region where the child lives and the formation of eating behavior in the family are leading ones (Gelashvili et al, 2018 and Namazova-Baranova et al, 2018)[5,8,11]. For some regions of the world, there is a problem of chronic malnutrition, which leads to the development of chronic nutrient deficiency in children and continues to be the cause of infant mortality, developmental disorders, including intellectual lagging, and increases the risk of various infectious diseases (Akhmedova et al, 2016; Izotova, 2015; Khodzhieva et al, 2016 and Lobstein et al, 2015)[1,7,12]. Rapid and excessive growth leads to a higher prevalence of cardiovascular disease and obesity. According to the WHO, in 2010, about 115 million children had experienced a reducein body weight, 55 million had low body weight in relation to growth, and 171 million children under the age of five had stunted growth (L.D. I. 2015. *Health in the European Union*, 2011)[7]. In addition, in 2010, 43 million preschool children in developing and developed countries were overweight or obese. The prevalence of childhood obesity in low- and middle-income countries has accelerated over the past 10 years; according to WHO estimates, in 2015 this coefficient should have reached 11%, which is close to prevalence in countries with incomes above the average (12%) (*WHO child growth standards*, 2016)[17].

In the world, great focus is given to the scientific and organizational-methodological studies in determining the characteristics of the physical development of children and improving rational nutrition, taking into account the regional factors in the system of medical prevention (D.T. A.Bogomolova, 2015)[2]and Tanagaet al, 2010)[9],[10]. In this regard, special attention is paid to conducting targeted research: assessment, taking into account regional characteristics of the physical development of children by introducing new standards for the growth and development of children recommended by WHO; determining the frequency of various forms of malnutrition and their relationship with major diseases and immunological reactivity of children; improving the system for assessing factors affecting the health, physical and intellectual development of children (*Health in the European Union*, 2011 and *WHO child growth standards*, 2016)[13,16].

Analysis of the literature showed that early assistance to the child is possible with the timely detection of developing deviations in the health, growth and development (Ashurova, 2015 and Namazova-Baranova et al, 2018)[8,11].

The WHO multifocal study of growth standards (WHO, 2006) was designed to provide data on "how children should grow up," including criteria for selecting children for the study: favorable socio-economic conditions for the growth of the child, breastfeeding (in the first 6 months - BF), compliance with the recommended method of feeding infants, lack of medical or environmental problems, mothers quitting smoking, giving birth to one full-term baby. In order to obtain useful information about the physical development of the child, it is necessary to have several successive measurements of the indicators of the physical development of the child according to the recommended dates of their implementation and apply them to the physical development curves derived from the corresponding reference groups of the population (Geht, 2015 and Lobstein et al, 2015)[14,15].

The aim of the study was to determine the characteristics of the physical development of children in their first five years of life and evaluate the effectiveness of programs to improve their nutrition based on modern organizational and methodological approaches.

Materials and Method

Study Population. A survey (monitoring the growth and development of children) of 3969 children of the first 5 years of their life in 6 regions of the Republic of Uzbekistan was conducted. Representatives of 5 geo-economic regions of Uzbekistan were included in the study: the Republic of Karakalpakstan and the Khorezm region - the West (1592 children), Bukhara region - Central (442 children), Tashkent region - Central-East (707 children), Ferghana region - East region (500 children) and Tashkent city (728 children).

Data Collection: At the first stage, for monitoring and evaluation of growth and development of children in the regions using growth curves according to WHO standards, a monitoring questionnaire was developed and approved by Order of the Ministry of Health of the Republic of Uzbekistan (No.145 dated March 30,

2007). In order to monitor the growth and development of children, anthropometric measurements were carried out in the following periods: the first measurements - at birth, the second and third - at the age of 15 days and 1 month, then monthly until the expiration of 12 months, 1 time in 3 months - between 12 and 36 months, every 6 months - between 36 and 60 months and then annually. If necessary, more frequent weight measurements were carried out, especially to check the adequacy of breastfeeding in the presence of deviations in the growth and development of the child and to evaluate their correction.

An immunological study was conducted in children with malnutrition. Determination of the absolute and relative content of lymphocytes, populations and subpopulations of lymphocytes (total pool of T-lymphocytes (CD3) and B-lymphocytes (CD20), subpopulations of T-helper cells (CD4), T-suppressors (CD8) and natural killers (CD16) in the blood was carried out according to the method of Zalyalyeva (2003) using monoclonal anti-lymphocyte antibodies produced by the Research Institute of Immunology of the Russian Federation (Moscow). Concentrations of serum immunoglobulins (IgG, IgM, IgA) were determined by the standard sets "IgA total - IFA-BEST", "General IgM - IFA-BEST", "General IgG - IFA-BEST" produced by VECTOR-BEST CJSC, Novosibirsk (Russia) by enzyme-linked immunosorbent assay, phagocytic activity of neutrophils - FAN was studied using melamine formaldehyde latexes. Immunological studies were carried out jointly with the Institute of Immunology of the Academy of Sciences of the Republic of Uzbekistan.

Statistical Analysis: To carry out correlation analysis and technological processing of the obtained results, the MS Excel - XP software was used.

Results

The assessment and monitoring of the growth and development of 1,592 children living in the Western region are given: 879 children in the Republic of Karakalpakstan and 713 children in the Khorezm region. It was found that children at birth corresponded to median indicators. In the Republic of Karakalpakstan, the average birth weight for girls was 3.32 ± 0.02 g, body length 50.3 ± 0.1 cm, body mass index (BMI) 13.06 ± 0.06 kg/m^2; in boys, respectively, 3.44 ± 0.03 kg, 51.2 ± 0.1 cm and 13.1 ± 0.08 kg/m^2. These indicators indicate that at birth, indicators of weight, body length and BMI relative to age corresponded to standard indicators according to the WHO growth curves. The weight, body length and BMI of children aged 0-6 months, regardless of gender, corresponded to the level of indicators in the field of -1CO + 1CO, which indicates the harmonious development of children. At the age of 12 months, the girls' body weight corresponded to 8.98 ± 0.05 kg, body length 73.9 ± 0.2 cm, BMI 16.4 ± 0.07 kg/m^2; in boys, respectively, 9.88 ± 0.06 kg, 75.6 ± 0.2 cm and 17.3 ± 0.1 kg/m^2. In girls, all indicators of physical development were in the range of -2CO - + 2CO, which corresponds to the standard. A similar dynamics of physical development by 12 months of life was also observed in boys in this region. However, starting from 7-8 months of life, the pace and development of 87.8% of children slowed down to a greater extent as a result of late (37.0%) and irrational feeding (39.4%). In dynamics from 12 months in girls and boys, body length / height indicators on average corresponded to -1CO. BMI on average in children from 12 months to 5 years old corresponded to normative indicators in accordance with WHO standards.

Among the examined children in the Khorezm region, 51.6% were boys (368) and 48.4% were girls (345). The average birth weight for girls was 3.43 ± 0.04 kg, body length 50.3 ± 0.1 cm, BMI 13.6 ± 0.2 kg/m^2, i.e. all indicators corresponded to normative indicators - median (O) according to the WHO growth curves. The weight, body length and BMI of children aged 0-6 months also corresponded to the median level. In children 9-12 months old, body weight was in the range + 1CO + 2CO, body length in the range - 0 + 1CO, in accordance with this BMI - in the range - 0 + 1CO. These data show that in this age period, physical development corresponds to the standard, but an increase in body weight is noted. It should be noted that most children (87.9%) were exclusively breastfed and breastfed. Indicators of weight, body length / height and BMI for children under the age of 5 years inclusive by region are presented in Figs. 1, 2 and 3.

Bukhara region located in the central geo-economic region. Anthropometric measurements were carried out in this region among 442 children, of which 46.6% were girls (206 children) and 53.4% were boys (236 children). At birth, the average weight, body length, and BMI were in the -1CO and median areas. After 9 months of life, deviations from the median are observed towards a decrease in body weight.

The study of growth and physical development indicators in the Central-Eastern region of Uzbekistan was carried out among 707 children in the Tashkent region, of which 443 were boys (48.5%) and 364 girls (51.5%). In children of the Tashkent region from 12 months to 5 years, the values of body length/height and body weight relative to age were in the region of -2CO and + 1CO.

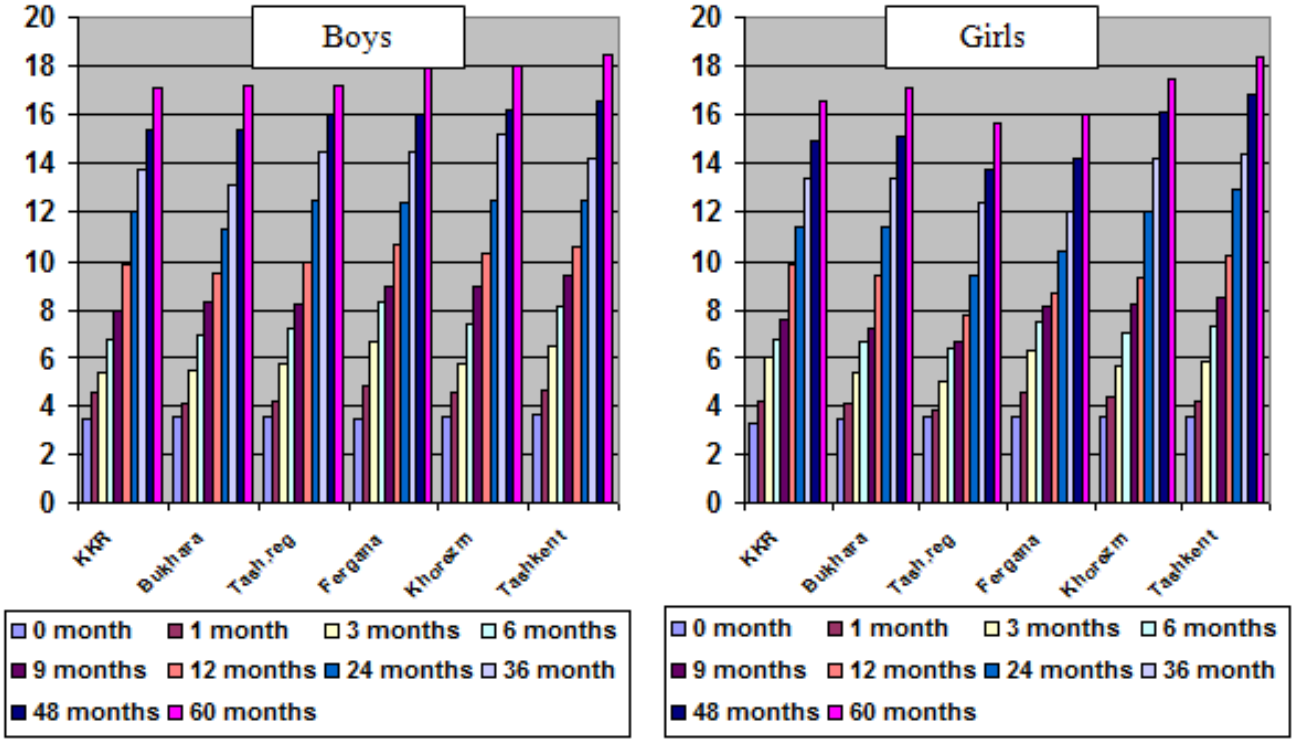

Fig. 1. Body mass index (g) of children under 5 years old inclusive

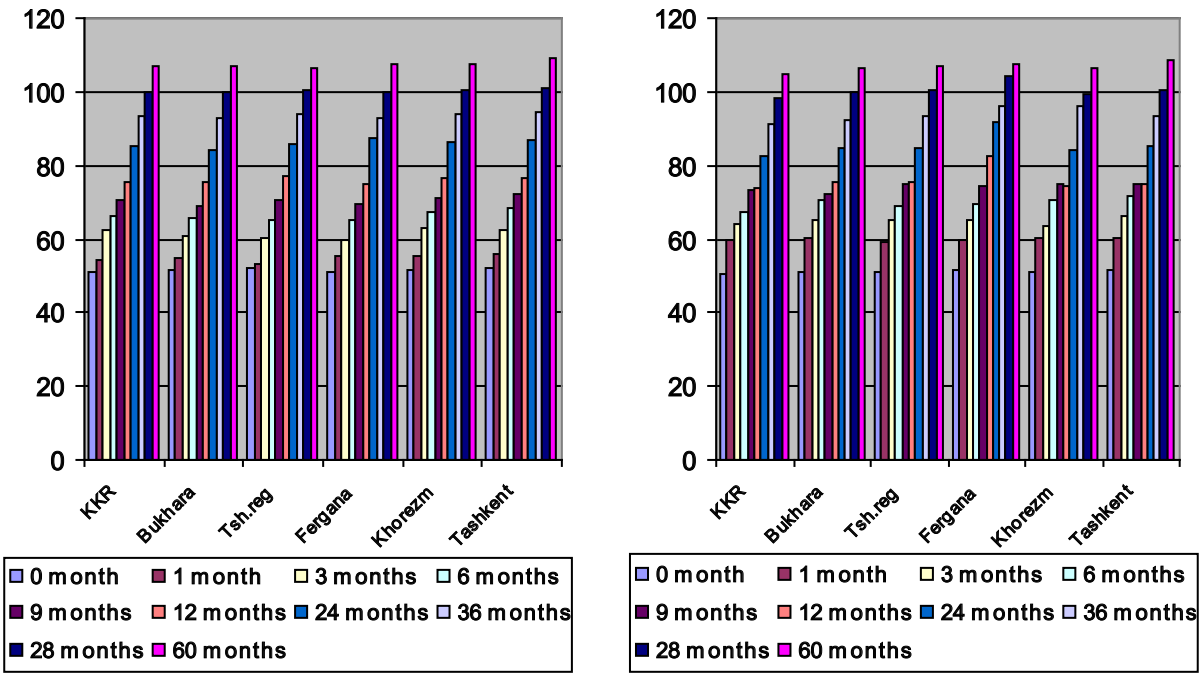

Fig. 2. Indicators of body length/height (cm) for children under 5 years old

Anthropometric measurements and monitoring of the growth and development of 500 children living in the Fergana region were carried out. Of the children examined, boys accounted for 49.2% (346 children), and girls 50.8% (354 children). An analysis of the studies showed that in children living in the Fergana region, up to 10 months of life, indicators of physical development corresponded to the range of -1CO and median (0). Subsequently, a decrease in body weight was observed in the dynamics, the indicators of which were on average in the range of -1CO. Body length/growth indicators were in the same range, BMI in the range -1CO + 2CO.

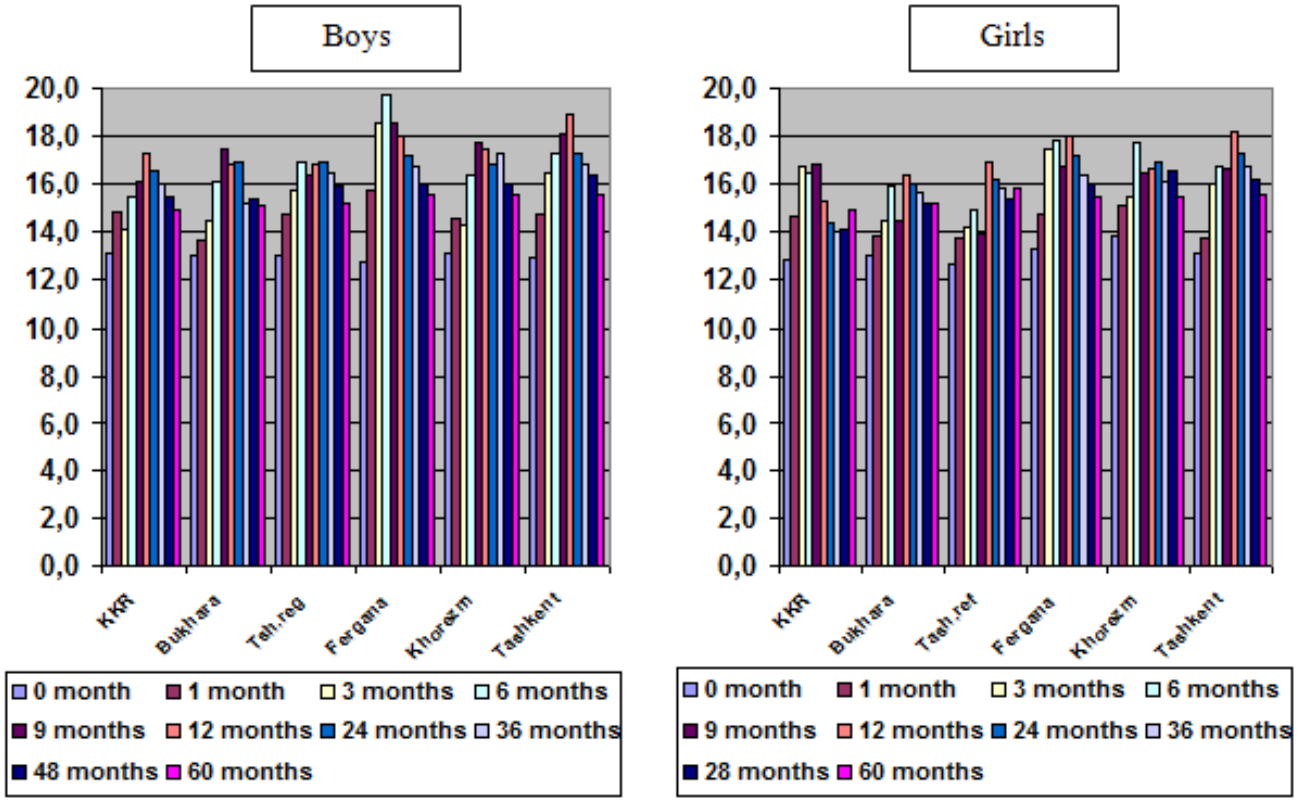

Fig. 3. BMI indexes for children (kg/m^2) up to and including 5 years old

The analysis of growth and physical development indicators was carried out among 728 children of the first 5 years living in Tashkent. The study included 364 girls and boys. Children living in Tashkent showed normative indicators, which in most cases corresponded to the range of -1 CO + median (O) according to the WHO growth curves for all age periods of life.

Anthropometric indicators of children living in the city of Tashkent correspond to the median values for all anthropometric data of the median level, the girls of the Fergana region in terms of body weight and, accordingly, BMI in the first 7-8 months of life slightly exceed their peers from other regions. From 9 months of age, there has been a decrease in the rate of increase in body weight in girls of the Fergana region, and starting from this age, the body mass index is higher for girls in Tashkent and the Khorezm region.

We examined children aged 1 to 2 years with moderate PEM living in the Khorezm region (43 children) and the Republic of Karakalpakstan (44 children), the control group consisted of 34 children in Tashkent. An analysis of the results of an immunological examination of children revealed that against the background of leukopenia relative to the control group, T-immunodeficiency was observed, expressed in a decrease in the level of CD3 + lymphocytes in 76.7% of the examined children of the Khorezm region and 84% in children of Karakalpakstan. A reduced number of immunoregulatory CD4 + subpopulations relative to the control group ($p < 0.01$) was observed in 34 of 43

examined children (79.0%) living in the Khorezm region, and 36 of 44 children (81.8%) living in Karakalpakstan. The content of the relative number of CD8 + lymphocytes in children of the Khorezm region did not significantly differ from the data of the control group, however, in 8 out of 43 children (18.6%) there was a reduced level of T-suppressors / cytotoxic lymphocytes. In children with PEM, the level of CD8 + lymphocytes was reduced ($p < 0.05$). Possibly, insufficient protein content in the diet causes a decrease in the expression of CD8 + lymphocytes in these children compared with children without PEM. There was a significant increase in the relative content of natural killer cells (CD16 +) against the background of the relative and absolute deficit of the total pool of T-lymphocytes (CD3 +). The increase in the relative CD16 + content in children of Karakalpakstan was more pronounced than in children of the Khorezm region ($p < 0.01$). Note that the absolute content of CD16 + in this case did not differ from the control (Table 2). Severe functional deficiency of phagocytes was also noted (the content of active phagocytes was less than 50%).

Table 2: Nonspecific protection factors and parameters of humoral immunity in children with PEM in the Aral Sea regions (M ± m)

Immunological index	Control group (Tashkent), n=34	Regions	
		Khorezm region, n=43	Karakalpakstan Republic, n=44
CD3+	44,5±0,4	39,6±0,2	38,5±0,2
CD4+	27,8± 0,3	25,6±0,2	23,1±0,2
CD8+	19,7± 0,2	19,2± 0,2	16,1± 0,1
CD4/CD8	1,42±0,02	1,33±0,02	1,44±0,02
CD16+,%	10,8 ± 0,1	15,7 ± 0,2*	17,4 ± 0,2*
CD16, 10^9/l	0,46 ± 0,01	0,43 ± 0,01	0,41 ± 0,01
ФАН - Neutrophil phagocytic activity NPA	57,5±0,3	36,4 ± 0,4*	34,2 ± 0,3*
CD20+	20,4±0,2	29,2 ± 0,3*	27,3 ± 0,3*

Note: * The values are significant relative to the control group ($p < 0.05$-0.001).

In general, expressed deviations by average in all regions of the examined children compared with new WHO standards are not observed. The indicators of physical development of children of the first 5 years of life who were breast-fed up to 2 years of age are practically at all age stages in all studied regions at the median level or in the range -1CO - + 2CO in terms of body weight and body length/height, from -1CO to + 1CO according to BMI.

The first stage of malnutrition is reduced weight, which can quickly occur, quickly stop and indicates the acute and/or chronic disease that caused this malnutrition (malnutrition, diarrhea, ARI, etc.). Monitoring results in 2007 showed that in Tashkent, the percentage of children with reduced weight relative to age was 2.7% in children aged 0-6 months, 4.3% in children of the first year of life; in the Tashkent region, respectively 4.5% and 8.4%; in the Fergana region - 4.1% and 6.2%; in the Republic of Karakalpakstan - 4.6% and 6.0%, in the Khorezm region - 5.9% and 7.1%; in Bukhara region - 5.7% and 6.5%.

As it is well known that the most effective intervention for this age group is exclusively breastfeeding (IHV). The percentage of BF in the city of Tashkent was 78.6%, Tashkent region - 66.4%, Khorezm region - 67.3%, Fergana region - 85.7%, Bukhara region - 72.2% and the Republic of Karakalpakstan - 89.0 % Based on those results, it can be stated that in the region

where the percentage of IHV was lower (Tashkent and Khorezm regions), the percentage of children with low body weight is greater. By the end of 2012 and the beginning of 2013, the percentage of children of the first 6 months of life with reduced weight decreased in all regions. The dynamics of reduced weight by the end of 2012 among children aged 6-12 months was positive, i.e. the percentage of children of this age with this form of malnutrition in all regions decreased. This percentage ranged from 2.2% in Tashkent to 3.9-3.5% in Tashkent and Khorezm regions.

The monitoring results showed that in 2007 in the group of children over the age of one year and under 5 years old, lower weight was more marked in Khorezm (8.4%) and Tashkent (7.0%) regions. In dynamics, by 2012 this indicator decreased in all regions and ranged from 2.0% in Tashkent to 5.3 and 5.9%, respectively, in Tashkent and Khorezm regions.

One of the main indicators of the physical development and nutritional status of young children is a growth indicator. The largest percentage of children over the age of 5 and up to 5 years old with low growth for a given age was found in Tashkent and Khorezm regions (6.7 and 7.0%), in Tashkent this figure was 3.6%, in Karakalpakstan - 6.0%, in the Ferghana region - 5.1%. In general, in all regions, there has been a positive trend in reducing this form of malnutrition by the end of 2012, and in early 2013 the indicator of low growth among children aged 5 years old in virtually all regions decreased by 1.2-1.5%.

Discussion

The nutritional status of young children is also assessed by the prevalence of low body weight for this growth, which is regarded as protein-energy malnutrition (PEM). The monitoring results showed that in 2007 the percentage of children with moderate PEM in Tashkent amounted to 2.7% in children aged 0-6 months, 2.8% in children of the first year of life, i.e. in age dynamics there is no deterioration of this indicator; in the Tashkent region, these indicators amounted to 6.2 and 3.0%, respectively. 2012 studies showed that PEM, regardless of the age and region of residence of children, decreased and ranged from 1.8% in Tashkent to 3.2% in the Tashkent region among children aged 5 years.

Today, according to WHO, obesity is an increasing problem in the growth and development of children. Monitoring showed that the percentage of overweight and obesity in Tashkent amounted to 3.9% in children of the first 6 months, 9.3% in children of the first year of life; in Bukhara region - 2.2% and 4.5%, respectively; in the Tashkent region - respectively 1.8% and 3.6%; in the Fergana region - 6.2% and 3.0%; in the Khorezm region - 2.2% and 4.2%, respectively; in the Republic of Karakalpakstan - 3.8% and 2.8% of children, respectively. As you can see, in the dynamics in the regions and the Republic of Karakalpakstan there is a decrease in the number of overweight and obese children. The opposite picture is noted in the capital - this indicator by the end of the year actually increased by 3 times.

In the Fergana region, overweight and obesity prevailed in the first 11 months of boys, on average, BMI at this age stage corresponded to the range of overweight relative to the body length of the corresponding age (+ 1CO + 2CO) with a fluctuation from median (0) and above + With. The lowest indicator of overweight and obesity in 2007 was observed among children of the first 6 months in the Tashkent and Bukhara regions, the first year - in the Republic of Karakalpakstan. In dynamics, by the end of 2012, in all age stages, the leading position in the frequency of overweight and obesity continues to be held in Tashkent (E.S B 2015)[4].

Thus, among the forms of malnutrition in all regions low body weight prevails relative to age, this form is more pronounced in regions where the rate of BF coverage is less. This fact also contributes to a more pronounced growth retardation. Malnutrition in children after 6 months is exacerbated by the untimely and inadequate introduction of complementary foods. For the capital of our republic, especially among children by the end of the first year of life, overweight and obesity are more characteristic.

In-depth analysis of the results of the survey of 356 children with malnutrition and various diseases. Among the surveyed, the most prosperous is the situation in Tashkent, where the highest percentage of children with functional impairments and transient deviations in health status is noted (2nd health group) - 88.6% of the examined. Among the children of the first 5 years of life, children with the 2nd health group made up 74.4% in the Republic of Karakalpakstan, 67.9% in the Bukhara region, 65.4% in the Tashkent region, 78% in the Fergana region, 78 1%. Among all examined children with chronic diseases and the risk of transition to chronic diseases in Tashkent city made up 11.4%. Respiratory diseases and anemia predominate in the structure of

functional disorders and transient diseases in a state of health. The leading positions in the structure of chronic pathology are occupied by diseases of the circulatory system (22.0% of children), pathology of the nervous system and behavior disorders (20.7% of children), and pathology of the digestive system (13.7% of children).

It is known that a diet affects the functioning of the immune system. Based on the results of monitoring and evaluating growth and physical development, we selected 32 children aged 3 to 5 years with PEM. With protein-energy malnutrition, a metabolic imbalance is noted, which, of course, should affect the child's immune system. The research results showed that already in the initial period of malnutrition in the immune system of children, changes take place. In particular, a decrease in the percentage of CD3 + (42.5 ± 0.2% versus 54.7 ± 0.2% in the control, $p < 0.05$) was recorded, mainly due to a decrease in CD4 + (26.6 ± 0.1% against 34.6 ± 0.2% in the control, $p < 0.05$). However, the absolute values of the content of T- and B-lymphocytes did not differ from the indicators of the control group, possibly due to the fact that in children with PEM, relative lymphocytosis was observed (60.4 ± 2.3%). The relative number of T-suppressors / cytotoxic lymphocytes (CD8 +) among children was reduced to 18.1 ± 0.1% versus 22.0 ± 0.2% in the control. The relative content of total B-lymphocytes (CD20 +) and natural killer cells (CD16 +) was reduced compared to the control group to the level of 21.5 ± 0.1% (at 28.1 ± 0.2% in the control, $p < 0.05$) and 11.4 ± 0.2% (at 17.5 ± 0.3% in the control, $p < 0.05$), respectively. The phagocytic activity of neutrophils was significantly lower than the control values - 40.1 ± 0.1% versus 46.4 ± 0.4% in the control ($p < 0.05$). Analysis of the functional activity of B-lymphocytes showed a significantly reduced level of immunoglobulins of the main classes by 2-2.5 times compared with the control. Thus, the level of IgG in children with malnutrition decreased to 4.1 ± 0.04 g/l, IgA to 0.68 ± 0.01 g/l and IgM to 0.38 ± 0.004 g/l compared with the data in the control group, where the level of IgG, IgA, IgM was respectively 8.2 ± 0.08 g/l, 1.05 ± 0.01 g/l and 0.83 ± 0.01 g/l.

Deficiency of phagocytic protection was detected in 43.7 ± 5.3% of the examined children. In the examined children of the Khorezm region, the percentage of active phagocytes was reduced by 1.3 times, and in children of the Republic of Karakalpakstan by 1.4 times relative to the control group.

The relative number of B-lymphocytes (CD20) exceeds the control group by 1.36 times ($p < 0.05$) in children in the Khorezm region and 1.27 times ($p < 0.05$) in children in Karakalpakstan, and the absolute content total B-lymphocytes significantly reduced relative to control values in both groups ($p < 0.05$).

Immunological disorders in children with respiratory and nutritional diseases were exacerbated in the presence of malnutrition. A feature of immunological reactivity in the examined children with BENP is a deficiency of phagocytic defense ($p < 0.01$), low blood levels of immunoglobulins IgG, IgA, IgM ($p < 0.05$).

Conclusion

Anthropometric indicators in children of the first 5 years of life, regardless of gender, in almost all studied regions in terms of body weight and body length/height in most cases were at the median level (0) at birth, in the range -1CO - + 2CO - at the age 0-6 months, in the range of -2CO - + 1CO - at the age of 6 months to 5 years; according to body mass index in the range -1CO - + 1CO - in children of all ages, which corresponds to normal indicators according to the standards of growth and development recommended by WHO. Furthermore, in children of the first year of life, low body weight relative to age prevailed among the forms of impaired physical development and nutrition in all regions. This form is more pronounced in regions where the coverage rate for exclusively breastfeeding in the first 6 months and breastfeeding up to 2 years of age is less (Tashkent and Khorezm regions). The same trend was observed in subsequent age stages. Violation of the physical development and nutrition of children after 6 months was exacerbated by the untimely and irrational introduction of complementary foods. In the dynamics of the 5-year monitoring, by the end of 2012 - the beginning of 2013, a decrease in the frequency of all forms of developmental and nutritional disorders, regardless of the age and gender of children, was noted in all regions. The leading position in the frequency of overweight and obesity was held by children in Tashkent and the Fergana region. In the Fergana region, overweight and obesity prevailed in the first 12 months in boys. In dynamics, by the end of 2012, in all age stages, the leading position in the frequency of overweight and obesity continues to be held in Tashkent. Immunological abnormalities in moderate early BENP were mainly manifested in defects of the T-cell immunity, which were characterized by a low content of CD3 + and CD4 + lymphocytes, which indicates that

T-cell proliferative response to antigens weakens. A decrease in the production of immunoglobulins, due to a violation of the T-cell regulation of their synthesis, is also characteristic. These immunological disorders have important prognostic value in determining the body's resistance to diseases.

Study Limitations: We could not include the prevalence of somatic diseases among children under 5 years old. If any research included such data, it might show more clear picture of influence of malnutrition on the general health condition certain regions. Thus, further researches may be required to describe the prevalence of malnutrition and its impact of the health condition of local children.

Acknowledgements: We are grateful to the staff of Department of pediatric surgery, Tashkent Pediatric Medical Institute for the cooperation in our research. The parents of the patients kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from all participants' parents of the research for publication of this paper and any accompanying information related to this study. A copy of the written consent is available for review by the authors.

Abstract

Introduction: During last few years, a novel scientific sphere has developed and is successfully growing, associated with the study of age-related changes in immune and allergic reactions at the cellular level. Although there is a fact that mast cells are the subject of many researches, many aspects of their physiology and pathology remain unsolved. Moreover, clarification in the age-related features of mast cell reactivity makes a great contribution to the expansion of our view of point on the characteristics of the clinic, etiology and pathogenesis of allergies in ontogenesis.

Materials and Method: We used 443 guinea pigs of both sexes of different ages, previously experienced 10-14 day-quarantine control under conditions of vivariums. Animals were constantly monitored, body weight was periodically determined, and rectal temperature was measured. Sensitization and anaphylactic reactions were reproduced by conventional method. Normal horse serum was used as an allergen. The resolving dose of a specific allergen was administered once intravenously or intraperitoneally 14-16 days after the start of the first sensitizing dose of the allergen. Collected digital data processed on electronic microcalculator Rokwell international Model 44 (USA).

Results: With age, the rate of filling mast cells with granules increases. In guinea pigs of an older age, as compared to newborns, the rates of filling mast cells with granules are 1.3-2.2 times greater ($p < 0.05$), which is consistent with the literature. Spontaneous mast cell degranulation was observed in intact animals. Their frequency ranged from 5.4 to 8.6% and, in principle, did not depend on age. A comparative analysis of the frequency of degranulation, depending on age, showed that the frequency of degranulation in sensitized newborns is slightly lower than in older animals. However, with age in sensitized guinea pigs, the frequency of degranulated mast cell forms increased and the mast cell reactivity in one month aged pigs became approximately the same as in mature animals.

Conclusion: In general, the functional activity of mast cells increases with age, and by the age of one month reaches the level of functional activity. In the development of specific therapy, a decrease in the titer of homocytotropic antibodies and the percentage of mast cell degranulation is vital.

Keywords: *Allergy,mast cells, sensitization, degranulation, allergens, age-related features.*

Introduction

During the life of organ systems of human body, namely, homeostasis, protective and adaptive reactions, metabolic processes, blood circulation, respiration and others, an important role is played by connective tissue and blood. Among various connective tissue cells, mast cells are particular and learnt with high interest by scientists (Nasonov, 2017)[1]. They accomplish

extremely important functions: participate in the regulation of homeostasis, secrete biologically active substances (heparin, histamine, serotonin, dopamine, etc.), affect the entire system of connective tissue, and are actively involved in allergic reactions. In this regard, during the recent years, a new scientific field has arisen and is successfully developing, associated with the study of age-related changes in immune and allergic reactions at the cellular level (Baglay et al, 2015)[2]. For a long time, the prevailing opinion in medical science was that cells are always damaged as a result of the formation of an immune complex on the surface of their membranes (Tsibulkina et al, 2017)[3]. It has now been clearly established that the formation of immune complexes on the surface of target cells is not always accompanied by cell destruction (Gushchin, 2019)[4]. In most cases, it is not destruction, but excitation, that is, an increase in their functional activity. This information opens up a new promising area that allows us to develop pharmacological method for the management of allergic reactions and not it is possible to use drugs that reduce and inhibit excitatory processes in mast cells (Kryshen et al, 2018)[5].

Despite the fact that mast cells are the subject of many researches, many aspects of their physiology and pathology remain unsolved[6]. So, for example, the question of age-related features of mast cell reactivity in normal and allergic reactions is of great scientific interest (Artishevsky et al, 2016). The fact is that mast cells are among the most reactive cells in the body. They quickly respond to various exogenous and endogenous effects (Namazova-Baranova et al, 2017)[7]. The study of mast cell reactivity in the dynamics of allergy development allows us to determine the pathological process in the early stages of their development, which is of great diagnostic, therapeutic and preventive value. It is believed that the clarification of the reactivity of mast cells allows one to indirectly judge the general condition of the organism as a whole. In addition, mast cell reactivity can be used to objectively evaluate the effectiveness of therapy (Abaturov et al, 2017)[8].

Thus, elucidation of the age-related features of mast cell reactivity contributes to the expansion of our ideas about the features of the clinic, etiology and pathogenesis of allergies in ontogenesis[9]. Above mentioned points make us to conduct this research. The identification of age-related features of mast cell reactivity in allergic reactions, in our opinion, will contribute to the successful solution of certain fundamental aspects of the National Program of the Ministry of Health of the Republic of Uzbekistan for the treatment and prevention of allergies[10].

The aim of the study was to identify age-related features of mast cell reactivity in allergic conditions and to develop criteria for therapeutic effectiveness based on an experimental model of specific hyposensitizing immunotherapy[11].

The age-related features of reactivity, quantitative content, filling of cells with granules, functional activity of tissue (mesentery) and peritoneal mast cells in intact guinea pigs have been established[12]. It was revealed that the body of guinea pigs in early postnatal ontogenesis (newborns, two weeks) is reactive to exogenous allergenic effects[13]. It was determined that the reactivity of mast cells of guinea pigs increases with age and reaches a level of reactivity in mature adults. It was established that mast cells of young guinea pigs are actively involved in the development of allergic reactions of an immediate (anaphylactic) type[14].

Criteria have been developed for evaluating therapeutic efficacy based on an experimental model of specific hyposensitizing immunotherapy in guinea pigs of different ages[8]. It has been established that the most important objective indicators of experimental specific therapy of anaphylactic allergy are the determination of the level of HCA titer in blood serum, the frequency of mast cell degranulation and the anaphylactic index[3].

Materials and Method

Study Population: The experiments were conducted on 443 guinea pigs of both sexes of different ages, which previously passed 10-14 day-quarantine control under conditions of vivariums: experimental - 274, control - 169. By age, guinea pigs were distributed as follows: newborns - 108 (24.4%), two-weeks - 117 (26.4%), one-month - 120 (27.1%), mature - 98 (22.1%).We paid attention to the general condition, feed intake, mobility, shine of the coat, absence of outflows from visible mucous membranes (eyes, nose, anal and genital openings). Animals were constantly monitored, body weight was periodically determined, and rectal temperature was measured. Animals were fed with normal (traditional) food. Before the experiments animals were not fed during one day. In general, we provided with all the necessary requirements for experimental research. Sensitization and anaphylactic reactions were reproduced by conventional method[1].

Normal horse serum was used as an allergen. The resolving dose of a specific allergen was administered once intravenously (hind paw) or intraperitoneally 14-16 days after the start of the first sensitizing dose of the allergen. The severity of general anaphylactic shock and the calculation of the anaphylactic index (AI) were evaluated by Weigle et al. The histamine shock is reproducible in two versions: 1) the deadly histamine shock was reproduced by intravenous administration of 0.1% histamine at the rate of 4-6 mg/kg of animal body weight; 2) non-fatal histamine shock was reproduced by subcutaneous administration of histamine at the rate of 2 mg/kg of animal body weight[2].

Homocytotropic antibodies (HCA) in the blood serum of sensitized guinea pigs are determined by the generally accepted method of reproducing a cutaneous passive anaphylactic reaction. The reaction was considered positive if the diameter of the stained spot on the skin was at least 6 mm. Tissue (mesentery of the small intestine) and peritoneal mast cells in guinea pigs were obtained by a well-known method in compliance with sterility.

Mast cells were fixed in absolute alcohol and stained with 1% solution of toluidine blue in 60° alcohol. The frequency of granular mast cell forms showed in percentage by viewing different fields of view of smears under a microscope with a magnification of 5x95. Specific therapy was carried out according to the scheme developed by us. To control animals, sterile saline was injected subcutaneously at the same time instead of a specific allergen.

Statistical Data Analysis: Digital data processed on electronic micro calculator Rokwell international Model 44 (USA). The following indicators were calculated: 1) arithmetic and geometric mean values; 2) the negative logarithm of the geometric mean titer of antibodies when the base is equal to two; 3) the correlation coefficient; 4) the significance of differences between the compared average values. Information was considered reliable provided that t22, and $p < 0.05$.

Results

An analysis of our own experimental studies revealed the age-related features of mast cell reactivity in normal and in allergic reactions, anaphylactic type. In intact guinea pigs, mast cells are scattered in all organs and systems of the body. However, their quantitative content in tissues compared with other animal species (rats, mice, hamsters) is much less.

Nevertheless, in the development of allergic reactions of guinea pigs, they are crucial (Eliseeva et al, 2016). In this regard, it was of some interest to clarify the age-related characteristics of the number of mast cells in guinea pigs. In the mesentery of the small intestine of intact newborn guinea pigs (with an increase of 100 times), the number of mast cells, in comparison with guinea pigs, is more than that of older age (two-weeks, one-month, sexually mature) for 1.9-3.7 times (Table 1), which is consistent with the literature.

It is believed that this phenomenon is associated with a deep change in the environment after birth, mechanical influences during childbirth, etc. According to some researchers, the decrease in the number of mast cells after birth is explained by the blockade of the color of the protein-polysaccharide interaction, which is more important for the proliferation of mast cells. The analysis of mast cell fullness by granules was observed with great interest; where biological active substances are concentrated (histamine, serotonin, etc.).

Guineapigsage	The number of mast cells in the field of view (M±m)	Mast cell degranulation rate (M ± m%)
Newborns (n=10)	268,9±11,2	5,4±1,6
Twoweeks (n=10)	136,0±6,2*	6,2±1,3
One month (n=10)	84,1+1,1*	7,6±0,6
Sexuallymature (n=10)	72,7+2,2*	8,6+0,7
Total: 40	---	---

Note: * The difference in comparison with the performance of newborns is significant ($p < 0.05$).

They determine the pathochemical phase of the pathogenesis of an allergy of an immediate type. The indicator of filling mast cells with granules is given great importance because a smaller filling with granules does not indicate that they are poorly developed, but, on the contrary, increase their functional activity. According to our data, age-related features of filling mast cells with granules are observed in intact guinea pigs. With age, the rate of filling mast cells with granules increases. In guinea pigs of an older age, as compared to newborns, the rates of filling mast cells with granules are 1.3-2.2 times greater ($p < 0.05$), which is consistent with the literature.

Thus, on the whole, the following regularity was revealed — in guinea pigs of different ages: in newborns, in comparison with older animals, the total number of mast cells is greater, and the nature of filling the cells with granules is less.

According to our data, spontaneous mast cell degranulation was observed in intact animals. Their frequency ranged from 5.4 to 8.6% and, in principle, did not depend on age (table. 1). However, the age-related features of mast cell degranulation in allergic reactions were clarified. Sensitization showed a significant increase in the mast cell degranulation rate, in comparison with similar indicators in intact guinea pigs, 1.2-3.0 times ($p < 0.05$). A comparative analysis of the frequency of degranulation, depending on age, showed that the frequency of degranulation in sensitized newborns is slightly lower than in older animals. However, with age in sensitized guinea pigs, the frequency of degranulated mast cell forms increased and the mast cell reactivity in one month aged pigs became approximately the same as in mature animals (Table 2).

Table 2: Age-related features of the frequency of degranulation of mast cells of the mesentery of the small intestine in guinea pigs with sensitization and anaphylactic shock (n = 145).

Age of animals	Sensitization (M± м%)	Anaphylactic shock (M± m%)	Control (M± м%)
Newborn	10(6,5+0,8)	21(15,2+0,8)*	6(5,3+1,3)
Two weeks	10(12,3+0,9)**	19(27,2+1,3)*	6(6,0+1,1)
One month	10(25,6±1,3)**	20(61,0±1,6)*	6(8,0+0,7)
Sexually mature	10(21,9+2,3)**	21(65,0+2,1)*	6(7,3+0,7)
Total	**40**	**81**	**24**

Notes: Between indicators of anaphylactic shock and control * (*). and also between the sensitization and control indicators (**) reliability ($p < 0.05$).

The study of the reactivity of guinea pigs of different ages with experimentally reproduced anaphylactic shock was also of some interest. In the literature, there is conflicting information on this issue. Some researchers believe that in the early postnatal age, the body does not respond to allergenic effects, asimmunocompetent system is poorly developed. Other researchers believe that newborns are actively sensitized. It turned out that guinea pigs in early postnatal ontogenesis are reactive to exogenous allergenic effects, as evidenced by the development of general anaphylactic shock with parenteral administration of a resolution dose of a specific allergen. Along with this, age-related features of anaphylactic shock were revealed: in young animals (newborns, two weeks old), cases of mild and moderate severity of anaphylactic shock (AI = 1.7-2.6) prevailed, and in one-month-old and mature ones, severe and fatal (AI = 2 9-3.7). In the mechanism of development of allergic reactions in general and anaphylactic shock in particular, mast cells and their biological active substances are crucial. In anaphylactic shock, the frequency of mast cell degranulation in comparison with similar indicators in sensitization was significantly ($p < 0.05$) higher in newborns - 2.3 times, two-week 2.2 times, one-month 2.3 times, and mature - 2.9 times. Similar results were noted in the study of reactivity of peritoneal mast cells sensitization and anaphylactic shock (table. 3). With sensitization, compared with intact guinea pigs, the mast cell degranulation rate was 1.6 times higher in newborns in two weeks, 3.4 times higher one-month - 5.7 times, sexually mature - 7.2 times (p-0, 5). With anaphylactic shock, the frequency of mast cell degranulation was even greater than with sensitization.

Table 3: Age-related features of the frequency of peritoneal mast degranulation in guinea pigs during sensitization and anaphylactic shock (n = 81).

Age of the animals	Sensitization (M± м%)	Anaphylactic shock (M± m%)	Control (M± м%)
Newborn	12(10,7+0,97)**	12(13,5+0,88)*	6(6,5:0,96)
Two weeks	15(22,2+0,37)**	15(26,4+1,11)*	6(6,5.0,96)
One month	16(39,8:0,70)**	16(50,8+0,70)*	6(6,8.0,98)
Sexually mature	14(45,8+1,4)**	14(73,9+2,43)*	6(6,3+0,7)
Total	57	57	24

Note: the differences between anaphylactic shock and control (*), as well as between sensitization and control, are significant ($p < 0.05$).

Discussion

In the mechanism of development of anaphylactic shock in guinea pigs, the decisivehistamine is important (Soldatov et al, 2016). According to our data, with histamine shock, the frequency of mast cell degranulation increased sharply, moreover in older animals, which indicates a sharp increase in the functional activity of these cells. In histamine shock, the mast cell degranulation rate in sexually mature guinea pigs was 4 times higher than the mast cell degranulation rate in newborn guinea pigs.

The question arises: why in rats, mice and hamsters, where there are many times more mast cells than guinea pigs, the clinical symptoms of anaphylactic shock are weakly expressed? Apparently, this is due to the fact that their mast cells are scattered in all tissues and organs more or less evenly. In addition, immunocompetent cells of these animals weakly synthesize humoral antibodies (Johansson et al, 2001). In the body of guinea pigs, the spread of mast, cells around the smooth muscles of the bronchioles, bladder and intestines is much greater than in other animals. In this regard, during allergic reactions on the cytoplasm of mast cells of guinea pigs, a large amount of histamine is released, which causes spasm of bronchioles, contraction of the smooth muscles of the gastrointestinal tract and bladder, and expansion of peripheral small arteries and arterioles (Reese et al, 2002). As a result of this, all the main symptoms of anaphylactic shock acutely develop: asphyxia, hypoxia, involuntary defecation and urination. One of our tasks was to study the importance of mast cells in the mechanism of development of specific therapy. Although specific therapy has been used in practical medicine for more than 90 years, nevertheless there are many unresolved issues, among which age-related features of indications and contraindications, the importance of mast cells in the mechanism of development of specific therapy, are important.

Studies have shown that specific HCA are detected in the blood serum of sensitized animals. However, the HCA titer depended on the age of the experimental animals: fewer (3.5 ± 1.2) y newborns and more (7.5 ± 0.6) in older guinea pigs. After specific treatment, the HCA titer in animals of all age groups, compared with the HCA titer before treatment, decreased 1.7-2.3 times ($p < 0.05$). The study of mast cell reactivity with specific therapy showed the following results. The frequency of mast cell degranulation compared with indicators before treatment significantly decreased ($p < 0.05$). Specific therapy also effectively prevented the development of general anaphylactic shock. All animals remained alive. Excellent results were observed in the sexually mature (AI = 0), good results were observed in the one-month (AI = 0.1), two-week (AI = 0.3) and newborns (AI = 0.6). Analysis of the actual material indicates that mast cells also take an active part in the mechanism of development of specific therapy, along with cells of the immunocompetent system.

In general, currently, there are various theories regarding the pathogenesis of specific therapy: increasing the synthesis of blocking antibodies, neutralizing specific allergic antibodies, switching the synthesis of allergic antibodies to the synthesis of blocking antibodies, strengthening the factors of nonspecific defense of the body, strengthening the synthesis of anti-inflammatory factors, etc.

All these theories are based on actual clinical and experimental facts (Nadein et al, 2012). Our data support the theory of neutralizing specific allergic antibodies.

Indeed, according to our data, after specific therapy, the titer of specific HCA significantly decreased in all age groups of animals, including newborns, two-week and one-month-old ones. However, the mechanism of this phenomenon is not clear. There is an opinion that when conducting specific therapy, the process of multifaceted "microshocks", that is, the interaction of HCA with allergens, occurs. Thus, allergic antibodies are gradually eliminated. However, not all scientists agree with this treatment. It is believed that inhibition of HCA synthesis is crucial in the mechanism of specific therapy. Our data are also consistent with the theory of inhibition of the synthesis of mediators by mast cells. According to our data, there is a significant decrease in the frequency of mast cell degranulation in all age groups of animals. Thus, using a complex of allergological and immunological method, it was possible to identify age-related features of the reactivity of tissue and peritoneal mast cells, both in norm and in allergic reactions of anaphylactic type.

Conclusion

The following age-related features of tissue (mesentery of the small intestine) mast cells in intact guinea pigs are noted: their quantitative content in newborns is greater in 1.9-3.2 times, and the filling rate of cells with granules is 1.3-2.2 times less than that of two-weeks, one-month and sexually mature ones; functional activity of some (minimum) partmast cells of all age groups of guinea pigs is increased, as evidenced by the presence de granulated cell forms; in general, the functional activity of mast cells increases with age, and by the age of one month reaches the level of functional activity, the characteristics of the reaction are fat and mature.

Furthermore, the organism of guinea pigs in early postnatal ontogenesis (newborns, two weeks) is reactive to exogenous allergic effects, as evidenced byidentification of specific homocytotropic antibodies in the blood serum of sensitized animals and the development of anaphylactic shock with repeated parenteral administration of a specific allergen, with mild and moderate cases predominate in young people (AI = 1.7 and 2.6),and in one-month-old and sexually mature - heavy and fatal (AI = 2.9 and 3.7). The functional activity of tissue and peritoneal mast cells significantly increases in all age groups of guinea pigs, and with active sensitization in1.2-3.0 times, anaphylactic shock - 2.8-8.9 times, histamine shock - 3.0-10.6 times.An experimental model of specific therapy with a positive therapeutic effect can be successfully reproduced on young guinea pigs(newborns, two weeks, one month). In the mechanism of development of specific therapy, a decrease in the titer of homocytotropic antibodies and the percentage of mast cell degranulation is essential.

Recommendations: It is fact that the indicators of the frequency of mast cell degranulation, in combination with other clinical and laboratory data, can be used to objectively assess the initial state of an allergic reactive organism, which will improve the quality of specific diagnosis of allergies in the early stages of its development, and also when clinical symptoms are absent, that is, with latent sensitization. An experimental model of a specific hyposensitizing immunoterium FDI in guinea pigs of different ages can be used to evaluate the therapeutic efficacy of different allergens non-infectious origin. The discovery of new scientific facts about the active participation of mast cell mast cells in early postnatal ontogenesis during sensitization and allergic reactions broadens our understanding of the age-related features of the pathogenesis of immediate (anaphylactic) allergy in developing organisms.

1. The age-related features of reactivity, quantitative content, filling the cells with granules and reactive tissue (mesentery of the small intestine) and peritoneal mast cells in intact guinea pigs are noted.
2. The reactivity of mast cells of guinea pigs increases with age and reaches a level of reactivity in mature adults.
3. The organism of guinea pigs in early postnatal ontogenesis (newborns, two weeks) is reactive to exogenous allergenic effects. As evidenced by the successful reproduction of sensitization and anaphylactic reactions.
4. The mast cells of young guinea pigs (newborns, two weeks) take an active part in the development of allergic reactions of the immediate type, as evidenced by a significant increase in their functional activity during sensitization, anaphylactic and histamine shock.
5. In young guinea pigs, an experimental model of specific hyposensitizing immunotherapy is successfully reproduced, in the mechanism of development of which a decrease in the titer of homocytotropic antibodies and the percentage of mast cell degranulation is essential.

Study Limitations: The study is animal based research. Expected outcomes and results of the interventions might be different on humans. Thus, in case of implementation the achievements of the study on patients, this factor has to be taken into account.

Acknowledgements: We are grateful to the staff members of laboratory of the Department of Pathological Physiology of Tashkent Pediatric Medical Institute for the cooperation and support in our research. Authors also appreciate the support of mathematicians and statisticians who contributed great effort on this paper.

Ethical Approval: During the study respected the principles of a human attitude towards laboratory animals. The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Correlation of the Main Parametres of Immun Systeminchildren with Localized Scleroderma by the Stages of the Disease

Mun Andrey[1], Abdushukur Mannanov[2]

[1]Scientific Researcher, MD, Teaching Assistant, Department of Dermatological and Venereal Diseases, Pediatric Dermatological and Venereal Diseases and AIDS, Tashkent Pediatric Medical Institute, 223 Bogishamol Str., Yunusobod district, Tashkent, Uzbekistan, [2]Doctor of Medical Sciences, Professor, MD, Department of Dermatological and Venereal Diseases, Pediatric Dermatological and Venereal Diseases and AIDS, Tashkent Pediatric Medical Institute, 223 Bogishamol Str., Yunusobod District, Tashkent, Uzbekistan

Abstract

Introduction: In spite of significant development in modern medicine, the tendency of increase in the number of patients with localized scleroderma (LS) remaining actual with more severe clinical courses. Therefore, LS remains as one of the urgent problems of healthcare system. The etiology and pathogenesis of the disease is still unclear. Yet, LS frequently associates with deep and wide immune disorders and subsequent complications.

Materials and Method: We studied 45 children with LS, of whom 25 patients had a linear form, 16 had plaque form, Pazini-Pieriniatrophodermia – in 2 participants, scleroatrophic lichen in 2. The control group included 30 conditionally healthy children. We conducted monitoring of the cellular immunity system with immunophenotyping using specific monoclonal antibodies to surface molecules CD3, CD4, CD8, CD16, CD20, CD25, CD54, CD95. Determination of the main classes of immunoglobulins in serum - IgG, IgA, IgM was also carried out.

Results: There was a significant decrease in the number of T-helpers - CD4: at the stage of erythema and edema by 1.3 times, with sclerotic and atrophic - by 1.2 times. The content of cytotoxic CD8-lymphocytes significantly decreased at the stages of erythema, edema and sclerotic on average by 19.4%. As a result of more significant inhibition of CD8, the CD4/CD8 ratio became larger (by 24%, 25%, and 11%, respectively, at the stage of erythema, sclerosis, and atrophy) than in the group of conditionally healthy patients. Patients with LS, a statistically significant decrease in the serum percentage of total T-lymphocytes - CD3, and at the stage of erythema and atrophic edema it was 11.4%, and at the stage compaction - 6.3% compared with the parameters of control group.

Conclusion: According to the level of inflammatory process with LS, immune dysfunctions are associated with a decline in the total amount of blood lymphocytes, namely CD4 T-helper cells and CD8 T-suppressors, CD54 endotheliocyte adhesion molecule, especially in the stages of erythema and edema or sclerosis. Learning these parameters may help to assess the immunological changes, and can be informative for the determination of the course, prognosis and further treatment.

Keywords: *Morphea, localized scleroderma, children, cellular immunity, humoral immunity, interleukin.*

Introduction

Localized scleroderma (LS) or “morphea” is a progressive lesion of the connective tissue of the dermis and hypodermis, without involvement of internal organs in the process with a predominance of fibro-sclerotic and vascular disorders, such as obliterating endarteriolitis with widespread vasospastic changes. The disease develops on the background of genetically determined

imperfection of immunoregulatory processes, resulting in the formation of antibodies to own cells and their components, the occurrence of immunocomplex inflammation, leading to tissue damage (Mannanov & Moon, 2018; and Moon, 2019)[1].

Despite intensive studies during the last few decades, there is a tendency to increase the number of patients with LS with a more severe clinical course, thus, LS remains as one of the urgent problems of modern medicine[2]. The etiology has not yet been identified well, and the pathogenesis of the disease is also unclear[3]. The issues of clarifying the links in the pathogenesis of LS, determining diagnostic markers of the severity of the process, and substantiating new treatment method based on certain disorders remain as actual problem today (Moon, 2019; and Shostak et al, 2015)[4]. However, the main role in the development of scleroderma is played by 3 theories of pathogenesis, immune disorders, metabolic pathology and vascular disorders in the connective tissue. One of the main links in the pathogenesis of scleroderma is immune disorder (O'Brien et al, 2017; and Torok et al, 2015)[5]. However, the data on this issue are still disputable and require some improvements. It is important to evaluate the immune disorders in the blood, leading to morphological changes in the lesions by considering the course of dermatosis.

With localized scleroderma, pathological autoimmune processes develop with signs of activation of the T-cell link of the immune system, associated with ineffective suppressor mechanisms in the immune system, which are represented by cytotoxic T-lymphocytes and some other subpopulations of T- and B-lymphocytes.An increase in IL-2, IL-4, IL-6, and soluble IL-2 receptors in patients with limited scleroderma indicates activation of cellular immunity (Suzanne, 2018)[6].

Dysregulatory disorders are accompanied by increased production of pro-inflammatory cytokines IL-2, TNFα and INF-γ, contributing to the development of early autoimmune inflammation[7].There is no doubt that the pathogenesis of scleroderma is associated with a dysfunction of human immunity[8]. Evaluation of the immune status with diagnostic, therapeutic, prognostic and preventive purposes in patients with limited scleroderma remains an extremely urgent issue[9].

The aim of our work was to study the characteristics of the immune status of children with LS at different stages of the disease[10].

Materials and Method

Study Population: We studied 45 children with LS from January 2013 to December 2019, of whom 25 patients (55.5%) had a linear form, 16 (35.5%) had plaque form, Pazini-Pieriniatrophodermia–in 2 participants (4.4%), scleroatrophic lichen in 2 (4.4%). The degree of severity, characterized by a mild course, was observed in 12 children, II degree, moderate in severity - 22, III degree, which was characterized by a severe course - in 11.Of the total number of patients with LS in the abdominal and linear form, 16 (35.6%) patients were diagnosed with the stage of erythema and edema.In 18 patients (40%), the stage of sclerosis was diagnosed (I degree of severity - 4, II degree - 9, III degree - 5), 11 - stage of atrophy (I degree of severity - 4 people, II degree - 5, III degree - 2).

All patients with Pasini-Pieriniatrophodermia were in the stage of sclerosis (I severity). Patients with scleroatrophic lichen were in the acute stage of II severity and II severity. Thus, we studied children with LS at the stage of erythema and edema - 16 (35.6%), at the stage of sclerosis -18 (40%), atrophy - 11 (24.4%). The number of boys was 12 (26.6%), and girls - 33 (73.3%). The mean age of the examined was 6.8 ± 0.8 years.

Clinical and laboratory tools: The diagnosis of LS was verified and established according to clinical and laboratory data, and the severity according to the dermatological indices of the LoSCAT (Localized Scleroderma Assessment Tool) including mLoSSI (Modified Localized Skin Severity Index), LoSDI (Localized Scleroderma Damaged Index), based on an assessment of 3 separate processes - erythema, skin tightening, the appearance of new elements or an increase in existing ones during the previous month, the degree of atrophy of the skin and subcutaneous fat, as well as the severity of pigmentation (Zulian, 2017; and Teske & Jacobe, 2018)[11].

The control group included 30 conditionally healthy children who permanently reside in Tashkent city and the Tashkent region (18 girls and 12 boys, average age 7.4 ± 0.9 years).

Monitoring the state of the cellular immunity system was carried out by immunophenotyping using specific monoclonal antibodies to surface molecules CD3, CD4, CD8, CD16, CD20, CD25, CD54, CD95 of the "Scientific-Production Center" LLC (Moscow). The determination of the main classes of immunoglobulins in

serum - IgG, IgA, IgM, is the main method for assessing humoral immunity and their determination is of great diagnostic value in the diagnosis and monitoring of primary immunodeficiencies and autoimmune diseases. The content of immunoglobulins A, M, G in serum was determined by the enzyme-linked immunosorbent method "Immunoglobulins A, M, G - IFA". The concentration of circulating immune complexes was determined according to the method of Grinevich and Alferov (Mannanov & Moon, 2018; and Shostak et al, 2015)[12].

Immunocompetent cells were verified using "Chemicon" monoclonal antibodies (MCAs) (product of USA) in mature T-lymphocytes (CD3), T-helpers (CD4), T-suppressors (CD8), B-lymphocytes (CD22), macrophages (CD16), IL-1 and IL-2. Cells expressing receptors for HLA-Drantigen were determined using the MCA HLA-Dr antigen of the same company. The relative volumes of immunocompetent cells were determined by the aqueous field of view of the microscope in terms of 100 cells.

Results

Immunomorphological studies were carried out in 45 children with LS, of which 16 patients (35.6%) of the abdominal and linear forms were diagnosed with erythema and edema (I severity -5 people, II degree - 8, III degree - 3), in 18 patients (40%) - the stage of sclerosis (I degree of severity -4 people, II degree - 9, III degree - 5), in 11 patients (24.4%) - stage of atrophy (I degree of severity -4 people, II degree - 5, III degree - 2). The age of patients ranged from 2.5 to 17 years (average age was 6.8 ± 0.8 years), among whom there were 12 boys (26.6%), and girls - 33 (73.3%), the duration of the disease from 1 month up to 6 years.

When analyzing the obtained data of the immune parameters of the blood of children with LS, inhibition of the T-system of immunity was revealed - a statistically significant decrease in the serum percentage of total T-lymphocytes - CD3, and at the stage of erythema and atrophic edema it was 11.4%, and at the stage compaction - 6.3% compared with the parameters of control group.

There was also a significant decrease in the number of T-helpers - CD4: at the stage of erythema and edema by 1.3 times, with sclerotic and atrophic - by 1.2 times. The content of cytotoxic CD8-lymphocytes significantly decreased at the stages of erythema, edema and sclerotic on average by 19.4%. As a result of more significant inhibition of CD8, the CD4/CD8 ratio became larger (by 24%, 25%, and 11%, respectively, at the stage of erythema, sclerosis, and atrophy) than in the group of conditionally healthy patients.

The content of CD8-lymphocytes at the atrophic stage increased up to the level of control group. Despite the revealed disorders of the immune system, no statistically significant differences were found in patients with different numbers of lesions.

An increase in the immunoregulatory index indicated an activation of the immune system in the stage of edema and erythema, as well as in the stage of early sclerosis, however, a decrease in this indicator in the stage of atrophy and sclerotherapy in the later stages showed inhibition of immunity (Table 1).

Table 1: The content of lymphocyte subpopulations in the blood of patients with LS depending on the stage of the disease in children

Indexes	Control n = 30	Stage of the disease		
		Edema n = 16	Sclerosis n = 18	Atrophy, n = 11
CD3+,% (Overall pool of T-lymphocytes)	56,5 ± 1,3	42,0 ± 1,3	47,8 ± 2,2	41,4 ± 2,9
CD4+,% (T-helpers)	33,8 ± 1,4	22,3 ± 1,2	26,2± 1,1	27,1 ± 1,8
CD8+,% (T-citotoxic lymphocytes)	22,6 ± 0,6	15,2 ± 1,8	16,3 ± 1,4	25,0 ± 1,7
CD4/CD8 (immunoregulation index)	1,8 ± 0,04	2,47 ± 0,22	2,27 ± 0,27	1,37 ± 0,18
CD16+,% (natural killers)	14,5 ± 0,8	18,5 ± 1,7	19,3 ± 2,6	19,9 ± 1,5
CD20+,% (B-lymphocytes)	20 ± 0,7	24,5 ± 0,5	25,3 ± 2,5	26,0 ± 1,0
CD25+,%	7,4 ± 0,5	15,4 ± 3,0	18,1 ± 0,5	16,5 ± 1,0
CD95+,% (factor of apoptosis)	17,2 ± 0,5	22,3 ± 1,3	26,8 ± 1,0	24,1 ± 1,5

Indexes	Control n = 30	Stage of the disease		
		Edema n = 16	Sclerosis n = 18	Atrophy, n = 11
CD54+,% (factor of adhesion)	23,4 ± 1,1	14,2 ± 1,2	11,8 ± 1,0	17,1 ± 1,8
Leucocytes, $x10^9$/l	5,98 ± 0,27	6,45 ± 0,42	6,71 ± 0,38	6,64 ± 0,33
Lymphocytes, $x10^9$/l	2,26 ± 0,19	2,05 ± 0,16	2,16 ± 0,15	2,63 ± 0,11

It was important that significant decrease in the blood serum of patients with respect to the content of intercellular adhesion molecules, which are surface antigens of activated B-lymphocytes-CD54, namely, 36% at the stage of erythema and edema, 38% at sclerotic, 28% at atrophic stages of the disease compared with the control group. The content of adhesion molecules of endothelial cells CD54 at the atrophic stage of the disease remained significantly increased compared with the sclerotic stage by 41.7%.

It should be noted that the number of CD95 + cells responsible for apoptosis in sick children at the stage of atrophy increased by 27.2%.Especially statistically significant differences in the number of lymphocytes of different phenotypes were found for CD16, CD25 and CD95, the content of which was increased compared with conditionally healthy patients.

The stages and nature of the immunological process reflect the expression data of activation markers that depend on the functional activity of immunocompetent cells. Interpretation of the expression of active markers on the surface of lymphocytes showed a significant increase in apoptosis processes, in patients with LS as evidenced by an increase in cells carrying apoptosis receptors - CD95, the most pronounced increase was at the sclerotic stage - by 57.6% compared with the control group.

The relative content of CD95 in the stages of edema and atrophy was 31.2% and 41.7%, respectively. At the same time, an increase in the expression of receptors for CD95 testified to a significant destruction of lymphocytes, which led to immunodeficiency, a decrease in the number of lymphocytes, inhibition of T-suppressors and an increase in circulating immune components (CIC)in the blood.

In the examined patients, the content of markers of the early stage of cell activation, IL-2 CD25 activators increased by 2.1 and 2.4 times in the cases of erythema and edema and atrophic, respectively, and 2.2 times in the sclerotic stage compared with the control. As you know, IL-2 is a pro-inflammatory cytokine, which leads to inflammation, the appearance of severe vasculitis. Its level remained high throughout the entire disease, which led to a chronic process, activation, and the appearance of a significant pool of proliferating lymphocytes in LS. The amount of natural killers - CD16 increased on average by 35.2%, a change in the content was especially pronounced during the sclerotic and atrophic stages. A significant increase in the percentage of activation markers of the B-cell chain of the CD20 immune system was 22.5%, 26.5%, 30%, respectively, at the stages of erythema and edema, sclerotic and atrophic, compared with the control group.

The dynamics of changes in the lymphocyte phenotype was observed in the sclerotic and atrophic stages of the OS against the background of an increase in the total number of leukocytes and a relative decrease in lymphocytes. A decrease in the number of T-lymphocytes with an imbalance of subpopulations against the background of the development of activation processes and their increased tendency to apoptosis probably leads to a loss of control of T-lymphocytes in relation to B-cells, with their subsequent activation.

Our results indicate a significant increase in blood levels of IgM and IgG in the examined LS patients compared with the control against the background of insignificant changes in the content of IgA. The most pronounced was an increase in IgG, the content of which increased by 24.3%, 15.1% and 39.8%, respectively, at the stages of edema, compaction and atrophy.

In children with LS in the blood serum, an increase in the level of large and small circulating immune complexes of the CIC by 47.4% and 26.9% in the sclerotic and atrophic stages of the disease, by 63.9% in the stage of erythema and edema compared with the control (table 2). The production of antibodies, including autoantibodies, is controlled by the corresponding cytokines.

Table 2: The main indicators of the humoral immunity in the blood serum of children with LS

Indexes	Control, n = 30	Stage of the disease		
		Edema n = 16	Sclerosis, n = 18	Atrophy, n = 11
Ig A, g/l	1,82 ± 0,11	1,93 ± 0,14	1,71 ± 0,09	1,74 ± 0,11
Ig M, g/l	1,4 ± 0,07	2,01 ± 0,05	2,1 ± 0,04	1,93 ± 0,07
Ig G, g/l	9,73 ± 0,32	12,1 ± 1,77	11,2 ± 1,48	13,6 ± 1,29
CIC, y.e.	38,2 ± 3,3	62,6 ± 8,4	56,3 ± 9,2	48,5 ± 4,6

In the blood serum of patients with LS in the stage of edema, a significant increase in the content of IL-1β was detected on average 4.9 times, IL-4 2.05 times and IL-6 8 times compared with the control. In the sclerotic stage, these indicators increased by 3.7 respectively; 1.93 and 5.7 times; at the atrophic stage - 5.7; 1.7 and 3 times (table 3).

Table 3: The main indicators of the content of cytokines in the blood serum of children with OS, depending on the stage of the disease

Indexes	Control, n = 30	Stage of the disease		
		Erythema and edema, n = 71	Sclerotic n = 47	Atrophic, n = 37
IL-1β	5,68±2,12	27,92±3,12	21,1±2,38	32,41±2,83
IL-4	5,75±2,05	11,81±1,23	11,07±1,24	9,93±0,9
IL-6	5,71±1,7	45,53±6,09	32,32±5,23	17,42±1,93
TNFα	2,85±0,63	11,36±1,2	9,74±1,61	8,18±1,52
IFN-γ	273,3±28,9	95,8±9,1	78,5±8,2	168,3±12,1

Discussion

IL-1β, which is a pro-inflammatory cytokine, has numerous common effects and can contribute to the development of the systemic nature of the pathological process by forming autoantibodies and increasing the concentration of CRP in the blood. It should be noted that IL-4 and IL-6 are one of the frequently determined cytokines in the blood serum of patients with scleroderma. (O'Brien et al, 2016; and O'Brien et al, 2017).

In addition to B-lymphocytes, monocytes, macrophages and fibroblasts are also sources of IL-6 in scleroderma (Toroket al, 2015; and Suzanne, 2018). IL-6 is involved in the induction of almost the entire complex of local manifestations of inflammation. It affects the migration of phagocytes, enhancing the production of chemokines that attract monocytes and lymphocytes, and weakening the production of chemokines that attract neutrophils. The pro-inflammatory effects of IL-6 are less pronounced than that of IL-1 and TNFα, in contrast to which it does not enhance, but inhibits the production of pro-inflammatory cytokines (IL-1, TNFα and IL-6) and chemokines by cells involved in the inflammatory process (Toroket al, 2015). Thus, IL-6 combines the properties of pro- and anti-inflammatory cytokines and is involved not only in the development, but also in limiting the inflammatory response (Speeckaert et al, 2016).

Cytokines play an important role in the regulation of all aspects of the functioning of the immune system, including the differentiation of lymphoid cells, inflammation, the development of the adaptive function of the immune response, and others. One of the most important regulators of reactions of both non-specific and adaptive immune responses is TNFα and IFN-γ. TNF is produced both by cells of the immune system (B and T lymphocytes, basophils, eosinophils, dendritic cells, nK-cells, neutrophils) and other types of cells (astrocytes, fibroblasts, glial cells, keratinocytes), however, the main producers are monocytes and tissue macrophages (Toroket al, 2015; and Florez-Pollack et al, 2018).

IFN-γ is synthesized by activated antigen-specific T-lymphocytes (CD4 + th1 type). Interferon-γ has a strong immunoregulatory effect and occupies one of the central places in the regulation of adaptive immune response (Florez-Pollack et al, 2018; and Suzanne, 2018). In the blood serum of patients with LS, an increase in TNFα content was observed compared with the norm, and it was most pronounced at the stage of erythema and edema of the disease by 3.9 times, its content was slightly lower at the sclerotic and atrophic stages - at 3.4 and 2.9 times, respectively, compared with the control.

Another dynamics was observed for the content of IFN-γ, in the form of a significant decrease of 2.9 times at the stage of erythema and edema, 3.5 times at the sclerotic stage and 1.6 times atrophic compared with the parameters of the group of conditionally healthy patients. Perhaps a decrease in the synthesis of IFN-γ is associated with a low content in patients with LS of their main producers of CD4 lymphocytes.

Thus, our results indicate that the leading link in the pathogenesis of LS is a significant change in the indicators of humoral and cellular immunity. In the studied stages of LS, against the background of an increased tendency of blood lymphocytes to apoptosis, there is a loss of control of T-lymphocytes in relation to B-cells, with their subsequent activation and a significant change in the quantitative and qualitative composition of the lymphocyte subpopulation. These changes are accompanied by immune disorders in the skin.Histological examination of the skin in the erythematous stage as a manifestation of acute vasculitis revealed volumetric intradermal lymphocytic infiltrates.A significant increase in the number of lymphocytes indicates the activation of the function of the mononuclear phagocyte system in response to the destruction of all elements of the dermis (Walker et al, 2017).

In the sclerotic stage of the disease, the total number of mature lymphocytes remained at the levels detected in the erythematous stage, while the number of macrophages tended to decrease.Such dynamics testified to a decrease in antigenic stimulation in the body, which was combined with the attenuation of alternative exudative processes, the beginning of the development of sclerotic processes in the papillary and reticular layers of the dermis, and partial atrophy of the skin appendages, especially hair follicles and sebaceous glands (Walker et al, 2017; and Florez-Pollack et al, 2018).A decrease in the number of IL-1 producing cells with a decrease in the number of lymphocytes indicates a subsidence of the inflammatory process in the skin and a decrease in the secretion of neutral proteases - collagenase and elastase, which stabilizes the structure of connective tissue and inhibits further collagen destruction.

Together with a decrease in the total number of T-lymphocytes and their varieties in the sclerotic stage, a significant change in the number of macrophages was detected, which was associated with the disposal and elimination of skin tissue destruction products. The decrease in the number of cells of the T-system of immunity compared with their content in the previous stage was consistent with the data of a histological study of biopsy samples of the skin of patients with LS in the sclerotic stage, when, against the background of pronounced sclerosis of the dermis, hypodermis and atrophy of the epidermis, signs of immune inflammation are either absent or weak with the exception of individual cases requiring a correct assessment of the nature of the process and the correction of conventional therapy.

In a histological examination of the atrophic stage of LS against severe sclerosis, developing hyalinosis, reduction of blood vessels and appendages of the skin, the extinction of alternative-destructive and inflammatory processes, the number of total T-lymphocytes reached low values, but did not decrease to normal values.Such dynamics of the indicators of immune homeostasis in the skin indicates that the final completion of immune inflammation in the body and skin does not occur, and therefore the patient has a chronic and relapsed disease. Thus, the results of histological analysis of the skin at the atrophic stage of OS reflect the extinction of the immune process as sclerotic and atrophic changes in the skin develop, but none of the indicators tend to normalize, and this is due to the fact that in the sclerotic, and even more so in the atrophic the stage of LS is no longer the decay products in the amount that was at the erythematous stage. The general state of histological changes in LS can be characterized as activation of the T-system of immunity, inhibition of the B-system of immunity. High rates of CD3, CD4 and CD8 from the very beginning of the disease and their weak dynamics indicate that a high activity of immune inflammation damages the walls of blood vessels with the development of plasma leakage, fibrinoid swelling and fibrinoid necrosis surrounding tissue with collagen destruction.

A significant decrease in the levels of CD4, IL-1 and IL-2 producing cells, the number of CD16 macrophages and a decrease in the immunoregulatory index are a prognostic sign of the transition to the next stage.

It should also be noted that in patients with LS in the atrophic stage, there is no normalization of all immunological parameters characterizing the absence of remission, but only clinical improvement against the background of persistent disease.

Conclusion

Depending on the stage of the inflammatory process of LS, immune disorders are accompanied by a decrease in the total amount of blood lymphocytes due to subpopulations, namely CD4 T-helper cells and CD8 T-suppressors, CD54 endotheliocyte adhesion molecule, especially in the stages of erythema and edema or sclerosis. Due to the destruction of cellular contacts of endotheliocytes, the vesselwalls thickened, develop plasma impregnation and migration of immune cells into the perivascular space and dermis, which is confirmed by histological studies at different stages of the pathological process.

The study confirmed the important role of the activation of the T-cell link of the immune system in the pathogenesis of OS development, characterized by the appearance of immune inflammation, mainly from CD4 and CD8 lymphocytes, as well as producing cells of IL-1 and IL-2, which are inflammatory mediators. Interpretation of the results of immunograms in patients with LS revealed a significant increase in the blood of pro-inflammatory - IL-1β, IL-6, TNFα, anti-inflammatory (IL-4) cytokines and macrophages CD16, B-lymphocytes CD20, activator IL-2 CD25 with a simultaneous decrease in IFN-γ, which is evidence of the activation of both T and B-systems of immunity.

LS at all its stages, accompanied by an increase in blood levels of class G and M immunoglobulins, CIC. A decrease in the level of CD8 lymphocytes contributes to an increase in the level of CICs, which damage the basement membrane, and contribute to the acquisition of damaged antigenic characteristics and production of autoantibodies and new immune complexes. The blood level of markers of the early stage of cell activation, CD25, IL-1β, IL-4, IL-6, TNFα, is a diagnostic sign of inflammatory activity in children with LS. These indicators represent highly sensitive markers in assessing immunological changes, and are also informative for the determination of the course, prognosis and further treatment.

Study Limitations: The amount of participant in the control group was less than that of main group to compare. It might have affect some of our results. Thus, further researches can be conducted with same amount of participants in each arm.

Acknowledgements: We are grateful to the authority and the staff members of clinical laboratory of Tashkent Pediatric Medical Institute for the cooperation and support in our research. The parents of the participants kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from all participants' parents of the research for publication of this paper and any accompanying information related to this study. A copy of the written consent is available for review by the authors.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Forensic-Medical Criteria for Evaluation of Poisoning by Alcohol Surrogates

Shokhsanam Yadgarova[1], Sherzod Ruziev[2], Khasankhodja Abidov[3]

[1]Head of the Department of Forensic Medicine, Tashkent Pediatric Medical Institute, Expert of the Highest Category at the Republican Scientific-Practical Center of Forensic Medicine. University Address: 223, Bogishamol Str., Yunusobod District, Tashkent, Uzbekistan, [2]MD, DSc, Docent, Forensic Medicine and Medical Rights, Tashkent Pediatric Medical Institute, 223, Bogishamol Str., Yunusobod District, Tashkent, Uzbekistan, [3]Councelor of a Rector for Youth Affairs, Tashkent Pediatric Medical Institute, 223, Bogishamol Str., Yunusobod District, Tashkent, Uzbekistan

Abstract

Introduction: According to statistical data, fatal poisoning by alcohol and its surrogates account for more than 55% of all poisonings. Fatal poisoning by alcohol surrogates equals for about 3-5%. The number of poisonings by organic solvents and technical fluids taken orally as alcohol surrogates has risen sharply. The widespread availability of these compounds and poor public awareness of their toxic properties lead to poisoning by these substances, and the frequency of such poisoning has a strong tendency to increase.

Materials and Method: 20 archival forensic medical reports on the corpses of people who received chemical intoxication due to poisoning by alcohol surrogates. The subject of the study was the effect of poisoning by alcohol surrogates on human systems and organs. Forensic medical examination of the corpses was carried out according to the generally accepted method in the first 10-18 hours, but no later than 24 hours after death. Quantitative determination of alcohol surrogates in biological material was carried out by gas chromatographic and spectrophotometric method.

Results: The most common signs of external examination of corpses in all cases studied during the study were clearly defined bluish-violet cadaveric spots (in 100% of cases), pale pink conjunctiva (in 86% of cases), and cyanosis puffiness of the skin of the face (in 74% of cases). Meanwhile, the most significant of the microscopic signs characteristic of most of the studied cases during forensic histological examination were: plethora of vessels in the lung tissue (in 100% of cases), edema of the pia mater and brain tissue (in 86% of cases), edema and focal hemorrhages in the lung tissue (in 84% of cases).

Conclusion: Respiratory, cardiovascular systems and pancreas are most vulnerable target organs for alcohol surrogates and leads to early morbidities in people who consume chronically. The changes can be found macroscopically as well as microscopically in corpses during forensic medical examinations.

Keywords: *Alcoholism, mortality, myocarditis, gas chromatography, cadaveric spots, alcohol substitute.*

Introduction

The term “surrogate alcohol” refers to a diverse array of products. Some researchers have defined surrogate alcohol as a subcategory of “unrecorded alcohol.” In addition to the definitions above for surrogate alcohol, unrecorded alcohol includes alcoholic beverages that are illicitly obtained or made legally for home use. Nonbeverage alcohol is another term used in the literature. Acute alcohol intoxication presents with a range of clinical challenges including behavioral disinhibition, metabolic derangements, and organ compromise. All acute alcohol intoxication may present with inebriation, gastroenteritis, and central nervous system depression. General management of ethanol-based alcohol intoxication consists of thorough history taking, supportive care, airway protection, trauma assessment, and correction of dehydration and electrolyte abnormalities. (Green et al, 2018)[1].

According to statistical reports, fatal poisoning by alcohol and its surrogates account for more than 55% of all poisonings (Ruziev & Yadgarova, 2018)[2]. Fatal poisoning by alcohol surrogates accounts for about 3-5%. The number of poisonings by organic solvents and technical fluids taken orally as alcohol surrogates has risen sharply (Iskandarov & Najmitdinov, 2018).[3] Poisonings with household and industrial fluids, which, apart from ethyl alcohol, include propyl, isopropyl, isobutyl and isoamyl alcohols (primus liquid, methylated spirits, brake fluid, technical glass washing liquid, various varnishes) are observed quiet often. Propyl alcohol poisoning accounts for 29% of all surrogate poisoning, 65% for isobutyl alcohol and 6.5% for isoamyl alcohol. Among these poisonings, the percentage of deaths is especially high (Shamsiev et al, 2017)[5].

The toxic effect of methanol is mainly associated with its metabolic products (formaldehyde, and especially formic acid), which suppress the cytochrome system and oxidative phosphorylation, thereby causing ATP deficiency, especially in the brain tissue and in the retina. Butyl alcohol causes a narcotic effect, acts mainly on the central nervous system (Ruziev, 2017)[4].Many surrogatesof alcohol, for example, ethylene glycol (EG) and its esters (cellosolves; CZ), at present, widespread use both in industry, in transport and in everyday life, and in the maintenance of various technical systems (Neufeld et al, 2016; Razvodovsky, 2017; and Rehm et al, 2015)[6]. The widespread availability of these compounds and poor public awareness of their toxic properties lead to poisoning by these substances, and the frequency of such poisoning has a strong tendency to increase.

In the Republic of Uzbekistan, this topic has not been studied enough; there is lack of information on exact definitions of which organs and how these organs are affected by poisoning with alcohol surrogates.

The aim of the research was to develop modern criteria for assessing acute poisoning by alcohol surrogates.

Materials and Method

Study Population: The objects of the study were 20 archival forensic medical reports on the corpses of people who received chemical intoxication due to poisoning by alcohol surrogates. The subject of the study was the effect of poisoning by alcohol surrogates on human systems and organs. The study was conducted at the Republican Scientific and Practical Center for Forensic Medical Examination of the Ministry of Health of the Republic of Uzbekistan.

Forensic Medical Examination: Forensic medical examination of the corpses was carried out according to the generally accepted method in the first 10-18 hours, but no later than 24 hours after death. Quantitative determination of alcohol surrogates in biological material was carried out by gas chromatographic and spectrophotometric method. For forensic histological examination, pieces of internal organs were fixed in 10-12% formalin solution and enclosed in paraffin blocks. Histological sections were stained with hematoxylin-eosin. In all expert cases, alcohol substitution poisoning was confirmed by case materials, the clinical picture of poisoning, the results of a forensic medical examination of a corpse, data from a toxicological laboratory, forensic chemical analysis and histological examination. The objects of toxicological analysis were the internal organs of the corpse, biological fluids, gastric lavage, vomit, as well as fluid residues in various containers found at the scene.

Results

Out of 20 materials, 12 men and 8 women aged from 30 to 50 years. Analysis of the distribution of victims by gender yielded the following results (Figure 1):

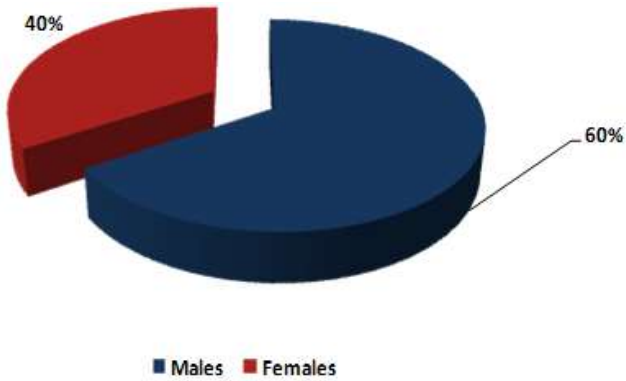

Fig. 1. Distribution of victims poisoned by alcohol surrogates by gender

The study of the results of an external study of corpses based on the materials of forensic medical examinations in cases of acute poisoning by alcohol surrogates allowed us to highlight some signs characteristic of a number of cases studied during the research. The frequency of occurrence of these signs is presented in table 1.

Table 1: The frequency of occurrence of signs characteristic for a number of cases of acute poisoning by alcohol surrogateslearned in an external study of a corpse

Signs	Absolute number of cases	Proportion of cases (%)
Cadaverous spots of cyanotic purple, well defined	20	100,0
Pale pink conjunctiva	17	86,0
Cyanosis and puffiness of the skin of the face	19	74,0
Mucus in the nasal passages and oral cavity	2	8,0
Exophthalmos	1	6,0

As it is shown in the table above, the most common signs of external examination of corpses in all cases studied during the study were clearly defined bluish-violet cadaveric spots (in 100% of cases), pale pink conjunctiva (in 86% of cases), and cyanosis puffiness of the skin of the face (in 74% of cases). Data on the occurrence of such signs as mucus in the nasal passages and oral cavity (in 8% of cases) and exophthalmos (in 6% of cases) in the materials of the study are not so significant.

An analysis of the results of forensic histological studies showed that in the microscopic picture of changes in acute poisoning with alcohol surrogates, some indicators characteristic of a number of cases studied can also be distinguished. The frequency of occurrence of these indicators is shown in table 2.

Table 2: The frequency of occurrence of microscopic changes characteristic of a number of cases of acute poisoning by alcohol surrogates studied in a forensic histological study

Signs	Absolute number of cases	Proportion of cases (%)
Edema of the pia mater and brain tissue	17	86,0
Vascular congestion in lung tissue	20	100,0
Perivascular hemorrhages in the tissues of the pia mater and brain	7	36,0
Edema and focal hemorrhage in lung tissue	17	84,0
Cardiosclerosis	15	76,0
Sclerosis of the blood vessels of the heart	14	68,0
Unbalanced pulp plethora in spleen tissues	8	42,0
Sclerosis of trabeculae and trabecular vessels in the tissues of the spleen	8	42,0
The process of pancreatic autolysis	14	68,0
Pancreatic hemorrhage	5	26,0
Fatty hepatosis	10	50,0
Dystrophic changes in hepatocytes	7	34,0
Dystrophic changes in the renal tubules	14	68,0
Uneven blood vessels in the kidney tissue	12	60,0

The data presented in the table shows that the most significant of the microscopic signs characteristic of most of the studied cases during forensic histological examination were: plethora of vessels in the lung tissue (in 100% of cases), edema of the pia mater and brain tissue (in 86% of cases), edema and focal hemorrhages in the lung tissue (in 84% of cases), cardiosclerosis (in 76% of cases), sclerosis of the blood vessels of the heart (in

68% of cases), the process of autolysis in the pancreas (in 68% of cases), dystrophic changes in the kidneys tubules (in 68% of cases) and uneven blood supply vessels in kidney tissues (60% of cases). Less significant were fatty hepatosis (in 50% of cases), uneven pulmonary congestion in spleen tissues (in 42% of cases), and sclerosis of trabeculae and trabecular vessels in spleen tissues (in 26% of cases). The least significant signs were signs of perivascular hemorrhage in the tissues of the pia mater and brain (in 36% of cases), dystrophic changes in hepatocytes (in 36% of cases), hemorrhage in the tissues of the pancreas (in 36% of cases). The figures given in these tables are characteristic for changes caused by chronic alcohol dependence, which indicates that the victims, in all studied cases of poisoning by alcohol surrogates, suffered from chronic alcoholism[10].

However, during the analysis of archival data, specific indicators were also found that were found in cases of poisoning with certain alcohol surrogates. In 6 cases of ethylene glycol poisoning, an external examination of the bodies of victims of acute ethylene glycol poisoning showed cyanosis of the skin and mucous membranes, as well as pinpoint hemorrhages on hyperemic conjunctiva of the eyes[11].

In an internal study of corpses, vascular endothelial damage, venous congestion of organs, hemorrhages in the pleura, epicardium, endocardium and gastric mucosa were observed[12]. The cyanosis of the membranes of the brain was detected. Expansion of the right heart regions and their overflow with blood were revealed, uneven blood filling and myocardial edema were noted. Puffiness and hyperemia of the mucous membranes of the upper respiratory tract, single subpleural and intrapulmonary hemorrhages, plethora, emphysema and pulmonary edema, swelling and plethora of the gastric mucosa with single small hemorrhages were observed[14]. An increase and swelling of the kidneys, tension of the capsule were detected. The tissue of the kidneys in the incision was cyanotic.

A study of the results of clinical and laboratory studies in cases of poisoning with alcohol surrogates showed that the most effective method for their determination are toxicological analysis and gas-liquid chromatography. The analysis of the results of chemical-toxicological studies allowed to distribute the victims of poisoning with alcohol surrogates as follows (Table 3.):

Table 3: Distribution of victims by identified alcohol surrogates

Alcohol surrogates	Number of cases	
	Abs	%
Ethylene glycol	2	10%
Methyl alcohol	3	15%
Amyl alcohol	1	5%
Chloral hydrate	1	5%
Dichloroethane	2	10%
Tetraethyl lead	1	5%
Propyl alcohol	7	14%
Butyl alcohol	1	5%
Acetone	2	10%

As the data in this table show, 4 detoxification method were used in victims of acute poisoning by alcohol surrogates. Moreover, hemodialysis was carried out in all cases of poisoning, hemosorption in 58% of cases, enterosorption in 36% of cases, and forced diuresis in only 14% of cases. This choice of detoxification method is explained, first of all, by the features of these method.

Among the microscopic signs, the most significant ones were: vascular congestion in the lung tissue, edema of the pia mater and brain tissue, edema and focal hemorrhage in the lung tissue, cardiosclerosis, sclerosis of the blood vessels of the heart, autolysis process in the pancreas, dystrophic changes in the renal tubules and uneven blood vessels in the tissues of the kidneys. In addition, specific signs and morphological features of poisoning by each of the alcohol surrogates were revealed.

Discussion

According to data we obtained during our study, cadaverous spots of cyanotic purple, pale pink conjunctiva and cyanosis and puffiness of the skin of the face are the most common macroscopic signs in corpuses died from unrecorded alcohol surrogates. Furthermore, the most significant of the microscopic signs characteristic of most of the studied cases during forensic histological examination were: plethora of vessels in the lung tissue, edema of the pia mater and brain tissue, edema and focal hemorrhages in the lung tissue, cardiosclerosis, sclerosis of the blood vessels of the heart, the process of autolysis in the pancreas, dystrophic changes in the kidneys tubules and uneven blood supply vessels in kidney tissues.

One clear example is that the index of lethal poisoning with ethyl alcohol and its surrogates in Russia remains one of the highest in the world. It is explained by high alcohol consumption in Russia (about 15 liters of pure alcohol per capita annually), consumption of mainly strong beverages (about 80%), extensive sales of adulterated strong alcoholic beverages (more than 25%), virtually no preventive work in the population, and other causes. The index of lethal poisoning with alcohol and its surrogates in the country and its regions is one of the most important parameters in evaluation of the socioeconomic well-being of the population (Tomilin et al, 1999)[7].

Unrecorded alcohol includes illegally distributed alcohol as well as homemade or surrogate alcohol which is unintended for consumption by humans (e.g., cosmetics containing alcohol). The highest unrecorded alcohol consumption occurs in Eastern Europe and some of these countries have an over proportional liver cirrhosis mortality. Compounds besides ethanol have been hypothesized as being responsible for this observation. On the other hand, chemical investigations were unable to prove that unrecorded alcohol regularly contains contaminants above toxicological thresholds (Lachenmeier et al, 2014)[8].

However, illegally produced spirits regularly contain higher percentages of alcohol (above 45% by volume), but for considerably less costs compared with licit beverages, potentially causing more problematic patterns of drinking. In this review, it is investigated whether patterns of drinking rather than product composition can explain the liver cirrhosis mortality rates.

Statistical examination of World Health Organization country data shows that the originally detected correlation of the percentage of unrecorded alcohol consumption and liver cirrhosis mortality rates disappears when the data is adjusted for the prevalence of heavy episodic drinking. It may be concluded that there is currently a lack of data to demonstrate causality between the composition of illicit spirits (e.g., higher levels of certain contaminants in home-produced products) and liver toxicity on a population scale. Exceptions may be cases of poisoning with antiseptic liquids containing compounds such as polyhexamethyleneguanidine, which were reported to be consumed as surrogate alcohol in Russia, leading to an outbreak of acute cholestatic liver injury, histologically different from conventional alcoholic liver disease (Lachenmeier et al, 2014)[9].

Conclusion

Among the microscopic signs, the most significant were: vascular congestion in the lung tissue, edema of the pia mater and brain tissue, edema and focal hemorrhage in the lung tissue, cardiosclerosis, sclerosis of the blood vessels of the heart, autolysis process in the pancreas, dystrophic changes in the renal tubules and uneven blood vessels in the tissues of the kidneys.

If morphological or histological changes characteristic of poisoning by surrogates of alcohol are detected, it is necessary to conduct comprehensive forensic toxicological studies of corpses.

Study Limitations: The amount of participant in both arms was less to prove the hypothesis. It might have affect some of our results. Furthermore, the type of surrogate was not clear in all cases. Some corpses did not have any relatives who might be asked for elucidation of the cases. Thus, further researches can be conducted with more amount of participants in each arm.

Acknowledgements: We are grateful to the staff members of Republican Scientific and Practical Center for Forensic Medical Examination of the Ministry of Health of the Republic of Uzbekistan and clinical laboratory of Tashkent Pediatric Medical Institute for the cooperation and support in our research. The relatives of the corpses, which participated in our research kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from the relatives of corpses of the research for publication of this paper and any accompanying information related to this study.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Abstract

Introduction: A wide range of oral hypoglycemic drugs with various mechanisms of effect are available for the treatment of patients with 2nd type diabetes mellitus today. Despite the high effectiveness of these agents in the normalization of glycemia, they cause different chronic complications in many patients with 2nd type diabetes mellitus. However, during the last years, a range of principal new data has been accumulated on the pleiotropic effects of the last classes of oral hypoglycemic agents — inhibitors of the 2nd type sodium-glucose cotransporter (SGLT2).

Materials and Method: Three electronic databases were checked to find out studies reporting the data on the mechanisms and clinical significance of the nephroprotective effect of inhibitors of the sodium-glucose cotransporter of 2nd type (glyphlozines) in patients with 2nd type diabetes mellitus. The primary outcome was to learn the worldwide tendency on this matter and to compare the results of different researchers.

Results: We found 25 studies as eligible for our review. The review presents data on the mechanisms and clinical significance of the nephroprotective effect of inhibitors of the sodium-glucose cotransporter of 2nd type (glyphlozines). The effects associated with the influence of representatives of this pharmacological group on the glomerular filtration rate, glycemia, diuresis, ketogenesis and other factors are discussed. The results of recent experimental and clinical studies aimed at studying certain aspects of the nephroprotective effect of SGLT2 inhibitors in 2nd type diabetes mellitus and other pathological conditions were analyzed.

Conclusion. SGLT2 inhibitors associate with a multicomponent nephroprotective effect, which confirmed by the results of both experimental and clinical studies. The nephroprotective potential of SGLT2 inhibitors is maximally realized in the presence of diabetes and remains not entirely clear in the case of another kidney pathology.

Keywords: *Diabetes mellitus, oral hypoglycemic drugs, 2nd type sodium-glucose cotransporter inhibitors, chronic kidney disease, diabetic nephropathy, nephroprotection.*

Introduction

Currently, a large number of oral hypoglycemic agents (OHAs) with various mechanisms of action are available for the treatment of patients with 2nd type diabetes mellitus (Thrasher, 2017)[1]. In spite of high effectiveness of OHA for normalizing glycemia,

in a significant proportion of patients with 2nd type diabetes chronic complications may develop[2]. Namely, the most unfavorable prognostic value associate with diabetic nephropathy and cardiovascular complications (Demidova, 2016)[1]. Thus, all modern drugs for the treatment of 2nd type diabetes are examined for their nephron- and cardioprotective properties (Muskiet et al, 2015; Bandanna et al, 2016)[2,3]. In recent years, a lot of principal novel data has been collected on the pleiotropic effects of representatives of the last classes of OHA — inhibitors of the 2nd type sodium-glucose cotransporter (SGLT2) (Vallianou et al, 2016; and Satoh, 2018)[3].

The main contribution of the kidneys to the regulation of carbohydrate metabolism is due to the processes of renal reabsorption of glucose[4]. Normally, in a one day, about 180 g of glucose is filtered through the kidneys (Maltese et al, 2015)[5].Reabsorption of glucose from the lumen of the renal tubule is provided by the carrier proteins (sodium glucose cotransporters) family of SGLT, which carry out active glucose transport[6], coupled with sodium, into the tubule cell[7]. Further, carrier proteins of the GLUT family located on the basolateral membrane, passively transport glucose from the cell to the interstitial space according to its concentration gradient (Prie, 2014)[8]. Almost 90% of glucose is reabsorbed in the S1 segment of the proximal convoluted renal tubule with the participation of SGLT2transporters[9], which have low affinity but very high capacity[10]. About 10% of glucose is absorbed more distally - in the S3 tubule segment using SGLT1 transporters, which, on the contrary, are characterized by high affinity, but low capacity.[11]

The combination of sequential effects of these transporters ensures the achievement of aglucosuria in healthy people.[12] The kidneys are the main location for SGLT2transporters.[13] The presence of a mutation in the SLC5A2 gene encoding these transporters leads to the development of a hereditary disease that occurs with a frequency of up to 0.3% in the family - renal glucosuria population (Vallon, 2015)[6],[14]. In familial renal glucosuria[15], in the absence of carbohydrate metabolism disorders and signs of tubular dysfunction[16], constant glucosuria is observed, which may exceed 100 mg/day.[17] In most patients, the disease proceeds without severe clinical symptoms, and renal function does not change[18].

Purpose of the studyis to learn the current literature data on the functional mechanisms and clinical significance of the nephroprotective effect of inhibitors of the sodium-glucose cotransporter of 2nd type[19], to investigate the clinical results and outcomes of treatment with hypoglycemic drugs in patients with 2nd type diabetes mellitus[20].

Materials and Method

Protocol and registration: The review was conducted following the guidelines set by the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) (Moher et al, 2009)[21].

Eligibility and exclusion criteria: Both primary and secondary studies were included for this review. We applied 10-year time filter (from 2010 to 2020)[22] for eligible studies. Only English papers were included. The review covered both prospective as well as retrospective data analyses. We did not used any restrictions regarding the place of publication[23].

Search Strategy: Three medical electronic databases (PubMed, EMBASE and Cochrane) were searched to find the studies reporting the conservative (influence of medicaments) effects on the renal function in patients with diabetes mellitus[24]. We applied 10-year time filter for eligible studies[25]. In the search strategy techniques on the web sites mentioned above, we used the following key words:

Diabetes mellitus, oral hypoglycemic drugs, 2nd type sodium-glucose cotransporter inhibitors, chronic kidney disease, diabetic nephropathy, nephroprotection.

Study Selection: Titles and abstracts of the papers screened by the authors of the review using the search method mentioned above in order to identify the studies that match the inclusion criteria[26]. Found items were searched and compared again for duplicate papers, deleted one were found any similar studies.[27]Eligible studies were checked to find any more interesting sources for our review. As soon as we found any interesting paper that suitable for our criteria of eligibility, full texts the study were reached and real till the end. Any disagreements between reviewers, resolved by discussion.

RESULTS

Study Selection: Overall, 1224 items found searching through electronic databases outlined above. Double checked the records obtained reviewing the titles and abstracts.[28] Next, we identified 450 identical studies that were deleted after wards.[29] Then, remaining 382

records were screened excluding 296 findings owing to different reasons. Further, the titles of 114 studies were read, 72 articles found as potentially eligible, which obtained in full text.[30] All full text articles were learnt by the authors of the review. Finally, we included 25 studies to our review. Owing to the colorful style, method and outcomes of the studies (heterogeneity), we did not perform meta-analysis.[31]

Study Characteristics: It was established that one of the mechanisms of regulation of SGLT2 expression is autocrine: pro-inflammatory cytokines (interleukin-6 and alpha tumor necrosis factor) produced by renal epithelial cells are capable of increasing SGLT2 expression by the same type of cells (Fig. 1.) (Maldonado-Cervantes et al, 2012).[32]

In another study, conducted using proximal tubules of human kidney cells, it was shown that up-regulation of SGLT2 does not occur directly under the influence of elevated glucose concentrations, but as a result of exposure to these cells transforming growth factor beta, overproduction of which is characteristic for diabetic kidney damage (Panchapakesan et al, 2013)[33].

A large number of studies have proved that inhibition of SGLT2 leads to a wide range of physiological changes that are potentially favorable for 2nd type diabetes[11]. The main direct and indirect renal effects of SGLT2 inhibitors in 2nd type diabetes are summarized in Fig. 2. Below, based on an analysis of the results of key experimental and clinical studies of recent years, certain aspects of the nephroprotective effect of SGLT2 inhibitors are discussed[34].

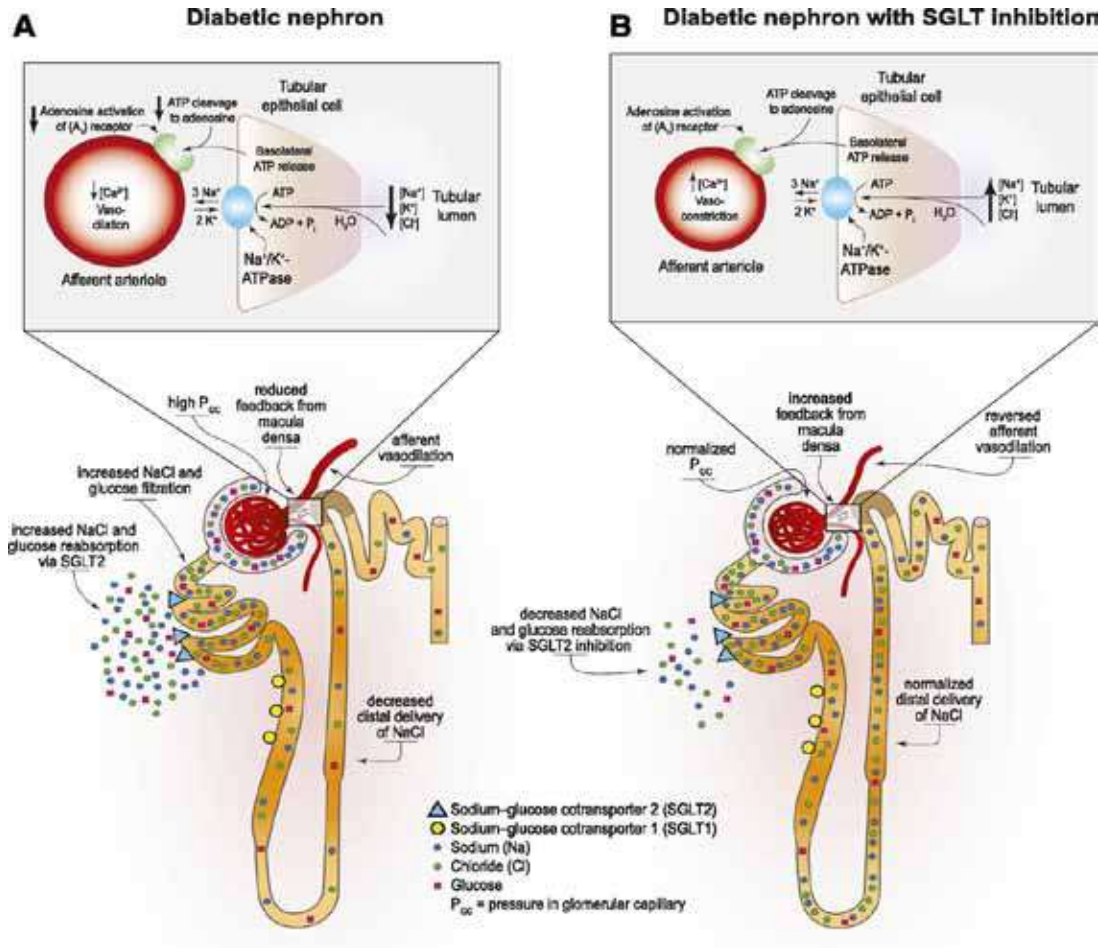

Fig. 1. The effect of diabetes mellitus and inhibition of SGLT2 on the hemodynamics of nephron. A: Increased glucose reabsorption with SGLT2 in the proximal tortuous tubule reduces the delivery of solutes to the dense spot. As a result, the release of ATP from the basolateral membrane of the tubular epithelial cells is reduced, the production of adenosine is reduced and the vessels of the afferent arteriole dilate. B. SGLT2 inhibitors restore the delivery of solute to a tight spot, followed by activation of adenosine and prevention of vasodilation of the afferent arteriole (Maldonado-Cervantes et al, 2012).

In the first experimental studies aimed at studying the nonprotective properties of the inhibition of the sodium-glucose cotransporter, florizin, a competitive inhibitor of SGLT1 and SGLT2 of natural origin, was not suitable for use in clinical practice owing to the presence of pronounced side effects (Vallon & Thomson, 2017)[35].

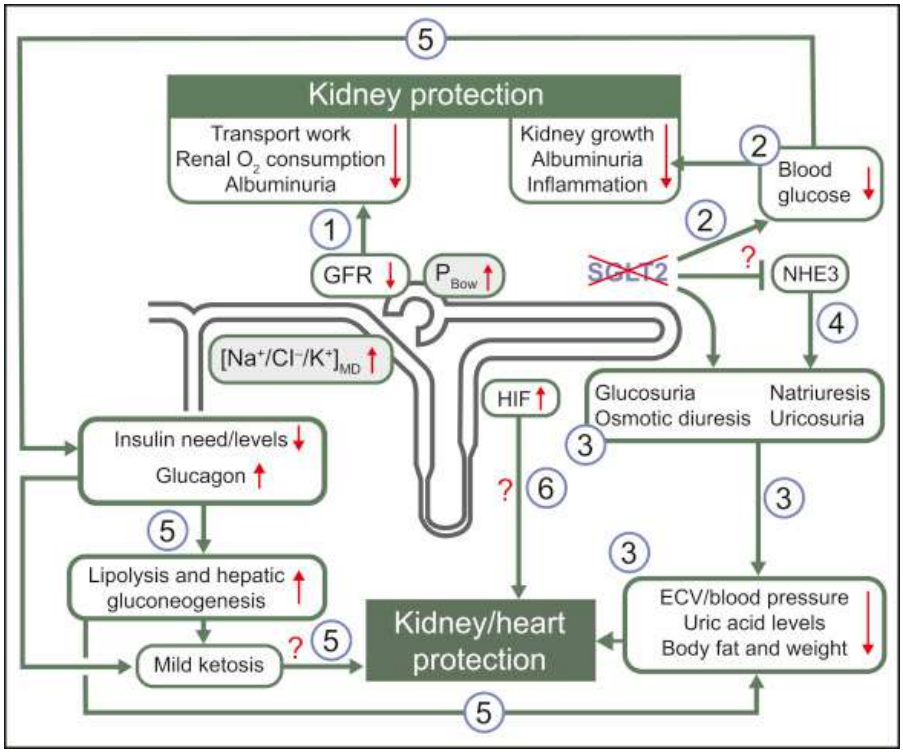

Fig. 2. The main mechanisms of the nephroprotective action of SGLT2 inhibitors (Vallon & Thompson, 2017) (1) A decrease in glucose and sodium reabsorption in the prochymal tubules leads to an increase in pressure in the Bowman space (BPM), and a decrease in glomerular filtration rate (GFR), and also affects the function of dense spot cells of the juxtaglomerular apparatus. [2] By normalizing blood glucose levels, SGLT2 inhibitors indirectly block the increase in the level of glycation end products, the overproduction of pro-inflammatory cytokines and other negative effects of hyperglycemia.[3] SGLT2 inhibitors have a diuretic, natriuretic and uricosuric effect, which helps to reduce extracellular fluid volume, blood pressure, uric acid level in the blood and body weight.[4] It is suggested that there is a relationship between the activity of the 2nd type sodium glucose cotransporter and the sodium hydrogen ion exchange protein (NHE3), which may have an additional beneficial effect on blood pressure.[5] A decrease in insulin demand and an increase in glucagon levels lead to the activation of lipolysis and gluconeogenesis and, as a result, to a slight increase in the level of ketones, which can have cardio- and nephroprotective effects.[6] Inhibition of SGLT2 may increase the production of renal hypoxia-induced factor (HIF), which has nephroprotective properties.

In a study by Malatiali et al. (2015)[14,36], florizin has been shown to reduce the severity of glomerular hyperfiltration in rats with streptozotocin-induced diabetes. The research conducted by Osorio et al. (2012)[16]proved a decrease in oxidative stress using the same model of diabetes[37]. In a study conducted on rat mesangial cells, the addition of Florizin blocked the resizing of these cells when they are incubated in a solution with a high glucose content (Wakisaka et al, 2016)[38].

Most studies conducted on various genetic and non-genetic models of diabetic kidney damage using modern synthetic SGLT2 inhibitors (empagliflosin, dapagliflosin, luseogliflosin, tofogliflosin) also confirmed the presence of pronounced nephroprotective properties in this pharmacologicalgroup.[39] It was shown in BTBRob/ob mice that the use of empagliflozin was associated with a decrease in the level of albuminuria and expression of inflammatory markers, a decrease in glomerular hypertrophy, and expansion of the mesangial

matrix, however, when these laboratory animals were administered angiotensin II, only the antialbuminuric effect was preserved (Gembardt et al, 2014)[40],[17]. In a study on db/db mice, the administration of empagliflozin reduced the expression of fibronectin and transforming growth factor beta genes[18], but did not affect the level of albuminuria and urinary excretion of markers of tubular damage KIM-1 and neutrophilic gelatinase-associated lipocalin (NGAL) (Gallo et al, 2016)[19,41]. In a study where authors used of empagliflozin (unlike telmisartan) did not have a nephroprotective effect on mice with knockout of the endothelial nitric oxide synthase (eNOS) gene, in which diabetes was induced by the administration of low doses of streptozotocin (GangadharanKomala et al, 2014)[42].

According to Ojima et al. (2015)[43], the use of empagliflozin in rats with streptozotocin-induced diabetes reduced the expression of the receptor for glycation end products, as well as decreased urinary excretion of the oxidative stress marker 8-OH-deoxyguanosine and the tubular lesion marker L-FABP (hepatic protein that bindsfatty acid)[22]. Moreover, in this study of relatively short duration (4 weeks), the antialbuminuric effect of SGLT2 inhibition was not observed[44].

Another SGLT2 inhibitor, dapagliflozin, also showed pronounced nephroprotective properties in a study on db/db mice. In particular, there was a decrease in kidney infiltration by macrophages, suppression of mesangial expansion and interstitial fibrosis, and a decrease in albuminuria. At the same time, creatinine clearance and blood pressure did not undergo significant changes (Terami et al, 2014)[45].

In a study on Akita mice (type 1 diabetes model), the effects of dapagliflozin and insulin therapy were compared[25]. After 12 weeks of treatment, no significant intergroup differences were observed in glycemia, HbA1c, body weight and blood pressure, but diuresis and fluid intake were higher in the group treated with the SGLT2 inhibitor. In mice treated with dapagliflozin, morphological changes in the kidneys (macrophage infiltration, interstitial fibrosis) were less pronounced than in animals that were on insulin therapy. When studying the proximal tubule cell culture, a decrease in the severity of oxidative stress under the influence of dapagliflozin was also demonstrated (Hatanaka et al, 2016)[26].

Another comparative study that compared the nephroprotective effects of tofogliflosin and losartan was conducted on db/dbline mice. It was shown that both tofogliflozin and losartan can reduce the level of albuminuria by 50-70%, however, only the SGLT2 inhibitor reduced the severity of glomerular hypertrophy (Nagata et al, 2013)[27].Most researchers agree that a decrease in the level of albuminuria in experimental studies is observed when using high doses of SGLT2 inhibitors, while other effects (antifibrotic, anti-inflammatory, inhibition of oxidative stress) are manifested in a wider range of doses (Kawanami et al, 2017)[28].

In a comparative study conducted using a non-genetic model of rats with insulin resistance against a high-fat diet, it was shown that the SGLT2 inhibitor dapagliflozin has a more pronounced nephroprotective potential than metformin (Jaikumkao et al, 2018)[29].

A study of combination nephroprotective therapy on a model of streptozotocin-induced diabetes in salt-sensitive rats (Dahl S line) showed that the use of the SGLT2 inhibitor luseoglyphlozin in combination with the ACE inhibitor lisinopril is associated with more pronounced beneficial effects (hypotensive effect, decrease in renal hyperfiltration) than the appointment of any of these drugs separately (Kojima et al, 2015)[30].

Gallo et al. (2016)[31]showed that the use of empagliflozin in conjunction with metformin has the advantage of influencing the synthesis of type IV collagen and connective tissue growth factor in the kidneys[32].In recent years, the effectiveness and safety of SGLT2 inhibitors in chronic kidney disease with a significant reduction in glomerular filtration has been actively studied.[33]

In a study completed by L. Li et al. (2018)[34], it was demonstrated that inhibition of SGLT2 in rats undergoing subtotal nephrectomy (without diabetes) does not lead to intrarenal and systemic activation of the renin-angiotensin-aldosterone system, which, according to several researchers, may be a side effect of this pharmacological effect in case of development of hyponatremia against the background of severe renal pathology[35].

Use of dapagliflozin in rats undergoing subtotal nephrectomy is not associated with a decrease in the expression of profibrotic cytokines in the kidneys and a slower progression of nephrosclerosis (Zang et al, 2016)[36]. With a less significant decrease in the volume of functioning renal tissue against the background of

diabetes, the nephroprotective properties of SGLT2 inhibitors are preserved, which was demonstrated in mice with 2nd type diabetes KK/Ay line undergoing unilateral nephroectomy(Tahara & Takasu, 2018)[37].

In a study of the effects of SGLT2 inhibition in animals with chronic kidney disease induced by a diet containing excessive amounts of oxalates, dapagliflozin did not show beneficial renal effects[38].

Thus, the presence of nephroprotective properties in this class of drugs with non-diabetic kidney damage and their practical significance are currently in doubt (Ma et al, 2017)[39].

Nevertheless, experimentally confirmed the presence of nephroprotective effects in SGLT2 inhibitors mediated by their effect on the expression of hypoxia inducible factor (HIF-1). Corresponding data were obtained on a model of ischemia-reperfusion of kidneys in mice (Chang et al, 2016).[40] Other authors have shown that under hypoxic conditions, the expression of SGLT1 and SGLT2 by tubule epithelial cells decreases (Zapata-Morales et al, 2014).[41]

Less studied is the question of possible organoprotective and, in particular, nephroprotective effects associated with the accumulation of ketogenesis products, which is activated against the background of SGLT2 inhibition.In an experimental study conducted by T[42]. Shimazu et al., It was shown that the administration of one of these metabolites, beta-hydroxybutyrate, to mice is associated with a decrease in the expression of oxidative stress and lipid peroxidation markers in the kidney after intravenous injection of paraquat (Shimazu eta al, 2013)[43]. In addition, there are experimentalstrong evidence of the use of ketone bodies by the kidneys as an energy substrate. Under conditions of ketonemia, their utilization increases sharply, which inhibits the uptake of other substrates by the kidneys and reduces oxygen consumption (Guder et al, 1986).[44]

One of the largest clinical studies that examined the nephroprotective effects of SGLT2 inhibitors is the EMPA-REG OUTCOME study. In this study, the nephroprotective effect of empagliflozin was manifested not only when it was prescribed at a maximum dose of 25 mg per day, but also when using a dose of 10 mg per day. Adding empagliflozin to standard therapy (about 80% of patients received ACE inhibitors or angiotensin receptor blockers) was associated with a 38% reduction in the risk of nephropathy progression with macroalbuminuria, a 44% increase in serum creatinine, and a 55% increase in renal replacement therapy. At the same time, SGLT2 inhibitor therapy did not reduce the likelihood of microalbuminuria in patients, which was a common event both in the main group and in the placebo group (51.5% and 51.2%, respectively).[45]

At the initial stage of empagliflozin therapy, predictable decrease was observedin GFR, however, in the future the GFR value in the main group remained relatively stable (decrease by 0.19 ± 0.11 ml/min/1.73 m^2 per year), while in the placebo group, a more pronounced decrease in GFR (by 1.67 ± 0.13 ml/min/1.73 m^2 per year).

In addition, after the cancellation of empagliflozin, an increase in GFR was observed, which further increased the intergroup differences in this indicator (Wanner et al, 2016)[46]. In addition to the obvious mechanisms of cardio- and nephroprotective effects of empagliflozin, clearly demonstrated in EMPA-REG OUTCOME, the possible clinical significance of enhancing ketogenesis and the role of the corresponding energy substrates are discussed in the scientific literature (Fig. 3) (Mudaliar et al, 2016).[47]

The CANVAS study examined the effect of the canagliflozin SGLT2 inhibitor on cardiovascular and renal outcomes in 2nd type diabetes. The results of the study showed that the addition of canagliflozin to standard therapy was associated with a 47% reduction in the risk of reaching a combined endpoint, which included a steady 2-fold increase in serum creatinine concentration, the development of the terminal stage of chronic kidney disease, and death from renal causes. In the placebo group, the average annual decrease in GFR was 1.2 ml/min/1.73 m^2 more. The mean urine albumin / creatinine ratio in the group of patients receiving canagliflozin was 18% lower (Perkovic et al, 2018).[48]

In the DECLARE-TIMI study, the administration of dapagliflozin to 58 patients with 2nd type diabetes in addition to standard therapy was associated with a 24% reduction in the risk of reaching a combined endpoint that included a sustained decrease in GFR of at least 40% to below 60 ml/min/1,73 m^2, the development of the terminal stage of chronic kidney disease and death from renal or cardiovascular causes (Wiviott et al, 2018).[49]

The nephroprotective effect of SGLT2 inhibitors in 2nd type diabetes is considered a class effect, which is indirectly confirmed by the results of the above studies and some secondary analyzes (Clegg et al, 2019).[50]

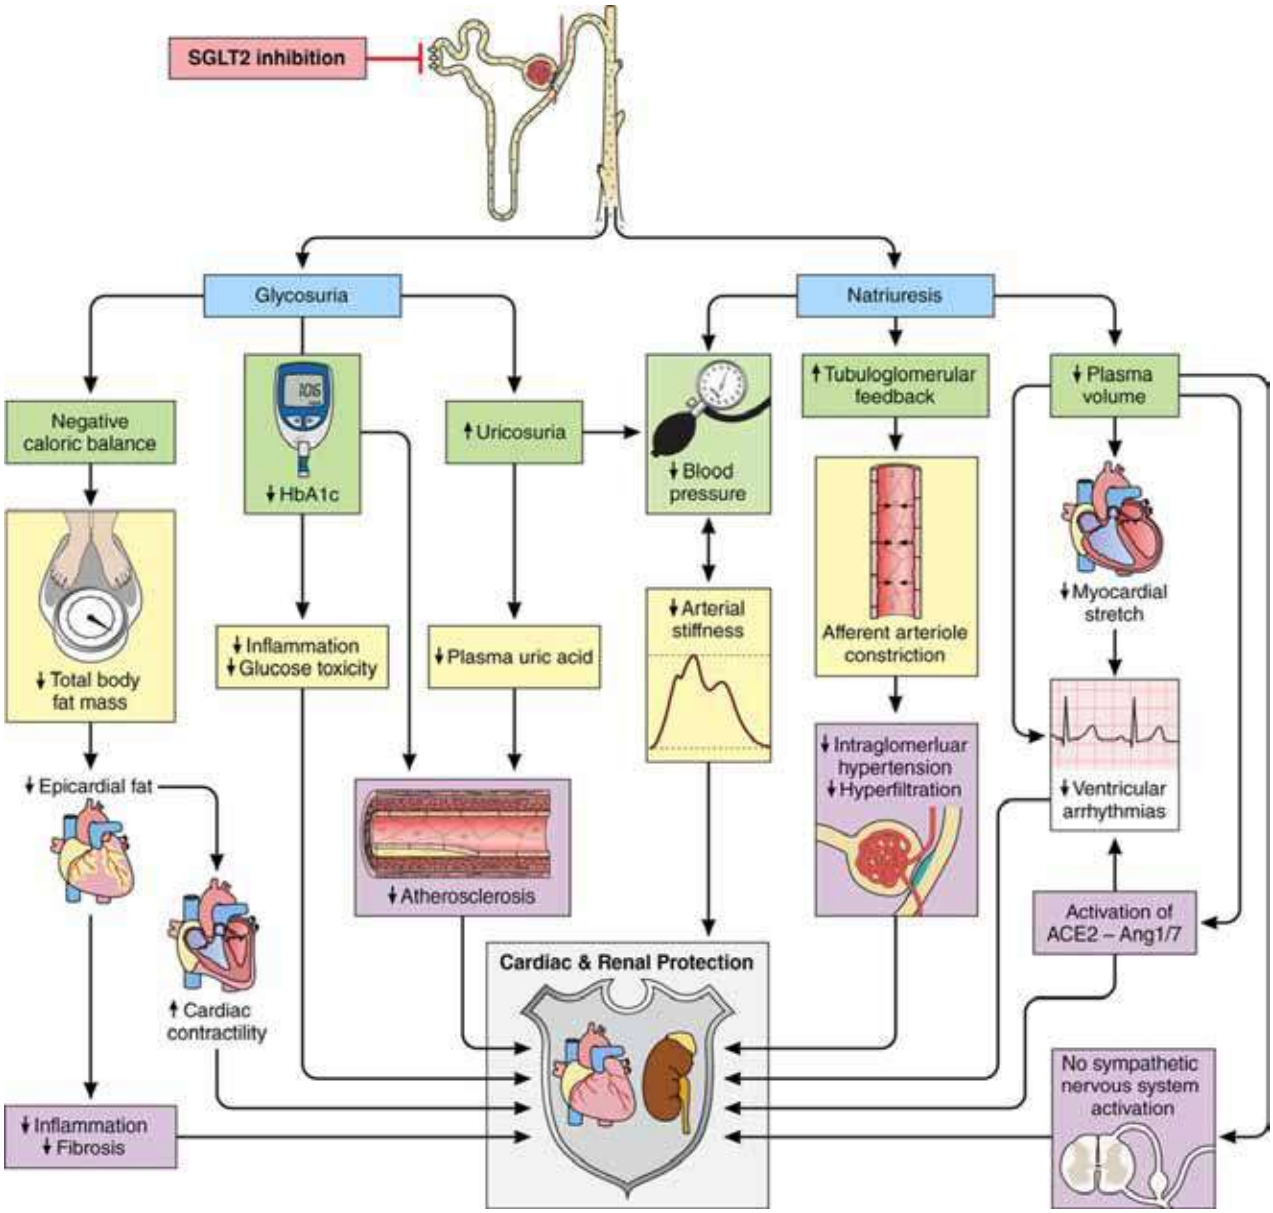

Fig. 3. Physiological mechanisms involved in cardio and nephroprotection during inhibition of SGLT2. (Mudaliar et al, 2016)

There is little data on the ratio of the nephroprotective effects of various representatives of this pharmacological group, and they were obtained mainly using indirect comparisons. In a large meta-analysis, summarizing the treatment results of more than 39 000 patients from 58 studies, the superiority of empagliflozin was indirectly confirmed. In patients on dapagliflozin therapy, according to the results of this work, the relative risk of adverse renal outcomes was higher than in patients taking placebo. In addition, empagliflozin was the only inhibitorSGLT2, which can reduce the risk of acute kidney damage compared with placebo (Tang et al, 2017).According to the results of the research conducted by Cherney et al. (2014), prescribed empagliflozin to patients with type 1 diabetes with renal hyperfiltration, lead to a decrease in serum nitric oxide concentration, an increase in renal vascular resistance, and a decrease in effective renal plasma flow and GFR. These changes were recorded both in hyper- and in normoglycemia. At the same time, these parameters did not significantly change with the use of empagliflozin in patients with type 1 diabetes and normal GFR values.

A secondary analysis of the results of this study with the calculation of the indicators of intrarenal hemodynamics according to the Gomez (1951) method showed that in patients with hyperfiltration even with normal systemic blood pressure and normoalbuminuria there was observed intrapulmonary hypertension, which decreased during treatment with empagliflozin due to a change in the resistance of afferent renal (Skrtic et al, 2014)[42].

When analyzing the effect of the dopagliflozin SGLT2 inhibitor on the excretion of markers of inflammation and damage to the tubules of the kidneys, the ability of this drug to reduce the excretion of the kidney damage molecule KIM-1 and interleukin-6 with urine was established. At the same time, the excretion of other markers (monocytic chemoattractant protein 1, neutrophilic gelatinase-associated lipocalin, and the hepatic form of the protein binding fatty acids) did not change (Dekkers et al, 2018)[43].

Researchers pay much attention to the study of the efficacy and safety of SGLT2 inhibitors in patients with CKD with a decrease in GFR. The EMPA-REG OUTCOME study demonstrated the beneficial renal effects of empagliflozin in 2nd type diabetes, both in patients with GFR ≥60 ml/min/1.73 m^2 and in patients with GFR 30-59 ml/min/1.73 m^2(Wanner et al, 2016)[34]. The DERIVE study evaluated the efficacy and safety of dapagliflozin in patients with 2nd type diabetes and stage 3 CKD. The use of dapagliflozin in this group of patients was associated with a statistically significant decrease in glycated hemoglobin, body mass index and systolic blood pressure without an increased risk of adverse events (Fioretto et al, 2014)[44].

In a meta-analysis that included 11 clinical trials, it was shown that the effect of dapagliflozin on hematocrit, body weight, and systolic blood pressure does not depend on the initial values of GFR. In addition, a more pronounced decrease in albuminuria occurs in patients with the lowest GFR (Petrykiv et al, 2017).[49]

Discussion

The review of the current literature on diabetic nephropathy showed that SGLT2 inhibitors were characterized with a multicomponent nephroprotective effect and it was confirmed by the results of both experimental and clinical researches. The renal influence of this pharmacological group is associated with many pathogenetic changes in diabetic nephropathy. Thus, the nephroprotective effect of SGLT2 inhibitors is maximally realized in the presence of diabetes and remains not full clear in the case of other kidney pathologies.

Of considerable interest is the study of the nephroprotective effects of combination therapy, including SGLT2 inhibitors. A RACELINES study is currently underway to study the renal effects of a combination of empagliflozin and a dipeptidyl peptidase-4 linagliptin inhibitor. The design of the study involves the addition of metformin in the first group - empagliflozin for 8 weeks, followed by the transition to the combination of empagliflozin + linagliptin, in the second group - linagliptin for 8 weeks, followed by the transition to the combination of empagliflozin + linagliptin, in the control group - followed by an increase in its glycoslid doses after 8 weeks. Based on the results, it is planned to evaluate the effect of empagliflozin and linagliptin on GFR, the excretion of albumin and electrolytes, urine pH, body mass index, pancreatic beta cell function, and biochemical parameters (US National Library of Medicine Clinical Trials Database). The safety of the combination of empagliflozin and linagliptin was demonstrated in a previous study (Lewin et al, 2015).[47]

Experience in studying the renal effects of SGLT2 inhibitors in non-diabetic patients is currently extremely limited. A study is currently being conducted in which, using the method of functional magnetic resonance imaging, the effect of empagliflozin on the oxygenation of the kidney tissue of healthy volunteers with different body mass index is evaluated (Muller et al, 2018).[48]studied the effects of dapagliflozin administration in patients with focal segmental glomerulosclerosis for 8 weeks and found no significant effect on renal hemodynamics and proteinuria.

The publication of the results of a placebo-controlled study RECEDE-CHF, dedicated to the study of the effects of adding empagliflozin to therapy with loop diuretics in a group of patients withheart failure. In addition to the effect on diuresis, the study plans to evaluate changes in the level of cystatin C, GFR, sodium and albumin excretion in the urine during combination therapy (Mordi et al, 2017).[50]

Conclusion

Thus, SGLT2 inhibitors are characterized by the presence of a multicomponent nephroprotective effect, which is confirmed by the results of both experimental and clinical studies. The renal effects of representatives

of this pharmacological group have points of contact with a large number of links in the pathogenesis of diabetic nephropathy, and therefore the nephroprotective potential of SGLT2 inhibitors is maximally realized in the presence of diabetes and remains not entirely clear in the case of another kidney pathology. Currently, the greatest scientific and practical studies are devoted to the comparative effectiveness of various SGLT2 inhibitors in nephroprotection, as well as the possibilities of personalizing treatment and combination pharmacotherapy.

Study Limitations: The review did not include the quality assessment and risk of bias within included studies. This might affect the general outcomes as well as conclusion of this review. Thus, further literature review and meta-analyses on this topic can be conducted with the quality assessment.

Acknowledgements: We are grateful to the staff of the library of Tashkent Pediatric Medical Institute for the cooperation and support in our review.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Abstract

Introduction: The objective of this study is to identify the prevalence and nature of auditory analyzer pathology in children with different forms of infant cerebral palsy by recording otoacoustic emission and recording short latency brainstem auditory evoked potentials.

Materials and Method: The subject group consisted of 75 children, 40 (53%) males and 35 (47%) were females, ranging from 3 to 14 years of age with a confirmed diagnosis of cerebral palsy on the basis of a psycho-neurological hospital in Tashkent. (Uzbekistan). The examination of children was carried out by the following method: clinical examination of patients (general and otorhinolaryngological) and functional research method of the auditory analyzer.

Results: All children underwent acoustic impedancemetry, including tympanometry with determination of the type of tympanogram and acoustic reflex. The data obtained revealed a bilateral lesion of the peripheral part of the auditory analyzer. Beilateral sensorineural hearing loss was detected in 21-I-II degree, in 12-III degree and in 15-IV degree. Marked changes in the main parameters of BAEP were detected in the study of the stem structures of the auditory analyzer in children with cerebral palsy. Thus, disorganization, configuration disturbances of the component composition (I, III, V) were noted.

Conclusion: Thus, the study revealed a disorder of auditory function by sound-detecting type and justified the need for hearing correction in these children. Evaluation of auditory function made it possible to determine the level of auditory analyzer injury and localization of the process from the results of a complex, objective examination.

Keywords: *Cerebral palsy, hearing impairment, otoacoustic emission, brainstem auditory evoked potentials.*

Introduction

Cerebral palsy is a complex disease of the central nervous system, affecting not only body movement and muscle coordination[1], but leading also to complications such as hearing impairment[2], which in turn affects the delay in speech and mental development[7].

In children with cerebral palsy, due to the delay of brain development 4 or its pathology of development[3], there may be a later formation of speech function, these children understand the speech addressed to them,[8] but their own speech is formed at a later date3. At the same time in pathogenesis of speech pathology the leading disorder can be damage of auditory analyzer, and disorder of hearing-motor conditional connections leads to insufficiency[9] of motor component of speech in children with cerebral palsy, which further forms delay and underdevelopment of phonematic hearing[10].

According to various sources, cerebral palsy develops in 2-3.6 cases per 1000 live births and is the

main cause of childhood neurological disability in the world[11]. The prevalence of cerebral palsy in Uzbekistan is 3.7 cases per 1000 newborns (Mutalova Z.D. The structure of diseases of children with disabilities in Uzbekistan[12] under 16 years old (2012-2014) Institute of Health and Medical Statistics).

Among premature babies, the incidence of cerebral palsy is 1%. In newborns [13]with a body weight of less than 1500 g, the prevalence of cerebral palsy increases to 5-15%, and with extremely low body weight - up to 25-30%[14].

Thus, the leading and main ones in cerebral palsy are motor disorders, in case of change of muscle tone, coordination disorders, presence of pathological synsikinesis and senergia, involuntary movements[14], as well as disorders of pose. Motor disorders have an adverse effect on the formation of mental, speech and auditory functions (Alieva Z.S., 2001,2005)[16].

A frequent disorder in children with infantile cerebral palsy is speech disorder, the frequency of which according to some authors is between 65 and 85% (Aidinov M.B., Pravodina-Vinarskaya, 1959; Bohme, 1966), others from 70 to 80% of children (Semenova K.A., 1984, Badalyan L.O., 1988; Aliyeva Z.S., 2001, 2005)[17].

Speech disorders can be associated with both deep mental retardation and the deafness bordering deafness. Often these speech disorders are combined [8].

In addition to damage to certain brain systems, secondary underdevelopment or later formation of those parts of the cerebral cortex that are extremely important for speech function and most strongly develop already in postnatal ontogenesis (premotor-frontal, dark-temporal regions of the cerebral cortex) plays an essential role in the genesis of speech disorders in these children (Klossovsky B.N., 1949; Megun G., 1960, Anokhin ILK., 1961). Since speech is a complex[19] multi-level functional system[21], correction of speech disorders in children with cerebral palsy is important,22 along with the study of auditory function[23]. Due to the fact that24 speech impairment may be due to hearing loss [25].

Four main forms of cerebral palsy are distinguished depending on muscle tone disorders:

- Spastic,
- Ataxic
- Dyskinetic (subdivided into athetoid and dystonic forms)
- Mixed forms of cerebral palsy.

Cerebral palsy is also classified regarding the affected parts of the body:

- Hemiplegia (damage to one half of the body - right or left),
- Diplegia (paralysis that affects both halves of the body, but more of the legs),
- Tetraplegia (damage to the arms and legs).

According to (Semenova K.A., Makhmudova N.A., 1979) hearing impairment is noted in 10-40% of children with cerebral palsy, more often with a hyperkinetic form[26].

When a diagnosis is correct and made in a timely manner[27], it gives an opportunity, as early as possible, to begin correction of auditory disorders and integration of the child[28] into the speech environment, thus improving the quality of life of the baby[29].

The aim of this study was to determine the prevalence and nature of auditory analyzer pathology in children with different forms of infant cerebral palsy by recording otoacoustic emission and recording short latency brainstem auditory evoked potentials.

Materials and Method

The subject group consisted of 75 children, 40 (53%) males and 35 (47%) were females, ranging from 3 to 14 years of age. Clinical examination of children began with a thorough history of the child, starting from the moment of birth to the present period. The largest number of children 48, which amounted to 64% (Table 1), was with frequent forms of cerebral palsy (spastic diplegia).

Table 1: The distribution of the examined children in the form of cerebral palsy

Forms of cerebral palsy	Amount of children		Total
	M	D	
Spastic diplegia	27	21	48
Hemiparetic	9	3	12
Atonic-astatic	4	4	8
Hyperkinetic	1	4	5
Bilateral hemiplegia	2	-	2
Total	**40**	**35**	**75**

A significant part of the children's history had a combination of several risk factors that inevitably entail the addition of other factors and thereby sharply increase the likelihood of hearing loss.

Such a factor, for example, is birth weight less than 1500 g, which entails hypoxia, the need for prolonged mechanical ventilation and the use of ototoxic drugs. Thus, it was found that most of the examined children 53 (70.7%) were born prematurely (from 24 to 36 weeks of gestation), 48 (64%) of children with low body weight.

At 64.5% (31 people) had burdened obstetric history: a history of abortion had a 15 (31%) women, the share of abortions and dead born had by 10.4% and 12.5%, respectively. Analysis and statistical processing of 23 (48%) labor histories of pregnant women with various gestoses.

The examination of children was carried out by the following method: clinical examination of patients (general and otorhinolaryngological) and functional research method of the auditory analyzer. All children underwent acoustic impedancemetry, including tympanometry with determination of the type of tympanogram and acoustic reflex.

When registering tympanograms, 48 % of children received type «A», 31% - type «B» and 21% - type «C».

In order to differential diagnosis of conductive and sensorineural hearing loss, as well as to study the correlation of data obtained during acoustic impedancemetry depending on the condition of the middle ear, childrenwere recorded caused by otoacoustic emission at the frequency of the distortion product. The stimulus intensity was used in the range from 50 to 70 dB, while the level of two tones was the same or varied by 5-10 dB. Based on measurements of the DPOAE amplitude obtained by presenting tones of different frequencies, a DP gram was automatically constructed — a graph of the dependence of the DPOAE amplitude on the tone frequency. For each point of the curve, the background noise level was also calculated. The amplitude of DPOAE exceeded the noise level by at least 3 dB.

One of the main objectives of this study was the differential diagnosis of auditory analyzer disorders. Currently, the use of acoustic auditory evoked potentials is of great importance toclarify the extent and location of lesions of the auditory analyzer. For this purpose, children underwent an electrophysiological study of hearing using the method of recording short latency brainstem auditory evoked potentials- an assessment of the state of the stem structures of the auditory analyzer. When registering the BAEP, broadband clicks, tonal pulses with a rise frequency and a duration of 2 ms were used as sound stimuli; with a presentation frequency of 11/sec, 2,000 responses accumulated, analysis time - 20 ms; bandwidth - 30-1500 (12 dB per octave).

Results

The data obtained revealed a bilateral lesion of the peripheral part of the auditory analyzer. Beilateral sensorineural hearing loss was detected in 21 - I - II degree, in 12 - III degree and in 15 - IV degree.

Marked changes in the main parameters ofBAEP were detected in the study of the stem structures of the auditory analyzer in children with cerebral palsy. Thus, disorganization, configuration disturbances of the component composition (I, III, V) were noted. The smoothness of the components was noted due to a decrease in the amplitude of the response by 2-2.5 times. The analysis of time parameters showed that, with a similar dependence of latency on changes in the intensity of the stimulus in children with cerebral palsy, in contrast to the norm, the time parameters of the main components of the BAEP (I, II,V) are significantly delayed: I - by 0.1±0, 6; III - by 0.2±0.06 and by V - by 0.37±0.07 ms. Peak intervals of the main components I - III; I - V; III - V are increased in comparison with the norm in the whole range of reactivity of BAEP. Studies have shown that the most pronounced peak-to-peak I - V intervals are increased by 0.18 ms compared to normal. In children with cerebral palsy with deep hearing impairment, a narrow dynamic range is observed, on average not exceeding 40-45 ms. An L - shaped dependence of latency on the increase in stimulus intensity was revealed; a significantly higher percentage of impaired volume function is noted.

Thus, the study allowed us to identifyimpaired auditory function in the sound-absorbing type in children with cerebral palsy. Assessment of auditory function allowed the results of a comprehensive, objective examination to determine the level of damage to the auditory analyzer and the localization of the process, as well as conduct electro-acoustic rehabilitation of this category of children.

As you know, the leading and main in cerebral palsy are motor disorders that have an adverse effect on the formation of mental, speech and auditory functions [26]. A frequent violation in children with cerebral palsy is speech disorder, the frequency of which, according to some authors, ranges from 65 to 85% [1,3], while others from 70 to 80% of children [8,12,34]. Speech disorder may be delayed speech development (late formation of the motor component of speech, especially its sound-producing side), dysarthria (pseudobulbar, extrapyramidal, cerebellar, cortical). Speech disorders can be associated with both deep mental retardation and hearing loss bordering deafness. Often, these speech disorders are combined.

The study of the stem structures of the auditory analyzer in children with cerebral palsy, having normal thresholds of auditory sensitivity, revealed pronounced changes in the main parameters of the BAEP: disorganization, disturbances in the configuration of the component composition (I, II, V) were noted; smoothing of components was noted due to a decrease in the amplitude of theresponse by a factor of 2-2.5. Analysis of time parameters showed that, with asimilar dependence of latency on changes in stimulus intensity in children with cerebral palsy, in contrast to the norm, the time parameters of the maincomponents of short avokedbreain (I, II, V) significantly tightened: I - by 0.1±0.7; III - by 0.1 8±0.05 and by V - by 0.39±0.08 ms. Peak intervals of the main components I - III; I - V; III - V are increased in comparison with the norm in the whole range of reactivity of SVP. Studies have shown that the most pronounced peak-to-peak I - V intervals are increased by 0.18 ms compared to normal. In children with cerebral palsy with deep hearing impairment, a narrow dynamic range is observed, on average not exceeding 40-45 ms. An L - shaped dependence of latency on the increase in stimulus intensity was revealed, a significantly higher percentage of impaired volume function (FCFN) was noted.

In a comparative aspect, the signal response in children with cerebral palsy was less mature. The amplitudes of the waves of auditory evoked potentials, as a rule, were smaller in comparison with normal values. In contrast, the peak-to-peak intervals in most cases corresponded to normal values. Table 2. presents the values of BAEP depending on the etiological factor of cerebral palsy.

Table 2: The values of BAEP depending on the etiological factor of cerebral palsy

Etiological factor	Number of patients	Peak Interval I-V	Amplitude V waves	% To I wave ratio
Very low weight	9	3.93 ± 0.25	0.35 ±0.10	1.25 ±0.66
Asphyxia	26	4.01 ±0.24	0.28 ±0.09	1.02 ±0.67
Unknown etiology	12	4.07 ±0.27	0.32 ±0.12	1.14 ±0.72
Control group	25	3.95 ±0.18	0.37 ±0.10	1.25 ±0.61

In the history of the mother, we paid great attention to the course of pregnancy and childbirth. The presence of toxicosis in the mother, its course and duration, the use of ototoxic drugs during the pregnancy (aminoglycoside series, “loop” diuretics).

Discussion

Of the 9 children we examined with cerebral palsy, 4 children were born using cesarean section before the 30th week of gestational age, of which three children had birth weight less than 1500g. 2 children born on time had hyperbilirubinemia (bilirubin content of more than 20 mmol/ l). With hemolytic disease of full-term newborns, there were 3 children.

A significant portion of the children have a history of a combination of several risk factors. Some of them inevitably entail the addition of other factors and thereby sharply increase the likelihood of hearing loss. Such a factor, for example, is birth weight less than 1500 g, which entails hypoxia, the need for prolonged mechanical ventilation and the use of ototoxic drugs.

In most cases, in children with cerebral palsy, the amplitude ofI and V waves and the ratio of V waves to I were less than the average values characteristic of this age. Thus, the obtained values showed a significant difference in the amplitude of the V wave during cerebral palsy, due to the birth of very low body weight,

asphyxiation, and unknown etiology. The amplitude of the V wave in children born with a very low birth was slightly reduced, but did not significantly differ from the control group.

Some children showed poor identification of waves 2 and 4, sometimes even I waves. Basically, this observation was made in children with cerebral palsy of unknown etiology, who had deep damage to the central nervous system.

The results showed that there are no significant differences from the control group in the values of the peak intervals I-V, I-III and III-V in children with cerebral palsy, regardless of its etiology. There were also no significant differences in the interaural difference in the latencies of the V peaks on both sides of the interaural difference for the interval I-V, I-III and III-V. Compared with the control group, the interval I-V was slightly longer in children with cerebral palsy of unknown etiology. In children with cerebral palsy, against the background of very low body weight, the interval I-V was shortened.

As the obtained data show, a significant decrease in the amplitude of the V wave and, accordingly, the V / I ratio is observed in children who survived asphyxia at the beginning of life. There is also a tendency to shortening of the 1st wave, which leads to a relative increase in the V / I ratio. Of the 78 children with cerebral palsy, 21 (26.1%) had a significant decrease in the amplitude of the V wave, and 10 (12.5%) had a significant decrease V / I ratio. Absence of waves was noted in 14 cases (17.5%).

Only 10 children with cerebral palsy (12.5%) had a significant lengthening of the interval I-V, which was often accompanied by a significant decrease in the amplitude of wave V. Deviations in intervals I-III and III-V and ratios III-V / I-III were rare. An increase in intraural difference (6.3%) was noted in 5 (6.3%) cases. This increase was mainly due to the unilateral shortening of intervals III-V and IV (2 children with very low birth weight) or the unilateral extension of 2 intervals (2 children with unknown etiology of cerebral palsy).

In total, 48 out of 75 children with cerebral palsy had deviations in auditory evoked potentials, which manifested itself in a significant decrease in the amplitude of the V wave, a decrease in the V/I ratio, an increase in the IV interval, and the absence of I or more response waves. The most often seen deviations were manifested during the registration of the V wave, which appeared by a decrease in its amplitude. In some children with cerebral palsy, more than one deviation from normative indicators was recorded. These children often, although not always, had profound disorders of the central nervous system.

The results showed a significant difference between children with cerebral palsy and the control group. The present study showed that the main changes in cerebral palsy are manifested in the form of depression of the signal and a decrease in the amplitude of the V wave, as a rule . These changes mainly reflect a decrease in the size, or synchronization of neural activity in the auditory part of the brain. These changes may be due to neurological abnormalities or be directly a manifestation of cerebral palsy. Summarizing, we can say that there is a depression of waves, including wave I. A decrease in the amplitude of the I wave is observed, accordingly, the V / I ratio increases. As a result, even with a significant decrease in the amplitude of the 5 wave, the V / I ratio changes little and remains within the normal range. This can largely explain why a significant decrease in the V / I ratio is less often detected compared to a decrease in the amplitude of the 5th wave. This result shows that, compared with the V / I ratio, the 5-wave amplitude is more sensitive when registering auditory evoked potentials with a reliable reflection of auditory function in clinical practice.

When assessing auditory evoked potentials, it should be taken into account that waves 2 and 4 are characterized by great variability and are less reliable than waves I, III, and V. In assessing the configuration of the curve, in some cases precipitation of individual components was noted. The curves with the loss of the first, third, and fifth peaks were not encountered in the analysis. The maximum loss occurred in the second, fourth and sixth components. According to the established opinion and literature data, it is these peaks that are distinguished with the least frequency. However, according to its own regulatory data, the secrecy of these peaks does not differ much from the secrecy of the rest, based on which we can conclude that configurational changes are quite common with spastic diplegia. The technique for recording auditory evoked potential includes mandatory monotonous audiometry, which allows you to get an idea of the state of auditory function. An increase in the auditory threshold above the laboratory norm was noted in 18 (30%) cases in 34 (28.3%) studies. That is, almost every third patient had a one-sided increase in the auditory threshold

The main trends in the parameters of the short-latency auditory evoked potential were a decrease in the amplitude and an increase in the latency of the components. A significant ($p < 0.05$) increase in latency was noted for the I, II, III, IV and VI components of the potential. An increase in absolute latencies per se cannot be a sign of conduction disturbance at the stem level, especially given how often disturbances in the function of the peripheral part of the analyzer were encountered. However, a significant increase in the inter-peak interval III – V indicates dysfunction of stem afferents at the bridge-mesencephalic level. The detected decrease in the amplitude of the I, II, V components of the potential ($p < 0.05$) is most likely a consequence of the dysfunction of the peripheral unit of the analyzer.

A fall in the amplitude V / I ratio below 0.75 was observed in 20%, below 0.5 - in 6.7% of patients in 5 (4.2%) studies. The analysis of peak-to-peak intervals indicates the truth of the revealed changes in the conductive ability of stem afferents. The analysis of amplitude relationships allows us to confirm the presence of a nuclear-dysfunctional component in the pathophysiological picture of spastic diplegia, however, the frequency of occurrence does not allow us to see in it the key mechanism of the pathogenesis of stem disorders present in the clinical picture of the disease. The revealed changes in the conductive properties of stem afferents contribute to the picture of the dysfunction of stem structures during spastic diplegia and can have residual demyelination nature.

Thus, the study revealed a disorder of auditory function by sound-detecting type and justified the need for hearing aids in these children. Evaluation of auditory function made it possible to determine the level of auditory analyzer injury and localization of the process from the results of a complex, objective examination.

Conclusion

1. The use of objective method for the study of hearing in children with cerebral palsy allows you to identify the nature and extent of hearing impairment.
2. The pathogenesis of cerebral palsy combines dysfunction of the nuclear apparatus of the brain stem and impaired conductive properties of stem afferents.
3. The study of hearing at an early age with the help of objective method helps to timely detect hearing impairment and delineation of deafness and hearing loss from a number of diseases that delay speech development, which is an important link in the chain of rehabilitation measures aimed at correcting difficult - the structure of the defect in children with Cerebral palsy.
4. Our study indicated the need for an early (from the first days of life) and comprehensive objective examination of auditory function in children with cerebral palsy. Early diagnosis of the pathology of the auditory analyzer provides timely correction of auditory-speech disorders in children with cerebral palsy.

Abstract

The aim of this study is to improve the results of surgical treatment of Hirschsprung's disease in infants by choosing the most effective method.

This article presents the results of the treatment of Hirschsprung's disease in 61 patients of infancy. However, immediate and long-term results of the children's treatment with HD, operated on in infancy, using the traditional Soave-Boley method and modern minimally invasive technologies according to TENTC and the Georgeson method, which show different results, have been studied. Among 26 patients who had been operated on by the Soave - Boley method, the following results were obtained : excellent - in 10 (38.4%); good - in 8 (30.7%); satisfactory - in 6 (23%) and unsatisfactory - in 2 (7.6%). Among 29 patients operated on by the TEPT method, except for one patient, excellent and good results were obtained in 28 (96.6%) patients. What is more, among 6 patients who had been operated on by the Georgeson method, excellent and good results were obtained in all cases; there were no satisfactory or unsatisfactory results. It should be noted that among the operated HD patients according to the Soave-Boley method, there were severe patients, of which 7 patients had a colostomy in the neonatal period.

At the same time, radical one-stage surgical treatment for distal forms of HD using minimally invasive TEPT method is a priority in infancy, which can reduce complications to a minimum with improved functional outcomes of treatment, relative to two-stage treatment.

Keywords: *Hirschsprung's disease, treatment, surgical, diagnosis, pediatric.*

Introduction

Recently, the authors have recommended effective early diagnosis and surgical correction, the priority of which is a one-stage radical correction of Hirschsprung disease (HD) and the use of minimally invasive method. In this regard, the choice of optimal method for surgical treatment of HD in infancy is of particular relevance.

Regarding the reliability of the diagnosis of children with HD, taking a biopsy from the rectal mucosa is the «Gold Standard» for morphological diagnosis[1]. However, there is evidence of controversy and debatable questions about the validity of biopsies in young children with HD in literature[3]. Many authors claim that by the time of birth, intramural, ganglion cells still do not reach full morphological maturity[6]. They are especially immature in the caudal part of the colon, in the submucosal layer in particular[8]. This immaturity is physiological; final maturation occurs gradually. Consequently, it is believed that at an early age, a rectal biopsy is contraindicated and unreliable[22]. If this concept is not taken into account and take a biopsy in cases of suspected GB, then this diagnosis will be made often and unreasonably, especially in premature infants[23].

Other authors believe that the lack of preliminary morphological diagnosis and the preservation of the proximal dysganglionic segment of the colon during radical surgical treatment leads to unsatisfactory results[5].

At the present stage, the cases when there were no clear signs of HD according to irrigography became the indication[4] for carrying out a laparoscopic biopsy of the colon[21].

There is information that in some cases the histological structure of the colon also had a deviation from the norm. In 50% of children[9], a histochemical reaction suggested a diagnosis of intestinal agangliosis, in other cases, it only complicated the further diagnostic search[10]. So, low information content of histochemical diagnosis is explained by the absence of not only a nerve ganglia and nerve cells in the intestinal wall[12], but also parasympathetic fibers with their total lesion[13].

The available histochemical and morphohistochemical research method for determining the activity of tissue AChE in HD have been carried out for a long time with high reliability[2], however, its radical applications are not always available[11]. The modern neurohistochemical express method for a short research time provides information with high reliability (97-99%), however, it requires highly qualified specialists, expensive equipment and reagents that are not always available[18].

As well as the inclusion in the examination program of infants suffering from chronic constipation to identify HD, a morphohistochemical method[11], was not always reliable, which was not always reliable14, moreover, the applied clinical, radiological and functional method did not always make it possible to make a correct diagnosis[16]. Thus, many-sided and debatable questions on determining the localization of taking biopsy material from the rectal mucosa or laparoscopically from all the muscular - submucous layers of the colon and the low reliability of the biopsy in the diagnosis of HD remain open. Moreover, in an inaccessible situation, pediatric surgeons need to optimize and accurately solve the issues of intraoperative diagnosis, measures for the prevention of complications and relapses of the disease in infants.

Moreover, in surgical treatment of HD in infants, against the background of many concomitant diseases, malformations of other organs and morphofunctional immaturity of a child's body[7], preoperative preparation and postoperative management of patients causes particular difficulties[2]. On the other hand, the use of existing modified abdominoperineal proctoplastics (APR) using Soave technology (Boley, Lenyushkin) is more traumatic[17]. Surgeries of lowering the colon through the serous-muscular case of the rectum according to the Soave method with the creation of a "seamless anastomosis" in 2 stages are the safest for a patient, and their effectiveness reaches 90% in children older than infancy[12]. Fundamentally, the operation of laparoscopically assisted intestinal reduction is not different from the operation of Soave, however, it allows treatment in one stage and has all the advantages of minimally invasive interventions[13].

Regarding the results of surgical treatment of HD in children, according to the authors, in the postoperative period, having bowel movements is disturbed in 37% of sick children. At the same time, astriction occurs in about 8-20% of children, enuresis occurs in 5-26% of cases, which is unsatisfactory and leaves much to be desired[18]. The authors note that the introduction of minimally invasive method for the correction of Hirschsprung disease has led to a change in the spectrum of complications, the main of which were : colorectal anastomosis failure (3.4%) and its stenosis (8.5%)[22].

Therefore, in order to prevent postoperative complications and relapses of the disease in infancy, each method of operation according to Soave - Boley, Georgeson and Transanal endorectal pull-through (TEPT) according to Delatorre - Mandragon and Ortego - Salgado, in solving tactical and operational-technical issues requires optimization of indications, a differentiated choice of method depending on the anatomical form, degree of compensation and the course of the disease, which is an urgent problem in pediatric surgery.

Objective: Improve the results of surgical treatment of Hirschsprung disease in infants by choosing the most effective method.

Materials and Method

The immediate and long-term results of surgical treatment of HD in 61 infants were studied by us for the period 2010-2019. Patients' age: up to 3 months. - 8 (13.1%); 3-6 months - 17 (27.8%); 6-9 months - 20 (32.7%); 9-12 months - 16 (26.2%). By the forms of the disease were: rectal - 13 (21.3%); rectosigmoidal - 43 (70.4%); subtotal - 5 (8.1%). According to the clinical course: acute - 9 (14.7%); subacute - 39 (63.9%); chronic - 13 (21.4%). Congenital concomitant pathologies occurred: Down's disease - 1, aplasia and hypoplasia of kidneys - 3, coccyx agenesis - 3. There were 53 boys, 8 girls.

All children underwent general physical, laboratory, radiation (plan radiography, polypositionalirrigography, U/S) and morphological (macro preparation of colon agangliosis zones resected during radical surgery) studies.

Patients were divided into 2 groups: 1 - group (control) - 29 patients operated on by the Soave - Boley, Lenyushkin method; 2 - group (main) 32 operated on patients, among them: 26 cases by the TEPT method (Delatorre-Mandragon) and in 6 cases by the Georgeson method.

The effectiveness of each method has been studied by evaluating on a point scale according to the questionnaire data of operated patients in a remote period of 1-4 years. Clinical results were evaluated as: excellent, good, satisfactory and unsatisfactory.

Results and Discussion

Early diagnosis of HD in infants has its own specific features, and at the same time, the degree of maturity of the child, the age category, associated pathologies, the length of the aganglinal and the degree of (compensatory) expansion of the suprastenotic zone are of no small importance.

Enterocolitis is known to be a serious complication of HD in pre- and postoperative periods. Enterocolitis can develop at any age, from the neonatal period to the older age, regardless of medication or surgery. Recurrent enterocolitis can occur even in the presence of an externalized colostomy [].

According to our observations, during the neonatal period and early infancy (up to 3 months) there were 7 patients who received a clinical picture of acute low intestinal obstruction, a history of which noted: diarrhea, bloating, fever, anxiety due to spastic pain in abdomen, intoxication, hypovolemia and loose bowel movement with an admixture of blood. At the same time, the first thing was to exclude enterocolitis associated with Hirschsprung disease. After a plan radiography of the abdominal cavity, these patients underwent irrigography (Fig. 1a, b).

(A) **(B)**

Fig. 1. A - plan radiography of the abdominal cavity; B - Irrigography

In which the narrowed (aganglionic) zone in the distal colon was clearly contrasted, the transition zone in the form of a funnel-shaped expansion over the affected area in 5 patients with subtotal and 2 patients with a long zone of rectosigmoid form of the disease and manifestation of enterocolitis.

Having concomitant enterocolitis against the background of irritation of the intestine with spasmodic areas that was created with a false appearance of pathological narrowing. It means that during the period of newborn and early infancy, the risk of false-positive, and false-negative results of irrigography increases by

almost 3 times. Therefore, the x-ray area of narrowing does not always coincide with the area of the taken biopsy and agangliosis.

And also in 6 hypotrophic, functionally immature infants with enterocolitis in the initial early diagnosis of HD, the implementation of a layer-by-layer rectal biopsy on the inflamed mucosa and thinned intestinal wall was impossible.

That is why, in almost all cases, due to inaccuracy, inaccessibility and sometimes the lack of possibility of biopsy immunohistochemically, morphohistochemically and neurohistochemically, we did not carry out express method [11,14,15,19].

In patients (in 19 cases) older than 3 months with HD with a long aganglionic zone, a more pronounced picture of obstruction with high pressure had been observed with increasing suprastenotic expansion of the colon - left subtotal and long rectosigmoid form (Fig. 5a., b.).

(A) **(B)**

Fig. 2. Hirschsprung disease in infants: (A) left-side subtotal; (B) rectosigmoid form with a long zone of aganglionosis.

In a short zone with compensatory courses of the disease (in 40 cases), it is not always shown as in the classical form: narrowed, transitional zone with suprastenotic funnel-shaped extensions of the colon. At the same time, the sensitivity and specificity of irrigography in newborns and infants was significantly lower due to only breastfeeding.

With supplementary feeding and the transition to mixed, artificial and natural feeding, the clinical picture of chronic bowel movement retention began to increase in patients, and against this background, the use of polypositionalirrigography in these patients has greatly expanded the range of diagnostic capabilities of HD in infants.

Despite the limitations or sometimes difficulties of using morphological and other research method in the early diagnosis of HD in infants, we consider polypositionalirrigography and preoperative diagnostic laparoscopy to be more optimal and reliable method. We carried out preoperative diagnostic laparoscopy with dubious diagnosis of HD and the length of the zone of aganliosis, taking into account the choice of the method of operation in 6 patients.

In the surgical treatment of HD, until recently, though STI according to Soave - Boley and Lenyushkina, which we performed in the first group of patients in 25 cases, were considered optimal and more physiologically substantiated method in children. These operations are performed in 2 stages, the abdominal stage is almost identical, but they are not free from shortcomings and complications. At the abdominal stage, in the depths of the pelvis against the background of technical difficulty during demucosis of the rectal wall, as close as possible to the anus, internal anal sphincters are often damaged and perforation occurs, which often causes pelvic peritonitis, interfacial abscess, and stenosis.

Moreover, with excessive blind demucosis of the intestine, blunt trauma (with instruments) and impaired blood and lymph formation in the adjacent pelvic organs (sphincter muscles, ovaries, prostate gland, urethra) in the long term, the consequences often lead to fecal and urinary incontinence, as well as are the background state in the development of diseases of the reproductive organs in boys and girls.

However, at the modern level, with the improvement of new minimally invasive and high-tech TEPT operations with video-assisting at the abdominal stage - with Georgeson's method and without it, we had the opportunity to operate sick children with HD during the neonatal and infancy years.

With the gain in experience, we have developed various tactical approaches for choosing the method of operation and optimizing the indications depending on the anatomical shape, degree of compensation, and the course of HD.

In case of subtotal and proximal left-sided long forms of HD disease in 6 cases (agangliosis zone length over 30 cm), in the main group of patients, in order to reduce intra-abdominal complications, the Soave-Boley method was replaced by laparoscopic diagnostics and colon mobilization. The perineal stage is an oncoming transanaldemucosis "from the bottom up" with the reduction of the mobilized intestine. After resection of the agangliosis zone, a primary colorectal anastomosis (Georgeson operation) was created, the results of which were successful outcomes.

In rectal and rectosigmoid forms of HD in infancy, a long zone of agangliosis in the rectum and sigmoid colon (up to 30 cm) was performed by TEPT (Delatorre - Mandragon and Ortego - Malgado), in which demucosis was performed by transanal access with lowering of the colon endorectally. After resection of the agangliosis zone, the primary colorectal anastomosis is transanally superimposed (Fig. 3.). The operation by using TEPT method was performed in 26 children with HD in infancy, a rectal and rectasigmoid form of the disease. Moreover, all operations were performed without prior colostomy.

Fig. 3. TEPT - Delatorre - Mandragon and Ortego - Malgado

When performing TEPT, it should be noted that it is possible to determine the level with wide gut resection in order to prevent relapse of the disease, since the younger the age of patients, the less clearly and contrast the narrowed area and suprastenotic enlarged part of the intestine are manifested during irrigography. This is most characteristic of subacute (rectal and rectasigmoidal form) and atypical (enterocolitis associated form) clinical course of the disease, which complicates early diagnosis and intraoperative determination of the level of resection. For that purpose, to determine intraoperatively the location of the level of wide resection and ensure the optimal radicality of TEPT method, we studied morphologically the state of the histostructure of the nerve plexuses, nodes, cells and fibers in the wall of the transitional and enlarged parts of the removed intestine near the gross specimen. At the same time, in 9 patients with HD, the gross specimen obtained by wide resection of the colon was subjected to a morphological study, the reason for which was the additional loops with dolichosigmoid.

The initial, middle and upper parts of the suprastenotic enlarged zone of the colon (Fig. 4). has been studied morphologically.

Fig. 4. A gross specimen obtained by a wide resection of the colon.

At the same time, in the initial section of the enlarged part of the intestine, at a distance of 3 cm from the transition zone, areas of dysgangliosis were noted, characterized by places of absence, atrophy, destruction, hypertrophy and hyperplasia of the preserved nerve plexus nodes.

Further, when studying the mucous membrane of the middle suprastenotic enlarged part of the intestine, at a distance of up to 5 cm, from the transition zone, their atrophicity was noted, expressed in wide gaps in the crypts, diffuse nature of the edema, loosening of its own connective tissue plate with foci of inflammatory infiltrate and sclerosis. There are relatively hypertrophic and hyperplastic nerve nodes due to swelling of nerve cells, fibers, and Schwann's cells hyperplasia (Fig. 5a).

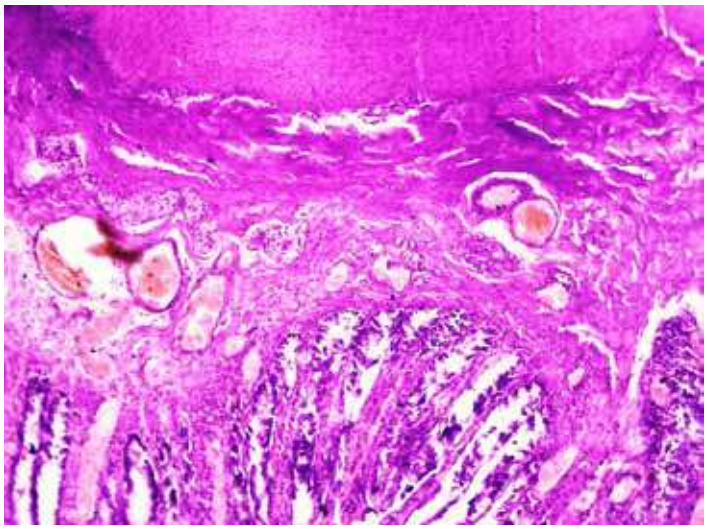

Fig. 5a. The submucous layer of the suprasthenic part of the intestine with HD in an infant is up to 3-5 cm long . Hypertrophy and hyperplasia of the nerve plexuses against the background of chronic inflammation. H & E stain Magn: 10x20.

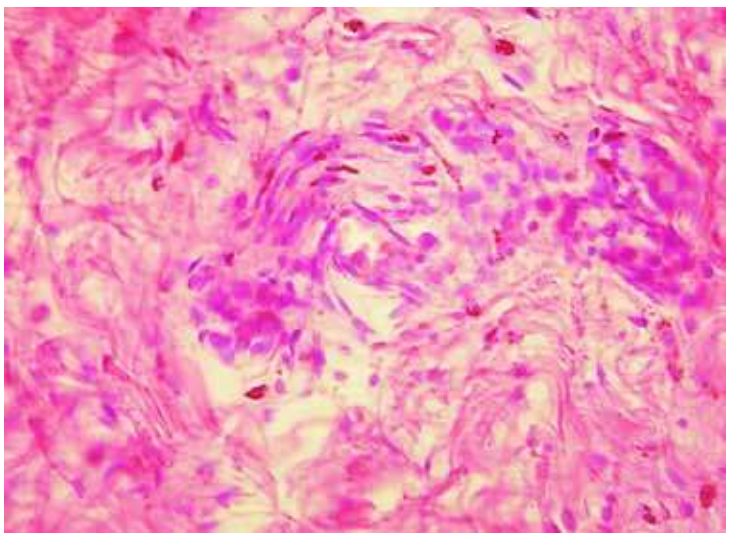

Fig. 5b. The submucous layer of the suprasthenic part of the intestine with HD in an infant is up to 3-5 cm long . Hypertrophy and hyperchromasia of Meissner nerve nodes with hyperplasia of Schwann's cells. H & E stain Magn: 10x40.

Nerve cells are located in one pole of the node with signs of hypertrophy and hyperchromasia, in the other pole of the node there are nerve fibers from hyperplastic Schwann's cells (Fig. 5b). In the submucosal layer of the middle expanded part of the intestine, at a distance of up to 5 cm from the transition zone, the presence of nerve nodes of various size and composition is noted. In these nerve nodes there are few nerve fibers and glial cells and they are located on the periphery.

Meissner nerve nodes of round shape with a small number of nerve cells (Fig. 6a), where, on the contrary, there are more nerve fibers circles of Schwann's cells form a thin membrane (Fig. 6b), which covers, depending on the degree of decompensation. These secondary morphological changes at the level of the less pronounced dilated "normal" part of the intestine lead to normalization of the structure of nerve nodes in the mucous and submucosal layer up to 5 cm from the transition zone, depending on the degree of compensation of the suprastenotic expansion of the colon.

Fig. 6a. The submucous layer of the suprasthenic part of the intestine with HD in an infant is up to 3-5 cm long . Meissner nerve nodes with a large number of nerve cells and a thin myelin sheath. Magn: 10x40.

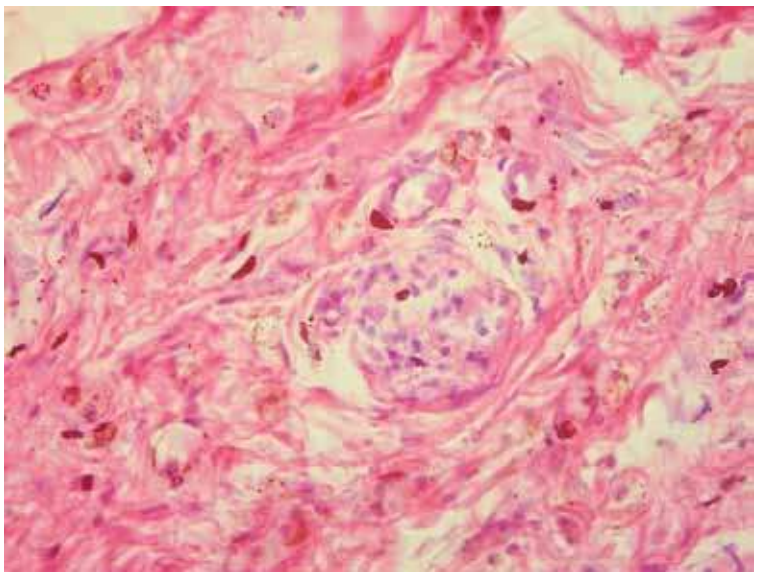

Fig. 6b. The submucous layer of the suprasthenic part of the intestine with HD in an infant is up to 3-5 cm long. . Meissner nerve nodes with a small number of nerve cells and a large amount of nerve fibers. H & E stain Magn: 10x40.

In the intramuscular layer of the enlarged part of the intestinal wall, separate Auerbach nerve nodes with dystrophic, atrophic, and destructive changes up to 5 cm long are noted (Fig. 7a). In this case, mainly nerve cells, glial cells and nerve fibers underwent dystrophic changes, and Schwann's membranes underwent atrophic changes. Microscopic examination of the wall of the intermediate part of the expansion of the colon shows a picture of the proliferatively inflammatory form of chronic colitis. The muscle layer is thickened due to hypertrophy of smooth muscle cells and the presence of interstitial lymphohistiocytic infiltrate with atrophy and destruction of the nerve ganglia. Auerbach's nerve nodes are compressed by inflammatory infiltrate, atrophic nerve cells are compressed and small, hyperchromatic. Pathomorphological changes of the nervous system of the colon correspond to hypogangliosis (Fig. 7b).

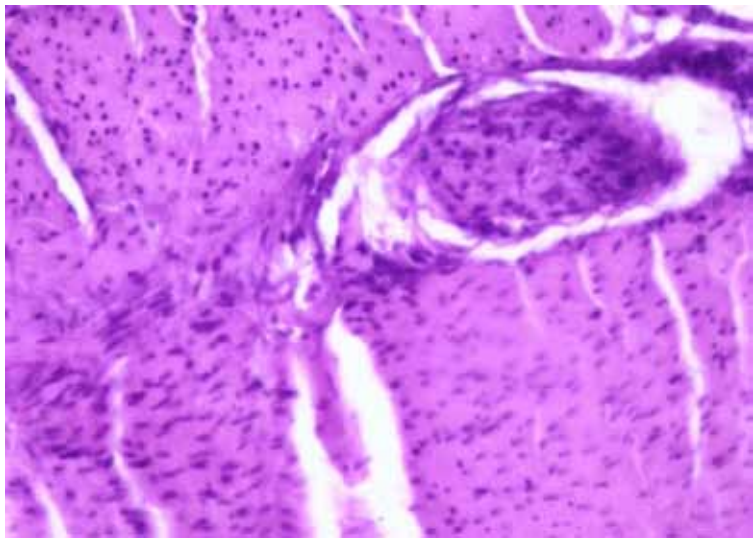

Fig. 7a. The muscle layer of the suprasthenic part of the intestine is up to 3-5 cm long. with HD in an infant. Separate Auerbach nerve nodes with dystrophic, atrophic and destructive changes. H & E stain Magn: 10x40.

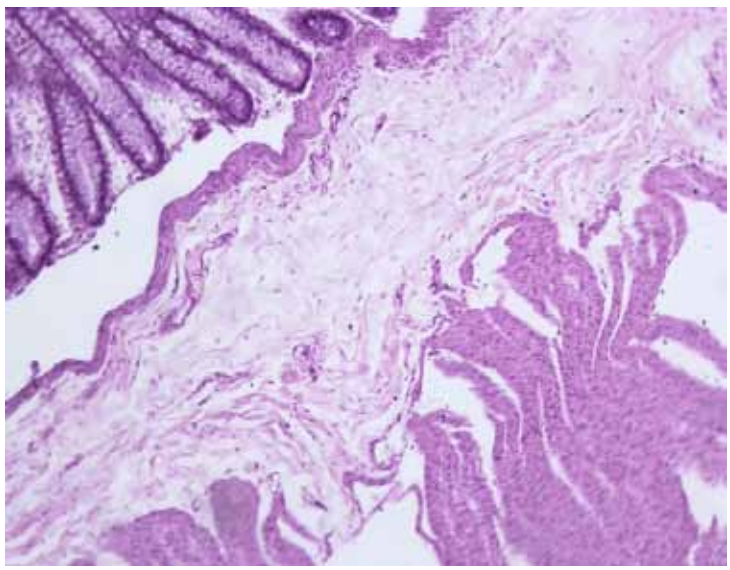

Fig. 7b. The muscle layer of the suprasthenic enlarged part of the intestine up to 5 cm long. Auerbach's nerve nodes are compressed by inflammatory infiltrate, atrophic nerve cells are compressed and small, hyperchromatic. The Auerbach nerve plexuses correspond to colon hypogangliosis. H & E stain Magn: 10x40.

Moreover, in different topographic sections of the wall of the enlarged part of the intestine, the Auerbach nerve plexuses differ in histoarchitectonics and sizes from each other. In the first section, where the mesentery is attached there are neurovascular bundles and nerve nodes are larger, there are many cells located rarely in one microscope objective, there is only one node. The farther the section of the intestinal wall from the zone of attachment of the mesentery, the denser the Auerbach nerve plexuses are located, in one microscope objective there are 2-3 nodes. They have few nerve cells, the nerve fibers are loosened, and the circumferences of the myelin sheaths are thick due to hyperplasia of Schwann's cells.

Thus, at the level of the suprastenotic enlarged zone at a distance of up to 5 cm, thesigns of irreversible sclerosis and fibrous degeneration of the muscle layer, degenerative -inflammatory changes in the mucous membrane,dysganglionic "inferior" sections of the nerve plexuses, which can subsequently serve as a source of development of hypoperistaltics, the cause of chronic colostasis in the long term after surgery have been diagnosed. Based on the data of histomorphology, we can conclude that to determine the optimal level of the upper border of the resection for rectal and rectosigmodal forms of HD, even with minor dilatation of the suprastenic zone, there are varying degrees of dysganglionic and "inferior" sections of the nerve plexuses. This is why, a wide resection at a distance of at least 5 cm from the enlarged zone is recommended and it is considered to be an optimal site for the resection zone and prevent recurrence of the disease.

Such intraoperative tactics for determining the level of wide resection in the mobilized part of the intestine was used in 28 patients with TEPT surgery, and in 8 patients it was established with diagnostic laparatomy. In the remote period, all patients with no signs of chronic constipation obtained excellent and good results.

At the same time, we have proved that the place and level of wide resection of the suprastenotic zone in infants depending on its compensatory expansion for the prevention of postoperative chronic constipation and relapse of the disease in a more distant period after surgery is of natural significance.

The advantages of TEPT were: radicalism; low injuries; one-stage; the absence of postoperative complications from the abdominal cavity and pelvic organs; smooth postoperative course. Contraindications were: severe vital malformations, acute severe enterocolitis, severe dilatation of the proximal intestine, severe general somatic state of the child, Hirschsprung associated enterocolitis (HAE), multiple, deep erosive ulcers in the mucosa of the rectum ampule and purulent inflammation of the parianal region.

In solving the tactical issues of diagnosis and treatment of HD in infancy, enterocolitis is the main and prognostically key condition for postoperative complications and mortality. Upon admission to the intensive care unit, newborns with HAE undergo intensive therapy, which includes correction of water-electrolyte and protein balance, cleansing and therapeutic enemas. If the length and localization of the agangliosis zone with an acute course of the disease is inaccurate, a colostomy is first applied above the site of obstruction and a floor biopsy from the distal sections is simultaneously performed. Further, when agangliosis is detected histologically, the zone in the lower part of the ostomy, within 3-6 months after the complete elimination of enterocolitis, the second stage is the operation of Soave-Boley with the simultaneous elimination of colostomy. We used this tactical approach in 3 patients with enterocolitis associated with HD, in whom, after surgical treatment, a successful fate was obtained in the late late period.

Also, we conducted 6 newborns and young children who had been accepted from the region with a severe course of HAE, where against the background of diarrhea syndrome, severe dilatation of the proximal intestine and with a general somatic status, a colostomy was imposed on an emergency basis. In the future, after removing the patient from the septic state and treating enterocolitis at the age of 7-9 months, a radical Soave-Boley operation was performed in the second stage with the simultaneous elimination of colostomy.

In other cases, with an uncomplicated form of HD and with the ex ception of total agangliosis, a one-stage correction of HD was performed. With incomplete primary diagnosis and with the presence of a very long zone of agangliosis, before TEPT, we used laparoscopic diagnostics in 10 patients to clarify the areas of elongation and expansion, localization and the true length of the zone of narrowing and suprastenotic expansion. After clarification of the above, the optimal location of the resection level was determined, the marks were left on the suprastenotic enlarged area, 5 cm from the transition zone, the proximal part of the colon agangliosis was

mobilized by separation of adhesions and the fixative ligament, where conditions for the possibility of TEPT were created.

With subtotal, total and left-sided disease with a long zone of agangliosis, clipping and resection of the blood supplying large mesenteric vessels of the second and third order. Then, a pull-through operation of the large intestine (Georgeson's operation) through the proctal access was performed . Moreover, the crucial points are: a meticulous execution technique, adequate hemostasis, maintaining good blood supply for the prevention of ischemia and preventing torsion and tension of the reduced intestine. These points prevent possible com plications in the postoperative period of HD in young children.

In acute type of HD, in the presence of intestinal obstruction, HAE with toxic dilatation of the colon, perforation of the blind and other parts of the colon, was carried out by colostrum with biopsy at different levels of the colon and rectal biopsy. With the subtotal and total form of HD in 3 cases, a Soave - Boley operation was performed with the simultaneous elimination of the colostomy. With the subtotal and total form of HD in 3 cases, the Soave-Boley operation was performed with the simultaneous elimination of colostomy.

According to our clinical observations, in all cases, complications in the intra- and postoperative period associated with the technique, the operation was not observed. In the postoperative period, in all cases, a Foley catheter No. 28-32 was inserted into the rectum, and turunda soaked in «Bakstims» balsam was left between the coloanal anastomosis and periodically changed after 2 days. The course of the postoperative period in all patients proceeded satisfactorily. Patients were usually discharged from the hospital 7 days after surgery.

Enterocolitis occurred in one patient in the early postoperative period. Stenosis in the area of the anastomosis often caused partial low intestinal obstruction against the background of circular and segmental-circular anastomosis, and was not a high risk factor. At the same time, the passage of a smaller Foley catheter through the anastomosis, the picture of mechanical intestinal obstruction was quickly eliminated. Two weeks later, during the control finger test, part of the stenosis was eliminated conservatively by dilating the narrowed area and rupturing the absorbable sutures of the colorectal anastomosis, which was carried out easily.

In the postoperative period, the failure of the coloanal anastomosis in our observations has never occurred. We didn't come across violations of bowel movement, including constipation, incontinence and enuresis. Functional constipation can be treated with conservative method, such as cleansing enemas and diet.

In addition to the use of Georgeson's surgery and TEPT, a 3-fold decrease in the number of postoperative complications was obtained in comparison with the control group.

During the monthly follow-up examination, complaints of constipation of varying intensity were observed only in 35% of patients. In these patients, with a long period, there were clinical signs of constipation until the filament was completely absorbed (up to 3 months) at the site of the anastomosis, due to its partial narrowing. At the same time, cleansing enemas and bougienage of stenosis to the age norm were performed. In order to restore the neuro-reflex connection in the anorectal zone, 1-3 courses of electrical stimulation were performed. In this case, the signs of functional disorders of the stool gradually disappeared and the normal act of defecation was restored.

To study long-term results, questionnaires were conducted 3 months after the radical operation, in 45 sick children with HD at the age of 1-3 years, by scoring on a point scale. The list of questionnaire questions is presented in table No. 1, where clinical violations of the act of defecation were evaluated as: good, satisfactory, unsatisfactory.

Table 1: Questionnaires to assess the long-term results of surgical treatment of Hirschsprung disease.

Symptoms	Long-term results					
	Good	Point	Satisfactory	Point	Unsatisfactory	Point
1. Abdominal distention	No	10	Often	5	Constantly	0
2. Difficulty in the act of defecation	No	10	After 3 days with difficulty, but independently	5	After 4-6 days, not on their own, after an enema	0
3. Incomplete bowel movements	No	10	Partially	5	Yes	0
4. Reducing bowel movement diameter	No	10	Partially reduced	5	Sharply reduced	0
5. Lack of a bowel movement and the urge to defecate	No	10	Partially	5	Yes	0
6. Fecal incontinence without the urge to defecate	No	10	Partially	5	Yes	0

Moreover, if the result was 45-60 points, we rated it good; 30-45 points - satisfactory; below 30 points - unsatisfactory.

Long-term results of surgical treatment of Hirschsprung disease in infants by choosing a method are presented in Table 2.

Table 2: Long-term results of surgical treatment of Hirschsprung disease in infants by method choices

Anatomical forms	Method operations	Amount of operated Patients (%)	Long-term results (n- 61)			
			Unsatisfactorily	Satisfactorily	Good	Excellent
Rectal 13(21.3%)	TEPT	13(21.3%)	-	-	34.9%)	10(16.4%)
Rectosigmoid 22 (36.1%)	TEPT	10(16.4%)	-	-	2(3.2%)	8(13.1%)
	Soave - Boley	12(19,7%)	-	2(3.2%)	5(8,1%)	5(8,1%)

	Soave - Boley	7(11.5%)	-	1(1.6%)	1(1.6%)	5(8,1%)
	Georgeson	6(9.8%)	-	-	2(3.2%)	4(6.5%)
Rectosigmoid with a long zone + HAE2(3,2%)	Soave - Boley	2(3.2%)	-	1(1.6%)	1(1.6%)	-
Subtotal form + HAE + colostomy 5 (8.1%)	Soave - Boley	5(8,1%)	2(3.2%)	2(3.2%)	1(1.6%)	-
Total		**61(100%)**	**2(3,2%)**	**7(11,5%)**	**17(27,9%)**	**35(57,3%)**

At the same time, we obtained long-term results in general for surgical treatment of HD in infancy: excellent - 57.3%, good - 27.9%, satisfactory - 11.5%, unsatisfactory - 3.2%.

Among 26 patients who had been operated on by the Soave - Boley method, the following results were obtained : excellent - in 10 (38.4%); good - in 8 (30.7%); satisfactory - in 6 (23%) and unsatisfactory - in 2 (7.6%). Among 29 patients operated on by the TEPT method, except for one patient, excellent and good results were obtained in 28 (96.6%) patients. And also among 6 patients operated according to the Georgeson method, excellent and good results were obtained in 100% of cases, there were no satisfactory and unsatisfactory results. It should be noted that among the operated HD patients according to the Soave-Boley method, there were severe patients, of which 7 patients had a colostomy in the neonatal period.

Thus, according to the study of the long-term results of the first group of patients operated on by the Soave-

Boley method: in the late period there was stenosis in the anastomotic zone with a violation of the bowel movement as a constipation with complete and partial absence of a feeling of urge. For children with satisfactory and unsatisfactory results, a stationary examination was proposed with irrigography, ultrasound of the abdomen and perineum, if necessary, examination of feces for coprology and dysbacteriosis, rectal ulceration, ESM and the complex rehabilitation treatment post-mortem until the symptoms disappear for 1-3 years.

In the second group of patients operated on by the TEPT method in the remote period after constipation surgery, they were episodic in nature, and urinary incontinence was not observed. Fecal incontinence was noted only in the form of a temporary nature by the type of increased stool and fecal incontinence were in the presence of loose stool. After receiving the ESM and bougieurage and the complex rehabilitation treatment, they gradually disappeared within 6–9 months.

Thus, the study of immediate and long-term results of the children's treatment with HD, operated on in infancy, using the traditional Soave-Boley method and modern minimally invasive technologies according to TENTC and the Georgeson method, shows different results.

At the same time, radical one-stage surgical treatment for distal forms of HD using minimally invasive TEPT method is a priority in infancy, which can reduce complications to a minimum with improved functional outcomes of treatment, relative to two-stage treatment.

Results

1. In the surgical treatment of distal forms of HD in infants, the TEPT method is the method that is preferred for selection and the colostomy is not placed on.
2. With proximal and decompensated forms of HD with the presence of a colostomy, the optimal method of radical surgery is abdominoperineal proctoplastics according to the Soave (Boley and Lenyushkin) technology with the simultaneous elimination of the colostomy.
3. In the complicated, acute course of the subtotal form of HD during the neonatal period, primary emergency colostomy application saves the life of a child and contributes to the treatment of bacterial and HAE and the subsequent use of abdominal-perineal proctoplasty according to the Soave technology (Boley and Lenyushkin) with the simultaneous elimination of the colostomy.

Abstract

The morphological changes in the myocardium of the offspring were studied when the mother had hypothyroidism in the rat to the female mother during the feeding of the rats.

The aim of our work was to identify structural and morphological changes in the walls of the heart of baby rats born to mothers in a state of hypothyroidism and the use of the antioxidant Mexidol.

The material for the experiment, served microscopic myocardial preparations of 50 rats of different periods of early postnatal ontogenesis.

Results: The morphological structure of the myocardium of the heart of baby rats born to mothers, dystrophic changes were observed in a state of hypothyroidism. The observed changes reached a maximum by the 14th day of studies, manifested by perivascular and interstitial lymphohistiocytic infiltrate. Changes should also occur in the ultrastructure of the heart, which leads to changes in myofibrils, damage to the mitochondria, which affect the microvessels with a violation of the components of the vascular walls, which are developing intercellular edema.

Keywords: *Heart, myocardium, hypothyroidism, myocytolysis, mexidol.*

Introduction

One of the most common forms of functional disorders of the thyroid gland is hypothyroidism, which develops as a result of a long-term persistent deficiency of thyroid hormones or decreasing their biological effect on the cellular level. Hypothyroidism may not be detected for a long time. This is due to the gradual, inconspicuous start of the process, satisfactory well-being of patients in mild to moderate degrees of illness, erased symptoms, regarded as overwork, depression, pregnancy.

Increasing of thyroid hormones causes systemic changes in the body[8]. Thyroid hormones regulate energy metabolism in the cells of organs, and their deficiency is manifested in a decrease in tissue oxygen consumption, a decrease in energy expenditure and the processing of energy substrates7. With hypothyroidism, the synthesis of various energy-dependent cellular enzymes necessary for the normal functioning of the cell is disrupted[12]. In the case of advanced hypothyroidism, mucinous (mucous) edema occurs - myxedema, most pronounced in connective tissue. Myxedema develops as a result of excessive accumulation of glycosaminoglycans in the tissues, which, having increased hydrophilicity, retain water.

The most frequent and serious complication of both thyrotoxicosis and hypothyroidism is damage to the cardiovascular system[6], so this problem is not only endocrinological, but also cardiological[5]. Heart pathology with thyroid dysfunction is often the leading disease in the clinic and often leads to disability, and in severe cases, to death in this category of patients[10]. The clinical picture shows a variety of complex cardiac arrhythmias[1], arterial hypertension, dishormonal cardiomyopathy with the development of chronic heart failure[2]. Meanwhile[3], data on the pathogenetic mechanisms of the development of "thyrotoxic" and "hypothyroid" hearts are scarce and contradictory[4]. An analysis of recent data shows that cardiovascular pathology remains the main cause of death in all developed worlds[14]. The heart is most often exposed to the pathological effects of endogenous and exogenous stimuli[13], as a result of which not only a violation of its function occurs, but also various pathological processes develop throughout the body[11]. It is known that heart damage is a very complex, poorly predictable and difficult to recognize based on clinical symptoms, medical and physiological process[9]. The defeat of any organ, in particular also the heart, naturally begins with the defeat of blood vessels and connective tissue stroma of the organ. In the subsequent lesions, the actual muscle tissue of the heart is exposed. Therefore, with heart lesions, the main quantitative and qualitative changes occur both in the stroma - vascular, and in the muscle structures of the heart. Structural changes are necessarily accompanied by clinical symptoms in the form of impaired cardiac activity.

The aim of our work was to identify structural and morphological changes in the walls of various parts of the heart of baby rats born to mothers in a state of hypothyroidism and the use of the antioxidant Mexidol.

Material and Method

The object of the study was the hearts of 50 white outbred rats of the following age groups: 3, 7, 14, 21, 30 days. Animals were divided into 3 groups. The first group of animals consisted of female rats receiving mercazolil at a dose of 5 mg per 100 g of body weight for 30 days, then for the month before pregnancy, a maintenance dose of mercazolil was used at a rate of 2.5 mg per 100 g. After pregnancy and during feeding, rats were injected with mercazolil in a maintenance dose of 2.5 mg per 100 g through a probe. As a solvent for mercazolyl used 1% starch paste. The second group of the experiment consisted of female rats who were injected with mercazolilum on the same days of the experiment as in the first group, and after pregnancy they received Mexidol at a dose of 0.5 mg per 100 g of weight together with mercazolilum. The third group included female rats of the mother of the control group, which, after birth, rat pups were daily fed on an empty stomach, depending on the term, for water. After each experimental week, the hormone level from the rat caudate vein was determined.

Results and Discussion

The control and experimental groups of animals were kept in the same vivarium conditions. At the end of the experiment, the rat pups of the experimental and control groups were killed under ether anesthesia. After that, the heart was isolated from animals, fixed in 10 per cent neutral formalin, followed by piping in alcohols, pouring in paraffin and preparing histological sections. Sections of 8-10 microns thick were prepared from paraffin blocks. Microsections were stained with hematoxylin and eosin, van Gieson.

The ventricular endocardium of the control group of animals consisted of longitudinally directed bundles of collagen fibers. A histological section reveals places where longitudinally lying bundles of collagen fibers interwoven with each other. Bundles of collagen fibers located closer to the ventricular myocardium are intertwined with bundles of collagen fibers from connective tissue layers located between bundles of cardiomyocytes of the myocardial inner layer (See App. A). The bundles of elastic fibers of the ventricular endocardium lie loosely compared to bundles of collagen fibers. In bundles of fibers adjacent to the myocardium of the ventricles, the density of arrangement increases, the direction of which changes from longitudinal to oblique, and are interwoven with bundles of connective tissue located between bundles of cardiomyocytes of the inner layer of the myocardium. Reticular fibers in the endocardium of the ventricles are located close to each other.

Upon further study of the slice, the cardiomyocytes of the outer layer of the myocardium are directed longitudinally, in the middle layer circular directed beams are detected; the inner layer contains weakly obliquely oriented bundles of cardiomyocytes. The inner bundles of fibers as they approach the endocardium acquire a more oblique direction and pass into the papillary muscles. A study of the direction of the bundles of ventricular myocardial fibers showed that the

circularly directed layer does not always have a clear orientation. The bundles of fibers of the middle layer on the lower wall of the ventricles are directed obliquely and deviate towards the endocardium. Between the layers of ventricular myocardial cardiomyocytes, the border is weakly expressed. They fit snugly together. The inner layer of the myocardium consists of parallel located bundles of cardiomyocytes running in parallel with the endocardium. The outer layer of the myocardium has a loose structure in which cardiomyocytes are located in different directions (See App. B).

In the middle layer of the myocardium of the left ventricle of the heart, bundles of cardiomyocytes are located perpendicular to the inner layer. In the center of cardiomyocytes, 1-2 oval-shaped nuclei are determined. The nucleus of cardiomyocytes is located in the center of the cell, while myofibrils are located on the periphery. In the right ventricle, bundles of cardiomyocytes in the layers of the myocardium are similar to the left ventricular myocardium. But unlike the left ventricle in the myocardium of the right ventricle, the thickness of the circular layer of cardiomyocytes is 2-3 times thinner than the thickness of the longitudinal layers of cardiomyocytes.

In the myocardium of the ventricles of the heart, depending on the site, bundles of collagen fibers have different directions. At the top of the heart, the bundles of collagen fibers are directed obliquely, while part of the bundles of collagen fibers changes direction from oblique to longitudinal. In the inner layer of the myocardium, bundles of collagen fibers lie in the longitudinal direction, separating bundles of cardiomyocytes from each other. In the middle layer of the myocardium, collagen fibers form bundles having a circular direction. When studying the outer layer of the myocardium, bundles of collagen fibers lie obliquely between bundles of cardiomyocytes. In the inner layer, the reticular fibers lie longitudinally and in the region of the apex of the heart they are intertwined with the reticular fibers from the outer layer of the myocardium of the heart. In the middle layer of the myocardium, the reticular fibers are located in a circular direction between the bundles of cardiomyocytes. Reticular fibers around bundles of cardiomyocytes form a network of various sizes and shapes (See App. C). The direction of the bundles of connective fibers depends on the direction of the cardiomyocytes.

The interventricular septum consists of two longitudinal and one circular layer. The longitudinal layers on the left and on the right are from the corresponding longitudinal layers of both ventricles, and the middle circular layer is formed due to the circular layer of the left ventricle of the heart. The internal diameter of the arteriole ranges from 9.5 to 15.2 microns and an average of 11.7 ± 0.6 microns. The inner diameter of the venules ranges from 15.7 to 20.5 microns. Myocardial sinusoids are elongated, oval or irregular in shape. The thickness of the inner diameter of the capillaries is from 5.7 to 11.4 microns, an average of 9.3 ± 0.6. Myocardial blood vessels are direct along the bundles of cardiomyocytes (See App. D). Around the cardiomyocytes and blood vessels are bundles of collagen and elastic fibers. The fibrous structure of the connective tissue of cardiomyocytes connecting with the blood vessels captures the capillaries around the muscle fibers.

In the epicardium of the ventricles of the heart, bundles of collagen and elastic fibers lie longitudinally, and have a higher density than bundles of collagen and elastic fibers of the endocardium. In the epicardium of the ventricles, the reticular fibers are located longitudinally.

The histological picture of 3-day-old rats undergoing hypothyroidism did not reveal significant differences compared with the control group. Cardiomyocytes had an oblong shape, formed muscle fibers, in the center of the fiber an oval-shaped nucleus was determined and myofibrils were clearly differentiated. In the subepicardial zone of the myocardium, dilated and full-blooded veins were detected with signs of redistribution of blood by the presence of clotted red blood cells, and in the myocardial stroma, beginning edema was observed. The endocardium is also somewhat thickened and uneven, in some places foci of depression and deepening in the form of cracks and vessels of Tebesia are visible. Endothelial cells are somewhat hypertrophied and hyperchromic, sometimes with foci of enlightenment in the basement membrane.

A morphological study of the heart of 7-day-old pups born to mothers in a state of hypothyroidism, with minor changes in the form of expansion of visible vessels (See App. E). An increase in the permeability of microvessels and vessels of the venous link was accompanied by the release of the liquid part of the blood through the vessel wall to the surrounding connective tissue (See App. F). Due to inflammatory infiltrate, the vascular wall thickens and the lumen narrows. These discirculatory

disorders lead to perivascular edema, loosening of the intramuscular space. At the same time, cardiomyocytes are loosened with the development of dystrophy and vacuolization in their cytoplasm. Myofibrils have a granular appearance, of different thickness and density. During this period, the epicardium of the heart is significantly thickened due to the proliferation of young connective tissue cells and swelling of fibrous structures. The endocardium is also swollen, in places forms uneven thickenings from proliferative endothelial cells.

At the age of 14 days, destructive and inflammatory phenomena join the above-described discirculatory and dystrophic changes. In the myocardial stroma, increased swelling was noted mainly in the perivenular and pericapillary spaces. Collagen fibers are swollen, loosened, in some places there is a separation of collagen bundles, swelling of the main substance of the connective tissue with the initial signs of surface disorganization. Connective tissue cells are also swollen, their nuclei slightly increase in size. Vascular disorders are common, endothelial cells in the vessels, acquire a rounded shape. In the cytoplasm of cardiomyocytes, small vacuoles were found filled with a clear cytoplasmic fluid, i.e. hydropic dystrophy develops. Intracellular edema is focal in nature, along with dystrophically altered cardiomyocytes, unaffected cells are found. In the myocardium of the left ventricle of the heart, around the vessels and in places in the stroma, inflammatory foci consisting of lymphohistiocytic cells appear (See App. G). In this case, cardiomyocytes are loosened with the development of dystrophy and vacuolization in their cytoplasm. Myofibrils have a granular appearance, different thickness and density. The endocardium is also swollen, in places forms an uneven thickening of proliferative endothelial cells. At this time, the epicardium of the heart is significantly thickened due to the proliferation of young connective tissue cells and swelling of fibrous structures. A histochemical study reveals a significant decrease in the number of collagen structures in the composition of the epicardium, instead of them, the content of SHIK-positive substance increases, especially in the walls of blood vessels. Endothelial cells are somewhat hypertrophied, hyperchromic, sometimes with foci of enlightenment in the basement membrane.

The study process of growth dynamics of the wall thickness of both the left and right ventricles of the heart of rat pups born by mothers in hypothyroidism state, depending on different parts of the heart, showed that the wall thickness of all departments is less than the by control indices. Comparing the thicknesses of wall of the right and left ventricles of the animals of the experimental group with the control group, a significant lag in myocardial indices is revealed. These changes are being most pronounced in pups of 14 days of age. The thickness of the left ventricular myocardium is less than that of the control group by 29 per cent. The thickness of the right ventricle compared with the control group is less by 17 per cent (Table).

On the 21st day, vascular disorders persist in the myocardium: pronounced plethora of veins, stasis, numerous perivascular hemorrhages of a diapedetic nature and an increase in the intensity of edema is noted. Edematous fluid is located between the muscle fibers, as if pushing them apart. Swelling of not only connective tissue cells, but also their processes was revealed. The swollen processes of neighboring fibroblasts are in contact with each other and, as it were, form syncytium. In the myocardial stroma, numerous small infiltrates from lymphocytes, histiocytes and fibroblasts. In cardiomyocytes, signs of protein hydropic dystrophy with the development of intracellular edema are observed, numerous foci of plasmolysis throughout the myocardium are determined. Plots of plasmolysis (intracellular myocytolysis) look like optically empty spaces. With intracellular myocytolysis, dissolution of myofibrils in certain sections of the fiber along its length is noted. In adjacent areas, myofibrils are preserved. With silvering according to Foote, the formation of reticular fibers in the form of coarse clumps and intermittent thick dark brown fibrous structures is determined. A histochemical study using the Van Gieson method reveals loosening and a decrease in the number of collagen structures, especially in the epicardium, and an increase in the content of SHIK-positive substance. Elastic fibers of the endocardium and in the intramuscular stroma in a state of loosening and tearing due to edema and disorganization of the connective tissue.

The study process of the dynamics of growth of wall thickness of both the left and right ventricles of the heart of rat pups born by mothers in a state of hypothyroidism with the use of Mexidol depending on different parts of the heart showed that the wall thickness of all departments is less than by the control indices. Comparing the wall thicknesses of the right and left ventricles of the animals of the experimental group with the control, a significant lag in myocardial indices is revealed. These changes are being most pronounced in pups of 21 days of age. The thickness of the left ventricular myocardium is less than

that of the control group by 29 per cent. The thickness of the right ventricle compared with the control group is less by 17 per cent (Table).

After 30 days, interstitial edema intensifies and spreads to the entire myocardium, reaching the greatest value in the perivenular spaces. Due to edema, swelling of collagen fibers, their delamination and shedding are observed. The main substance swells and collapses, signs of disorganization of the connective tissue appear (See App. H). When stained with toluidine blue, the phenomenon of metachromasia is observed. Dystrophic changes in the myocardium acquire a diffuse character, increased resorption of the cytoplasm, intracellular edema is noted. The foci of plasmolysis are numerous and larger than on the 21st day. Intracellular myocytolysis extends to the entire myocardium; total damage to cardiomyocytes is noted. In the focus of myocytolysis, most myofibrils are absent, single fibrils are visible. At the same time, marked loosening of the subendocardial and intramural layers of the heart wall due to edema and dissociation of cardiomyocytes is noted.

The study process of the growth dynamics of thickness of wall of both left and right ventricles of a heart of baby of intact rats at different stages of postnatal ontogenesis depending on the parts of the heart walls has showed that by the 30th day of the current study, comparing to 3 days of age, thickening occurs on average in all parts of the heart 1.7 times, only in the interventricular septum - 1.5 times. These morphometric data are confirmed by microscopic rearrangements occurring in the dynamics of postnatal ontogenesis (Table).

The subepicardial layer of the myocardium remains dense, where cardiomyocytes form large muscle bundles. Inflammatory infiltrate and sclerosis are defined around the vessels. When staining according to the Weigert method, it is noted that in the walls of the arteries the inner elastic membrane is thickened, winding, sometimes homogenized. In the muscle layer and in the surrounding connective tissue, elastic fibers are fibrous and lysed.

In cardiomyocytes with small foci of myocytolysis, the nuclei are preserved. In cardiomyocytes with large foci of myocytolysis, the nuclei are destroyed with the development of collicational necrosis. Remains of fibers in the form of tubules surrounded by a sarcolemma are found in foci of collication necrosis; the contents are not stained. Sarcolemma is thickened and well stained with picrofuxin. The described tubules are collapsed, around them there are excessive deposits of glucosaminglycans.

In some areas, counter-abnormalities and small foci of coagulation are determined, fragmentation of muscle fibers is observed in some places. However, collision processes dominate in the myocardium.

Since metabolic imbalance primarily affects the energy supply system of cells, the therapy should be aimed at increasing energy generation and increasing myocardial resistance to hypoxia. The second experimental group included 26 rats, which were daily injected with mercazolyl and antioxidant Mexidol.

In rat pups 3 days old born from mothers to hypothyroidism and receiving Mexidol, the normal histological picture is determined in the rat myocardium, pathohistological changes in the myocardium are not detected.

After 7 days of birth, vascular disorders in the form of plethora and expansion of veins, stasis, plasmorrhagia are noted (See App. E). Vascular disorders persist, there is an increase in plasmorrhagia, plasma impregnation and fibrinoid swelling of the walls of the arteries.

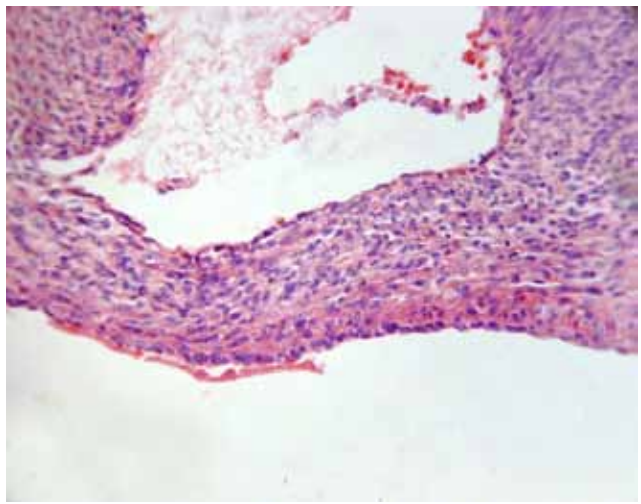
After 14 days from the start of the experiment, against the background of the use of Mexidol in the myocardial stroma, a small edema was found mainly around the veins. In individual cardiomyocytes, intracellular edema was detected in the form of accumulations in the cytoplasm of vacuoles filled with tissue fluid.

Intracellular edema is focal in nature. In the myocardial stroma, vascular disorders persist in the form of plethora, stasis and venous stasis. When staining with toluidine blue, metachromasia was not detected; fibrinoid swelling of the walls of the artery is observed.

After 21 days, edema was found in some places in the myocardial stroma, which is focal in nature and has a lower intensity than in the first experimental group. In areas of edema, collagen fibers swell and homogenize. There is a superficial disorganization of connective tissue with the accumulation of glycosaminoglycans. On histological preparations, mucoid swelling is observed (See App. I).

In places in the cytoplasm of cardiomyocytes, hydropic dystrophy is observed, which is focal in nature. The transverse striation of muscle fibers is preserved, in some areas myofibrils swell. Vascular disorders become less intense.

After 30 days, against the background of daily use of the antioxidant Mexidol, partial relief of vascular disorders is noted. In the myocardial stroma, edema develops, which extends to almost the entire myocardium, however, the intensity of the edema is less pronounced compared with the experimental group I. In the connective tissue of the myocardial stroma, swelling and decomposition of the main substance, accumulation of glucosaminglycans, swelling, homogenization and partial decomposition of collagen fibers with the formation of a fibrinoid are observed. At this time, for the first time in the stroma, small focal infiltrates from lymphocytes, histiocytes, and fibroblasts were detected (See App. J).



At the indicated times, a picture of intracellular edema is observed in the myocardium and for the first time against the background of Mexidol use, small foci of plasmolysis (myocytolysis) appear. These foci are optically empty portions of the cytoplasm with complete preservation of the plasmolemma. Compared with the experimental group I, the processes of myocytolysis are focal in nature.

Thus, with the daily use of the antioxidant Mexidol in rats of the experimental group II, no histological changes in the myocardium were detected in the first 7 days. The first signs of myocardial damage (beginning periventricular edema of single cardiomyocytes) appear on the 14th day, that is, 7 days later than in the first experimental group. An expanded picture of a change in the myocardium such as diffuse intracellular edema, myocytolysis was detected on the 28th day, then the network was later compared by comparison in the first experimental group. Destructive processes with total damage to the myocardial fibers in the experimental group II of rats were not detected. Regenerative processes with the replacement of damaged myocardial cells with connective tissue proceeded more intensively in comparison with the experimental group I. The above suggests that Mexidol has a protective effect on the myocardium under conditions of hypothyroidism.

Findings:

1. In transient experimental hypothyroidism, the use of mercazolil in animals in the ventricular myocardium results in dystrophic, destructive and atrophic changes in cardiomyocytes, diffuse edema and stromal fibrosis. The first signs of hypothyroidism were detected on days 7-14, a detailed picture develops on the 21st day.
2. When using an antioxidant in the myocardium of experimental animals, signs of hypothyroidism occur on the 21st day, and a detailed picture on the 30th day.
3. The intensity and prevalence of morphological changes are less pronounced, destructive changes in the myocardium are not detected.

The use of antioxidants in experimental hypothyroidism in laboratory animals has a protective effect and prevents the development of severe destructive changes in the myocardium.

Abstract

The authors have scientifically determined an immunoreactivity enhancement, which one can indicate by a change in the level of neurotropic autoantibodies in relation to proteins and neurotransmitter receptors in epileptogenesis and the formation of aberrant plasticity among patients with symptomatic and idiopathic epilepsy. Epilepsy is a variant of autoimmune dysregulation, in which an increase in the content of autoantibodies in relation to neuro-specific proteins and neurotransmitters causes the genesis, progression and preservation of the pathological process in accordance with the etiological factor.

A new impulse to study the problem of epilepsy immunopathogenesis should be the ideas of in the last decade about the function inseparable integration of the two main integrative body systems: the central and the immune nervous systems[2]. On the basis of information about neuroimmune interaction, new scientific disciplines — Neuroimmunology and neuroimmunopathology formed[5].

Keywords: *Epilepsy, pathogenesis, immunoreactivity, neurotransmitter, serum, protein.*

Introduction

Currently, thanks to the researchers of immunoneuroendocrine regulation, we know that in the regulation of homeostasis involves plenty of natural autoantibodies (Ab) that reversibly interact with different antigens (AG) of its own body[3]. Natural autoantibodies pass through the synthesis within the body of healthy persons since the fetal life and throughout life [8].

As a result, healthy persons of different genders and ages have only minimal differences (immune fingerprints) in the serum content of various AT. We found that the AT production of different specificity regulates (by the principle of feedback) by the content of the appropriate target antigens4. It indicates the presence of powerful mechanisms for maintenance of the physiological (normal) level of production and secretion of various AT variants[6]. The part of Ab does not have a specific organ orientation and interacts with the ubiquitous AG (collagen, DNA, cytochromes, etc.). The other part interacts with organ-specific antigens (neuro-specific proteins, organ-specific isoenzymes, insulin, etc.). This also applies to Ab which interacts with nerve cell proteins or neurotropic Ab (NAb).

Among the patients with diseases of the nervous system, there are often changes in the serum content of NAb. Whereby, the researchers mainly pay attention to situations characterized by an increase in the neurotropic antibodies content of a certain specificity, which stands as pathological autoimmune aggression[7]. However, in accordance with the regulatory functions of Ab, the disorders of serum ratios in refard to different types of NAb can also be important, and the growth in the production of certain Ab can have not only a pathological, but also an adaptive-compensatory value[6].

Recently, there is more and more attention in regard to the participation of a single neuroimmunological network within the genesis of many diseases[3]. There is a wide discussion of epilepsy immunological aspects in modern literature8.

The pathogenic role and the diagnostic value of Ab to the brain proteins and the receptors of neurotransmitters require further study[2].

The Purpose of the Research: To study the immunoreactivity of neurotropic autoantibodies and neurotransmitters in case of symptomatic and idiopathic epilepsy.

Materials and Method

The study bases on a survey in relation to 86 patients with epilepsy in the age of 16 to 70 years, among them 23 patients had idiopathic epilepsy and 64 patients had symptomatic focal epilepsy. Each patient passed thorough preliminary anamnestic and clinical selection under method of stratified randomization through inclusion and exclusion criteria. The criteria for patients inclusion within the study: adults, epileptic attacks at the time of hospitalization or in history, idiopathic and symptomatic epilepsy. The exclusion criteria: children, cryptogenic epilepsy, pseudepileptic seizures, psychogenic reactions, conversion seizures (hysteria). The scope of the study included: clinical neurological examination, physical status research, neuropsychological testing of higher cortical functions, neurophysiological examination (EEG), laboratory method (clinical blood analysis, blood biochemistry, immunity status test), functional research method (ECG, EchoCG), neuroradiological research method (MRI or CT scan of the brain).

The seizures type determination is in accordance with the International League Against Epilepsy (1981). The diagnosis of epilepsy correspond to the International classification of epilepsy (ILAE 1989, 2001)[12].

Quantitation of serum immunoreactivity of antibodies in relation to neurotransmitter receptors (glutamate, GABA, dopamine, serotonin, and holinoreceptors) and neuro-specific proteins (NF200, Gfap, S100, and OBM) performed by means of solid-phase immunoenzyme method ELI-N-Test and test kits of the same name, manufactured by international research center "Immunculus" (Russia). We determined the values of AAb immunoreactivity within the range from 80 to 140 Units, and the Ab1/AIAb2 immunoreactivity index within the range from 0.8 to 1.2[16] as the norm.

We compared the results of the study with data from a control group output that included 32 clinically healthy individuals (in the age from 24 to 65).

We performed the analysis of the obtained indicators by the software package "SPSS for Windows" and "STATISTICA" Microsoft Excel with material processing with the method of variation statistics. We maintained the reliability assessment of the obtained results by the paired method with the Student's t-test . We considered the differences significant at $p<0.05$.

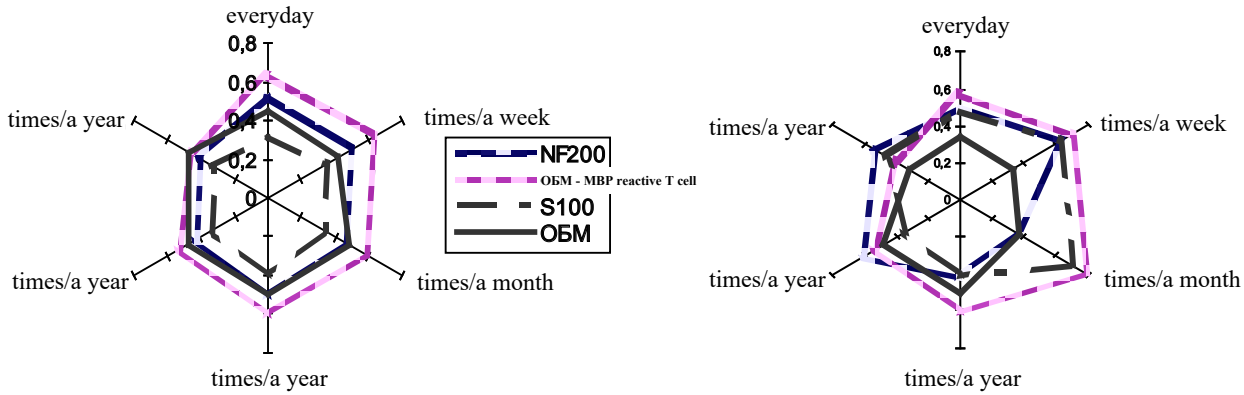
Research Results

We determined the level of AAb in relation to neurotropic proteins and neurotransmitters in the blood serum of 59 patients with epilepsy. We formed the following clinical groups to conduct immunology research : the first group - 17 patients with idiopathic epilepsy; the second group – 42 patients with symptomatic epilepsy. The control group consisted of 16 clinically healthy individuals.

The results of the conducted studies showed that among clinically healthy individuals (control group), natural AAb in relation to the studied neurotropic proteins within certain limited titers are normal components of the blood serum among practically healthy people, and therefore, in accordance with the recommendations of the test system manufacturers, they determined the design as "internal standard serum" (table 1).

In case of immunology research results assessment, we found that both groups of patients differed from the control group, both in terms of the level and degree of the immunological indicators dispersion under research. In order to identify possible pathogenetic features, we performed the analysis of neuroimmune relationships in both groups in comparison with the control group.

Table 1: The level of serum autoantibodies in relation to neurotropic proteins among patients with symptomatic and idiopathic epilepsy, ie.



Indicators of	SE (n=42)	IE (n=17)	Control (n=16)	SE and IE, P<	SE and KG, P<	IE and KG, P<
NF200	121,8±8,2	97,6±8,9	72,9±7,1	0.05	0.05	0.05
GFAP	102,5±8,3	80,4±7,2	57,9±5,7	0.05	0.01	0.05
S100	124,1±4,6	150,3±11,8	77,5±7,6	0.05	0.01	0.05
MBP	102,4±8,0	78,8±7,7	58,8±5,5	0.05	0.01	0.05

We found that in the group of patients with SE, the levels of the studied AAb in relation to all neuro-specific proteins significantly exceed the values of not only the «internal standard serum», but also similar indicators of patients with IE. Thus, we found that the highest level of AAb in both groups was the level of AAb in relation to S100, whereby among patients with SE this indicator exceeded the standard values by an average of 1.6 times (P<0.01), and among patients with IE – of 1.9 times (P<0.05). At the same time, there was a significant increase in the AAb output within the group with IE in comparison with SE (150.3±11.8 cu vs 124.1±4.6 cu, P<0.05). Such a significant increase in the level of AAb in relation to the S100 protein, which is a calcium-binding protein, may be a confirmation of the hypothesis that one of the links in the pathogenesis of epileptic attacks is a growth in the permeability of neural membranes for Ca2+ ions with an increase in their intercellular space concentration.

The examination of the AAb level in relation to the NF200 protein also revealed a significant increase in their titers among patients of both groups (on average of 1.7 times for SE and 1.3 times for IE, respectively, P<0.05). Whereby, there was also a significant predominance of the AAb level in relation to NF200 among the patients with SE (121.8±8.2 units vs. 97.6±8.9 units, P<0.05), which indicates excessive plasticity, which apparently contributes to the preservation of stronger pathological connections of the epileptic system among patients with SE (Johnston M. V., 2004).

The level of serum AAb to the neuro-specific protein MBPa,ong patients of both groups also significantly exceeded the values of the "internal standard serum" (on average of 1.7 times among patients with SE; p<0.01 and 1.3 times among patients with IE; p<0.05), while on average of 1.3 times higher than these indicators among patients with SE in relation to patients with IE, (102.4±8.0 cu vs 78.8±7.7 cu, P<0.05).

The level of serum AAb in relation to GFAP was approximately at the same level as AAb to MBP and was 102.5±8.3 cu among patients with SE, and 80.4±7.2 cu among patients with IE, significantly exceeding the indicators of the control group by an average of 1.8 (p<0.01) and 1.4 times(p<0.05), respectively. The comparative analysis between the groups also revealed a statistically significant increase in AAb in relation to MBP among patients with SE in comparison to IE by 1.3 times (P<0.05). As a result of this analysis, we found a positive correlation between the duration of epilepsy and AAb levels in regard to all neurotropic proteins under study, which mostly referred to patients with SE. We found a similar direct relationship between the level of AAb output and the frequency of seizures among the patients under examination. Moreover, this relationship did not depend on the etiological factor of epilepsy (Fig. 1).

Symptomatic epilepsy **Idiopathic epilepsy**

Fig. 1. The correlation relationship between the frequency of seizures and the level of autoantibodies in regard to neurotropic proteins in accordance with the type of epilepsy

Thus, clinical and immunological analysis revealed a clear pattern relation between the content of antibodies and the neurotropic proteins in conformity with the aetiology, duration and course of SE and IE. The regularity of the detected increase of neurotropic AAb in close relationship both with each other and with the

frequency of seizures is evidence of the neuroimmune dysregulation aggravation with the increase of the clinical course severity among the patients with epilepsy. The disruption of the brain's immune barriers permeability leads to the AAb formation in regard to neurotropic proteins, which increases the lack of the brain trophic support and the progression of damage processes. In case of differentiation of the obtained results in accordance with the form of epilepsy,we found that the greatest sensitization of immune cells to the neuro-specific antigens NF200, GFAP and MBP is with SE, which, in turn, is a reliable reflection of the destructive process and pathological penetrance of the blood-brain barrier.

The table 2 contains the research results of the AAb level in relation to neurotransmitters. Within the comparative analysis of the indicators which refer to patients with both IE and SE against the data of the "internal standard serum", we found a significant unidirectional increase in the individual level of serum AAb immunoreactivity in relation to the receptors of all neurotransmitters under study. We obtained an interesting data in regard to patients with concern to the level of AAb in relation to choline receptors. In particular, the patients with IE had the level of AAb in relation to this neurotransmitter 162.9±5.3 cu, with above-limit value of the "internal standard serum" by 4.8 times ($p<0.01$), and the indicators of patients with SE by 3.5 times (46.7±4.9 cu, $p<0.05$).

Table 2: The level of serum autoantibodies in relation to neurotransmitters among patients with symptomatic and idiopathic epilepsy, cu.

Indicators of	SE (n=42)	IE (n=17)	Control (n=16)	SE and IE, P<	SE and KG, P<	IE and KG, P<
CHL	46,7±4,9	162,9±5,3	33,9±3,3	0.05	0.05	0.01
GLU	73,8±5,3	98,1±8,8	57,2±4,9	0.05	0.05	0.01
GABA	53,7±5,4	71,8±4,7	45,4±4,9	0.05	-	0.05
DA	62,6±5,0	74,4±4,2	46,9±4,9	0.05	0.05	0.01
SER	62,9±5,3	76,9±3,4	56,2±4,6	0.05	-	0.05
V-zav.(B-зав.) Ca-channel	98,5±7,0	78,6±6,4	45,9±4,2	0.05	0.05	0.01

The further analysis of neuroimmune relationships among patients with epilepsy showed that the level of AAb in regard to glutamate and voltage-dependent Ca-channels was also significantly high among the AAb under study within both groups.

Thus, the indicators of patients with SE constituted 73.8±5.3 and 98.5±7.0 cu, respectively, which exceeded the indicators of the "internal standard serum" by an average of 1.3-2 times ($p<0.05$), and in regard to patients with IE – 98.1±8.8 and 78.6±6.4 cu, respectively with increase of the standard indicators by an average of 1.7-2 times ($p<0.01$).

Among patients with IE, the AAb in relation to glutamate significantly exceeded not only the control values, but also the indicators of patients with SE (respectively 98.1±8.8 and 73.8±5.3 cu, $p<0.05$). Such a significant increase in the level of AAb in regard to glutamate among the patients of both groups indicates the evident disorder of the excitative processes as activation result of membrane neurotransmitter receptors and mechanisms of glutamate excitotoxicity. Whereby, we note more significant disorders of the glutamateergic system within the course of IE.

One a priori can determine the obtained output as evidence of a gross imbalance within the glutamatergic system among patients with IE, which is the starting point for the neuronal sprouting processes.

The levels of AAb to GABA, dopamine and serotonin within the examined groups also exceeded the standard indicators and were approximately at the same level. However, we found the significant differences from the "internal standard serum" only among patients with IE (AAT GABA 71.8±4.7 cu, $p<0.05$; AAT DA 74.4±4.2, $p<0.01$; AAb SER 76.9±3.4 cu, $p<0.05$).

We found the significant differences among the

patients with SE only within the ratio of AAb in regard to dopamine (62.6±5.0 cu, P<0.05).

The high level of autoantibodies in regard to GABA is evidence of disorders within the GABA-ergic system, which increase the neurotoxic effects of glutamate on the one hand, and inhibit the structure of the antiepileptic system on the other hand (Gusev E. I., Geht A. B., 2009).

In particular, AAb significant increase in relation to this neurotransmitter among patients with idiopathic epilepsy may indicate a gross imbalance in the glutamatergic system and a marked depletion of the GABA-ergic system within this group of patients, which is the starting point for the processes of neuronal sprouting.

The high levels of AAb in relation to dopamine and serotonin among patients with IE and their significant difference from the indicators of the "internal standard serum" confirm the close relationship of the glutamateergic system with the system of biogenic amines, whose dysregulation leads to a detrimental effect on neurons and has a proepileptic effect. One can interpret such ratio of AAb as evidence of a significant autoimmune response from the nervous tissue, which, in turn, contributes to the maintenance of the pathological epileptic system among patients with IE.

Thus, the AAb increase in relation to the ligand-binding site of neurotransmitter receptors (Glu-P, GABA-P, DOF-P, Ser-P, and Hol-P) indicates changes within the corresponding neuron systems. More high serum level of AAb in regard to neurotransmitter receptors may indicate the presence of different mechanisms in order to implement the neurotransmission and neuroplasticity among patients with IE and SE.

As a result of correlation analysis, we found a positive relationship between the duration of epilepsy and the levels of AAb in regard to the receptors of all neurotransmitters, most closely expressed among patients with IE in comparison with SE. The study of correlation relationships between neurotransmitters and the frequency of paroxysms has established a direct average and strong dependence of the number of paroxysms on the level of neurotransmitters. The strength of correlation relationships did not depend on the form of epilepsy.

The obtained output confirms the assumption in regard to multi-factorial causes of the development and progression within the epileptic process (Fig. 2).

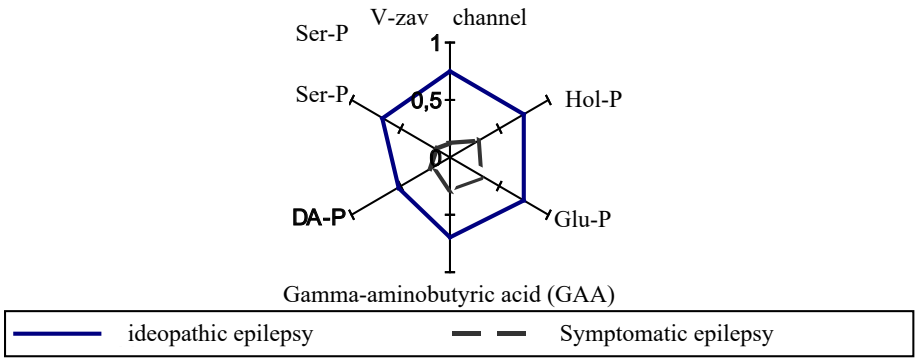


Fig. 2. The correlation indicators between the duration of epilepsy and levels of AAb in regard to neurotransmitter receptors

Thus, the regularity of the autoantibodies detected increase in regard to all neurotransmitters under study within close relationship with each other, as well as with the frequency of seizures and duration of the disease is evidence of neuroimmune dysregulation aggravation as the clinical course severity in cases of epilepsy .

The correlation analysis of the cognitive disorders relationships and the content of antigens in relation to the main neurotransmitters, in particular GFAP, among the patients with SE found a strong relationship between the indicators of clock drawing test (r=-0.753 and -0.755) and MMSE (r=-0.806 and -0.892), as well as with tests for speech activity (r=-0.736, -0.540 and r=-0.562, -0.642), words memory (R=-0.679 and R=-0.753, respectively) and repeating numbers in reverse order (R=-0.568 and R=-0.695, respectively).

With the level of AAb in relation to the rest of the neurotropic proteins, there was a weak relationship, and in some cases it was absent at all. The relationships of AAb level in regard to neurotransmitter receptors and cognitive disorders among patients with SE were weak.

The influence of the AAb level in relation to GABA by the indicators of clock drawing test (r=-0.274), MMSE (r=-0.272), phonetically mediated associations (r=0.268), word memorization (r=-0.204) and repetition of numbers in reverse order (r=-0.265), which expressed by the indicators of inverse and direct weak correlation relationships.

Thus, we found the only significant inverse correlation among the patients with SE between the level of AAb in relation to GFAP and MBP and the indicators of neuropsychological tests. The obtained data once again convincingly confirm both the fact of pathological BBB permeability among patients of this group, and the significance of this fact in the occurrence and maintenance of cognitive disorders in case of SE.

The study of correlation relationships between similar neuroimmune indicators and the results of neuropsychological tests among patients with IE showed a different nature of the relationships within this group in comparison with SE. Thus, in case of correlation analysis among patients with IE, we found weak relationships between the indicators of AAb in regard to GFAP and MBP and the parameters of the cognitive sphere. In particular, we registered the most significant indicators of reverse correlation within the clock drawing test assessment (R=-0.361 and r=-0.355, respectively) and the speech activity test (R=-0.322 and r=-0.298, respectively).

There was a high, medium, and weak correlation relationship between the indicators of neuromediators and neuropsychological tests. We obtained the particularly evident output within the relationship of cognitive disorders with the level of AAb in relation to choline and GABA receptors. Thus, one can establish the following relationships with the indicators of clock drawing test (R=-0.852 and r=-0.869, respectively) and MMSE (R=-0.795 and r=-0.790, respectively), as well as with the indicators of the speech activity test (r=-0.697 and r=-0.872 with semantically mediated associations and r=-0.872 and r=-0.635, respectively), word memory (R=-0.697, r=-0,826) and the numbers repetition in reverse order (R=-0,725 and R=-0,822).

The obtained data presents a great scientific interest and a priori helps us to determine the identified cognitive disorders among patients with IE, since it is known that GABA receptors mediate “long-term” GABA - dependent reactions within the central nervous system by complex processes trigger in relation to various neurotransmitter systems interactions (in particular, GABA and cholinergic). The identified neuroimmune dysregulation causes the neurotransmitter processes disorders at all levels of synaptic regulation, and as a result, there is a neurotransmitter imbalance formation, a priori in the cortex and hippocampus – the leading ares of the cognitive functions implementation.

In case of neuroimmunological indicators study inregard to patients with epilepsy, we found that circulating AAb in relation to neurotransmitter receptors, in particular to glutamate, GABA, dopamine, serotonin and holinoreceptors, in the blood serum of patients with epilepsy indicate changes within the corresponding neuron systems. A higher serum level of AAb in relation to neurotransmitter receptors among patients with SE may indicate the presence of different mechanisms for the implementation of neurotransmission and brain plasticity in cases of IE and SE.

Thus, we indicate the heterogeneity of patients with epilepsy in terms of molecular development mechanisms, the causes of epileptic attacks. In particular, one can use the circulating AAT in relation to neurotropic proteins and neurotransmitter receptors within the blood serum of patients with epilepsy as additional prognostic “immunobiochemical” criteria for the course of the disease and the efficiency of antiepileptic treatment.

Conclusions

1. One of the leading mechanisms within the epilepsy pathogenesis is a complex change of neuroimmune relationships under a unidirectional increase in the level of autoantibodies in relation to the neuro-specific proteins S100, GFAP, NF-200, MBP and the neurotransmitters glutamate, GABA, dopamine, serotonin, serotonin and voltage-dependent Ca-channel. Whereby, the key link within the pathogenesis of idiopathic epilepsy is a neurotransmitter imbalance, and in the pathogenesis of symptomtomatic epilepsy – an increase in the level of AAb in relation to GFAP and MBP.
2. The changes in the levels of antibodies in relation to the neuro-specific proteins S100, GFAP, NF-

200, MBP and the neurotransmitters glutamate, GABA, dopamine, serotonin, serotonin and voltage-dependent Ca-channel depend on the form and duration of epilepsy, the nature and frequency of seizures. We noted a high specificity of increasing antibody levels in regard to patients with increase of disease severity.

3. The rise of antibodies level in relation to neurospecific proteins S100, GFAP, NF-200, MBP and the neurotransmitters glutamate, GABA, dopamine, serotonin, serotonin and voltage-dependent Ca-channel within epilepsy can serve as a prognostic criterion of severe disease and used at an early stage in the selection of adequate antiepileptic therapy and the choice of further tactics patients management.

Abstract

Situs viscerumtotalis is a fairly uncommon anomaly of the mirror-imaged arrangement of the peritoneal cavity organs with a frequency of distribution in the range from 1: 5000 to 1: 20 000. Such an arrangement of internal organs is found in one case per 10 million[2]. In the early embryonic stage, the internal organs are located along the midline of the body. Normally, in the course of their subsequent development, they grow and rotate to the right, and – exceptionally rarely – to the left, which leads to the reverse arrangement of internal organs, i.e., to their transposition. In the case of complete (total) transposition of internal organs, all of them are inverted. In the case of partial transposition, it involves inversion of all or some organs of one of the body cavities (heart, stomach, duodenum and caecum, spleen). Dextrocardia, a condition in which the cardiac apex is pointed to the right, was first described by Marco Severino, in 1643. Matthew Baillie first described situs inversus more than a century later.

Keywords: *Patient, abdominal, organ, internal, surgical.*

Introduction

In 1600, Fabricius reported the first known case of liver and spleen reversal in humans. Kuchenmeister in 1824 recognized situs inversus in a living person for the first time. In 1897, Wehsemeyer was recognized for being the first to demonstrate the transposition of internal organs with an x-ray. This unusual anatomy of internal organs causes difficulties in diagnosing and treating diseases.

Situs viscerum inversus is an autosomal recessive genetic condition. Although itdoes not form a pathology in itself, it may be associated with certain abnormalities, mainly cardiac, which can be potentially life-threatening[2]. In case of complete or partial inversion of internal organs (viscerum inversus totalis or partialis), the abdominal organs are located on the opposite side. That means that the liver is placed on the left, the heart on the right, the spleen on the right, etc. According to Russian and foreign researchers, there are too few data on surgical interventions, in particular laparoscopic ones, in such patients[1]. The cases of acute surgical pathologiesin patients with complete transposition of internal organs are extremely rare in the world science literature.

Acute appendicitis is the most common surgical disease that surgeons, therapists, gynecologists, and other medical specialists deal with on a daily basis[3].

For the first time, the vermiform appendix of the cecum was described and drawn by Leonardo da Vinci in 1472. The term 'appendicitis' was first proposed by American surgeon Reginald H. Fitz, in 1886, at the Convention of the American Medical Association. In 1725, the first appendectomy was performed by Claudius Amyand, in England. The first fully laparoscopic appendectomy was carried out by K. Semm in 1983. Acute appendicitis is the reason for about 7% of abdominal surgeries. The incidence of acute appendicitis in patients with situs inversus totalis is about 0.016-0.024%[4].

Among urgent surgical pathologies, perforation of gastric and duodenal ulcers is about 1.5%, and, according to various researchers, among patients with peptic ulcer, it occurs in 5-30% of cases.

The main diagnostic criteria for ulcer perforation are free gas in the abdominal cavity which is found during the plain radiography and an ulcer with signs of perforation detected during fibrogastroduodenoscopy (FGDs). However, the removed clinical picture of perforation (covered and atypical) occurs in almost 36% of cases. In this regard, diagnostic laparoscopy is of particular diagnostic significance, since it allows to verify the diagnosis, assess the prevalence of peritonitis and determine further treatment tactics. As it is known, the main method of treatment of patients with ulcer perforation is operative[4]. With that, this pathology combined with situs inversus totalis is much less common than other urgent surgical pathologies[5]. The first case of perforation of duodenal ulcers with dextroposition was described in 1986.

Based on data from foreign literature, we can conclude that the occurrence of surgical pathologies in patients with situs inversus totalis is extremely rare. According to many researchers, to date, about 60 cases of laparoscopic cholecystectomy, 7 cases of colorectal cancer, isolated cases of pancreatoduodenal resection, hemihepatectomy and angiographic interventions in patients with situs inversus totalis have been described in the world scientific literature[3].

In clinical practice, when examining patients with a mirror-imaged arrangement of internal organs, there is a high probability of anatomical disorientation, which can lead to incorrect diagnosing or treating the disease. In this regard, we decided to share our experience of diagnosis and treatment of acute surgical diseases of the abdominal cavity with complete transposition of internal organs.

Below are 3 clinical cases of acute surgical pathologies with complete transposition of internal organs.

Case 1 and 2. In September and October 2019, patient A (23 years old) and patient B (21 years old), sought medical attention in the Department of Surgery of the TMA Multidisciplinary Clinic. Both patients complained of pain in the left iliac region, nausea, and fatigue. According to anamnesis, patient A. had been ill for the last three days, and experiencedpain of this nature for the first time. The patient A. also complained of aching pain in the right iliac region, followed by spreading to the left iliac region and area around the navel, nausea, expulsion of gastric contents, dry mouth and fatigue. At home, patient A took Mezyme and No-shpa medicines, which had a short-term positive effect. Subsequently, there was an increasing pain in the left iliac region. According to anamnesis, patient B had been ill for one day, and experienced pain of this nature for the first time. The patient B. also complained of aching pain in the epigastric region with subsequent spread to the left iliac region and around the navel. Among other symptoms, there was nausea, a single expulsion of gastric contents, dry mouth and fatigue. The patient B. did not seek medical attention in any medical institutions, andtook painkillers which had a temporary positive effect. Subsequently, there was an increasing pain in the left iliac region and around the navel.

According examination data, in both patients, abdomen participates in respiration, it is symmetrical, soft during palpation; in the left iliac region there is pain and local tension of the muscles of the anterior abdominal wall. The Kocher-Volkovich, Rovsing, Sitkovsky, Razdolsky, Obraztsov, Voskresensky, Bartomier-Michelson's signs results are positive. The Shchetkin-Blumberg sign's result is negative in all abdomen areas. Intestinal peristalsis noises are heard.

In the course of laboratory and instrumental research method, both patients underwent chest x-rays (Fig. 1).

Description of x-ray images: the chest is symmetrical. The edge shadows are not deformed, with a uniform structure. Soft tissue shadows without features. The pulmonary fields are fully pneumatized, without focal and infiltrative shadows. The roots of the lungs are poorly structured. The pulmonary pattern is not reinforced. Pleural sinuses are free. Heart: dextraposition is not enlarged, aorta without features.

On an abdominal MSCT scan, it was found: stomach, spleen, tail and body of the pancreas are located on the right side; liver, gall bladder, head of the pancreas, inferior vena cava – on the left. The shapes, sizes, and structure of organs have not been changed. The lymph nodes of the abdominal cavity and retroperitoneal space are not enlarged.

Both patients were diagnosed with acute appendicitis based on their anamnesis, physical examination, and instrumental data. Both patients underwent Laparoscopic appendectomy, using the RZ Medizintechnik, Germaniya device (Fig. 3).

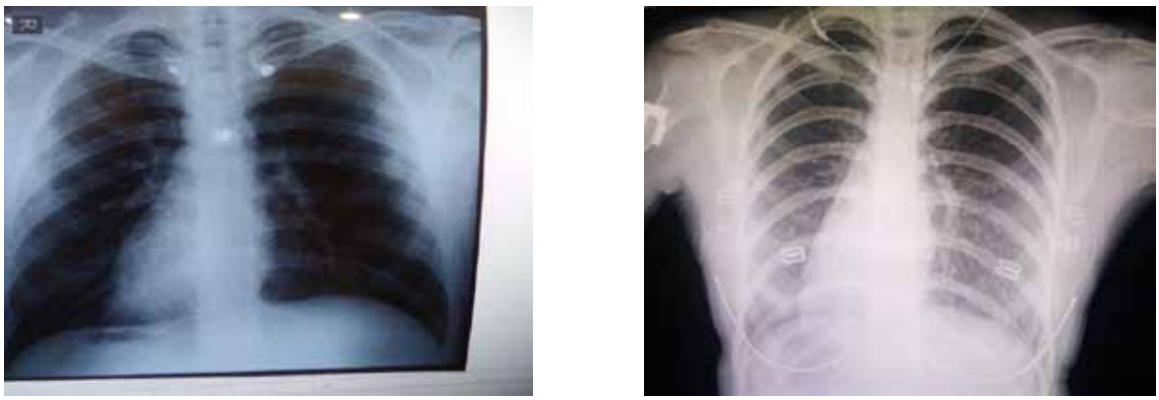

Fig. 1. Chest x-ray (patient A and B)

In order to clarify the diagnosis, an abdominal MSCT scan was performed, using a Siemens device (Fig. 2).

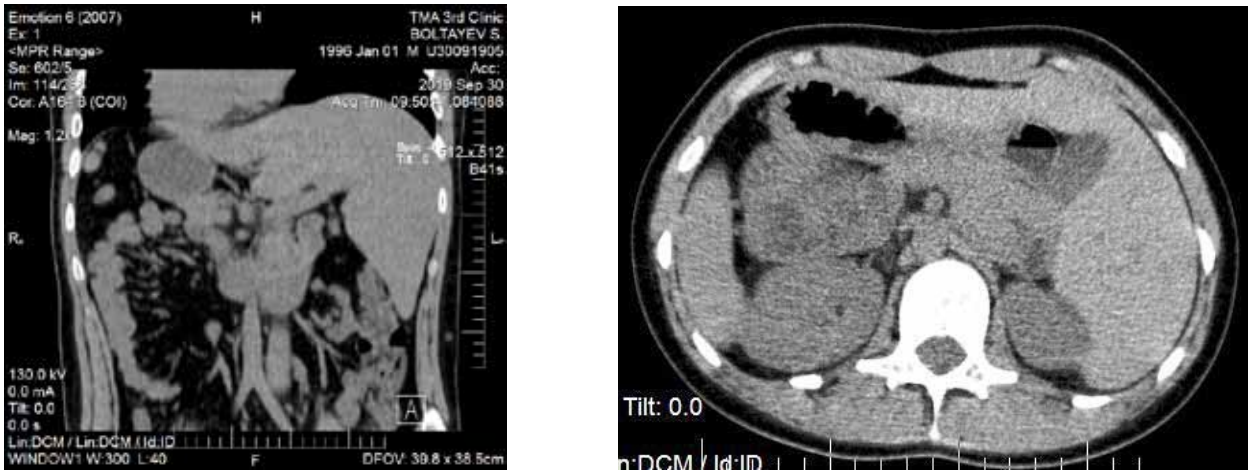

Fig. 2. Abdominal MSCT scan (patient A and B)

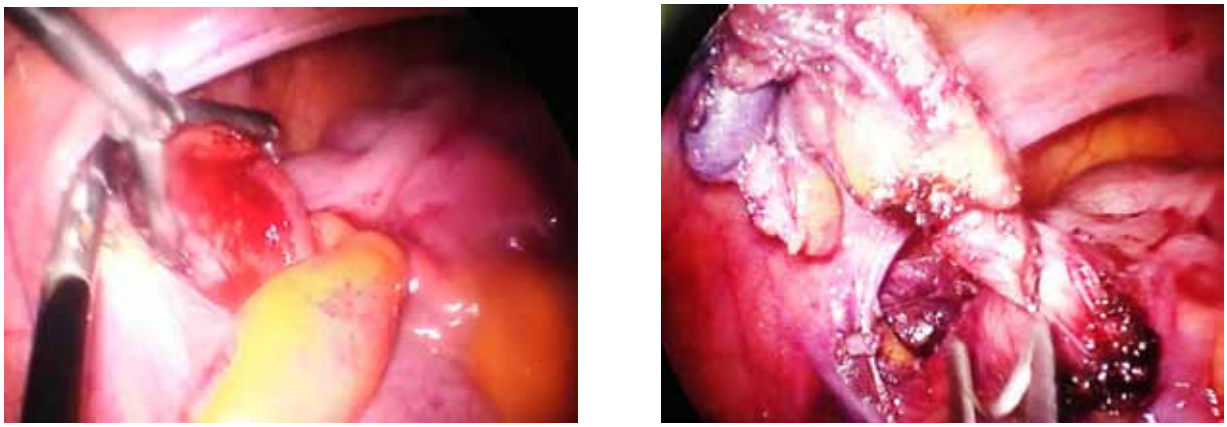

Fig. 3. Laparoscopic appendectomy (patient A and B)

The position of the surgeon and assistant, as well as the location of the trocars was opposite to the standard location for laparoscopic appendectomy (Fig. 4).

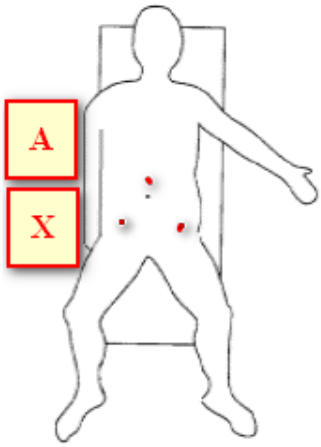

Fig. 4. Position of surgical team (X – surgeon; A-assistant) and location of trocars in laparosocpic appendectomy for patients with situs inversus viscerum

In both patients, surgical intervention proceeded without technical difficulties. For control purposes, a drainage was installed in a small pelvis. Postoperative diagnosis for both patients: *Main diagnosis:* acute phlegmonous appendicitis. *Related diagnosis:* aitus inversusviscerum. (histological study No. 3717-20 and No. 3717-35). The postoperative period proceeded without complications. On the 2nd day after the operation, after aabdominal ultrasonography (no free fluid was detected in the abdominal cavity and pelvis), the drainage tube was removed. Both patients were discharged on the 3rd day after the operation.

It can be concluded that performing laparoscopic appendectomy for patients with situs inversus totalis is not convenient in terms of ergonomics. It is also technically difficult.

Case 3. In September 2019, patient S applied to the Department of Surgery with complaints of pain in the epigastric region (in the left half of the abdomen), nausea, vomiting that did not bring relief, and fatigue. According to anamnesis, the patient denied ulcerative anamnesis. The aspect of the disease corresponded to a perforation of a stomach ulcer or duodenum: the 'knife-like' pain began in the epigastric region. During a local examination, the following data were found: the tongue is dry, with a white coating, the abdomen is not involved inrespiration, symmetrical, there is a surgical scar 10x0.5 cm in the right iliac region, consistent; during palpation, sharp pain in the epigastric region and in the left half, throughout the abdomen, the tension of the muscles of the anterior abdominal wall is determined, the Shchetkin-Blumberg sign result is positive in all abdomen parts.

Taking into consideration the previous appendectomy and identified situs inversus totalis in the patient, wehave performed the following instrumental research method:

Ultrasound impression: Total inversion of internal organs, free fluid in the abdominal cavity (Fig. 5).

Fig. 5. Abdominal ultrasound (patient S)

Chest and abdominal x-ray: Cardiac dextroposition!!!Abdominal radiography shows a free gas under both domes of the diaphragm (Fig. 6).

Fig. 6. X-ray of the chest and abdomen (patient S)

The patient underwent an emergency Laparoscopic repair of duodenal ulcer perforation and abdominal drainage (Fig. 7). Performing laparoscopic surgery was technically difficult, given the non-standard position of surgical team and location of trocars.

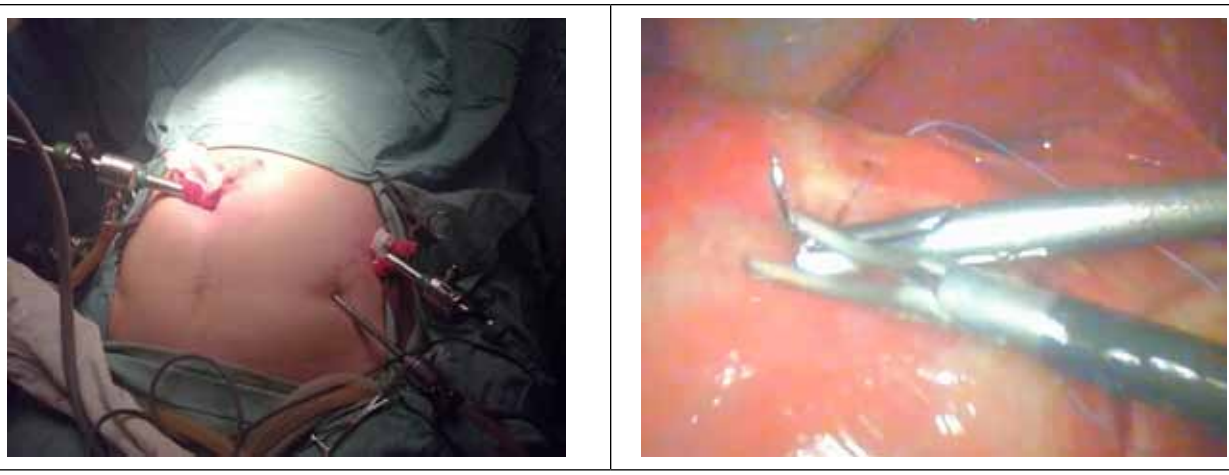

Fig. 7. Laparoscopic repair of duodenal ulcer perforation (patient S.)

The surgery lasted 1 hour and 20 minutes, and was completed with no complications. During the revision in the subhepatic region, the presence of dried serous-fibrinous fluid is found. With the further revision, no free fluid was detected in the suprahepatic region, in the right and left lateral channels, in the pelvis and in the interstitial spaces. On the anterior wall of the duodenum there is a perforating hole measuring 0.5x0.5 cm, with the infiltrative torus around it, up to 1 cm. The perforation is repaired with two-row interrupted sutures. Postoperative diagnosis: Primary diagnosis: duodenal peptic ulcer. Complication: duodenal ulcer perforation. Local serous-fibrinous peritonitis. The postoperative period proceeded without complications. On the 3rd day after the surgery, nasogastric tube was removed, on the 4th day after the surgery, drainage of the abdominal cavity was removed, after the control abdominal ultrasound. On the 5th day after the operation, the patient was discharged from the hospital in satisfactory condition.

Careful collection of anamnesis and performing all necessary diagnostic method (x-ray, ultrasound) makes it possible to timely and correct diagnosis and choice of treatment tactics.

Conclusion

The presence of a complete inversion of internal organs in patients with acute surgical diseases of the abdominal cavity does not form a contraindication to laparoscopic surgery. However, such arrangement of organs can create some inconvenience for surgeons. Due to this, correct installation of laparoscopic ports and rational positions of the operating team members seem to be necessary. The high probability of iatrogenic injuries during manipulations in the abdominal cavity requires increased attention from the surgeon. The operation should be performed by a team with significant experience in endovideosurgery.

State Rubricator of Scientific and Myoma, Senior Reproductive Age and IVF/IVF+ICSI is there Any Connection?

M.M. Maksudova

Associate Professor, Republican Specialized Scientific and Practical Medical Center for Obstetrics and Gynecology. Tashkent

Abstract

In women of older reproductive age, due to the physiological decrease in the ovarian reserve and more frequent concomitant gynecological disorders, the effectiveness of the IVF/IVF-ICSI protocols is significantly reduced, which is associated with a smaller number of obtained oocytes and low quality of embryos 5.

Keywords: *Myomectomy, myoma, numb, embryo.*

Introduction

According to World Health Organization report in 2010, 20–25% of women suffer from myoma, and it is estimated that around 235 million women are affected worldwide, representing 6.6% of the global female population[1]. The location of myoma is crucial in the results of ART. In particular, submucous myoma reduces significantly the implantation and pregnancy by ART. It was found that the submucous myoma, which deforms the uterine cavity, compromises a risk ratio of 0.3 for pregnancy and 0.28 for implantation after ART compared with infertile and women without myoma[3].

Myomectomy is an alternative to hysterectomy for women who want to save their uterus, regardless of their reproductive plans. A number of studies have been conducted to determine the effect of myoma and myomectomy on fertility; the research data were widely miscellaneous [3].

We studied 124 women aged 35-43 years who were treated in the Department of Assisted Reproductive Technologies, which used in vitro fertilization and/or intracytoplasmic sperm injection.

The goal of the research was to study the effect of the presence of intramural or subserous myoma and myomectomy (laparoscopically or laparotomically intramural-subserous or subserous) in the anamnesis on the number of oocytes derived, the dose of gonadotropins expended, the quality of the embryos, and the effectiveness of IVF/IVF-ICSI.

Patients with submucous or intramural uterine myoma (according to the FIGO III-VII classification) up to 4 cm. Patients with submucous uterine myoma (FIGO 0-II) were not included in the study group.

The Method of Research

Clinical examination of patients included a medical history, primary inspection, pelvic examination, ultrasound investigation of the pelvic organs using a vaginal probe.

The following indicators of ovarian stimulation in IVF cycles were analyzed in the study:

- Course dose of gonadotropins;
- Number of growing follicles;
- Frequency of paracentesis of ovary;
- The average number of oocytes obtained by paracentesis;
- The frequency of paracentesis of ovary in which no oocytes were obtained;

The following indicators were used in the study to describe the character of the early development of the embryo:

Morphological characteristics of embryos (on the 3rd day of development)

In addition, the analysis of the dependence of the effect of ovarian stimulation on the presence of

uterine myoma and myomectomies (laparoscopic and laparotomic) in the history.

Results

During stimulation and paracentesis of patients of older reproductive age, an accurate difference in the number of oocytes was obtained in the IVF/IVF-ICSI protocol with uterine myoma. So, 22 oocytes (75.86%) were obtained in patients with uterine myoma, 87 oocytes (92.55%) (p * <0.05) were obtained in patients without uterine myoma.

The connection of uterine myoma with the number of oocytes:

	Patients without uterine myoma	Patients with uterine myoma	Total	p
Oocytes not obtained	7	7	14	
	7,45%	24,14%	11,38%	
1 or more oocytes obtained	87	22	109	*<0,05
	92,55%	75,86%	88,62%	

The same connection was observed in the group of patients with myomectomy. During paracentesis of patients with myomectomy, 11 oocytes were obtained, without myomectomy, 98 oocytes.

Table: The connection of the number of oocytes obtained with the presence of myomectomy in the history

	Patients without myomectomy	Patients with myomectomy	Total	p
Oocytes not obtained	10	4	14	
	9,26%	26,67%	11,38%	
1 or more oocytes obtained	98	11	109	0.05
	90,74%	73,33%	88,62%	

The following table shows the accurate difference in the higher dose of gonadotropins expended in myomectomy, in contrast to non-operated patients. So, for myomectomy, an average of 2437.67 ± 241.15 MU of gonadotropins is expended during stimulation. And with stimulation of patients not operated on for fibroids 1953.57 ± 80.35 MU.

The number of follicles and subsequently oocytes is greater in patients without uterine myomectomy. And also, the number of correctly fertilized zygotes with two pronuclei is almost 2 times higher in patients without uterine myomectomy, which is associated with the initially large number of oocytes obtained. The total number of embryos is also greater in patients without myomectomy in a history, in particular class B embryos.

Table: Character of the cycle in patients with myomectomy

Indicant	Myomectomy	M±m, ME	Number	ANOVA	p
The total dose of gonadotropins expended	Yes	2437,67 ±241,15	15	0.040	0.013
	No	1953,57 ±80,35	107		
Number of follicles	Yes	5,866667 ± 0,735926	15	0.256	0.362
	No	7.17	107		
Number of oocytes	Yes	4,33 ± 0,89	15	0.116	0.167
	No	6,40 ± 0,47	107		
2 polar bodies (fertilization +)	Yes	2,75 ± 0,60	12	0.260	0.308
	No	3,78 ± 0,29	107		
Class B embryos	Yes	0,25 ± 0,18	12	0.071	0.085
	No	1 ± 0,134	107		

When analyzing the effectiveness of pregnancy with and without uterine myoma in the fresh transfer cycle, differences in pregnancy were not obtained.

	Without myoma	With myoma	Total
Biochemical pregnancy	23	4	27
	28,05%	18,18%	25,96%
The presence of an ovum on an ultrasound scan (21 day after embryo transfer)	20	4	24
	24,69%	18,18%	23,30%

Conclusions

The number of oocytes obtained is reduced due to the physiological decrease in ovarian reserve in women of older reproductive age, when using ART. A history of surgery on the ovaries reduces undoubtedly the ovarian reserve, and in the future the number of oocytes obtained during paracentesis. It would seem, surgical measures on the uterus should not have affected the ovarian reserve. In this study it was found that surgical measures on the uterus, in particular, myomectomy, reduce ovarian reserve. So, accurately more oocytes were obtained in the absence of myomectomy in a history in patients of older reproductive age (?). It can be assumed that after myomectomy due to the formation of adnations, impairment of blood flow in the ovaries, the ovarian reserve decreases.

The presence of myomectomy in a history does not affect the quality of oocytes, embryos

The presence of myomectomy in the patient's history can lead to an increase in the dose of gonadotropins for stimulation, which increases the financial costs of the stimulation cycle.

In a fresh transfer cycle, the presence of uterine myoma in women of older reproductive age does not affect pregnancy.

Perhaps if uterine myoma is not symptomatic, in women of older reproductive age who have not carried out their reproductive plans, it is advisable to conduct a myomectomy after receiving oocytes, before embryos transfer. which, in turn, will not increase the dose of gonadotropins expended, and will allow to obtain a larger number of oocytes.

Abstract

Cesarean section is currently the most common delivery surgery, which leads to the occurrence of diverse in nature changes from the internal genital organs. This primarily concerns the uterus, where a postoperative scar forms in the area of the former incision. This article presents histomorphological and immunohistochemical signs of a uterine scar after cesarean section in the lower uterine segment. The features of tissue regeneration in the area of the incision made on the uterus after cesarean section were revealed. Some method for diagnosing and treating uterine scar failure are also presented.

Keywords: *Cesarean section, uterine scar, ultrasound, hysteroscopy.*

Introduction

In all countries of the world there is a steady increase in the frequency of Caesarean section (CS). Over the past few decades, the frequency of this operation in the world has more than doubled and in Uzbekistan is on average about 24%. According to data published in world literature, one in four women has a cesarean section and a fifth has complications in the early postoperative period and in the long term.

The increase in abdominal delivery is due to the expansion of indications to it from the fetus, an increase in the number of older primiparas[4], with existing comorbidity, and the emergence of new reproductive technologies[25]. At the same time, according to the literature, a small number of criteria or features of the course of the postoperative period in patients with inconsistency of sutures on the uterus after cesarean section were isolated[34].

Currently, issues of repair of the suture on the uterus after CS, which largely determines the favorable course of subsequent pregnancies and childbirths[5], are becoming increasingly urgent[25]. A study of literature data showed a significant variability of information about the causes of the formation of an insolvent scar on the uterus.

Numerous studies have found that the increase in infectious[1] complications in obstetrics is largely due to an increase in the frequency[20] of cesarean section[24]. The increase in abdominal delivery is explained by an increase in severe somatic and obstetric pathology, frequent repeated operations, an increase in the age of primiparas in combination with other factors of obstetric and gynecological history[6]. A little justified tendency to an increase in the frequency of abdominal delivery during pregnancy and childbirth complications or severe somatic pathology poses a risk of secondary or late uterine suture failure[7].

Purulent-inflammatory complications after cesarean section are 8-10 times more common than after spontaneous[24] delivery and occupy one of the first places in the structure of maternal morbidity and mortality[32]. The frequency of peritonitis after CS ranges from 0.2 to 1-1.5% [1, 20, 35].

A large number of factors influence the formation of a suture on the uterus after CS: the presence of somatic and gynecological diseases (especially chronic inflammatory diseases), the course of pregnancy, the duration of labor, the technique of performing CS, the duration of surgery, the amount of blood loss and the adequacy[44] of its replenishment[2], and the course of the postoperative period[8]. It is believed that the main reasons leading to the development of an insolvent uterine scar are postoperative purulent-septic complications[17] in the early postoperative period[17], termination of pregnancy or the presence of any intrauterine interventions during the first year after CS [19]. Many authors consider intrauterine interventions after CS as a possible cause of direct trauma to the area of the postoperative[22] suture and violation of the formation of a scar on the uterus[8],

It is known that the postpartum period, even in the physiological course, and especially in the presence of risk factors, is favorable for the development of infectious complications, with surgical delivery, the postoperative period and associated additional significant risk factors (edema, ischemia, tissue destruction in the seam area, the presence of microhematomas, foreign suture material). Therefore, if the frequency of endometritis after spontaneous labor on average is 5%, then after surgical labor it varies significantly (from 2 to 54.3%), averaging up to 15% [34]. The consequences of severe endometritis are devastating for women's reproductive health: these are chronic endometritis, chronic pelvic pain syndrome, menstrual dysfunction, miscarriage, and secondary infertility [23].

According to some authors, the structure of complicated forms of purulent inflammation was dominated by complications caused by prolonged wearing of intrauterine contraceptives (44%), and postpartum diseases took the second place (16.9%) [50], while the risk factors for the development of purulent-septic puerperal complications were : "Inflammatory" obstetric and gynecological history (endometritis after childbirth - 35.3%; mastitis - 8.2%; wound infection - 23.5%; endometritis after abortion - 18.2%; cervical erosion - 23.6% acute and chronic salpingoophoritis - 12.7 and 29.1%, respectively); a previous history of infertility (21.8%); wearing an intrauterine contraceptive prior to a real pregnancy (4.1%); previous or existing chronic diseases of the bronchopulmonary system (29%); placenta previa in incision (38.6%); surgery in conditions of sharp thinning of the lower segment (22.7%); the presence of technical errors during the operation (using the Gusakov method - 72.7%; the use of rough manual method for removing the head - 13.6%; the use of a continuous suture for suturing the uterus - 38.6%; the use of reactogenic suture material - 9%; inadequate hemostasis - 9%); the duration of the operation is more than 2 hours (4.5%); the presence of pathological blood loss (9%).[51]

As you know, the optimal technique for conducting COP is still debatable. Most obstetrician-gynecologists are supporters of a "blunt" uterine dissection after a small incision is made with a scalpel according to the Gusakov[47]– Zanchenko method and less commonly, the uterus is dissected using scissors according to Derfler[49]. V.A. Ananyev et al. Found that biopsy specimens during surgery according to Derfler do not affect the most intracellular systems that are most sensitive to damage. Moreover, maintaining the integrity of the cell membranes and the respiratory apparatus of the cell ensures the maintenance of organelles homeostasis and oxidative phosphorylation[16]. At the same time, in the Gusakov – Zanchenko section, deep, mostly irreversible, ultrastructural changes prevail, reflecting the destruction of not only the trophic, but also the contractile apparatus of the myometrium cells [41].

At the same time, there is evidence that the determining factor in the formation of a wealthy scar is the nature of the healing of the wound surface with the predominant formation of muscle or scar tissue. So, if healing proceeds according to the type of primary (with the predominant formation of muscle tissue), then such additional risk factors as placenta localization, the period of time after CS, the production of medical abortions after CS in the final outcome are of unprincipled importance[46]. Gabidullina R.I. et al., based on histochemical studies, noted the complexity of the healing process of the uterus after CS surgery [13]. In later works, it was shown that during the healing of the uterus, two types of regeneration can be observed: substitution, which is defective regeneration, and restitution[45], in which the scar is not clinically detected. Naturally, the replacement of a myometrial defect not with an inert connective[117], but with smooth muscle tissue exhibiting contractile activity is more adequate[146].

Undoubtedly, the main etiological factor in the formation of an inferior uterine scar and generalization of infection is postpartum endomyometritis[15]. Features of the clinical picture of postpartum endometritis are: primary chronic course or short acute phase of

the manifestation of the disease, often hidden behind various "masks" (lochio and hematometer); further erased clinical course, caused, as a rule, by the use of massive antibacterial therapy (on average, two courses - 4–5 antibiotics) and various method of local uterine sanitation: vacuum aspiration, curettage of the uterus, lavage (in 75.5% of puerperas); latent or late (after discharge) manifestation of the inflammatory process with a undulating course of the disease[2] (remission - exacerbation); the predominance of infiltrative and necrotic forms of inflammation in the absence of typical clinical and laboratory signs of infection[3].

All diseases, including postpartum and postoperative, have specific symptoms, reflected in subjective complaints and data from an objective study.

The development of inflammatory and postoperative complications always "goes through" successive stages and is clearly identified when collecting information about the history of the disease, provided that the doctor knows the possible course of the disease and poses directed questions (the presence of risk factors, the initiation of the disease, its development, duration and frequency of hospitalizations, the nature and duration of treatment). Moreover, almost always, even after a certain time, you can identify the cause of the formation of an insolvent scar after CS (more often - endometritis, less often - obvious technical errors of the operation).

It should be noted that information on technical difficulties in performing the operation (difficulties in removing the fetal head, tears in the lower segment, difficulties in hemostasis, additional suturing, etc.) is almost impossible to obtain from extracts from the maternity hospital, while at 40 % of patients with an unsuccessful suture on the uterus after CS, if the extract contains a standard description of the operation, hematomas of parametria and/or hematomas of the postbubble tissue were revealed clinically and by ultrasound, and during the repeated operation[25], multiple unsystematic ad mass ligatures outside the suture line on the uterus (more often in the area of vascular bundles with ligation of one or both uterine arteries) [26].

Risk factors for the formation of an insolvent uterine scar after CS[48]:

- The patient has an "inflammatory"[22] obstetric and gynecological history (endometritis, mastitis, wound infection after previous birth, postabortion endometritis; endocervicitis, acute and chronic salpingo-oophoritis, infertility)[47];
- The presence and exacerbation during pregnancy of chronic inflammatory extragenital diseases (especially diseases of the bronchopulmonary system), the presence of anemia;
- Long-term operation, the presence of pathological blood loss;
- Placenta previa in the incision, the operation in conditions of sharp thinning of the lower segment in patients with clinically narrow pelvis ("low" or cervical CS);
- Urgency of the operation, especially the need for rapid delivery due to the development of acute fetal hypoxia, including in patients with premature detachment of the normally located placenta (in this group, the highest perinatal losses are 154 ‰);
- The use of a continuous suture for suturing a wound on the uterus;
- The use of Gusakov's technique, rude manual techniques for removing the head.

Clinical manifestations of a failed seam (scar) on the uterus after CS: Since the main reason for the formation of an unsuitable suture (scar) on the uterus after CS is endometritis, these patients are characterized by a complicated postoperative period and a later discharge from the obstetric hospital (on the 10-11th day).[2] Unfortunately, at present, postpartum endometritis in general and postpartum endometritis after CS[3], in particular, in most patients has a "erased"[9], subclinical course and is characterized by the following,[49]:

- At best, a short "acute" phase of the manifestation of the disease with a further "erased" clinical course of endometritis, often "hiding" under the masks of uterine subinvolution and lochio-hematometers (with a mild or mild inflammatory-intoxication syndrome);
- Late manifestation of the disease, often after discharge from the maternity hospital;
- The appointment in the postoperative period of long or repeated courses of antibiotic therapy;
- Insufficient effect of conservative treatment, which is often supplemented by the use of various instrumental method of sanitation of the uterus: vacuum aspiration, diagnostic curettage, hysteroscopy, lavage (47%);
- The wave-like course of the disease during its progression and episodes of deterioration of the state

of puerperas after the end of antibiotic treatment (short-term effect).

– The predominance of infiltrative, necrotic forms of inflammation in the absence of both typical clinical and laboratory signs of acute inflammatory process. Due to the absence of typical signs of purulent inflammation, necrotic forms of panmetritis were especially difficult for clinical and ultrasound diagnosis and were detected only with hysteroscopy;

– The rapid progression of the disease, despite its "erased" course.

Complaints upon admission of patients do not reflect the actual severity of their condition, therefore, a thorough history and examination are crucial for making a diagnosis. With a vaginal examination, the size of the uterus exceeds the value corresponding to certain days of the postpartum period, its consistency is soft. In most patients, the main pathological changes are observed in the area of the operation zone, i.e., the area of the anterior wall of the uterus, isthmus and neck, while the severity of inflammatory-necrotic changes in the anterior wall of the uterus and isthmus reflects a lag in the formation of the cervix (the neck is free in the form of " sails "hangs in the vagina, freely passes 1-2 fingers). The presence of infiltrates (hematomas) behind the gallbladder is a characteristic unfavorable clinical sign, indicating the development of secondary failure of sutures on the uterus. Even in cases where infiltration is not determined, the uterus is fixed to the tissues of the anterior abdominal wall in the region of its lower segment.

At present, also the features of the course of postpartum infectious diseases are the "worn out" laboratory picture. It is inappropriate to focus on leukocytosis as the main marker of the inflammatory process (it is observed only in 11% of postpartum patients, in the rest the indicators do not exceed the normative). More typical for puerperas with endometritis are an increase in ESR, the presence of moderate anemia (on average, 97.8 g/l), hypo- and dysproteinemia, which is expressed in a decrease in the concentration of albumin and an increase in globulins, as well as an increase in the concentration of C-reactive protein (72, 3%). Leukopenia is a poor prognostic sign indicating a septic course of the process. In severe forms of postpartum infection, systemic disorders prevail, for example, severe hemostasiological disorders (with the presence of uterine and pelvic vein thrombosis), immune disorders with damage to the receptor link (an excessive pathological concentration of antibodies to γ-interferon receptors appears, blocking receptors). Sepsis is a manifestation of a systemic inflammatory response, which is based on a generalized inflammatory reaction[9] - a kind of "malignant intravascular inflammation", leading to endothelial damage and the development of multiple organ failure [42].

Ultrasound diagnosis of insolvent uterine scar: The leading ultrasound method for identifying postpartum endometritis and especially a failed uterine scar[15]. To date, the most informative criteria for the condition of the scar are: the structure of the myometrium, the presence of areas of high acoustic density, vascularization of the uterine segment[38]. The results of echoscopy coincided with intraoperative data in 80.3% of cases. False positive results, when with unsatisfactory echographic parameters, the scar on the uterus was without features, amounted to 12.1%. False negative, when an insolvent uterine scar was an accidental find during surgery, in 7.6% of cases [40].

Analysis of echograms in postpartum patients with complications after CS revealed a number of common characteristic signs indicating the presence of endomyometritis and impaired repair processes in the suture or scar on the uterus:

– Subinvolution of the uterus, an increase and expansion of its cavity;

– The presence in the uterine cavity of inclusions of various sizes and echogenicity (intracavitary serous fluid, pus); the presence on the walls of the uterus of linear echopositive structures (in the form of an intermittent or continuous contour), reflecting the imposition of fibrin in all patients;

– Heterogeneity of the myometrium in the region of the scar, anterior and posterior walls of the uterus.

The main ultrasound signs of a failed scar on the uterus after CS are:

– of the cavity - the presence of a "niche" conical shape with a depth of 0.5 to 1.0 cm or more, when the top of the niche reaches the outer contour of the anterior wall of the uterus;

– A local change in the structure of the myometrium in the region of the scar or a diffuse change in the myometrium of the anterior wall of the uterus in the form of multiple inclusions of reduced echogenicity with fuzzy contours (microabsection sections);

– Local circulatory disturbance in the scar area - the absence of a diastolic component of blood flow (focal necrosis) or a sharp decrease in blood supply to the entire front wall of the uterus, when it was not possible to visualize the blood flow velocity curves;
– A sharp decrease in blood supply to the anterior wall and an increase in blood flow in the region of the posterior wall.

The following echographic signs are prognostically unfavorable, indicating complete failure of the suture (scar) on the uterus after CS:

– Expansion of the uterine cavity over the entire length of more than 1.5 cm;
– Sharp deformation of the cavity in the scar area: the presence of a cone-shaped niche, the apex of which reaches the outer contour of the anterior wall of the uterus (complete divergence of sutures);
– Diffuse change in the structure of the myometrium of the anterior wall of the uterus in the form of multiple inclusions of reduced echogenicity with fuzzy contours (areas of microabsection);
– A sharp decrease in blood supply to the anterior wall of the uterus (it is not possible to visualize blood flow velocity curves) with an increase in blood flow in the region of the posterior wall (systolodiastolic ratio <2.2 and resistance index> 0.5);
– The presence of echographic signs of hematomas, abscesses or infiltrates in the parameters, pelvis and abdominal cavity.

The development of criteria for the viability of the uterine scar after cesarean section using ultrasound has been the subject of many works by domestic and foreign authors [25, 38,40]. In the study, pay attention to the thickness of the lower uterine segment, its uniformity, the presence or absence of acoustic seals, their heterogeneity, fragmentation. According to the researchers, on the basis of the obtained echograms, scars with a total thickness of less than 4 mm, individual thinning sites (less than 3 mm), heterogeneous scars with a large number of acoustic seals, indicating the growth of connective tissue in the thickness of the anterior wall of the lower uterine segment, are considered insolvent. Almost all authors note the high information content of this method for the study of the uterine scar[2].

Some authors noted that hysteroscopy is indicated for all obstetric patients with endometritis, and the sooner this intervention is undertaken (with a diagnostic or therapeutic diagnostic purpose)[3], the better the outcome of the disease. The only exceptions are patients who have indications for surgical treatment (panmetritis, purulent lesions of the appendages and fiber, the presence of complete failure of the suture (scar) [38]on the uterus according to ultrasound), and hysteroscopy in this case does not make sense[40].

Hysteroscopy allows not only to identify postpartum endometritis and determine its shape (fibrinous, purulent, due to residues of placental tissue, necrotic), determine the condition of the suture on the uterus after CS, but also sanitize the uterine cavity and conduct differential treatment [50].

Morphological and histochemical changes in the uterine scar after CS: The presence of morphofunctional "solvency" of the uterine scar is one of the main criteria that determine[28] the outcome of pregnancy and childbirth[30] in women with a history of cesarean section[32], however, due to the complexity of the object of study, data on factors and mechanisms to date underlying the formation of a full scar on the uterus is not enough. Uterus scar formation should be considered as part of the modern concept of wound healing.

The wound and reparative processes are a complex of successive[30] local changes and the numerous common reactions[19] associated with them, which can be combined in three stages regardless of the location of the wound: the stage of inflammation[29], the stage of repair and the stage of remodeling [40]

By remodeling, the authors understand not only the reorganization of the scar, but also (to varying degrees)[28] the morphofunctional[29] restoration of lost tissue[32] (smooth muscle, epithelial, mesothelium, etc.). The wound process, which results in the formation of scar tissue, is accompanied by complex multicomponent interactions of cellular elements[30]: it is carried out mainly with the participation of mast cells, lymphocytes, macrophages and fibroblasts[29]. The interconnection of cells is carried out through cytokines[32] and growth factors: platelet growth factor, transforming β-growth factor, main fibroblast growth factor, epidermal growth factor, vasculoendothelial growth factor, etc.[32] . Studies show that macrophage-fibroblastic and collagen-fibroblastic interactions, through which the feedback between the breakdown[28] and production of collagen is realized, play a key role in the regulation of reparative

growth of connective tissue and sclerogenesis[29]. The optimal course of intercellular interactions underlies physiological neoangiogenesis, since it is the formation of small vessels that is necessary for the full regeneration of the connective tissue and muscle components in the initial stages of wound healing[2]. Hemomicro circulation determines[36] the level of tissue metabolism and oxygenation: the more severe the defeat of the individual components of the microcirculation[46], the more pronounced are violations of the transcapillary exchange and rheological properties of the blood [29].

In a number of works devoted to the study of reparative processes after various operations on the uterus, it has been shown that during the healing of the dissected uterine wall, two types of regeneration can be observed: both substitution (inferior regeneration) and restitution, in which the scar is not clinically detected [36]. Replacing a defect not with an inert connective, but with smooth muscle tissue exhibiting contractile activity is more advantageous. The morphofunctional usefulness of the uterine scar after cesarean section surgery largely depends on the course of the processes of its formation.[5] The various clinical manifestations of anatomical and functional inferiority of the uterus due to inferior wound healing after cesarean section are combined [29]with the concept of "operated uterus disease", the most severe manifestation of which is uterine lacerations in the scar during subsequent pregnancies and childbirths[32].

Features of the repair of uterine tissue determine the formation of the solvency of the scar after CS. Many factors influence the course of repair in the uterus, for example, anemia, preeclampsia, inflammatory processes, immune status, technique of surgical intervention and suture material used, duration of surgery and blood loss, postoperative period, and the time until the next pregnancy [11]. A number of complications (intrauterine interventions, inflammatory diseases of the genitals, intra- and postoperative complications) 1.5 times increase the risk of scar failure [14]. Many researchers have found that the formation of morphofunctional usefulness of the myometrium in patients with CS by a transverse section in the lower segment of the uterus occurs within 1–2 years after surgery [15].

An analysis of the literature on wound repair issues showed that individual, genetically determined features of the course of the wound process, as well as the nature of abdominal delivery, can be considered promising areas in this area. Today, the field of molecular genetic research continues to develop: numerous studies have shown the role of genetic factors, as well as gene polymorphism in the healing process [9]. A certain effect on the nature of wound healing on the uterus can be exerted by the time of the operation of cesarean section - in a planned or emergency manner. The effect of this indicator on the outcome of labor for the fetus is shown.

According to the results of the analysis of significant clinical and statistical material, the most favorable outcome for the fetus is observed with the so-called planned abdominal delivery, when the operation is performed with the beginning of regular labor. This is explained by the influence on the fetus of mechanical and metabolic factors from the mother's body, which lead to a powerful release of stress hormones that provide more optimal conditions for the adaptation of a newborn to extrauterine life [16]. The results of modern and, unfortunately, few studies indicate that the nature of the operation of cesarean section can play an important role in the process of scar formation on the uterus. The potential impact of cesarean section time on wound repair on the uterus can be assumed on the basis of modern ideas about the reparative process described above, taking into account the specific changes occurring in childbirth both at the body level and at the level of the uteroplacental-fetal complex[43]. A change in the reactivity of the immune system during childbirth has been shown to predominate over proinflammatory factors, which leads to structural changes in the cervix, rupture of the membranes and initiation of labor [34].

With the development of regular labor in the myometrium of the lower uterine segment, an increase in the content of leukocytes that produce interleukin (IL) -1β, tumor necrosis factor alpha (TNF-α) and IL-6 is observed [33]. The migration of neutrophils and macrophages into the myometrium during childbirth is due to increased production of chemoattractants for monocytes (MCP-1) and IL-8 [31]. IL-1β and TNF-α stimulate the formation of endogenous prostaglandins due to activation of phospholipid metabolism [43]. IL-6 increases the expression of oxytocin receptors in the myometrium [13]. In addition, IL-1β and TNF-α increase the production of matrix metalloproteinase-9 by myometrial cells, which can play an important role in the process of placenta separation[13]. A study of the concentration of endothelial cell adhesion molecules in the lower uterine segment showed that during urgent delivery there is a significant increase in the level of the intercellular adhesion-1 molecule (ICAM-1),

which provides adhesion of neutrophils, monocytes and lymphocytes to activated vascular endothelium with subsequent extravasation and migration to the lesion inflammation. ICAM-1 is also involved in cell contact interactions in immune responses: a T-lymphocyte with a monocyte, a cytotoxic T-lymphocyte with a target cell [13]. In a study on the mechanical properties of the lower uterine segment during full-term pregnancy and urgent delivery, it was shown that the viscoelastic properties of the myometrium change during childbirth, while the lower uterine segment becomes denser [27]. The time taken to perform a caesarean section affects the thickness of the lower uterine segment in subsequent pregnancies: with abdominal delivery during pregnancy, the thickness of the lower uterine segment, according to ultrasound, is 2.4 mm (interquartile range from 2 to 3.2 mm), while as with the operation in the active phase of labor, 3.1 mm (interquartile range from 2.5 to 3.9 mm)[37]. It has been suggested that the migration of leukocytes into the uterine wall during childbirth and their production of proinflammatory[26] cytokines play an important role not only in initiating and maintaining normal labor[14], but also in the process of repairing the wound surface in the placental area in the postpartum period, however, detailed studies in this direction[2] have not been carried out[9].

Therefore, it is necessary to further study the process of wound repair on the uterus using modern molecular genetic[9] and immunological method[15], which will expand the existing understanding of the course of the wound process with the subsequent development[29] of new diagnostic method, as well as optimizing the prevention of "insolvency" of the uterine scar after cesarean section[14] .

In their observations, the authors noted the expression of vascular endothelial growth factor VEGF and epidermal growth factor receptor EGFR, which is also common for transforming growth factor[29]. It is these growth factors that provide mitogenic activity of endothelial cells and fibroblasts, cell migration and differentiation, stimulate angiogenesis and the development of granulation tissue, which occupied a significant amount of the forming scar[31]. It should be noted that the presence of extensive areas of granulation tissue in the period of 6 months[14] or more after cesarean section indicates a slow healing process[27]. This fact may be associated with massive areas of necrosis[19]. A large volume of necrotic tissue slows down the process of granulation formation and their maturation into connective tissue, the organization of the extracellular matrix, scar formation and, moreover, its remodeling. The formation of foci of disorganization in fibrous and smooth muscle tissue lacking cellular components, collagen, fibrin, blood vessels, acid mucopolysaccharides and glycoproteins, proteinases, with perifocal expression of the macrophage marker CD68 may be associated with the outcome of persistent granulomatous inflammation[39].

Hence, the main reason for the formation of an insolvent uterine scar after CS is the primary severe inflammatory or traumatic necrotic damage to the endo- and myometrium with delayed and inferior maturation of connective tissue[29].

Given the high frequency of postpartum complications in women after cesarean section, as well as the absence of a tendency to reduce it[31], there is a need to determine preclinical markers of complications[19], in our case, uterine suture failure, to develop an algorithm for managing them[39], depending on the degree of risk of complications and new highly effective method of surgical treatment that can preserve the reproductive function of women.

The significance of immunological and biochemical changes in the development of uterine suture failure after cesarean section in their functional relationship, as markers of preclinical diagnosis, remains virtually unexplored, which determines the urgency of the problem and the need for targeted research in this direction.

The diagnosis of uterine scar (suture) on the uterus and the possibility of reconstructive surgery remain poorly understood.

Discussion

Diagnosis of a failed suture (scar) on the uterus after CS is always difficult, therefore, the diagnosis should be verified during a consultative examination after a sequential comprehensive examination including a clinical examination (special attention is paid to a thorough medical history, study of the features of the course of a previous pregnancy, surgery and postoperative period, analysis of discharge from obstetric and other hospitals), ultrasound and endoscopy. Even if it is possible to use the most modern research method, the main diagnostic method that determines the professional qualifications, the level of clinical thinking of a doctor and the subsequent direction of diagnostic measures is clinical.

Currently, laparoscopic metroplasty is known only at the stage of pregnancy planning with localization of the postoperative scar within the lower segment of the uterine[27] body, while hysteroresection with "smoothing" of the edges of the niche and ablation of the endometrium in the defect zone in patients not planning pregnancy[16], which allows to effectively save woman from complaints and significantly improve the quality of her life [40].

Conclusion

In view of the increase in the frequency of CS and its complications, it becomes important to search for prognostic criteria for the usefulness of the uterine scar in the postpartum period. However, the currently accepted[38] method for assessing the usefulness of the scar are not sufficiently informative and are often invasive, which limits their application. Currently, the issues of diagnosis and reconstructive surgery for an inconsistent uterine scar after a cesarean section in the postpartum period, as well as the volume and advisability of surgical intervention in patients with this pathology, have not been fully studied.

Abstract

Research objective is to study the stability and shelf life of Biomayrin capsules, which were obtained by chemical modification of high-molecular weight compounds by incorporation into polymers.

Materials and Method: "Biomayrin" capsules weighing 600±6 mg containing isoniazid, rifampicin, ethambutol, polygalacturonic acid and calcium stearate, obtained by disk dosing into capsules No.0. The shelf life was set by the method of "accelerated aging" when the samples were stored in PVCA1 blister packs (20 capsules each) at the temperature of 60^0C in the thermostat TV-80-1. The tests "Decomposability" of capsules and "Average mass and homogeneity by mass" were conducted in accordance with the requirements of the State Pharmacopoeia of the XIV edition. Experiments were conducted in at least three repetitions. Decompressibility of capsules was determined on PJ-3 Tablet Four-usage Tester (China). Isoniazid, rifampicin and ethambutol were quantitatively determined in solution by spectrophotometry (SF). The analysis was performed on SHIMADZU UV-1601, UV-VISIBLE spectrophotometer in 1 cm cuvette against the background of the solvent. The pH value was controlled with the EV-74 universal ionometer. Mathematical processing of the results was carried out according to General monograph. 1.1.0013.15 "Statistical processing of chemical experiment results" using standard computer programs MsExcel.

Results: The results on properties of capsules at storage of 60^0C and 25^0C are shown, after dissolution the content of active substances (isoniazid, rifampicin and ethambutol) in preparations was within the limits of regulated norms (60-120 mg), at 60^0C it is for isoniazid 101, 7-106.7 mg, at 25^0C 100.1-106.0 mg for rifampicin the regulated norm was 72-132 mg and at 60^0C it was 94.2-92.2 mg, and at 25^0C it was 94.7-91.2 mg, as well as ethambutol hydrochloride content was 60-120 mg and at 60^0C it was 62.5-60.5 mg, and at 25^0C it was 62.0-60.2 mg.

Conclusion: "Biomainrin" capsules with different expiration dates were investigated, and also the change of their quality according to the indicators "Active substance content" and "Dissolution" was found. It was shown that after the expiration of the shelf life there is a gradual decrease in the active ingredient content.

Keywords: *Anti-tuberculosis drug, biomayrin, isoniazid, rifampicin, ethambutol hydrochloride, spectrophotometry, shelf life, stability study, dissolution, capsules.*

Introduction

During the production of solid formulations[1] the corresponding required indicators of finished product quality should be provided[2], including appearance, decomposition[3], average mass and homogeneity by mass, dissolution, foreign impurities and stability during storage[4].

Nowadays, in medical practice, the problem of treatment of lung tuberculosis patients occupies an important place in the structure of phthisiologicalpathology[5]. Lung tuberculosis is an infectious disease which occupies the second place among infectious diseases by mortality. Approximately 9 million people in the world get TB every year and about 2 million die from it[6]. This figure is increasing due to unfavorable living conditions, frequent stressful situations, contact with tuberculosis patients, poor and unhealthy diets, and the presence of diseases and bad habits that weaken immunity[7]. Low-molecular synthetic drugs currently used for tuberculosis treatment are highly toxic and have no ability to penetrate selectively into phagocytes (eaters of cells) containing the tuberculosis pathogen[8]; in addition, they are rapidly excreted from the body without providing a prolonged action, since they only have an effect on extracellular tuberculosis[10] pathogens [9]. WHO has recommended a tuberculosis control strategy known as the Directly Observed Treatment Short course[11]. An integral part of the program is the creation of a reliable system for supplying high quality, effective TB medicines to health care institutions[12]. First of all, it is relevant for standard "first-line" medicines used for treatment of common (sensitive) tuberculosis[13]. Poor quality of one of the medicines taken by patients at this stage violates the whole system and may lead to transition of easily treatable sensitive form of the disease to multidrug-resistant tuberculosis[14]. Improving the efficacy as well as reducing the side effects of anti-TB drugs remains a topical issue [15].

The combined anti-tuberculosis drug "Biomayrin" was developed at the Institute of Bioorganic Chemistry in the Academy of Sciences of the Republic of Uzbekistan by chemical binding of isonicotinic acid hydrazide with modified dialdehyde of polygalacturonic acid, with subsequent inclusion of ethambutol and rifampicin in the macromolecule by means of ionic bond [16].

The combination of isoniazid, ethambutol, and rifampicin along the chain of modified polysaccharides allowed creating a drug[17], which not only combines the properties of these drugs, but also manifests new properties due to its macromolecular nature[18] - prolonged action, membranotropicity, change of activity, possible synergetic action, and others[19]. Creation of combined drug of macromolecular nature "Biomayrin" due to activity increase (at lower content of individual drugs in macromolecule) and latitude of pharmacological action leads to significant reduction of side effects[20].

The research purpose is to develop method of standardization, study stability and establishment of shelf life of "Biomayrin" 600 mg capsules.

This article presents the results of the study of stability of the capsule form of the anti-tuberculosis drug "Biomayrin".

Subject of Research: The subject of research is capsules "Biomayrin" with the mass of 600±6 mg containing isoniazid, rifampicin, ethambutol, polygalacturonic acid and calcium stearate obtained by disk dosing into capsules No.0.

Materials and Method

The research on development of standardization method, stability studies and determination of shelf life for "Biomayrin" capsules was carried out using materials and equipment on the basis of the Institute of Bioorganic Chemistry of the Academy of Sciences of the Republic of Uzbekistan[16]. Besides, we considered it expedient to study the dissolution profiles of "Biomayrin" capsules, since their change in time provides additional information when studying the stability of drugs and to justify the shelf life.

Shelf life time of capsule "Biomayrin" was set by the method of "accelerated aging" at storage of samples in PVCA1 blister packages (20 capsules each) at 60^0C in the thermostat TV-80-1.

Testing "Decompossibility" of capsules and "Average mass and homogeneity by mass" were conducted in accordance with the requirements of the State Pharmacopoeia of the XIII edition. The experiments were conducted in at least three repetitions. Decompressibility of capsules was determined on PJ-3 Tablet Four-usageTester (China). Isoniazid, rifampicin and ethambutol were quantitatively determined in solution by spectrophotometry (SF). The analysis was performed on SHIMADZU UV-1601, UV-VISIBLE spectrophotometer in 1 cm cuvette against the background of the solvent. The pH value was controlled with the EV-74 universal ionometer. OFS.1.1.0013.15 "Statistical processing of chemical experiment results" using standard computer programs MsExcel. The "Dissolution" of the combined drug was investigated according to [20] using the RCZ-6C3 device of the "Rotating Basket" type. At the first stage, purified water (pH 7.0) in the volume of 900 ml at a temperature of 36.5±0.50 C was used as a medium for dissolution at a basket rotation speed of 150 rpm and the duration of

the analysis was 60 min. At the second and third stage, when determining the dissolution profile of the capsules, two dilution media similar to pH of human stomach (pH 1.2) and pH of duodenum (pH 8.0) were consistently used. Sampling for analysis was carried out every 15 min during 1 h. Release of isoniazid, rifampicin and ethambutol as one of the main groups of biologically active substance of the combined drug was determined by direct spectrophotometry on the device "UV-7504" in a cuvette with thickness of 1 cm at wavelength 262±2; 336±2 and 450±2 nm.

Results and Discussion

To determine the quantitative content of isoniazid, the content of 10 capsules was thoroughly stirred and selected 100 mg (precise attachment) of powder, placed in a measuring flask of 100 ml, 50 ml 0 was added, 1 M of hydrochloric acid solution dissolved in an ultrasonic bath for 15 minutes, brought the volume of the solution with the same solvent to the mark, 5 ml of the resulting solution was placed in a measuring flask with a capacity of 100 ml and brought the volume of the solution to the mark 0.1 M with hydrochloric acid solution. The obtained solution was filtered through a "White Ribbon" filter, discarding the first 10-15 ml of filtrate, optical density was measured at 262 nm wavelength. At the same time the optical density ofisoniazid solution was measured.

Calculation of isoniazide (mg) content in Biomayrin capsule was performed by the formula:

$$\frac{D \times 100 \times 100 \times m_{st} \times 1 \times m_{caps}}{D_0 \times 5 \times m_{test} \times 100 \times 100},$$

Where: D1 – optical density of the test solution.

D0 – optical density of SSS (Solution standard samples) isoniazid solution.

m_{caps}– average mass of content of one capsule, in mg.

m_{test}– precise hinge of the test specimen, in mg.

m_{st}- precise attachment of standard sample, in mg.

The quantitative content of rifampicin was determined using the above method and optical density was measured at a wavelength of 472 nm. The optical density of rifampicin SS solution was measured in parallel. The calculation of rifampicin (mg) content in Biomayrin capsule was carried out by the formula:

$$\frac{D \times 25 \times 100 \times 2 \times m_{st} \times m_{caps}}{D_0 \times 5 \times m_{test} \times 100 \times 100},$$

Where: D_1 – optical density of the test solution.

D_0 – optical density of SS rifampicin solution.

m_{caps}– average mass of content of one capsule, mg.

m_{test}– precise hinge of the test sample, in mg.

m_{st}- accurate attachment of standard sample, in mg.

Determination of the quantitative content of ethambutol by the above method, with a difference after filtration to 10 ml of leachate was applied 1 ml solution of iron ammonium alum, thoroughly stirred and left for 5 minutes. Then 0.2 ml of solution of mercury rhodiumized was added and stirred again. In parallel, a similar treatment with 10 ml of SS solution of ethambutol dihydrochloride was performed. After 10 min the optical density of the analyzed solutions was measured at a wavelength of 457 nm.

The calculation of the content of ethambutol (mg) in the Biomayrin capsule is done by the formula:

$$\frac{D \times 100 \times m_{st} \times m_{caps}}{D_0 \times m_{test} \times 100}$$

Where: D_1 – optical density of the test solution.

D_0 – optical density of ethambutol SS solution.

$m_{капс}$– average mass of one capsule content, mg.

$M_{исп}$– precise hinge of the test sample, in mg.

$m_{ст}$- accurate attachment of standard sample, in mg.

According to SF (State Pharmacopoeia) XIV, a formula based on the Vant-Goff law is used to determine whether the experimental storage period at elevated temperature (C) corresponds to the storage period (C) at 25^0C:

$$SP=K*P_{ex},$$

Where the coefficient of conformity $K=A(t_e–t_{xp})/10$, the temperature coefficient of chemical reaction speed (A) is 2.5. At a temperature difference $t_e–t_{xp=}60\text{-}25=35^0$C the conformance coefficient K=9.0. Calculated terms of experimental storage at 60^0C are given in Table 1, the results of studies are shown in Table 2.

The results of determining the content of active substances in dissolution in the studied preparation are presented in Tables 2 and 3.

As follows from the above data on the properties of the capsules during storage of 60^0C and 25^0C, after dissolution the content of active substances (isoniazid, rifampicin and ethambutol) in preparations with the shelf life up to 2018. is within the limits of regulated norms (60-120 mg) at 60^0C is for isoniazid 101.7-106.7 mg, at 25^0C 100.1-106.0 mg for rifampicin the regulated norm should be 72-132 mg and at 600C is 94, 2-92.2 mg, and at 25^0C 94.7-91.2 mg, and also the content of ethambutol hydrochloride should be 60-120 mg and at 60^0C of storage its content was 62.5-60.5 mg, at 25^0C 62.0-60.2 mg. In the study of samples with expired shelf life (2018) a moderate decrease in the level of active substances was noted.

In order to obtain the most complete picture of Biomayrin quality changes during storage, we considered it expedient to study its release from the investigated samples along with the tests of "Active substance content" [22].

The results of the experiments to study the release of the active ingredients of the combined preparation from the capsules in the device "Rotating basket" are presented in Fig. 1 - 3.

The graphs show that the amount of substances transferred to different solvents in 60 min varies within the limits for:

- Isoniazid in water purified from 74.0 to 92.0%; in acidic medium from 56.0 to 84.6%, and in buffer solution from 65.5 to 83.0%;
- Rifampicin in the first medium from 58.3 to 84.0%; in the second medium from 44.0 to 77.0%; in the third medium from 62.0 to 85.0%;
- Ethambutol on Wednesday from 65.0% to 85.0%; on Wednesday 2 from 67.0% to 85.0%; on Wednesday 3 from 64.0% to 77.0%.

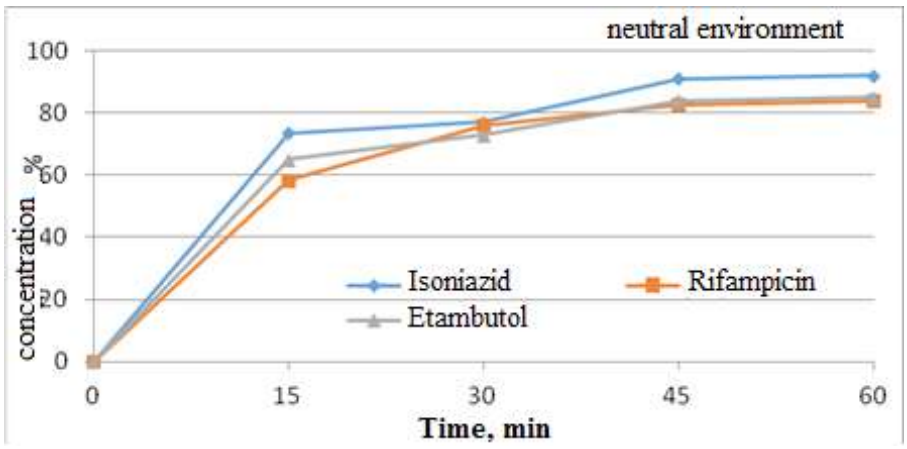

Figure 1: Kinetic release profile of DS (drug substance) from capsule at 36.5±0.5^{0}C and V = 900 ml, pH = 7.0 (dissolution test method)

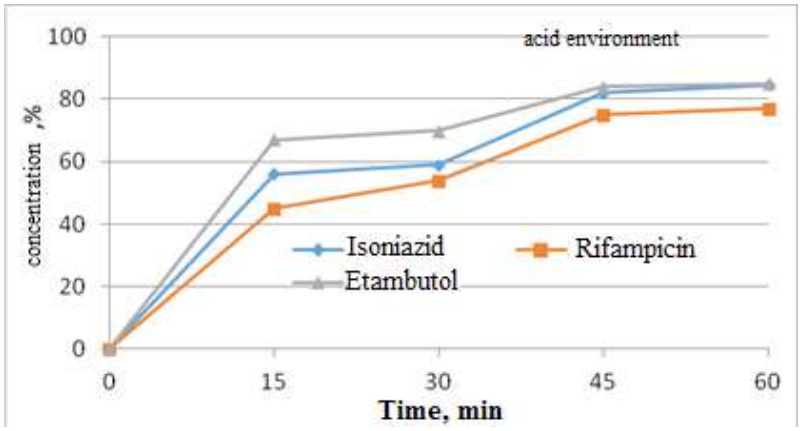

Figure 2: Kinetic release profile of DS (drug substance) from capsule at 36.5±0.5^{0}C and V = 900 ml, pH = 1.2, 0.1 m hydrochloric acid (dissolution test method)

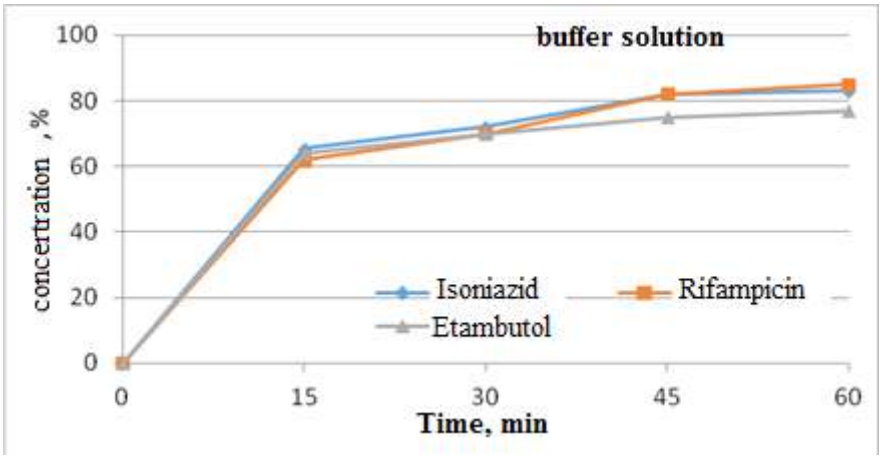

Figure 3: Kinetic release profile of DS (drug substance) from capsule at 36.5±0.5^{0}C and V = 900 ml, pH = 8.0 (buffer solution) (dissolution test method)

Based on the results of the first set of experiments in the dissolution test, we can conclude that isoniazid, rifampicin and ethambutol dissolve well within 60 minutes in all the solutions we used.

Based on the above studies, a table was made on the results of the accelerated stability test for Biomayrin capsules. The results are given in Table 4.

Table 4: Results of the accelerated stability test of "Biomayrin" capsules

Test	Specifications	0 Days (Start)	6 Days (3 Months)	12 Days (6 Months)	18 Days (9 Months)	24 Days (12 Months)	36 Days (18 Months)	48 Days (24 Months)

Conclusion

In the research of samples with expired shelf life (2018) was found out that capsules “Biomayrin” at storage of 60^0C and 25^0C, after dissolution the content of active substances (isoniazid, rifampicin and ethambutol) in preparations is within the limits of regulated norms (60-120 mg) at 60^0C is for isoniazid 101, 7-106.7 mg, at 25^0C 100.1-106.0 mg, for rifampicin the regulated norm 60^0C was 94.2-92.2 mg, and at 25^0C 94.7-91.2 mg, and also the content of ethambutol hydrochloride at 60^0C was 62.5-60.5 mg, at 25^0C 62.0-60.2 mg. This indicates that, when stored at different temperatures the content of active substances is within the limits of regulatory standards, as well as a moderate decrease in the level of active substances.

As well as, according to the results of the test “Dissolution”, it was found that the number of active ingredients transferred to water purified from “Biomayrin” capsules is 87% on average, in acidic environment - 82.2% on average, in buffer medium - 81.6%. Comparison of the data allows us to conclude that the release of active substances in the buffer solution is slower than in a neutral environment (purified water). The results show that the method of “dissolution”: the degree of release of biologically active substances in 1 hour is at least 81%.

It was found that at the end of the shelf life (2 years) gradually reduces the rate of “dissolution” from 93.6% to 89.5% and changes the profile of release of active substances from the capsule forms of drugs.

Abstract

The article highlights the problematic issues of implementing of the best international practices in protection of a human and human rights, and counterfeiting medicines in the context of globalization. Every state exists for man, for the protection of universally recognized rights and freedoms. Counterfeiting of medical products and other similar crimes require attention in any country in the world.

Counterfeiting is not an exception in developed countries in Europe, such as the Netherlands, Belgium, Sweden, Switzerland, Finland, Norway, Denmark, and Austria. This problem is global for, both, legal and public administration science. It is widespread throughout the world, and the negative effects of this crime have severe consequences that affect people's lives and health.

Keywords: *Counteraction management, counterfeiting of medicines, globalization, digitization, protection of a human and human rights.*

Introduction

The development of Europe, Asia, North and South America, Africa, Australia and Oceania is currently linked with the implementation of a number of urgent reforms, including the modern transformation of crime-fighting method. The global problem of counterfeiting in medicines is in need of immediate solution worldwide.

When a person dies because of adulteration of medicines or loses health, the consequences are deplorable. Buying medicines from pharmacies, a patient does not always pay attention to their quality. The regulation of this issue at the international level makes it possible to issue responsibility for the above-mentioned crimes in the states and stop it, or at least significantly reduce their number normatively. In the case of purchase of counterfeit medicines, a person may file a lawsuit with the administrative court to protect their rights in the field of public-legal relations in the event of inaction or unlawful decisions by the relevant authorities.

Literature Review: Counterfeit products reach the highest levels in countries with imperfect legal frameworks in the regulation of drug trafficking and lack of efficiency in regulatory oversight of counterfeit drugs. In most countries with developed regulatory framework and market control, such drugs are rarely found[1,2], [p. 29]. Ukrainian scientist Khromykh A.G. conducted an expert survey to determine the main factors affecting the adulteration of medicines by developing a questionnaire with more than 150 experts. Therefore, according to experts, the most important factors influencing the circulation of counterfeit medicines are identified as follows: a developed system of selling medicines

through the global Internet information network and mail that does not allow the control bodies to check their quality; high cost of imported medicines, which makes the sale profitable; etc. These practices and the review of scientific sources have made it possible to identify also the most promising at the present stage of the technology of protection of pharmaceutical products from adulteration[3], namely: their origin through electronic registration.

The World Health Organization estimates that counterfeit drug sales are about $ 200 billion annually, equivalent to 10-15% of the global pharmaceutical market[4]. In Russia, the problem of counterfeiting of medicines, as in most countries of the world, remains urgent and needs to be addressed by amending the legislation.

A number of international acts have been adopted in order to address the problem of counterfeiting of medicines. For example, in Ukraine, the Council of Europe Convention on Counterfeiting of Medical Products and Similar Health-Related Crimes[5] entered into force on 1 January 2016. The Universal Declaration of Human Rights[6], promulgated by the General Assembly of the United Nations on 10 December in 1948; and the Convention for the Protection of Human Rights and Fundamental Freedoms, issued in1950 and its number ETS No. 5[7]; the European Social Charter, issued in 1961, ETS No. 35[8]; the Convention on the Development of the European Pharmacopoeia (1964, ETS No. 50)[9]; and Protocol thereto 1989, ETS No. 134); the Convention on the Protection of Rights and Dignity on the application of biology and medicine; Convention on Human Rights and Biomedicine, issued in 1997, ETS No. 164)[10]; Additional Protocols, issued in 1998 ETS number 168; issued in 2002; ETS number 186, issued in 2005; CETS number 195, issued in 2008; CETS number 203; the Convention on Cybercrime issued in 2001, ETS number 185 are International instruments for governing these issues[11]. Rule makers have duly drawn attention to other relevant international legal instruments and programs. They were paid to those which were conducted by the World Health Organization and included the work of the IMPACT Group, the European Union, and the G8 (since 2014 - G7). Determined to effectively achieve the overall goal of combating crime, which includes counterfeiting of medical products and similar health-threatening crimes, in particular, by fixing new crimes and criminal penalties relating to these crimes[12].

Aims: Studying and generalizing the best international experience in counterfeiting medicines, as well as exploring the problematic issues of its implementation in the context of globalization.

Method

The research material is a modern international regulatory framework governing the fight against counterfeiting of medicinal products, foreign and domestic scientific works of specialists. The system method, structural and functional method, techniques of logical method (analysis, synthesis, deduction and induction), method of legal statistics, legal modeling were used in writing the article.

Results

For example, it is worth noting that Article 165 of the Criminal Code of Poland establishes responsibility for actions such as the manufacture and putting into circulation of harmful substances, foodstuffs or other public goods, as well as pharmaceuticals that do not meet the mandatory requirements, which do not meet the requirement of conditions of quality[13]. Denmark's criminal law, for example, establishes liability for actions such as the sale of medicines that do not meet these goals and may cause harm to health[14]. In the United States, the Food and Drug Administration is the primary body responsible for monitoring compliance with pharmaceutical law. Along with the Food and Drug Administration, as a federal body, each state has its own supervisory authority[15].

For example, in October 2011, pharmaceutical giant subsidiary Glaxo Smith Kline was found guilty of four counts of counterfeit medicines. The lawsuit is also considered a civil suit filed by the Office of Criminal Investigations alleging that Glaxo Smith Kline has accused the Food and Drug Administration Medicaid program of thinking information about low-quality drugs of its own manufacture. The case, in which the Office of Criminal Investigations employees represented the State, resulted in the fine of Glaxo Smith Kline. It was fined $ 140 million in criminal proceedings and $ 600 million in civil proceedings[15;16]. During the unscheduled audit, 18 violations were detected. One of them was critical. Nine were significant. There were eight non-essentials. In view of the presence of a critical disorder, which may lead to the production of substandard medicines and which may harm the health or life of a person, a decision was made to issue an order to remedy the violations

of the License terms. The enterprise is obliged to stop the production of medicines until the critical breach of the License Terms. However, considering the available material and the facts of the case, examining and evaluating the evidence presented in their totality, the court decided to dismiss the claim in its entirety. The court considers that on the day of the court hearing there are no grounds for taking the measures mentioned in the claim. The violation, which were classified as critical ones after an unplanned measure of state supervision (control) with respect to compliance by the entity with the requirements of the Licensed Conditions of Business Activity in the Production of Medicinal Products "Zaporizhzhia Autogeneous Plant" and the Company", was independently eliminated by the defendant. The company[17].

Discussion

Counterfeit drugs cause both social and economic harm to society according to V. Pashkov, A. Soloviov, A. Olefir. Counterfeit and substandard medicines should be distinguished. Although there are recommendations for patients to identify counterfeit drugs, the law is essential in counteracting their circulation. Opposite actions can be carried out at the level of general rules, as well as through specific regulatory requirements. The latter can be divided into economic (setting rules for market participants, how to detect and remove counterfeit medicines) and those, imposing penalties for offenses. In all European Union countries studied, the use of counterfeit medicines is strictly prohibited and administrative liability is envisaged for such actions. At the same time, there is no single approach to criminal liability as defined by national governments[18],[p. 848].

Being studied the regulatory framework and the work of international scientists; it is fair to point out that the leading countries in the development of the digital economy are Great Britain, Japan, Singapore, New Zealand, Estonia, United Arab Emirates, Israel and more.

It is important to give a theoretical characterization of the term "digitization", which comes from the English "digitalization" and in translation means "digitization", "digitization", or "digitization". At the same time, nowadays domestic scientists are increasingly using this term, based on the requirements of practical transcription, and therefore the terms "digitization" or "digitization" have become widespread. This approach has several advantages, since the term "digitization", by the right remark of K. Lapina-Kratasyuk, covers a wider range of meanings than its synonym "digitization". This is due to the fact that it is in European and American research traditions that the effects of the transition from analogue to digital type of information encoding have been studied not only as technological but also as social, cultural, and anthropological processes[19]. According to K.O. Kuprina and D.L. Khazanova, digitization is theway of bringing any kind of information into digital form[19; 20]; with. [259]. The Polish Government[21] adopted the Digital Government for 2014-2020. Digitization in the country is developing quite actively. Special Ministry of Digitization or Digitization - Ministerstwo Cyfryzacji is engaged in the introduction of new technologies.

Having conducted research of scientific sources, it is right to emphasize that scientists Vasylieva T. A., Lieonov S. V., Rubanov P. M., Vasilyeva TA, note that the digitization of the economy is considered to be a fundamental factor of economic growth, innovation and competitive environment, job creation and social progress in general[22; 23]. In Russia, there is a law on the circulation of medicines, in which the terminology has been successfully developed, for example, the concept of pharmaceutical activity, etc.[24], which, for example, is absent in the Law of Ukraine on Medicines, is enshrined. Pursuant to Article 9 of the Law, medicinal products are allowed to be used in Ukraine after their state registration, except in cases provided for by the Law. Registered by the competent authority of the United States of America, Switzerland, Japan, Australia, Canada, a medicinal product registered by a competent authority of the European Union under a centralized procedure for use in the territories of those countries or Member States of the European Union, only materials on method of quality control of medicinal product are added. Materials of the registration dossier and samples of the packaging of a medicinal product, labeled in a language for the labeling of medicinal products, instructions for the use of a medicinal product in a language must be in accordance with the requirements of this Law; document confirming payment of the registration fee are added too[12]. This makes it possible to regulate this issue legally and avoid crimes in Ukraine, since the person, his life and health, according to Article 3 of the Constitution of Ukraine, is of the highest legal value[25].

The problem of counterfeiting of medical products and other similar crimes require attention in every state, because the negative consequences of this crime have

serious consequences that affect the lives and health of people. The introduction of positive foreign experience makes it possible to legally secure the responsibility for the aforementioned crime in international countries and stop it.

Conclusion

Because of the conducted research, we propose strengthening of legal responsibility for falsification of medicines in the countries of the world, the legislation of which provides insufficiently severe criminal penalties or even administrative liability. We believe that the manufacture and trade (both domestic and export) of counterfeit medicines should be a particularly serious crime, for which criminal liability in the form of imprisonment for 15-20 years with confiscation of property should be provided. The rights of individuals should be protected by an administrative court in the sphere of public-legal relations when appealing against decisions, actions (inaction) of state bodies.

However, in the first place, it is necessary to create the appropriate conditions for the effective fight against counterfeit medicines at the international level. This requires the use of innovative digital technologies already in use in the leading countries of the world, including the European Union. It is necessary to create in each country a unified electronic system for the identification of goods, including medicines that would be publicly available on the Internet for everyone, including every consumer of medicines. When buying these products from their smartphone, they will be able to open the program, take an electronic ID photo, and verify the authenticity of the medicinal product, obtain information about the manufacturer, date and place of manufacture, etc. Such programs should also be used by business entities to prevent counterfeiting. At the same time, both the persons who manufactured the product and the guilty officials of the economic entities that sell them must be prosecuted. Legal entities and entrepreneurs must be subject to considerable administrative liability - € 100,000, such as in Spain.

A significant aspect of the problem of drug identification is its global, international level. The worldwide locomotive of digitization in counterfeiting of counterfeit medicines should be the World Health Organization, which is already taking care of these problems. To counteract the counterfeiting of medicines globally, it is necessary to develop an international program coordinated by WHO. Authoritative intergovernmental associations, such as the European Union, the Eurasian Economic Union and other trans-state entities, should be involved in the development and implementation of this program. At the national level, such work should be undertaken by relevant health ministries through the creation of appropriate structures of their own subordination or through interaction with national digitization bodies. In the positive experience of Poland, it is appropriate to create special ministries (or other authorities) that would develop modern technologies.

In the future, a global database of certified medicinal products should be created for use of any citizen of any country in the world in the age of the pharmaceutical market globalization. And also give access to such a court system.

Thus, the implementation of the proposed approach will significantly reduce the number of counterfeit drugs in the world, as the inevitability of criminal punishment for such crimes will become evident.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

Cytology and Genotyping of High-Risk Human Papilloma Virus from Female Sex Workers in Makassar

Juan[1], Sharvianty Arifuddin[2], Abdul Rahman[3], St. Nur Asni[1], Syahrul Rauf[2], Masita Fujiko[4]

[1]Obstetrics and Gynecology Department, [2]Division of Gynecology Oncology, [3]Division of Social Obstetrics and Gynecology, Department of Obstetrics and Gynecology, [4]Division of Maternal and Fetal Medicine, Department of Obstetrics and Gynecology, Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan KM. 10, Tamalanrea Indah, Kota Makassar, Sulawesi Selatan 9024, Indonesia

Abstract

Objective: This study aims to determine the results of cytological examination and genotype of high risk HPV in women work as femalesex workers (FSW)at Makassar, South Sulawesi.

Method: This study designed as analytical study with a cross sectional analysis approach and sample came from female sex workers in the Makassar city. Research was conducted in the localization area of sex worker, and conducted from March 2019 - September 2019. The research sample consist of women with reproductive age who sex workers, and meet the inclusion criteria. The cytological examination was performed using the Thin Prep Pap Test and the DNA HPV detection (genotyping) using the reverse dot blot "flow through" hybridization method. Data were analyzed with SPSS.

Results: Our study found that most of the FSWs who were sampled are > 30 years old (61.3%), had <9 years of education (66.3%), were married (77.5%), nulliparous (62.5%), being FSW> 1 year (86.3%), age at FSW ≥ 15 years (73%), age at first coitus ≥15 years (82.3%), number of sex partners within a month ≥5 (61.3%), the last number of sexual partners in the last 1 month<5 (58.8%), did not have an Sexual Transmitted Infection (STI) (96.3%). The number of FSWs who using and not using condoms was comparable (50% each), and all samples had never vaccinated with HPV vaccine. It was found that based on the type of lesion, most FSW samples had non-specific and non-bacterial cervicitis (60%) and the remaining 40% had no lesions. Based on the distribution of HPV genotypes in commercial sex workers, most of the samples had a high risk HPV of 25%. Duration to be FSW connected with high risk HPV ($p < 0.05$).

Conclusion: There is a significant relationship between duration of being FSW and high risk HPV genotype. Our study highlited that FSWs who work for >1 year are prone to having high risk HPV.

Keywords: *Cytology of FSW, HPV genotype of FSW, Makassar.*

Introduction

Cervical cancer is the third most common type of cancer in the world, and is the only cancer that can be detected early therefore prevented its development. It is estimated that in 2008 worldwide there were 530,232 women diagnosed with cancer and 275,008 of them died.[1] Most cervical cancers (85%) occur in developing countries such as Indonesia.[2] The growth rate of cervical cancer has a drastic difference in developed countries compared to developing country. Globally, the burden of cervical cancer in developing countries is around 85% -88% of deaths from cervical cancer. The growth rate of cervical cancer in developing countries is still increasing, by adding the incidence of both of cervical

e-mail: gregoriusjuan@gmail.com

and breast cancer will be the main cause of death in women of reproductive age by 2025.[3]

Cervical cancer often found in women aged> 50 years, but in developing countries the incidence frequently found in women with reproductive age. In countries that do not have good screening programs, cervical cancer sufferers are mostly diagnosed at an advanced stage with incurable stage.[4] In addition, the prevalence and genotype of HPV infection differ in each population. There are currently two types of HPV vaccines, namely for types 16 and 18, both of which significantly reduce the prevalence of HPV infection caused by these two types of HPV.[5] However, the effect of HPV vaccination on the prevention of HPV infection and cervical cancer also differs based on the distribution of HV genotypes in each region.

Cervical disease is highly contagious and the risk of infection increases with increased sexual activity.[6,7] Female sex workers are among the high-risk groups who most likely infected and transmit HPV because having more than one sexual partner.[7] Studies on female sex workers in Cambodia show the highest prevalence of HPV types 51 and 70 dominant compared to types 16, 71 and 81.[8] However, other research in Turkey shows that female sex workers are mostly infected with HPV types 18, 16 and 50.[9] A meta-analysis of HPV infections in female sex workers in Asia shows that there are differences in the prevalence of HPV types among southeast and eastern Asia. The predominant types of HPV that infect in eastern Asia consist of types 16, 18, 58, 56 and 52 while HPV infections in southeast Asia are mainly caused by types 52, 16, 58, 18 and 66.[10]

Cytological examination has become a standard examination of cervical cancer screening over the last 50 years. Cervical cancer screening examination with cytology has reduced the incidence and mortality rates due to cervical cancer. Screening of cervical cancer is effective step because the nature of this cancer has a long preinvasive phase so that minimal changes can be detected before it turns into a malignancy or metastasis. This examination evaluates the existence of cell abnormalities resulting from cervical epithelial specimens. Conventional cytological examination has a sensitivity level (70% -80%) and specificity (94-97%) to detect high-grade precancerous lesions.[1]

The high level sensitivity of HPV DNA testing has the advantage of a very high negative predictive value even against adenocarcinoma precursors, which are often not detected by cytological examination.[11]

Research on the cytology and genotype of HPV in commercial sex workers has never been conducted in South Sulawesi, especially Makassar. Therefore, it is necessary to conduct research on the cytology and genotype of HPV in women commercial sex workers in Makassar to stabilized data of this area and for women commercial sex workers regarding the risk of HPV infection and transmission and the importance of educational programs for to prevent the transmission of cervical cancer.

Method and Sample

Our study conducted as an analytical study with cross sectional analysis approach which was carried out in a localization area of Makassar City for 6 months, starting from March 2019 to September 2019. Sampling was done by consecutive sampling i.e subjects in the study sites that meet the requirements inclusions were taken as research samples. The sample of this study consist of women with reproductive age who work as commercial sex workers, who meet the inclusion criteria that is female subjects who work as commercial sex workers, aged 15 - 50 years, actively engaging in sexual relations with more than 1 sexual partner in the past 1 month, the patient is not menstruating, the patient is not using tampons, vaginal medicines, vaginal contraception, vaginal douche for 48 hours before the examination, the patient is not allowed to have sexual course within 24 hours before the examination, and the patient is not pregnant. Our sample including 80 commercial sex workers who were willing to be involved in the study.

Subjects were asked to fill out a questionnaire accompanied by a research assistant. Furthermore, subjects were given an oral explanation of the examination and taking swabs in the endocervix. After the subject understands, it can be asked for willingness to participate in research. Informed consent sheet are provided for patient thatwilling to participate in this study.

The process of collecting specimens is carried out by the clinician using a broom like brush or endocervical brush and spatula to the ecto-endocervical transformation area. Then the endocervical brush is inserted into a container containing the PreservCyt solution (Cytyc, Boxborough, MA) by turning/rinsing about 10 times. By using Thin Prep Processor homogenisation of specimens

with a certain centrifuge speed, and separating materials such as mucus, debris and washing blood from cells without damaging the grouping of cells. After going through the dispersion process, the cells are transferred to specific glass objects in a representative and accurate way through the filtration process and form a thin layer of one layer of cells (thin layer - monolayer cell). The next process of closing and closing the slide is in accordance with the routine process of pap's smear inspection.

Specimens from HPV (cervical swab) examination were put into a sterile 1ml Phosphate Buffered Saline (PBS) solution and then cortized for 3x15 seconds. Furthermore, 0.5 ml of each sample was used for the extraction of nucleic acids and the remaining preparations were frozen at -20 ° C. Extraction, detection and determination of HPV type genotypes were performed using the PCR method. Data were analyzed with SPSS.

Result

During the study period, 80 female sex workers were involved in the study. Data distribution were normal by Kolmogorov Smirnov test when the p value is> 0.05. In this study, the value of p> 0.05 was obtained indicating all data were normally distributed therefore chi-square statistical tests would be carried out.

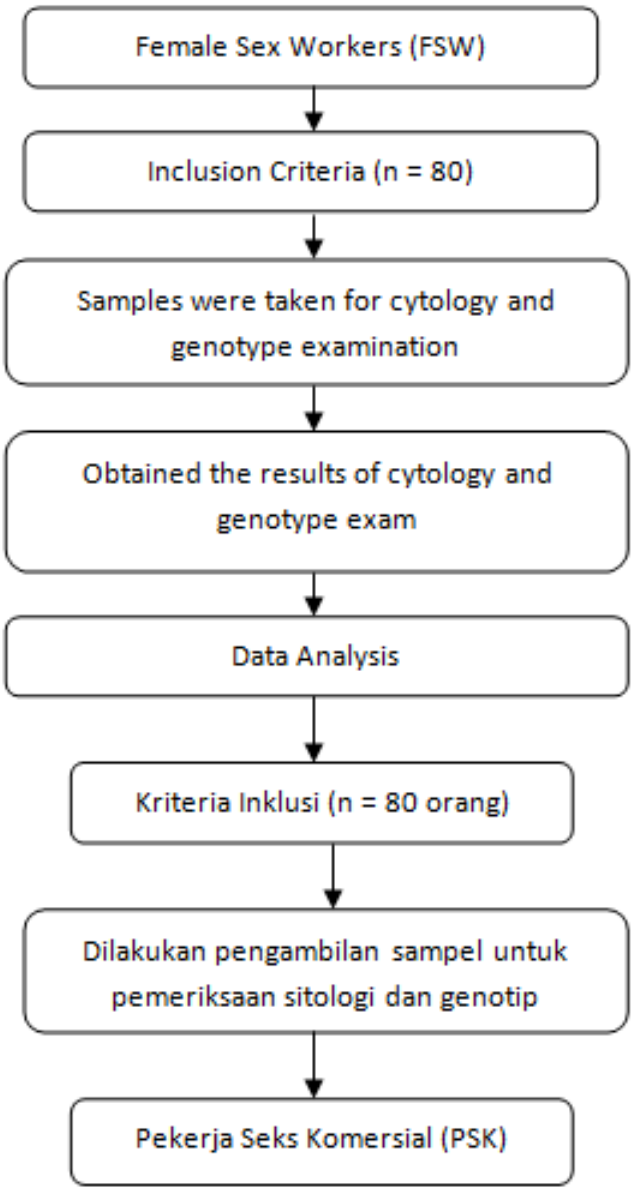

Figure 1 Flow chart

Tabel 1: Frequency Distribution of Variables

Variabel	N	%
Age		
<30 years	31	38,8
>30 years	49	61,3
Education		
<9 years	53	66,3
≥9 years	27	33,8
Marital Status		
Not married	18	22,5
Married	62	77,5
Parity		
Multiparous	16	20,0
Primiparous	14	17,5
Nuliparous	50	62,5
Duration being FSW		
<1 years	11	13,8
≥1 years	69	86,3
Age become FSW		
<15 years	7	8,8
≥15 years	73	91,3
Age ar first coitus		
<15 years	14	17,5
≥15 year	66	82,5
Sex partners in one month		
≥5	49	61,3
<5	31	38,8
Sex partners in last month		
≥5	33	41,3
<5	47	58,8
Condome usage		
Never/occasionally	40	50
Always	40	50
Sexual transmitted disease (STD)		
Yes	3	3,8
No	77	96,3

Table 1 showed that the majority of CSWs who became our sample were> 30 years old (61.3%), had received education in <9 years (66.3%), were married (77.5%), nulliparous (62, 5%), became CSW >1 year (86.3%), age at CSW ≥15 years (91,3%), age at first coitus ≥15 years (82.5%), number of sex partners in a month ≥ 5 (61.3%), the number of last sexual partners in the last 1 month <5 (58.8%), did not experience sexually transmitted infections (96.3%). The number of CSWs using and not using condoms was comparable (50% each), and all samples has never vaccinated.

Table 2: Pre-Cancer LesionsCategoriesAccordingto CervicalCytology Examination Based on Fluid (SSBC) in Female Sex Workers

Tipe Lesi	n	%
Non-specific bacterial cervicitis	48	60,0
Negatif lesion	32	40,0

Our result in table 2 showed that most of samples have Non-specific bacterial cervicitis (60%) and the remaining 40% do not have lesions.

Table 3: Distribution Genotipe HPV in Female Sex Workers

Lesion Type	n	%
High-risk HPV	20	25
Low-risk HPV	6	7,5
High-Low risk HPV	24	30
No HPV and other types	30	37,5

Table 3 showed the distribution of HPV genotypes in female sex workers, most of the samples had a 25% high risk HPV, a 7.5% low risk, a 30% high and low risk and 37.5% did not have an HPV.

Based on Figure 2 our study showed that 5 people infected with type 16 HPV, people infected with type 18 HPV were not found, 44 people infected with other types of High Risk HPV, 43 people infected with Low Risk HPV .

In Figure 3 it can be seen that of the 49 HPV types of high risk women of FSWs, HPV type 45 were detected in 6 people, type 51; 6 people, type 16; 5 people, type 33; 5 people, type 35; 5, type 52; 3 people, type 39; 2 people, type 66; 2 people, type 56; 2 people, type 68; 2 persons. And types 5,42,53,58,73 and 82 each in one person, respectively. The other types obtained in 5 people.

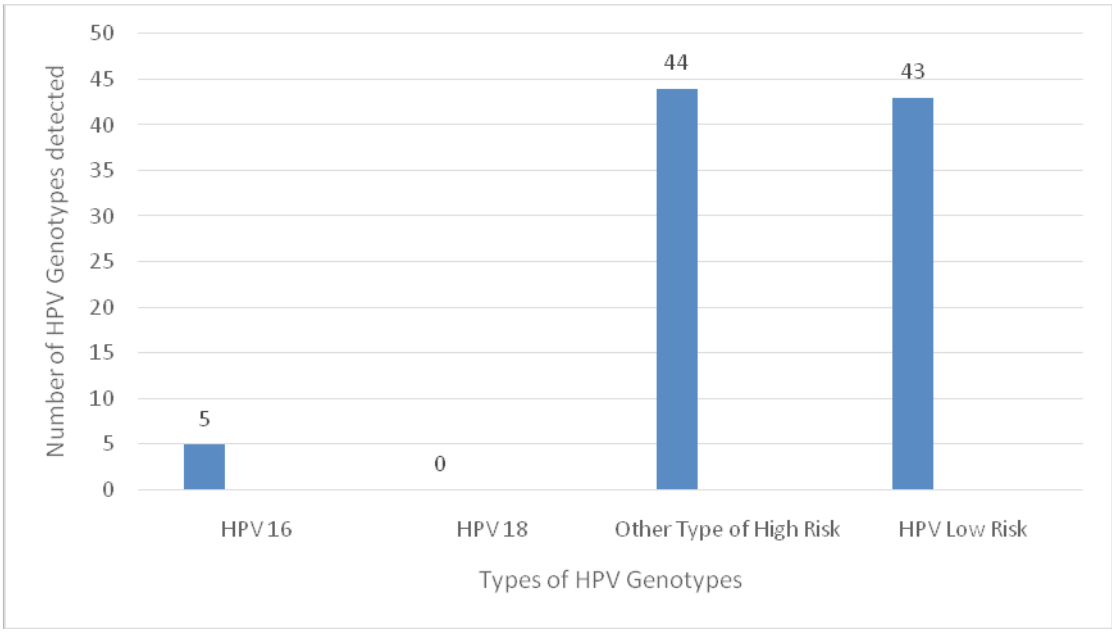

Figure 2 Distribution of HPV type 16, HPV type 18, high risk HPV, low risk HPV in female FSWs in Makassar

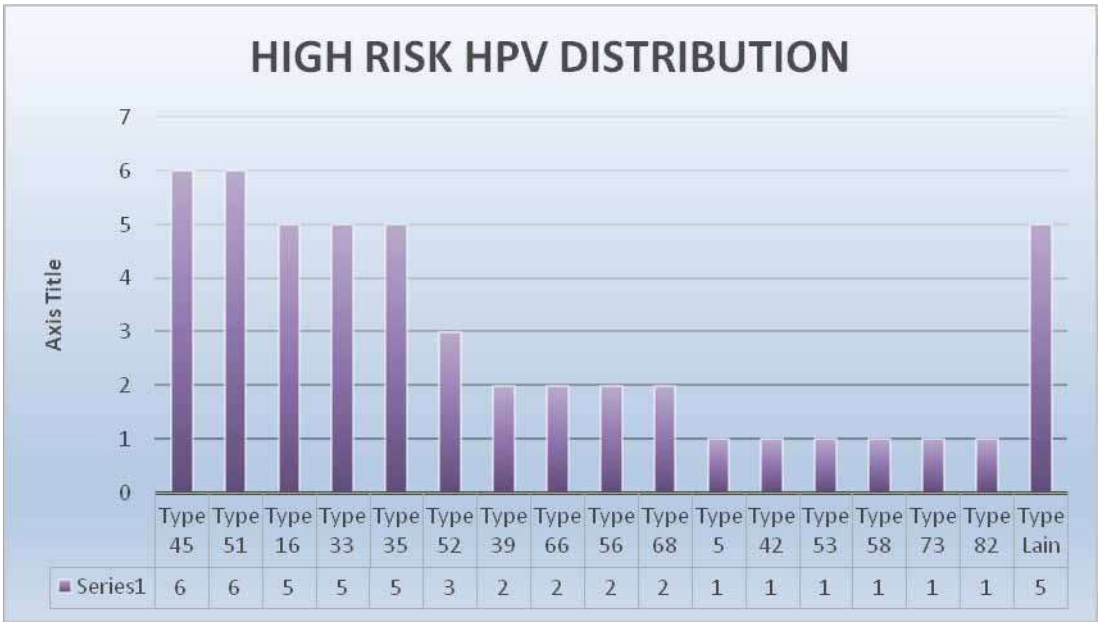

Figure 3 Distribution of High Risk HPV types in women of CSW in Makassar

Table 4 illustrates the relationship between the type of cytology of pre-cancerous lesions and the characteristics of commercial sex workers. No association was found between age, education, marital status, parity, length of time a prostitute, age at prostitution, age of first coitus, number of sex partners in the past 1 month, use of condoms and STIs with the type of cytology of pre-cancerous lesions (p <0.05). While the relationship to vaccine use cannot be analyzed because all samples have never received an HPV vaccine.

Chi Square test $p<0.05$

Table 5 illustrates the relationship between the High Risk HPV genotype and the characteristics of female sex workers. No relationship was found between age, education, marital status, parity, age at becoming a sex worker, number of sex partners in the past 1 month, use of condoms and STIs with the HPV genotype ($p <0.05$).

There was a significant correlation between duration of FSW and High Risk HPV genotype (p = 0.015) with an OR value of 4.714. That is, FSWs who have peddled sex for >1 year 4,714 times are more at risk of having high risk HPV.

Discussion

Cervical HPV infection is very contagious and the risk of infection increases with increasing sexual activity. Female sex workers are in a high-risk group infected and transmit HPV because having more than one sexual partner. In this study we tried to analyze the risk factors for pre-cancerous lesions and HPV genotype in female sex workers in Makassar City.

Based on the type of lesion, the majority of samples from FSW had non-specific and non-bacterial cervicitis (60%) and (40%) the rest had no lesions. The results of this study are also not much different from previous studies which showed that femalesex workers had more positive cervicitis (80.4%) results compared with negative results (19.6%). [12] Cervicitis is a frequent case of sexually transmitted infections occur in female sex workers where cervical inflammation occurs as a result of infection by sexual organisms, most often caused by Chlamydia trachomatis or Neisseria gonorrhoeae.[13]

Based on the distribution of HPV genotypes in female sex workers, most of the samples had high and low risk HPV (62.5%) and 37.5% did not have HPV. A meta-analysis of HPV infection in female sex workers in Asia found that the prevalence of HPV among female sex workers was 12.8 - 84.8%. Female sex workers are 10 times more likely to have HPV infection compared to the general population. The analysis also showed that the prevalence of HPV in the Southeast Asian region was dominated by HPV types 52 (12.9%), 16 (8.5%), 58 (5.2%), 18 (5.0%), and 66 (4 9%). [10]

Age is one of the factors causing precancerous lesions and HPV infection. In this study the majority of FSWs with non-specific cervicitis lesions and bacteria aged> 30 years. High-risk HPV infections are also more common in women> 30 years old (16,25%). However, in the bivariate analysis there was no association between age with lesion type (p = 0.640) or HPV genotype (p = 0.691). The results of this study are supported by previous studies which showed that women aged 31 - 40 years and 41 - 50 years were most at risk of having pre-cancerous lesions (65% and 63.5%, respectively) 14 However, contrary to the results of studies in women workers sexually reported in the Philippines that age 25 years or younger is more at risk of having an HPV infection.[15]

In this study, the majority of samples were low-educated. In samples with non-specific cervicitis and bacterial lesions 70.8% received education for <9 years, while based on genotype type 18.75% samples with education <9 years were infected with high-risk HPV. But in the bivariate analysis, education was not significantly related to the type of lesion and HPV genotype (p = 0.412 and 0.339, respectively). The results of this study are supported by research in Nepal which found that HPV infection was lower in educated women compared to uneducated one.[16]

Most of the samples in this study were married. The prevalence of nonspecific and bacterial cervicitis lesions is higher in married women (81.2%). High-risk HPV infection is also more common in married women (18.75%). However, in the bivariate analysis no relationship was found between marital status and lesion type (p = 0.447) and high-risk HPV genotype (0.757). The results of this study are supported by previous studies which reported that the prevalence of HPV infection was higher in married women, especially married more than once. [16]

In this study the majority of samples were nulliparous women. Nonspecific and bacterial cervicitis lesions are higher in nulliparous women (60.4%). Low and high risk HPV infections are also more common in nulliparous women (17.5%). But in the bivariate analysis parity was not related to the type of lesion and HPV genotype (p = 0.232 and 0.716, respectively). Most groups with positive pre-cancerous lesions had children <4 (34.2%) and they also did not find a significant relationship between parity number and risk of developing cervical pre-cancerous lesions (p = 0.280) .[17]

In this study non-specific and bacterial cervicitis lesion were higher in women who became FSWs for >1 year (81.2%) but in contrast to high-risk HPV infections were more common in women who had FSWs> 1 year (17.5%). In the old bivariate analysis, FSW was not related to the type of lesion (p = 0.185) but significantly correlated with high-risk HPV genotype (p = 0.015) with OR 4,714 (95% CI 1,254-17,717) meaning that being FSW >1 year was at risk. against high-risk HPV infection. This is consistent with the results of previous studies that reported that women who worked as FSWs for 6 months

- 2 years were more at risk for HPV infection. But after 2 years, the risk of HPV is proven to decrease. This was hypothesized due to immunity to HPV in women who have worked as sex workers> 2 years.[15]

Most of the samples aged ≥15 years when they became FSWs, and the age at first coitus was mostly at the age of ≥15 years. No significant relationship was found between age at FSW and age at first coitus with nonspecific and bacterial cervicitis lesions as well as with high-risk HPV infection (p = 0.429 and p = 0.952); (p = 0.253 and p = 0.089). Women with non-specific bacterial and bacterial lesions and high and low risk HPV genotypes have more sexual partners ≥5. However, no significant relationship was found between the number of sexual partners with the type of lesion and high-risk HPV genotype (p = 0.963 and 0.508, respectively). The benefits of condoms in preventing HPV in women are still a matter of debate. There has been a reported decrease in HPV infection in female sex workers who use condoms, but it is not fully effective in protecting against HPV infection. In this study, no relationship was found. There is an argument that condoms cannot completely cover the infected area

This study has several limitations including the small sample size and cross-sectional design. And in this study the sample collected is still under the institution where the results obtained may be different from the free sample or freelance. Further research is needed with larger samples and better designs to confirm the results of this study.

CONCLUSION

Based on cytological examination of precancerous lesion types in female sex workers in Makassar, most of the FSW samples had non-specific and bacterial cervicitis (60%) and the remaining 40% had no lesions. No relationship was found between age, education, marital status, parity, age at becoming a sex worker, number of sex partners in the past 1 month, use of condoms and STIs with high-risk HPV genotype (p <0.05). There was a significant correlation between duration becameFSW and high risk HPV genotype (p = 0.015) with an OR value of 4.714. That is,FSWs who have work as sexual worker for >1 year 4,714 times are more at risk of having high risk HPV.

Abstract

Introduction: Trigger finger is a common hand disorder characterized by locking, catching, or clicking with range of motion of the affected finger. Purpose: The aim of this study was to compare the effectiveness of combined therapy of extracorporeal shockwave therapy (ESWT) and ice massage to the combined therapy of therapeutic ultrasound (US) and paraffin wax bath in treating trigger finger. Method: 19 patients were assigned to the US + wax bath group while the remaining 10 were assigned to ESWT + ice massage group. The effectiveness of the treatment was assessed using visual analog scale (VAS) to measure pain score and Quick-Disabilities of the Arm, Shoulder, and Hand (Quick DASH) questionnaire to assess the functionality of the affected limb at 1st, 2nd, 3rd and 4th week after the initial treatment. Results: The US + wax bath group had reduced more pain and improved more hand function than the ESWT + ice massage group for all visits. Conclusion: This study was not able to prove the hypothesis that ESWT + ice massage group was better than US + wax bath in treating trigger finger. However, a similar study like this but with larger sample size, individualized protocols for ESWT participants, longer study durations and conducted by experts in ESWT is able to show which treatment is better in treating trigger finger.

Keywords: *Trigger finger, shockwave therapy, ultrasound, paraffin wax bath, ice massage.*

Introduction

Trigger finger also known as Stenosing tenosynovitis is one of the most common hand disorders. It occurs when there is difference in size between the tendon and the pulley which the tendon passes through[1]. This difference may due to Narrowing or thickening of the A1 pulley or enlargement of tendon (flexor digitorum profundus and flexor digitorum superficialis) secondary to Degeneration or Tendinosis.[2] This abnormality results in characteristic locking, catching, or Clicking with range of motion. Women are six-times more likely to develop trigger finger than men, with a higher Incidence in patients with Diabetes Mellitus (DM) and Rheumatoid Arthritis (RA) (Adams & Habbu, 2015)[3]. Trigger Finger has no known cause. Female gender, DM, RA, gout and occupations that requiring repetitive finger motions are known risk factors for developing trigger finger (DynaMed, 2017)[4]. Patient may complaint of pain at the level of the A1 Pulley (around the metacarpophalangeal joint)[5], reduced grip strength, and clicking, triggering or locking of digi[6]t. He/she also having difficulty in the extension of digit, a full range of Motion of the affected digit can only achieved by using the opposing hand to assist. In advanced disease, flexion contracture may occur (digit becomes fixed in flexion)

(DynaMed, 2017)[7]. Initial conservative management in adults with trigger finger is recommended by the European HANDGUIDE Group (Huisstede et.al)[8]. Conservative treatments that can be used include oral nonsteriodal anti-inflammatory drugs (NSAIDs) for temporary pain relief, corticosteroid injection[9] (first line treatment for trigger finger), splinting and physical therapy[10]. Surgical intervention is only recommended if the symptoms persists and are significant in nature after the start of conservative management more than one month (Huisstede et.al)[11]. Ultrasound (US) has been used in clinical practice since the 1950s and still remains as a popular intervention for a various clinical problems (Watson, 2017). US waves can be delivered continuously or in pulses. Continuous US generate heat which increases the tissue temperature[12]. This thermal effect is often used in chronic sprains and strains, and for pain relief. Pulsed US tend to generate non-thermal effects such as cavitation and micro streaming. The non-thermal effects are used in stimulation of tissue regeneration, protein synthesis in fibroblasts and tendon repair (Tsai, Tang & Liang, 2011).Since the early 1990s, extracorporeal shock wave therapy (ESWT) has been used in the management of tendon pathologies to ease pain and improve function (Malliaropoulos et.al, 2016)[13]. The physiological and therapeutic mechanism of ESWT is not fully identified but there are some effects that have been confirmed (Watson, 2015). One of the reasons of using ESWT in therapy is that it can bring a tissue from a more chronic to a more acute stage and stimulates repair sequence that has been stalled [14]. There are several treatment effects of ESWT that have been confirmed: mechanical stimulation, increased local blood flow, increased cellular activity, analgesic effect on afferent nerves and breaking down of calcific deposits (Watson, 2015).Therapeutic ultrasound (US) and extracorporeal shockwave therapy (ESWT) have been compared in various conditions in other studies but there are no studies comparing these two modalities in treating trigger finger [15]. So this study is able to compare the 2 modalities and see which one is better in treating trigger finger. Yildirim et.al (2015) had conducted a randomized clinical trial that compared the efficacies of ESWT and corticosteroid injection for the management of trigger finger. In his study, 40 patients with trigger fingers were randomly assigned to ESWT or corticosteroid injection group (20 patients for each group). Visual analogue scale (VAS) was used to measure pain. A 0- to -10 point trigger finger assessment was used to measure the frequency of triggering (FT), the severity of triggering (ST) and functional impact of triggering (FIT)[16]. The Quick-Disabilities of the Arm, Shoulder, and Hand (QuickDASH) self-administered questionnaire was used to measure the symptom severity and functional status of the patient. All these clinical measures were assessment before treatment and after one, two and six months. At the end of study, 36 patients out of the original 40 patients completed the study (19 from ESWT group; 17 from injection group). Both groups showed statistically significant improvements in all outcome measures after treatment. In conclusion, ESWT was suggested as an alternative treatment for patients who didn't prefer corticosteroid injection. Malliaropoulos et.al (2016) had conducted a retrospective cohort study to evaluate the effectiveness of radial extracorporeal shockwave therapy (rESWT) for the treatment of trigger finger. 44 patients with 49 affected fingers or thumb who took part in the study were each given an individually adapted rESWT protocol. The Roles and Maudsley score was used to assess functional outcome after rESWT treatment. VAS was used to measure pain severity. Outcome measures were assessed at baseline (pretreatment) and after one, three and twelve month follow-up appointments (post-treatment). At the end of study, significant reductions in pain score and functional improvement were seen between baselines and all follow up assessments. The study was able to prove the effectiveness of rESWT in treating trigger finger but requiring randomized controlled trials to provide further evidence of the effect [17]. Dogru et.al (2017) had conducted a study that investigated the effect of rESWT in treating trigger finger. 16 patients (18 affected fingers) diagnosed with trigger finger grade 1, 2 and 3 according to Quinnel classification took part in the study. They were subjected to 10 sessions, twice a week of rESWT. Pain scores, general functional, range of motion, grip strength and pinch strength were assessed at every week for five weeks during treatment and 3 months after treatment. It was observed that the patients shown decrease in pain levels and increase in general functional capacity, range of motion, grip strength and pinch strength[18].

Methodology

This was a prospective randomized controlled clinical trial with follow-up at 1st, 2nd, 3rd and 4th week after the initial treatment. Patients who signed informed consent were selected after they were given a brief but detailed explanation of the study aims, benefits and the study procedures. The research protocol was reviewed and approved by the AIMST University

Human Ethics Committee (AUHEC), and it was carried out in accordance with the principles of the Declaration of Helsinki. A formula for a two sided-test of 5%, is $m(size\ per\ group) = \frac{2c}{\delta 2} + 1$ where $\delta = \frac{[\mu 2 - \mu 1]}{\sigma}$ is the standardized size and μ1 and μ2 are the means of the two treatment group, σ is the common standard deviation . The study was started at 17th December 2018 and ended at 13th February 2019. The treatment duration for each visit was about one hour including examination of the patient's condition, and retaking the measurement of pain score and QuickDASH score, and providing the necessary treatments to treat the patient. The details of the treatments are in 3.8 Techniques. There are 2 groups in this study: the US + wax bath group (Group A) and the ESWT + ice massage group. (Group B) These 2 groups will be using different techniques: Group A will be using ultrasound and wax bath; Group B will be using ESWT and ice massage. However, both groups will be given identical exercises that are beneficial in treating trigger finger.

	Intervention
Group A: US, paraffin wax bath and therapeutic exercise	US: Sonopuls 490 that was available in the hospital was used to administer US. The dosage was 3MHz, intensity of 0.5 W/cm^2 and duty cycle 50%. Duration: 5 minutes. The ultrasound gel was applied at the top of the skin of the palm. An electrode was then placed on the area covered by the gel. The electrode was then moved in uniform speed and in circular motion at the affected area for 5 minutes. Paraffin wax bath: The subject was asked to wash his hand before dipping his hand into the wax bath. The subject dipped his hand inside the wax bath for 1 second and then lifted up his hand from the wax bath. He needed to dip his hand 7 times to form a coat of wax around his hand. Subject's hand was wrapped by a plastic before further wrapped by an insulator grove to prevent the heat from dissipating. Treatment duration: 15 minutes. Stretching. The subject's affected finger was stretched by hyper-extending his affected finger and held the position for 10 seconds. The stretch was then released. This was repeated for 15 times. Resisted finger spread using rubber band. Begin by pinching the tips of fingers and thumbs. Put an elastic band around the fingers. The fingers were moved away from the thumb so that the band became tight The position was held for 10 seconds and the stretch was released. This was repeated for 15 times.
Group B: ESWT, ice massage and therapeutic exercise	ESWT: It was administered using Shock Master 500. The dosage is 1000 shocks, 2.1 bars and 15 Hz. Ultrasound gel was placed on the skin of the affected area. The d-actor electrode was placed on subject's affected area. Ice massage for 5 minutes. It was being performed on the area which ESWT was given by using cyrocup. Stretching. The subject's affected finger was stretched by hyper-extending his affected finger and held the position for 10 seconds. The stretch was then released. This was repeated for 15 times Resisted finger spread using rubber band. Begin by pinching the tips of fingers and thumbs. Put an elastic band around the fingers. The fingers were moved away from the thumb so that the band became tight The position was held for 10 seconds and the stretch was released. This was repeated for 15 times.

Data analysis was done by using Statistical Package for the Social Sciences (SPSS) verison 21 (Armonk, NY, IBM Corp). Analysis of varience (ANOVA) with repeated measure was used to test differences in the pain score and QuickDASH scores between 2 groups at the baseline (initial visit) and subsequent visit. Independent t-test was used to compare the difference between US + wax bath group and ESWT + ice massage group on the 1st visit and subsequent visit.

Result

Table 1: Demographics And Clinical Data Of The Patients

	Frequency	Percentage (%)
Study Group		
US+ paraffin wax bath	19	65.5
ESWT+ ice massage	10	34.5
Gender		
Male	6	20.7
Female	23	79.3

	Frequency	Percentage (%)
Ethnicity

Mean Difference of pain score between 4th and 5th visit		
US + wax bath	-.2632	.56195
ESWT + ice massage	.0000	1.15470

Note: SD: standard deviation

Table 4 showed the mean difference of pain scores between visits of both study groups: US + wax bath group and ESWT + ice massage group.

Table 5 Result of mean difference in Pain Score between US + wax bath group and ESWT + ice massage group in First and Subsequent Visits

	t	df	P	Mean difference	Std. error Difference	95% Confidence Interval of Difference	
						Lower	Upper
Pain score difference between 1st and 2nd visit	-2.388	18.000	0.28	-.42105	.17631	-.79147	-.05063
Pain score difference between 2nd and 3rd visit	-8.500	18.000	.000	-.89474	.10526	-1.11589	-.67359
Pain score difference between 3rd and 4th visit	-4.065	26.784	.000	-.88421	.21754	-1.33074	-.43768
Pain score difference between 4th and 5th visit	-.832	27	.413	-.26316	.31618	-.91190	.38559

Note = df: degree of freedom

Table 5 showed the comparison of the mean difference of pain scores between visits in the US + wax bath group with the mean difference of pain scores between visits in the ESWT + ice massage group.

Discussion

The findings of the study show that the combined therapy of therapeutic US and wax bath is more effective than the combined therapy of ESWT and ice massage in reducing pain scores and improving upper limb functionality of trigger finger patients in all visits. The effectiveness of both groups in treating trigger finger can be seen clearly in figure 4.1 and figure 4.2 as both groups show that the US + wax bath group is able to decrease pain score and QuickDASH score steadily throughout the visits but there are no improvement in the ESWT + ice massage group

Ethical Clearance: No ethical approval is needed.

Perintis Kemerdekaan KM.10, Tamalanrea Indah, Kota Makassar, Sulawesi Selatan 9024, Indonesia

Abstract

Introduction: Women underwent caesarean section tend to have higher pelvic floor muscle strength;however, pelvic floor muscle strength in women underwent caesarean section in the second stage of labor have not been widely studied. This study aimed to assess correlation between duration of the second stage of labor with pelvic floor muscle strength in primiparous women underwent vaginal delivery and caesarean section.

Materials and Method: In this prospective study, 58 primiparous women underwent vaginal delivery and second–stage caesarean section were recruited from hospitals affiliated with Hasanuddin University in Makassar, Indonesia. Pelvic floor muscle strength was measured at 6 weeks following delivery. Correlation analysis was performed to estimate the correlation between pelvic floor muscle strength and duration of the second stage.

Results: Demographical characteristics were similar between groups. Primiparous women in caesarean section group had longer duration of second stage than women in vaginal delivery group(206,38 + 107,66 minutes versus 61,89 + 36,67, $P < 0.001$). Mean pelvic muscle floor strength in primiparous women underwent second stage caesarean section were similar to women underwent vaginal delivery(41,99 + 8,59 cm H_2O versus. 41,83 + 12,44 cm H_2O, $P = 0.954$). Duration of the second stage had no correlation with pelvic floor muscle strength in both vaginal delivery (r= 0,248; $P = 0.195$) and caesarean section (r = -0,083; $P = 0.669$).

Conclusion: Duration of the second stage may not alter pelvic floor muscle strength regardless of mode of delivery.

Keywords: *Pelvic floor muscle strength, duration of second stage, vaginal delivery, caesarean section.*

Introduction

Pelvic floor is an important structure that serves as mechanical and functional support of pelvic organs[1,2]. Damage to pelvic floor muscles may lead to increased morbidity associated with pelvic organ dysfunction such as urinary incontinence, anal incontinence, and pelvic organ prolapse[3]. Delivery and aging are both known as significant risk factors that may contribute to pelvic floor dysfunction[3].

Pelvic floor integrity is provided by coordinated mechanism from pelvic muscles, nerves, and connective tissues. Pelvic connective tissue may become principal support system when damage occur to pelvic floor muscles and eventually lead to pelvic organ dysfunction[4].

In many studies, pregnancy and childbirth were the main risk factors for decreased pelvic floor muscle strength and function through stretch and denervation mechanisms[5–7]. Numerous studies have demonstrated that vaginal delivery was considered as the main risk factor for developing pelvic floor dysfunction compared with caesarean delivery[8–10]; however, the studies did not specifically compare the second–stage caesarean section and vaginal delivery in primiparous women.

Prolonged second stage of labor is still widely found in our regions especially at primary health center. Complicated geographic and administrative system may delay referral process and management, thus lead to extremely prolonged second stage of labor.

The current study was undertaken to find correlation between duration of second stage of labor and pelvic floor muscle strength in vaginal delivery and second – stage caesarean section. Besides, we also would like to find if there had been any difference in pelvic floor muscle strength between two groups.

Materials and Method

This study was an observational prospective study conducted in several regional hospitals affiliated with Hasanuddin Univeristy in Makassar, Indoensia between February 2019 – February 2020. Primiparous women underwent vaginal delivery and second – stage caesarean section were recruited by consecutive sampling. Inclusion criteria of this study were primiparous woman with a history of term delivery, 20–35 years old, birthweight from 2500 g–4000 g, no prior gynecologic surgery and troublesome systemic illnesses, and without third to fourth degree perineal tear.

Ethical and research approval for this study were obtained from Hasanuddin University Ethical Committee. All participants were provided by written informed consent. Eligible participants were then evaluated at 6 weeks following delivery. Pelvic floor muscle strength was measured by Peritron perineometer 9300 V. The device consists of a 28 mm diameter – compressible vaginal probe connected to microprocessor. Pelvic floor muscle strength was measured in cm H_2O following insertion into vagina. The measurement are reliable and reproducible as demonstrated by previous studies[11,12].

Before performing measurement, pelvic muscle contraction was ascertained by digital palpation into vagina. Participants were then instructed to contract their muscles as they were trying to hold in gas. Contraction of the abdominal and gluteal muscles had to be excluded in this maneuver. Participants were requested to contract their pelvic muscles as strong as possible, and maintain their contraction as long as possible. Pelvic muscles were than allowed to relax after contraction. After confirming correct pelvic contraction, the probe, covered with condom, was inserted into vagina and three contractions were measured, with a 10 second rest interval. Pelvic floor muscle strength was averaged over the three recorded contractions.

Demographical and clinical data were mainly acquired from medical record. Pelvic floor dysfunctions such as urinary incontinence, anal incontinence, and pelvic organ prolapse were assessed concomittanly with pelvic floor strength measurement. We used Questionnaire for Urinary Incontinence Diagnosis (QUID) to identify any postpartum urinary incontinence following delivery[13]. Anal incontinence was assessed by Wexner scoring system[14]. Pelvic organ prolpase was assesed by Pelvic Organ Prolaps Quantification system (POP-Q)[15].

Demographical and clinical characteristics, such as age, occupation, antenatal care frequency, education, maternal body mass index, active phase progression, and birthweight were analyzed by Pearson chi square or Fisher's exact test. Duration of second stage and pelvic muscle floor muscle strength in both groups were tested for normality by Shapiro Wilk normality test. Independent *t* test or Mann Whitney test were used to compare pelvic floor muscle strength and duration of the second stage between groups. Spearman rank test was used to estimate the correlation between duration of the second stage and pelvic floor muscle strength in both groups. Data regarding urinary incontinence between groups which assessed by Questionnaire for Urinary Incontinence Diagnosis was analysed by Mann–Whitney test after performing Shapiro Wilk normality test. Fisher's exact test was used to analyse Wexner score and POP-Q system between groups.

All data analyses were performed using SPSS 24 statistical software. Statistical significance for all analysis was defined at 5% significance level.

Results

This study focused on primiparous women underwent vaginal delivery and second – stage caesarean section. Secod–stage caesarean section is not as common

as other caesarean sections performed before entering second – stage caesarean section; however, we were able to evaluate 29 participants in this group. Moreover, in our region the duration of the second stage of labor may be extremely long as demonstrated in our study which revelaed the longest duration of second stage of labor was 450 minutes.

Of 58 participants fulfiled eligibility criteria of our study, demographical and clinical characteristics such asmaternal age, occupation, educational level, number of antenatal care visits, neonatal birthweight, and active phase progression were analysed as summarized in Table 1. Primiparous women in vaginal delivery group tended to be younger (P = 0.061). Both groups were likely to have a role as housewife at evaluation (P = 0.256). Educational level was not different between groups (P = 0.083). Almost all women in both second – stage caesarean section and vaginal delivery group had more than 4 times antenatal care visits during pregnancy (89.7% versus 96.8%). All demographical characteristics did not show any significant association with mode of delivery (P> 0.05).

Twenyty–one women (72.4%) women in both groups had normal body mass index (P = 0.771). Abnormal body mass index was not likely to be found in our study population. Twenty–one women (72.4%) in second – stage caesarean section group had neonatal birthweight > 3000 g compared with only 14 women (48.3%) in vaginal delivery group. Women underwent vaginal delivery were more likely to have lower neonatal birth weight even if it was not statitically significant (P = 0.060). Of 29 women in second–stage caesarean group, 21 women (72.4%) had slower progression of active phase of labor, whereas only 13 (44.8%) women in vaginal delivery had this progression abnormality (P = 0.033).

Mean duration of the second stage of labor in women underwent caesarean section was 206.38 + 107.66 minutes. This finding was extremely different with mean duration of the second stage of labor in vaginal delivery group, which was 61.89 + 36.67 minutes (P< 0.001) as shown in table 2. The longest duration of the second stage of labor in caesarean section and vaginal delivery were 450 minutes versus 180 minutes. Mean pelvic floor muscle strength in second – stage caesarean section and vaginal delivery group were similar (41.83 + 12.44 cm H_2O versus 41.99 + 8.59 cm H_2O, P = 0.954). One women in second – stage caesarean section had lowest mean pelvic floor muscle strength among all participants, which was 14.9 cm H_2O. The comparison is shown in figure 1.

Our main goal in this study was to determine if there was any correlation between duration of the second stage of labor and mean pelvic floor muscle strength in both groups (Table 3). We found there was no correlation between duration of the second stage and pelvic floor muscle strength in (r = – 0.083, P = 0.669). Moreover, duration of the second stage and pelvic floor muscle strength in vaginal delivery group also did not show any correlation (r = 0.248, P = 0.195). These correlations are depicted in figure 2a and 2b.

Postpartum urinary incontinence was assessed by Questionnaire for Urinary Incontinence Diagnosis (QUID) as shown in table 4. Stress urinary incontinence was more prone to occur in second – stage caesarean group than vaginal delivery (0.34 + 0.18 versus 0.24 + 0.51 P = 0.044). Maximum QUID stress score in second – stage caesarean was 2.0. QUID urge scores were similar between second – stage caesarean section and vaginal delivery (0.17 + 0.47 versus 0.10 + 0.40, P = 0.410).

Anal incontinence was assessed by Wexner score. Score of zero means perfect anal continence, whereas score equal to or more than 1 indicates any anal incontinence. There was no woman in vaginal delivery group that had experienced any episodes of anal incontinence (Table 5). Three women (10.3%) in second – stage caesarean group had experienced some episodes of anal incontinence, all of which were flatal incontinence. However, they did not have persistent symptom at 6 weeks following delivery. Ultimately, anal incontinence had no associations with mode of delivery (P = 0,237).

Anterior pelvic organ prolpase was found in 2 women (6.9%) in both groups. Uterine prolapse occured in 2 women in second – stage caesarean group and 1 women in vaginal group. In contrast to 2 women (6.9%) with posteior pelvic organ prolapse in second – stage caesarean section, there was no posterior pelvic organ prolapse found in vaginal delivery group. Pelvic organ prolapse and mode of delivery did not show any significant association (p > 0.05).

Discussion

We determined all primiparous women in the main

inclusion criteria as to avoid any confounding variables that may be found in multiparous women. In addition, nulliparous women are considered to have higher mean pelvic floor muscle strength[16]. There were no significant differences in sociodemographic characteristics between groups in our study ($P > 0.05$)

Women lived in rural areas were at increased risk to have prolonged second stage of labor due to referral delays. This may be caused by geographical and administrative obstacles. In addition, women underwent second – stage caesarean section were more likely to have prolonged active phase of labor as reflected by previous study[17]. In our study, we may not be able to identify the exact cause of prolonged second stage as we did not rule out cephalopelvic disproportion as our exclusion criteria.

Our findings suggest that there is no correlation between duration of the second stage of labor and pelvic floor muscle strength in both groups when measured at 6 weeks following delivery. Previous study demonstrated that prolonged second stage may confer greater risk to have decreased pelvic floor muscle strength but the study did not specify delivery method and duration of the prolonged second stage[18]. Fetal head compression at second – stage of labor may incite high pressure to birth canal[19]. This process may severely injure pelvic floor muscles especially in prolonged second stage of labor. This effect may not be accurately determined because most women with prolonged second stage would eventually end up in caesarean section, as demonstrated in our study.

Duration of the second stage in our study was extremely different between groups. Mean duration of the second stage in second – stage caesarean was 206.38 + 107.66 minutes, meanwhile in vaginal delivery group the second stage duration was 61.89 + 36.67 minutes. Difference between groups may result from prolonged length of time to find referral facilities, differences in response time between hospitals, and the ability of health care provider to assess labor progression.

Prolonged second stage of labor which dominantly managed by caesarean section is not likely to decrease pelvic floor muscle strength. There was no difference in pelvic floor muscle strength between groups in our study. We were not able to find primiparous women underwent vaginal delivery with remarkable prolonged second stage of labor as in caesaren section. This limitation did hinder us to find the exact relationship between prolonged second stage of labor and vaginal delivery. Nonetheless, we are still able to infer that prolonged second stage may not have detrimental effect on pelvic floor muscles when managed by caesarean section.

Mean pelvic floor muslce strength in primiparous women underwent vaginal delivery did not differ significantly with second – stage caesarean group (41.99 + 8.59 cm H_2O vs 41.83 + 12.44 cm H_2O). This findings differ from previous study demonstrated that mean pelvic floor muscle strength in women underwent vaginal delivery with episiotomy was 32.71 + 14 cm H_2O and without episiotomy was 53.88 + 20.9 cm H_2O [16]. In addition, the study also found that mean pelvic floor muscle strength in women underwent elective caesarean section was 52.9 + 21.29 cm H_2O and in emergency caesarean section was 48 + 21.04 cm H_2O. Another study found that mean pelvic floor muscle strength in women underwent vaginal delivery and second – stage caesarean section were 27 cm H_2O versus 36.5 cm H_2O, though the study did not performed exclusively for primiparous women[18]. Different results between studies may result from distinct subject characteristics, as well as time interval between delivery and pelvic floor evaluation in which we performed at relatively shorter duration following delivery.

Our study demonstrated that there was no significant difference in pelvic floor muscle strength between groups. This may result from full recovery of pelvic floor muscle that may take place at 6 weeks following delivery. However, a study has stated that restoration of pelvic floor muscle strength may be achieved at 8 weeks following vaginal delivery. Moreover, pelvic floor damage exclusively occurs in a woman with a history of vaginal delivery[5]. This may confirm similarities of pelvic floor muscle strength between groups in our study in which no extensive pelvic damage occured in second – stage caesarean section and full restoration of pelvic muscle did take place in vaginal delivery.

Women in second – stage caesarean section group were more likely to experieced stress urinary incontinence as evaluated by *Questionnaire for Urinary Incontinence Diagnosis* (QUID). In contrast to our study, some studies described that women underwent vaginal delivery were more prone to have stress urinary incontinence compared with women underwent caesarean section[19,20]. The difference with our study may result from special population enrolled in our study, which limited to second

– stage caesarean section. In addition, our study suggests that stress urinary incontinence was more likely to occur in older women and women with a history of prolonged second stage. Another study demonstrated that there was no relationship between duration of the second stage of labor and urinary incontinence occurence[21]. However, the study did not specify the mode of delivery. All women with episodes of stress urinary incontinence had neonatal birthweight more than 3000 g. This finding is different with previous study demonstrated that there was no association between birth weight and stress urinary incontinence; nevertheless we did not estimate this association as the number of subjects with stress urinary incontinence were ultimately low[22].

In contrat to stress urinary incontinence, urge urinary incontinence tend to occur in younger women with normal body mass index. Many studies suggest that urge urinary incontinence is not associated with mode of delivery and may occur sporadically following delivery[23]. Although urge urinary incontinence was more likely to occur in women with second – stage caesarean section, we were not able to determine if it was a true urge urinary incontinence as we did not perform urinalysis examination to rule out genitourinary tract infection. Our study suggests that both stress and urge urinary incontinence may occur transiently following delivery as none of our participants had persistent symptoms.

Perfect anal continence was found in all women underwent vaginal delivery, whereas 3 women in second – stage caesarean group had experienced some episodes of anal incontinence following delivery. This findings may indicated that second – stage caesarean section may confer greater risk to have anal incontinence especially in prolonged second stage of labor. Prevalence of anal incontinence following delivery is extremely small and flatal incontinence is the most frequent type occur following delivery[24,25]. Moreover, postpartutm anal incontinence tends to occur sporadically without identifiable risk factors as shown in our study[26].

Pelvic organ prolapse occurences were low regardless of mode of delivery. A previous study described that about 18% primiparous women underwent vaginal delivery and 7% women underwent caesarean section would eventually have second stage pelvic organ prolapse when evaluated at 6 months following delivery[9]. The study may indicate mode of delivery as a risk factor for pelvic organ prolapse; however, the study did not specifically conducted in second – stage caesarean section[27]. Another study found that only 11% women would eventually have pelvic organ prolapse regardless of the mode of delivery[18].

In our study, prolonged second stage and vaginal delivery may not be a risk factor for developing pelvic organ prolapse; however, we were not able to estimate the effect of extremely prolonged second stage in vaginal delivery. Previous study suggested that prolonged second stage of labor may increase the risk of levator anii muscle damage about 5.32 times, but he did not specify the duration of the second stage[28]. However, even if damage occurs in levator ani muscle, it may eventually recovered following delivery.

Limitations to our study were that there was siginificant difference of the duration of the second stage of labor between groups. This would impede our ability to predict the correlation between groups accurately. Nevertheless, we are able to infer that even extremely prolonged second stage would not cause extreme detrimental effect on pelvic floor muscle strength when managed by caesarean section. Relatively low sample size in our study may serve as a model for further study to be conducted in larger sample size and longer duration for evalution following delivery.

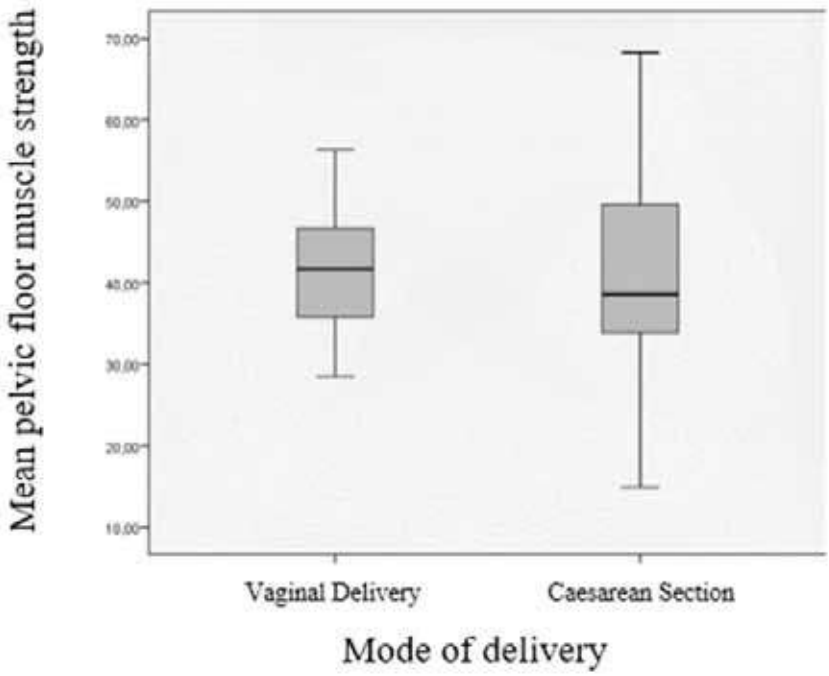

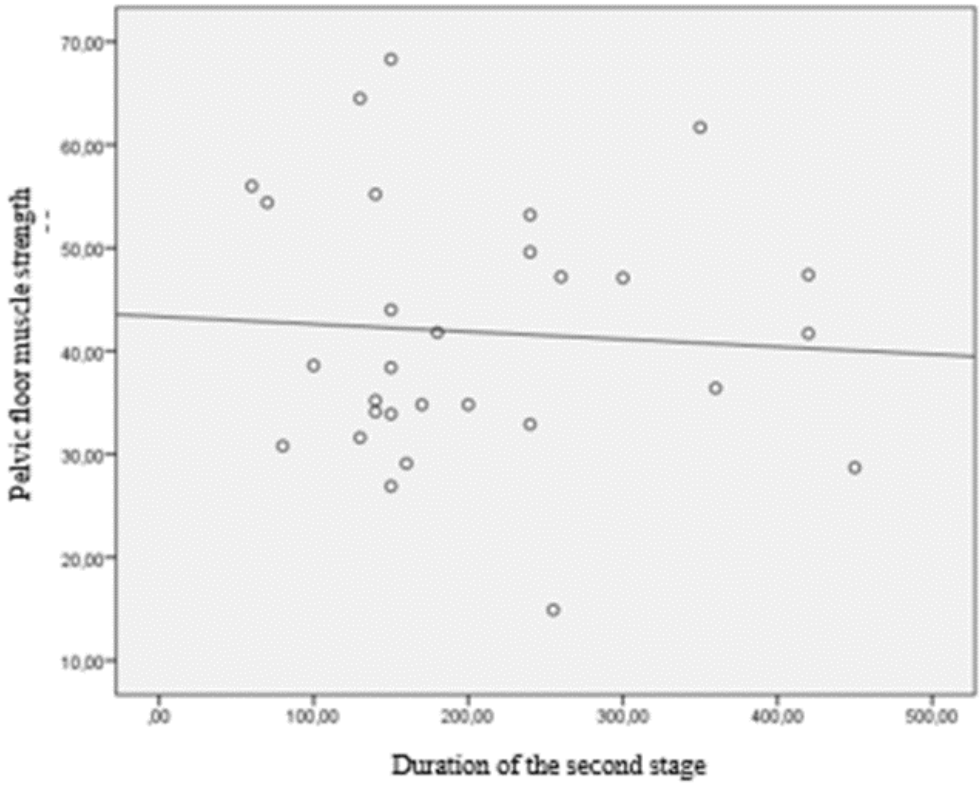

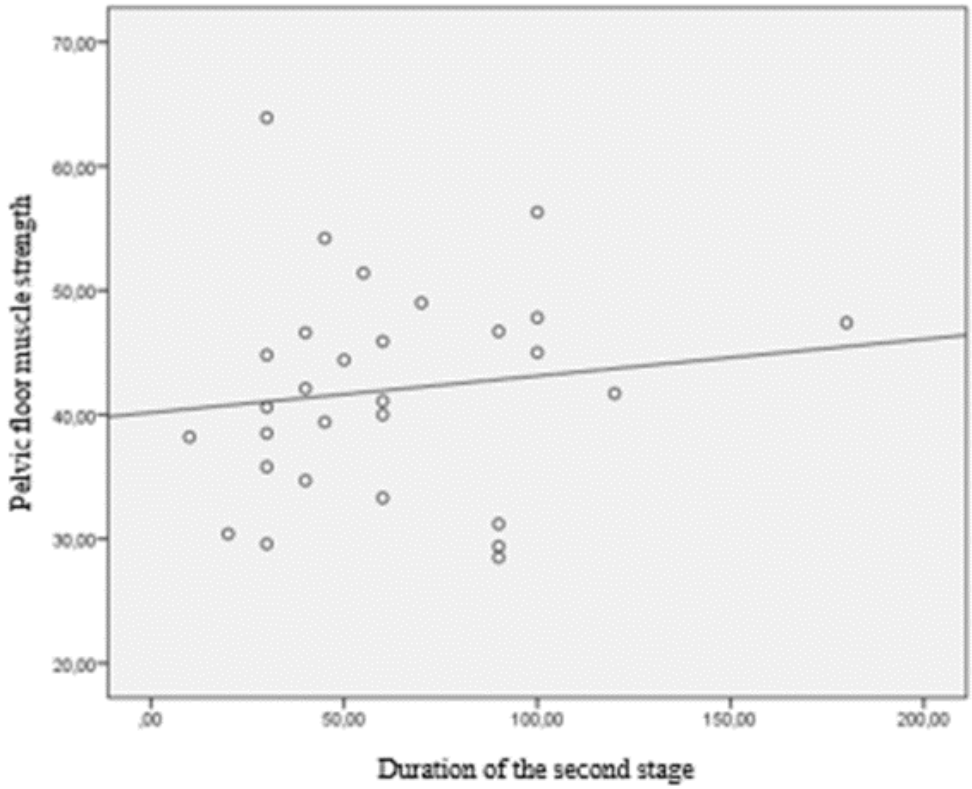

Figure 1. Comparison of mean pelvic floor muscle strength between caesarean section and vaginal delivery.

(a)

(b)

Figure 2. Correlation between duration of second stage and pelvic floor muscle strength in caesarean section (a) and vaginal delivery (b).

Conclusions

Pelvic floor muscle strength in primiparous women underwent second stage Caesarean section and vaginal delivery did not differ significantly after evaluation in 6 weeks following delivery. Duration of the second stage between groups was extremely different. Moreover, there were no correlation between duration of second stage and pelvic floor muscle strength on both groups. There were no differences in pelvic organ dysfunction between groups.

User Centered Portable Suspension Therapy Unit Design & Testing on Healthy Volunteers

Kaviarasu Mahalingam[1], Karthikeyan Jayabalan[1], Sree Vamsi[1], Yu Chye Wah[2], Angeline Qnah Lie Mun[3], Khor Yi Wei[3], Winnie Tan[3]

[1]Lecturer, [2]Assoc. Professor, [3]Research Scholar, School of Physiotherapy, Faculty of Allied Health Professions, AIMST University (Malaysia)

Abstract

Background: Suspension is a therapeutic skill that suspends a body and eliminates effects of friction to ease the movements. It is very beneficial in both musculoskeletal and neurological field.

Objective: To make suspension therapy more accessible for a physiotherapist domestically which provide an opportunity for patient to receive suspension therapy in any occasion.

Study Design: Pilot study.

Sample Size: 30 healthy subjects from Hospital or AIMST University (with various body sizes).

Discussion: The overall satisfaction level for the Portable Suspension Kit is pleasant. The subjects acknowledge that suspension therapy helps to improve range of motion and is suitable for home rehabilitation and both statements score the highest which is 3.9667±0.66868 out of 5. On the contrary, the subjects agree less on the stability of the frame which results show 3.7±0.98786 out of 5. Whereas, for R.A. tracker, the outcome of accuracy level turned out to be 65.2% which is of moderate range and the result is acceptable for a new prototype. $P > 0.652$ is not statistically significant due to the sensor sensitivity of calibration. Thus, we strongly agree that the deficiency needed to be improved to allow accurate visual feedback.

Conclusion: The making of 'Portable Suspension Kit' is successful and indeed is convenient to carry around. Suspension therapy can now be widely used in any occasion on the patients. Nevertheless, it still has more to improve especially on the stability and the material used to make it safer, lighter and easier to carry.

Introduction

Suspension therapy is very beneficial in both musculoskeletal and neurological field; it has some disadvantages which are yet to be overcome. It is big, heavy and immobile causes it impossible to Transport and limit the suspension exercise only to a specific location. In medical search engines such As Pub Med, NCBI, and Medscape is lack of information and article for sling suspension Therapy[1]. This may be due to suspension therapy is not widely used in the medical field as it requires

More time to set up the slings and cuffs. Besides, this topic is overlooked[2]. Although had some research did the research or study, most of them were focused on low back pain or urinary incontinence, which was lack of information focus on musculoskeletal and neuromuscular[3]. Suspension therapy also known as sling therapy is one of the therapeutic technique where a part of the body is supported by a sling and suspended by ropes to the fixed point on suspension frame[4]. It frees the body from friction and helps to move the body easier with less resistance. (John George B, 2002)[5]. Hence,

this helps the patient in reducing the axial load on the joint while the patient is performing the exercises. Suspension therapy can be either used as an assistance exercise or resistance training[6]. There are 3 main principles used in suspension therapy which is friction, pendulum and eliminating gravity movements. Firstly, fiction is produced when a particular surface moves on another. In suspension, friction is less, therefore causes smoother and easier movement. Secondly, a pendulum is a heavy material suspended by a weightless thread. When the force is applied to the pendulum it results in movement[7]. In the human body, pendular motion occurs mainly at the shoulder and hip joints, forward leg movement and arm swing while walking[8]. This helps to maintain muscle properties, increase range of motion and strengthen the muscle. Lastly, it comes to eliminating gravity movement, the patient should at least have muscle power grade 2 for suspension exercise[9]. The therapist is able to alter the patient's position while doing the exercise[10]. The accessories used in suspension therapy, e.g. suspension frame, connecting rope, wooden cleat, dog clip or S-hook and spring. Connecting ropes provide attachment for a sling to the steel and able for adjustment in length[11]. Though its effect such as strengthening muscle, increase range of motion, and improve coordination are similar to those of other forms of exercise[12], additional characteristics of suspension therapy make it[13] particularly useful and unique. Other than those mentioned[14], the suspension also helps to improve stability of the joint, stimulate the sensorimotor system and improve patient confidence to undergo exercise or rehabilitation programme[15].

Method and Subjects

A qualitative research model in the form of a prospective type quasi experimental study design is carried out in this study. The study is conducted in collaboration with AIMST University Malaysia, University of Indonesia, NMT Institute Italy & USA, Institute of Paramedical Sciences, Kannur, India and Mekelle University Ethiopia. In this study all Academic and non-academic professionals are the population for this study. Conveniently 800 participants among the academic professionals are selected in collaboration with AIMST University Malaysia, University of Indonesia, NMT Institute Italy, USA, and Mekelle University Ethiopia & Institute of Paramedical Sciences, Kannur, India.

Standard Application procedure: Patients diagnosed by Low back and neck pain for at least 6 months,

Features: Width Cm 5 and Length 30 cm.

Reference points: Intergluteal line - Vertebral column.

Patient standing with hands resting on a table, anterior lumbar flexion of 45°. Apply the base of the tape on the interglutea line and laterally 2 cm from the vertebral column. Remove the paper leaving only a small piece to hold the strip. Ask the patient to round the lumbar section (ask to "pull in the belly", the skin over the lumbar area must be stretched). The tape is applied with absolutely no tension[16]. The tape is applied parallel to the column and must end at exactly the same level. The treatment was given twice per week for 6 weeks (8-10 sittings). The cure tape is approved by the FDA and the product name is Tape and bandage, adhesive. Before the primary neuromuscular taping application VAS (visual analogue scale for pain scaling) and back pain index (Oswestry Low Back Pain Disability Questionnaire) were collected and this procedure was continuing till the end treatment sessions. This portable suspension kit is invented to help the physiotherapist to make use of the suspension therapy domestically. Because we found out that there is difficulty in applying suspension therapy in a ward, home-based rehabilitation and nursing house[17]. The difficulties are due to the large size and heavy weight of the suspension frame which make it not portable and mobile. The new invention portable suspension kit is foldable and light in weight which can be carried by the physiotherapist. It can follow the patient wherever he is and can be easily kept. It offered a portable and mobile frame to perform the suspension therapy in need of the patient which is very beneficial in the rehabilitation progression. The reason why we are inventing a R.A tracker is to calculate the repetition and accuracy of the patient performing the movement instructed which is very important for the outcome of the rehabilitation. Setting a target for a patient to complete can be a motivation in rehab. Sometimes, they may get bored, sleepy and during exercise and forget in counting the repetition. Hardship may be felt during rehab, so patient sometimes will find excuses for not completing the exercise that is given[18]. This tracker is now useful in this case by helping them calculate the repetition when they are performing the exercise and cheating is prevented because a repetition can only be counted as one when u reach a targeted angle and during back to starting position

it should be less than 5 degrees. Repetition is important during rehabilitation because the neuronal circuits can be changed by the neuroplasticity in the brain's ability. For example, increasing the amounts of the task repetitions proved that it can help in cortical changes and functional improvement in a post-stroke patient. The main point to focus on rehabilitation professionals should be the number of repetitions and the type of activity performed per session. According to the current research shows that most of the physiotherapy session does not contain the proper and sufficient amount of repetitions in each session to cause actual changes in the brain. Thus, one item of focus for rehabilitation professionals should be the number of reps and type of activity performed in each session. Current research, however, shows that most therapy sessions do not contain the proper amount of repetitions per session to cause actual changes in the brain. Typical therapy sessions, whether physical, occupational, speech, or behavioral, last about one hour per session with the therapist employing various tasks and exercises throughout the session[19].

Methodology

The study duration is about one year and treatment duration is one treatment twice a week with 30 minutes per session which held at AIMST University Physiotherapy Clinic and private clinic with the size of 30 samples from AIMST University Physiotherapy clinic and private clinic. The sample was contacted twice a week and one treatment session is 30 minutes.

Results

Table 1: Sample Characteristic

	Frequency	Percentage
Gender		
Male	15	50%
Female	15	50%
Age Category		
21 - 30	13	43.3%
31 - 40	9	30.0%
41 - 50	4	13.3%
51 - 60	2	6.7%
61 - 70	1	3.3%
70 - 80	1	3.3%
Weight Category		
Less than 50 kg	4	13.3%
51kg – 70kg	12	40.0%
71kg – 90kg	9	30.0%
91kg – 110kg	5	16.7%
More than 110kg	0	0%
Height Category		
Less than 150cm	2	6.7%
151cm – 160cm	4	13.3%
161cm – 170cm	8	26.7%
171cm – 180cm	12	40.0%
More than 180cm	4	13.3%

Table 1 shows this demographic characteristic of samples participated in this study. In this study, consists of 15 male and 15 female as a sample with a percentage of 50% respectively. The sample was divided into 6 groups in the age category. Between the age of 21 to 30 consists of 13 samples (43.3%); 9 samples (30.0%) in the age between 31 to 40; 4 samples (13.3%) in the age group within 41 to 50; 2 samples (6.7%) with age range from 51 to 60; the age group with the range of 61 to 70 and age within 71 – 80 only have 1 sample each (3.3%). We divided the weight category into 5 groups. We have 4 persons (13.3%) in the group with a weight of less than 50kg. weight range from 51kg to 70kg is 12 persons (40.0%) from the weight range from 51kg to 70kg; 9 samples (30.0%) from the weight group of 71kg to 90kg and 5 samples (16.7%) from the last weight group with the range of 91kg to 110kg. In this study, we did not include any sample with the weight that exceeds 110kg. There were 5 different groups divided in the height category. For the height less than 150cm consists of 2 samples (6.7%); 4 samples (13.3%) with the height range of 151cm to 160cm; 8 samples (26.7%) with the height range of 161cm to 170cm; 12samples (40.0%) with the height range from 171cm to 180cm and 4 samples (13.3%) with the height more than 180 cm. Table 5.1 shows the weight, height and after 4 sessions of 2 weeks treatment samples satisfaction level on pain relief, range of motion, muscle strength, home rehab, and stability. The mean weight value of the samples is 69.0667±18.69710 and the mean height of the samples is 169.3000±11.16383. The average satisfaction level on pain relief is 3.8333± 0.59209; improving in range of motion is 3.9667±0.61495; improving in muscle strength 3.8000±0.66436; for home rehabilitation purpose is 3.9667±0.66868 and stability of the frame is 3.7000±0.98786. Table 5.2 shows the correlation

between weight, height, and stability. The correlation test shows that body weight is significantly related to height (r= 0.851, P< 0.01). In comparison between body weight and stability, r= -0.692 which demonstrates that body weight is significant to stability (P< 0.01). In regards to the correlation between height and stability, the result depicts the coefficient -0.652 which clearly shows that height is significant to stability (P< 0.01) in figure 1.0 which is the receiver operating characteristic (ROC) graph with the angle of movement against repetitions. In table 5.3 the result demonstrates the area under the curve is 0.652. The percentage of the sensitivity is 65.2% and the result of the area under the curve is not statistically significant (P> 0.05). Even though the result is not significant but it is still considered moderate and acceptable. The coordinates of the curve in table 5.4 shows that if the test results can be improved to 27.5 % than the sensitivity can be enhanced to 96 %.

Table 2: Descriptive state of weight, height and satisfaction level on pain relief, range of motion, muscle strength, home rehab, and stability.

Variable	Mean	Std. Deviation
Weight	69.0667	18.69710
Height	169.3000	11.16383
Pain relief	3.8333	0.59209
Range of motion	3.9667	0.61495
Muscle strength	3.8000	0.66436
Home rehab	3.9667	0.66868
Stability	3.7000	0.98786

Table 3: Correlation between weight, height and stability.

Area	Std. Error	95% Confidence Interval		P
		Lower Bound	Upper Bound	
0.652	0.120	.416	.888	0.290

Discussion

The 'R.A. Tracker' is advantageous for physiotherapists in decreasing the workloads, the mission of counting the repetition and observing the angle can now be done by the tracker. It alleviates the burden on the physiotherapists so that they can pay attention to observing any secondary movement or the appropriate muscle action. The tracker uses battery-powered liquid-crystal display (LCD) as display of the device. The repetitions and angle can be pre-set which makes the treatment effective by providing biofeedback to the patient. This allows the patient as well as the therapist to be aware of the quantity and quality of the movements, at the same time enables the therapist to set a target to the patient. In general, the 'Portable Suspension Unit' performs a more professional appearance in contrast to the traditional suspension therapy. During the trial of the R.A. tracker, 15 repetitions of specific movements are prescribed to the subjects. The examiner was beside the subject comparing the exact movement and angle while comparing it to the tracker. The outcome turned out to be 65.2% which is in mid-range. The accuracy is acceptable for a new prototype. There are many reasons that caused it to be less precise and further enhancement is needed to make it more perfect. $P > 0.652$ is not statistically significant due to the sensor sensitivity of calibration. Sensitivity is significant as it refers to the input signal required to project the output of the device and it shows the true positives in some situations. Therefore, its deficiency needed to be improved to allow accurate visual feedback. The calibration process takes time due to the Auto-Calibration process in the Digital Motion Processor (DMP) itself. The DMP uses an algorithm to Auto Calibrate the values over time.

This time varies across each MPU6050 sensor as there is a slight variation and offset in the sensor due to the manufacturing process. This would affect the speed of the auto-calibration process. One way to improve the auto-calibration speed is to supply an offset for the sensors prior to the auto-calibration. The offsets are unique to every MPU6050 sensors due to the manufacturing process and slight variations in each sensor. (V. Christ, 2017) the sensor becomes less accurate over time due to gyro drift in the gyroscope within the sensor. The gyroscope has an internal bias or noise within the sensor. The bias or noise changes over time due to various factors such as temperature or just an inherent noise in the sensor. Hence when the raw values are fed into the DMP it would auto-calibrate based on the current bias or noise.

Conclusion

In conclusion, we found out that suspension therapy still very high demanding for rehabilitation treatment in our country no matter in hospital, private clinic, etc. through our survey, the heavy, big and immobile suspension frame brings a lots of inconvenience for the physiotherapist who wish to do home rehabilitation, ward and for patient with difficulty in ambulation and more. The survey result shows that the majority agreed that suspension therapy brings tons of benefits to the patient and our invention The Portable Suspension Unit will help in fulfilling their needs for domestic purpose. We also gained some bits of advice from the minority which not satisfied with our invention. From here we'll have more discussion and enhancement regarding the limitation of our portable suspension kit and take into consideration to make changes such as the design, materials, and weight to make it more convenient and functional.

The Comparison of Gestational Diabetes Mellitus Screening between the One Step Method and the Two Step Method

Arini Estiastuti[1], Deviana Soraya Riu[1], Nur Rakhmah[1], St. Maisuri T. Chalid[1], Nugraha Utama Pelupessy[1], Johnsen Mailoa[1]

[1]Department: Obstetrics and Gynecology, Researcher at Faculty of Medicine, Hasanuddin University, Jl. Perintis Kemerdekaan KM.10, Tamalanrea Indah, Kota Makassar, Sulawesi Selatan 9024, Indonesia

Abstract

This research aimed to compare the results of gestational diabetes mellitus (DMG) screening based on the One Step and Two Step method. This research was a cross-sectional study conducted in pregnant women 24-28 weeks of gestation who meet the research criteria. The diagnosis of gestational diabetes using the One Step and Two Step method was each carried out on 53 pregnant women so that the total sample of the research was 106 pregnant women. The results showed that 28.3% of pregnant women (15/53) were diagnosed with DMG with the One Step method compared with 3.8% (2/53) of pregnant women diagnosed by the Two Step method. There was a significant difference ($p < 0.05$) between the diagnosis results of the two DMG diagnosis method. Further analysis of DMG risk factors showed that the highest positive likelihood ratio (LR +) was found in the history of macrosomia with LR + = 4.45 with the One Step method while the highest LR + for the Two Step method was found in obesity factors for pregnant women with LR + = 6.57. The highest positive predictive value (PPV) for the One Step method of 46.70% was found in pregnant women with risk factors for obesity while the Two Step method was found in pregnant women with a history of DM (PPV = 100%). Pregnant women diagnosed with DMG were significantly greater in the One Step method than the Two Step method. History of macrosomia (is found) as a risk factor for pregnant women diagnosed with DMG with the One Step method, while a history of DM for the Two Step method.

Keywords: *Diabetes mellitus, pregnancy, screening, risk factors.*

Introduction

Gestational diabetes mellitus (DMG) is a carbohydrate intolerance of varying degrees that occurs or is first known during pregnancy. Diabetes mellitus is a medical complication that often occurs during pregnancy. According to the American Diabetes Association (ADA) in 2004 gestational diabetes mellitus occurred in about 4% of all pregnancies in the United States, and 3-5% in the United Kingdom. The prevalence of gestational diabetes mellitus in Europe is 2-6%[1].

Increased perinatal morbidity and mortality in pregnancy with DMG is directly correlated with maternal hyperglycemia. The effect shown by mothers with gestational diabetes mellitus is that they have high risk of excess weight gain, the occurrence of preeclampsia, eclampsia, cesarean section, and cardiovascular complications to maternal death. After delivery occurs, the mothers are at risk of developing type 2 diabetes mellitus or recurring gestational diabetes in subsequent pregnancies while babies born to mothers who have gestational diabetes are at high risk of experiencing macrosomia and birth trauma. In addition, babies are also at risk of developing hypoglycemia, hypocalcemia, hyperbilirubinemia, respiratory distress syndrome, polycythaemia, obesity and type 2 diabetes mellitus[2].

Screening is done to identify asymptomatic individuals who are at high risk for having or are in the development of certain diseases. Screening can be done as a two-step or one-step process. In the two-step technique, the first step is carried out to identify individuals who are at risk of disease, so that the second step (a more definitive diagnostic test, but usually more expensive and complex than screening) is only done in groups that are truly at risk and not carried out in groups low risk. While the One Step technique is done by filtering all individuals. Over the past three decades, the procedure and criteria which are most widely used to detect early DMGs is the two-step procedure (wherein): oral glucose tolerance test 1 hour 50 g and is followed by 3 hours 100 g for positive cases at initial screening. The One Step procedure is carried out with a simple step of performing an oral glucose tolerance test of 2 hours 75 g but (it) requires fasting for 8-14 hours before the glucose check[3].

Until now, there is still no agreement on the most appropriate screening method or DMG screening for pregnant women in Indonesia. For this reason, an approach is needed about screening for DMG so that it can improve pregnancy outcomes for both mother and baby.

This research aimed to compare the results of gestational diabetes mellitus (DMG) screening based on the One Step and Two Step method.

Methodology

This research was an analytic study with cross-sectional approach. Sampling was done by simple random sampling with the ordinal method until the required number of samples was met. The minimum sample required for this research is 53 samples for each of the One Step and Two Step method so that the total sample of this study was 106 samples.

Sample: The sample in this research were pregnant women who came to the Obstetrics and Gynecology clinic in Wahidin Sudirohusodo Hospital, Jumpandang Public Health Center, Tamalanrea Jaya Public Health Center, to undergo a pregnancy check during the research period that met the inclusion and exclusion criteria. Inclusion criteria in this research were pregnant women — who are 18 years old or older, gestational age are between 24 and 28 weeks, who have single pregnancies, and who are willing to be involved in the research. The exclusion criteria in this research were pregnant women who are having medical or obstetric complications during pregnancy, being treated for diabetes mellitus, and not being able to undergo an Oral Glucose Tolerance Test (TTGO) due to nausea or vomiting.

Procedure: The way this research worked was by explaining the purpose and objectives of the research to pregnant women, if they are willing to take part in the research, pregnant women sign an agreement. Anamnesis was conducted on the research participants and other data were recorded in the research sheet, then DMG diagnosis test with the One Step method and Two Step method were carried out.

GDM diagnosis using the One Step method: Patients were asked to fast for at least 8 hours before the test. OGTT was performed in the morning after fasting — with 75 grams of glucose in 250 mL of water. Glucose level examination was done when the patient was fasting, 1 hour and 2 hours after OGTT. Analysis of blood glucose levels was carried out using the GOD-PAP method in serum at Prodia Laboratory Makassar. The diagnosis of GDM is positive if one or more of the following criteria has an abnormal (greater) value:

Glucose Examination	Glucose level	
	mg/dL	mmol/L
Fasting blood sugar	92	5.1
Glucose at 1 hour	180	10
Glucose at 2 hour	153	8.5

GDM diagnosis using the Two Step method:

Step 1. 50 gram glucose loading test (without fasting) was carried out, plasma glucose levels were measured 1 hour after glucose loading. If the plasma glucose level on 1 hour after glucose loading> 140 mg/dL (7.8 mmol/L) then (the test)would be followed by OGTT 100 grams of glucose.

Step 2. OGTT 100 grams of glucose was performed on patients in a state of fasting. Glucose level examination was performed when the patient was fasting, 1 hour, 2 hours and 3 hours after OGTT. Analysis of blood glucose levels was carried out using the GOD-PAP method in serum at Prodia Laboratory Makassar. The diagnosis of GDM is positive if two of the four plasma glucose measurements exceed the following values:

Glucose Examination	Glucose level	
	mg/dL	mmol/L
Glucose 50 mg/dL	105	5.8
Glucose 100 mg/dL at 1 hour	190	10.6
Glucose 100 mg/dL at 2 hour	165	9.2
Glucose 100 mg/dL at 3hour	145	7,9

Data analysis: Differences in the characteristics of the research sample between the two groups were tested by the independent t test, the Mann Whitney test and the Chi square test. Differences in diagnosis results between the One Step and Two Step method and differences in the characteristics of the research sample based on the diagnosis of DMG were tested by Fischer's exact test. Data were analyzed with SPSS with significance level (p) <0.05.

Results

This research involved 106 pregnant women consisting of 53 pregnant women getting DMG diagnosis test with the One Step method and 53 pregnant women with the Two Step method. This research was carried out on pregnant women with 24-28 weeks gestation and had passed the screening process for DMG as a research sample.

Table 1. The characteristics of research samples

Characteristics	One Step Method (n = 53)	The Two Step Method (n = 53)	
Mother's age (mean ± SD year)	27.3 ± 5.1	29.4 ± 6.1	0.056 *
Parity			
Primipara	26 (49.1%)	22 (41.5%)	0.558 ***
Multipara	27 (50.9%)	31 (58.5%)	
Gestational age (mean ± SD week)	25.8 ± 1.2	25.9 ± 1.3	0.487 **
Family history of DM			
Yes	5 (9.4%)	4 (7.5%)	1,000 ***
Not	48 (90.6%)	49 (92.5%)	
Macrosomia History			
Yes	4 (7.5%)	2 (3.8%)	0.678 ***
Not	49 (92.5%)	51 (96.2%)	
BMI (kg/m^2)			
≥ 30	44 (83%)	46 (86.8%)	0.786 ***
<30	9 (17%)	7 (13.2%)	

*Independent t test, **Mann Whitney Test, ***Chi Square Test

Table 1 shows (that) the proportions for the age of pregnant women, parity, gestational age, risk factors for family history of DM, history of childbirth, macrosomia and BMI ≥30 kg/m^2 for both DMG diagnosis method is almost the same. The results of further statistical tests on the research sample in the two diagnosis groups showed no significant difference in characteristics (p> 0.05) between the two research groups so that the two groups were comparable.

Table 2. The diagnosis of DMG based on the One Step and Two Step method

DGM diagnosis	One Step Method (n = 53)	Two Steps Method (n = 53)	p*
Positive	15 (28.3%)	2 (3.8%)	.001
Negative	38 (71.7)	51 (96.2%)	

* Fischer Test

Table 2 shows (that) the general prevalence of DMG in this research was 16.04% (17/106). DMG was diagnosed more in the One Step method than the Two Step method. DMG diagnosis results of this research consisted of 15 pregnant women (28.3%) diagnosed by the One Step method and 2 pregnant women (3.8%) diagnosed by the Two Step method and there were significant differences ($p < 0.05$) between the diagnosis results from both method of diagnosis of DMG.

Table 3. The comparison of DMG screening diagnosis results based on risk factors

Risk Factors	One Step				Two Step			
	PPV (%)	NPV (%)	LR +	LR -	PPV (%)	NPV (%)	LR +	LR -
DM history	26.70	97.40	3.49	0.26	100.00	96.10	-	0.50
Macrosomia History	26.70	100.00	4.45	0.00	0.00	96.10	0.00	1.04
BMI	46.70	94.70	4.28	0.27	50.00	88.20	6.57	0.88

PPV = positive predictive value, NPV = negative predictive value, LR + = positive likelihood ratio, LR- = negative likelihood ratio

The data in table 3 shows (that) the highest positive likelihood ratio (LR +) was found in the history of macrosomia with LR + = 4.45 with the One Step method while the highest LR + for the Two Step method was found in the obesity factor of pregnant women with LR + = 6.57. The highest positive predictive value (PPV) for the One Step method of 46.70% was found in pregnant women with risk factors for obesity while the Two Step method was found in pregnant women with a history of DM (PPV = 100%).

Discussion

This research aimed to compare the results of gestational diabetes mellitus (DMG) screening based on the One Step and Two Step method. In this research, the prevalence of DMG was 16.04%. Research by Melchior et al (2017), reports that regardless of the screening method used, the prevalence of DMG has tended to increase in the past decade[4]. Another study by Ferrara (2007), reports that in the last 20 years there is an increase in the prevalence of DMG between 10-100% in the world[5]. This increase is in line with the increasing epidemic of type 2 diabetes mellitus and obesity. Globally, the prevalence of hyperglycemia in pregnancy (DMG and type 2 diabetes in pregnancy) is estimated to reach 15%. A retrospective cohort study of 567,191 pregnant women found a prevalence of 13.2% [4]. The prevalence of DMG varies between 1-28% depending on the characteristics of the population.

The true prevalence of DMG is difficult to estimate because of differences in risk factors in the study population, such as maternal age, BMI, diabetes and ethnic prevalence. In addition, the screening strategy, the testing method used, and the glycemic threshold used also differ. The use of data in reporting also greatly influences the prevalence of reported DMG.

The research also showed that pregnant women diagnosed with DMG were higher in the One Step method compared to the Two Step method. Some researches show the same results as this research. Research in Turkey in pregnant women with gestation of 24-28 weeks and using universal screening of 50 grams of TTGO reports a prevalence of DMG of 14.5% with the One Step method and 6% with the Two Step method[6]. Another research in Thailand also shows a greater diagnosis of DMG done by the One Step method (32%) compared to the Two Step method (10.3%)[7]. Research in Iran also shows the incidence of DMG is also higher with the One Step method (9.3%) compared to the Two Step method[8]. Conversely, a meta-analysis in 2. 333 pregnant women reports no significant difference in the incidence of DMG between the One Step and Two Step method [9]. However, this meta-analysis also shows that the One Step method is associated with better maternal and perinatal outcomes compared to the Two Steps method in terms of lower incidence of preterm labor, NICU care and neonatal hypoglycemia. The Two Step Method also deals with reducing the number of DMGs that cannot be followed up (lost to follow up) by about 5% thereby reducing the incidence of DMG [10]. lower NICU care and neonatal hypoglycemia. The Two Step Method also deals with reducing the number of DMGs

that cannot be followed up (lost to follow up) by about 5% thereby reducing the incidence of DMG [10]. The One Step Method increases the prevalence of DMG from 1.03 to 3.78 times compared to Two Step [11]. The results of this research are comparable to Brown's research that found a positive diagnosis of DMG with the One Step method increased about 2-fold from the positive diagnosis result by the Two Step method. Another research based on differences in the risk of DMG in pregnant women which are low risk and high risk shows DMG increased from 7% to 11.7% in high risk pregnant women using the One Step method [12]. Other researches have even reported a higher incidence of DMG (between 16% to 27%) with the One Step method compared to Two Step [13,14].

The difference in the prevalence of DMG between the One Step and Two Step method between researches can be caused by differences in population characteristics such as sample size, ethnicity/race, and DMG risk factors. Several studies have shown that ethnic/racial factors have implications for the prevalence of DMG worldwide. The prevalence of DMG increases significantly in European populations in the One Step method compared to Two Step.

The DMG diagnosis approach is still being debated to this day. Based on the results of this research it was found that the diagnosis of DMG was significantly higher by the One Step method compared to Two Step method. There are several arguments related to the benefits and risks of using the One Step method as a DMG diagnostic approach. The One Step method is superior to the Two Step method because the women examined and showed positive results with the One Step method but negative with the Two Step method (meaning, having symptoms of lighter glucose intolerance) still have a higher risk for experiencing pregnancy complications such as gestational hypertension, preeclampsia and cesarean section, moreover, the babies born are also at risk of complications. Thus women who tested positive for the One Step method are eligible to be diagnosed with DMG and given treatment to reduce the risk of complications. Another advantage of the One Step method is that the level of patient compliance is higher compared to the Two Step method which is reported to be around 15% of patients not taking the second test. The use of the Two Step method can be a burden on patients. In addition to these two reasons, the One Step method is also more cost effective and results in maternal and neonatal outcomes have been proven to be better. A meta-analysis of 4 randomized controlled researches comparing these two approaches shows that the diagnosis and treatment of DMG with the One Step approach is associated with better maternal and neonatal outcomes. Compared to the One Step method, the second step with the Two Step approach will delay diagnosis and treatment. The One Step Method improves patient compliance and diagnosis can be established earlier. In high risk cases such as history of DMG, history of macrosomia, older maternal age, multiple pregnancy and others, screening with the One Step method can be done at the first antenatal visit.

Meanwhile, a counter argument was put forward by Hosseini et al (2018), who reports that the One Step approach tended to identify low-risk women as DMG positive[8]. This will increase anxiety and health costs because more antenatal visits and more ultrasound examinations will be needed, including an increase in the need for additional laboratory tests without clear benefits. ACOG does not recommend the use of the One Step method because there is not enough data available that the use of these criteria will increase maternal and neonatal outcomes and may even increase health costs.

Based on this research the DMG diagnosis results are higher when it is diagnosed with the One Step approach compared to Two Step. The One Step Method is recommended by IADPSG and ADA because it is more sensitive for identifying DMG. DMG diagnosis using the One Step method is used to uniform DMG diagnosis procedures for all pregnant women so as to increase the sensitivity of the screening method and the prevalence of DMG, pregnant women diagnosed with DMG earlier are expected to improve pregnancy outcomes for both mother and baby [15]. Increased sensitivity is associated with a low threshold for positive results (only one abnormal value is needed) and a cut-off value is also low.

Research conducted in Thailand states that the One Step method is not suitable for routine screening in clinics with as many ANC patients as in developing countries, because screening tends to be complicated for it requires prior fasting, with no real evidence of clinical improvement in pregnancy outcomes [7].

The One Step Method provides benefits for patients and health care providers because it can provide diagnostic results in just one ANC visit. But the increased prevalence of pregnant women with DMG also increases health costs, without any real evidence of the benefits of

treatment. Women diagnosed with DMG are also likely to face unintended consequences, such as increasing the risk of labor by cesarean section, requiring intensive newborn assessment, increasing the cost of care, and possibly experiencing psychosocial burdens.

This research also found that the possibility of pregnant women diagnosed with DMG was greater if they had a history of macrosomia and obesity in the One Step method while a history of DM and obesity for the Two Step method. This means that pregnant women who have a high risk of DMG will be more likely to experience DM during pregnancy compared to pregnant women without risk factors or low risk. Hosseini's research shows that pregnant women who are older than 35 years old and having a family history of DM significantly increased DMG development for both in the One Step and Two Step method. It further shows that a high BMI before pregnancy and lack of exercise during pregnancy and a history of previous cesarean section supports the development of DMG especially for the Two Step method [8]. Therefore, the presence of high risk factors for DMG supports the formation of DMG diagnoses for both DMG diagnosis method.

Some weaknesses of this study are (1) the sample used is different for the two diagnostic method so that diagnostic tests cannot be performed to see the sensitivity and specificity of both method; (2) it does not compare the results of pregnancy outcomes (from) both maternal and neonatal between the two examination method so that further research is needed with larger samples to conclude the most effective screening method.

Conclusions

Based on the results and discussions, it can be concluded that pregnant women diagnosed with diabetes mellitus by the One Step method were 28.3% and by the Two Step method were 3.8%. The prevalence of gestational diabetes mellitus is significantly greater with the One Step method compared to the Two Step method. History of macrosomia and obesity were found to be risk factors for pregnant women diagnosed with DMG by the One Step method while a history of DM and obesity (were found to be risk factors) for the Two Step method.

To Compare the Effectiveness of Taping and Arch Support on the Flexible Flat Foot on a Random Population

J. Karthikeyan[1], Kshtrashal Singh[1], Susmitha Govind[1], Kaviarasu Mahalingam[1], Sree Vamsi[1], Pavithra A/P Annamalai[2], Yu Chye Wah[3]

[1]Lecture, [2]Research Scholar, [3]Assoc. Professor, School of Physiotherapy, Faculty of Allied Health Professions, AIMST University, Malaysia

Abstract

Background: Flat foot is also known as Pes planus caused by injury, prolonged stress on the foot, obesity, and faulty biomechanics. This will cause the posterior tibial tendon dysfunction, collapse of the foot arch and developed flat foot (Pes planus).

Objective: Many of the research studies show the prevalence of flexible flat foot is on raise in recent times due to any number of factors. The majority of researchers focused independently on the effectiveness of Kinesio taping and arch support. So we aim to compare the effectiveness of Kinesio taping and medial arch support.

Method: The study design is an experimental study. The study will be conducted at Aimst University, Kedah, Malaysia. Total of 30 participants of both the gender, age between 18 to 30 years, who have a limitation of ROM and pain while performing dorsiflexion and plantar flexion, will be recruited. Each participant will undergo pre-test and post-test screening for an assessment of Body Mass Index (BMI), ROM, pain, physical examination, and Staheli Arch Index. Later the participants will be divided into two groups by a convenient sampling method. Group A participants will undergo exercises related to strengthening of foot muscles along with non-allergic taping technique while Group B participants will undergo exercises related to the strengthening of foot muscles along with medial arch support.

Data Analysis: Data collected is using IBM SPSS Statistics 23 for analyzing the data. For statistical analysis of the range of motion, VAS scale and Staheli Arch Index, Wilcoxon Signed Ranks Test was used. To compare the outcome of Kinesio Taping and Medial Arch Support, Mann-Whitney U test was used.

Result: After statistical analysis, a significant improvement was found in the range of motion and VAS Scale. The level of improvement ($p<0.05$) was significantly high with Kinesio Taping in flat foot.

Conclusion: The present study concluded that the application of Kinesio tape to flat feet was an effective intervention method for immediately reducing abnormally increased foot pressure and tone and stiffness in the lower extremities muscles and considered to be the most effective intervention for subjects with flat foot.

stress on the foot, obesity, and faulty biomechanics[1]. This will cause the posterior tibial tendon dysfunction, collapse of the foot arch and developed flat foot (Pes planus). Flat foot can sometimes contribute problems in knees because this condition can alter the optimal alignment of legs. Clinical assessment will determine the characteristics and deformity of the joint[2]. Along with assessment, range of motion (ROM) would place a major roll on the assessment. The ankle is the part of the lower limb, the distal portion of the leg and proximal portions of the foot [3]. The foot contained 26 small bones for weight-bearing, and force distribution. The bony alignment creates three arches to provide efficient weight distribution while avoiding compression of plantar neurovascular structures. There are, lateral and medial longitudinal arch and the transverse arch together create an architectural vault which is one of the strongest load-bearing structures known to mankind[4]. The ankle joint is formed by talus, articular surface of the lower tibia and medial malleolus and lateral malleolus of the fibula. The movements that allow by ankle joint are plantar flexion, dorsiflexion, inversion, and eversion[5]. The foot is anatomically and biomechanically, subdivided into three parts, hindfoot, midfoot and forefoot[6]. The Rearfoot and the hindfoot is the talus and calcaneus bone. The midfoot consists of navicular, cuboid and three cuneiforms and the forefoot consist of fourteen bones of toes and five metatarsals[7]. Flat foot defines as a postural deformity in the combination of the medial longitudinal arch collapse[8]. According to the International Journal of Physiotherapy and Research (2015), the flat foot is also known as Pes planus caused by injury, prolonged stress on the foot, obesity, and faulty biomechanics[9]. This will cause the posterior tibial tendon dysfunction, collapse of the foot arch and developed flat foot (Pes planus). Galen is the most famous physician and he is the first author of the flat foot (Pes planus). Galen didn't use the term (flat foot), but he described it and characterize the patients as liopothes or smooth feet people. There are two types of flat foot[10]. Flexible flat foot is a common type of flat foot. The foot arch will be normal at rest (not during standing or walking), and it will disappear when contact with the ground[11-13]. A rigid type was fixed deformation in the flat position on ankle joint, with or without weight-bearing. Normally the pain will appear in the medial part of the hindfoot and along into posterior tibial tendon. Flat foot can sometimes contribute problems in knees because this condition can alter the optimal alignment of legs. Clinical assessment will determine the characteristics and deformity of the joint. Along with assessment, range of motion (ROM) would place a major roll on the assessment [14].

Methodology

The study design is an experimental study. The study will be conducted at Aimst University, Kedah, Malaysia. Total of 30 participants of both the gender, age between 18 to 30 years, who have a limitation of ROM and pain while performing dorsiflexion and plantar flexion, will be recruited. Each participant will undergo pre-test and post-test screening for an assessment of Body Mass Index (BMI), ROM, pain, physical examination, and Staheli Arch Index. Later the participants will be divided into two groups by a convenient sampling method. Group A participants will undergo exercises related to strengthening of foot muscles along with non-allergic taping technique while Group B participants will undergo exercises related to the strengthening of foot muscles along with medial arch support.

Result

Total of 30 participants of both the gender, age between 18 to 30 years, who have a limitation of ROM and pain while performing dorsiflexion and plantar flexion, will be recruited. Each participant will undergo pre-test and post-test screening for an assessment of Body Mass Index (BMI), ROM, pain, physical examination, and Staheli Arch Index. Later the participants will be divided into two groups by a convenient sampling method. Group A participants will undergo exercises related to strengthening of foot muscles along with non-allergic taping technique while Group B participants will undergo exercises related to the strengthening of foot muscles along with medial arch support.

Group A: Group A participants will undergo to perform a 30 min exercises related to the strengthening of foot muscles that consisted of a 5 min warm-up exercise, a 20 min main exercise, and a 5 min concluding exercise along with a non-allergic taping technique.

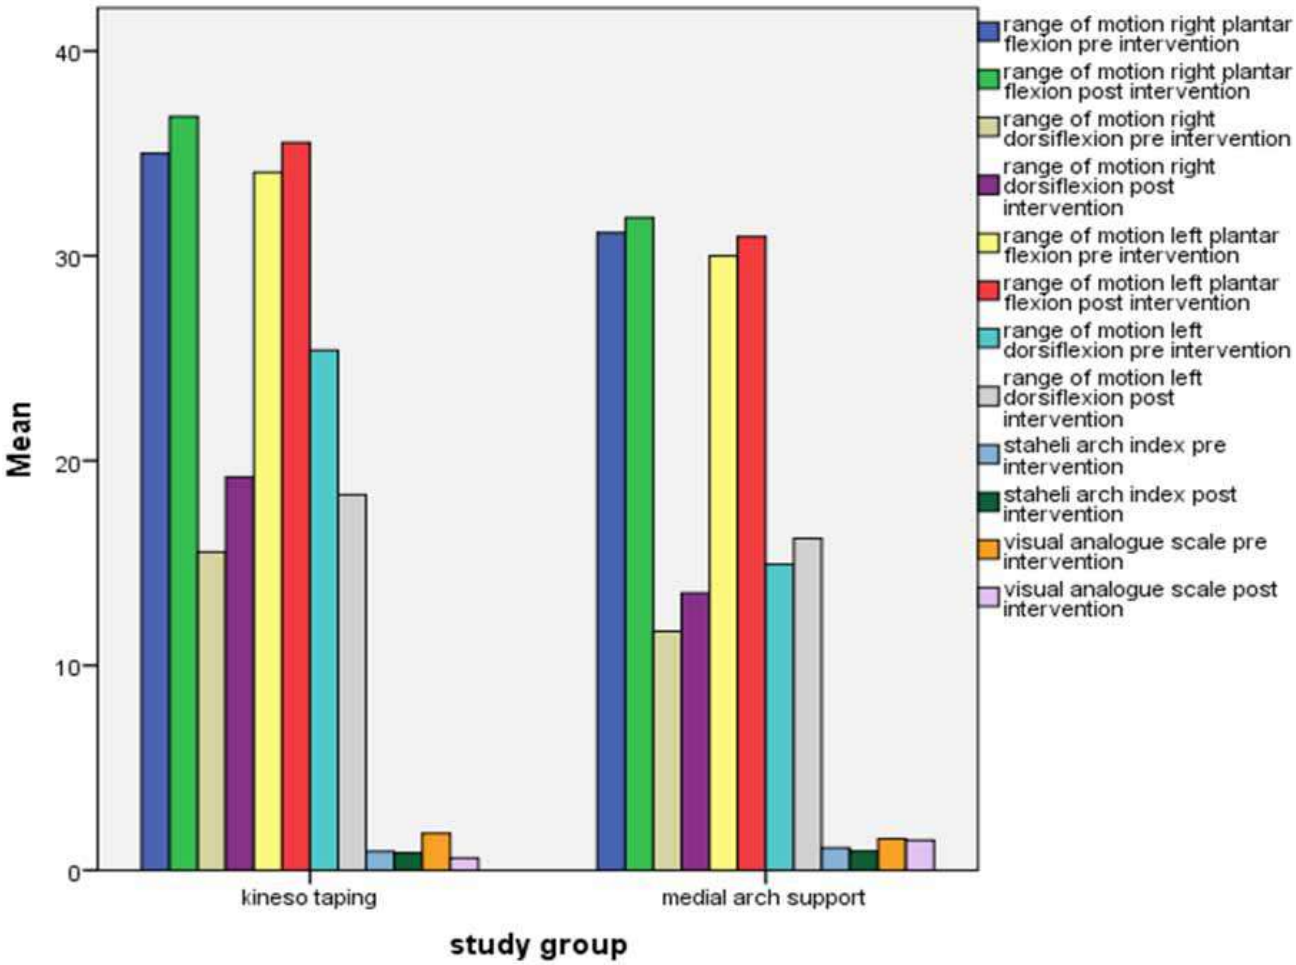
Group B: Group B participants will undergo to perform a 30 min exercises related to the strengthening of foot muscles that consisted of a 5 min warm-up exercise, a 20 min main exercise, and a 5 min concluding Body Mass Index (BMI). The height of each subject was measured using sewing tailor tape and the weight was measured using a digital weight scale. The BMIs of the subject was calculated by divided the body weight by the square of height (kg/m^2). BMI was taken during

assessment because there is a relationship between Body Mass Index and flat foot. Obesity is one factor that causes flat foot. It increases static and dynamic plantar pressure. As a result, the appearance of flattened medial longitudinal arch4. BMI categories – Underweight: below 18.5. Normal: 18.5 – 24.9. Overweight: 25 – 29.9 and Obesity: 30 – 39.95. Range Of Motion (ROM): Ankle joint range of motion was measured by using goniometer as a measurement tool for ankle joint to find out any limitations in the range. For ankle dorsiflexion, the subject is supine with legs off the table. The fulcrum is aligned with the lateral malleolus. The stationary arm is in line with the midline of the lower leg; use the head of the fibula for reference. The moving arm is parallel to the fifth metatarsal. Normal ROM of dorsiflexion is between 0 and 20 degrees. Ankle plantarflexion, the subject is supine with legs off the table. Goniometer alignment is the same as for dorsiflexion. Normal ROM is 45 degrees. For subtalar inversion, the subject is prone to lying with the foot hanging off the table. The fulcrum is placed in the two malleoli. The stationary arm is aligned with the midline of the leg and moving the arm with the midline of the calcaneus. The ROM is between 0 and 30 degrees and subtalar eversion, method are the same as subtalar inversion. The ROM is between 0 and 25 degrees. Pain Scale: Pain evaluated by using the Visual Analog Scale (VAS Scale). A briefly explained to the subjects and showed the scale; that they rated their pain using numbers, faces and words. Toe Raising Test: A toe raising test was conducted under a physical examination of all the subjects. The purpose of this test to check the flexibility of Pes planus. The test was performed with the patient weight-bearing, while the therapist dorsiflexes the hallux. Positive result: (arch formation) from the flat foot being flexible. Negative result: (lack of arch) from the flat foot being rigid. This special test was described by Jack and explained by Hicks due to the "windlass action" of the plantar fascia6. After done with the assessment, the participants equally divided into two groups. Each group 15 participants. Group A was provided exercise and taping technique and Group B was provided exercise and arch support. Exercise along with medial arch support.

Figure 1: Toe raising test

The collected data were recorded and tabulated. The data was analyzed using statistical package for social science (IBM SPSS Statistics 23) to present the finding of the study - compare the effectiveness of Kinesio taping and medial arch support on random population. Range of motion, VAS scale, and Staheli Arch Index, Wilcoxon Signed Ranks Test was used for statistical analysis. The Wilcoxon Signed Ranks Test used to determine whether there were changes in between pre-test and post-test. To compare the outcome of Kinesio Taping and Medial Arch Support, Mann-Whitney U test was used. After statistical analysis, a significant improvement was found in the range of motion and VAS Scale. Results were considered significant at $p<0.05$.

Table 1: Demographic Characteristics of Study Samples



Gender	Mean (SD)	Frequency	Percentage (%)
Male		12	40.0
Female		18	60.0
Race			
Malay		3	10.0
Chinese		10	33.3
Indian		17	56.7
Study group			
Kinesio taping		15	50.0
Medial arch support		15	50.0
Age	21.6 (2.5)		
Weight	64.1 (18.3)		
Height	162.7 (9.4)		
BMI	24.0 (5.5)

Graph 1: The distribution measures of pre and post-intervention for ROMPFR, ROMPFL, ROMDFR, ROMDFL, SAI and VAS between Kinesio Taping and Medial Arch Support

Table 1 shows the demographic characteristics of 30 subjects included gender, race, study group, age, weight, height, and body mass index category. According to Table 2, for the subjects treated with Kinesio tape, the ankle range of motion, showed significant differences in pre-test and post-test of plantar flexion on the right side with 'Z' value -2.226 at $p<0.05$. There was a significant difference between pre-test and post-test of Medial Arch Support in plantar flexion on the right side with 'Z' value -2.041 at $p<0.05$. There was a significant difference in pre-test and post-test of Kinesio tape in plantar flexion on the left side with 'Z' value -2.536 at $p<0.05$. Comparison of pre-test and post-test of Medial Arch Support in plantar flexion on the left side with 'Z' value -1.841 at $p>0.05$, thus stating that there is no significant difference. There was a significant difference

in dorsiflexion of the right sides between the Kinesio tape group and the Medial Arch Support group ($p<0.05$). Pre-test and post-test of Kinesio tape in dorsiflexion on the left side with 'Z' value -1.791 at $p>0.05$, thus stating that there is no significant difference. For the subjects treated with Medial Arch Support, the pre-test and post-test of dorsiflexion on the left side show a significant difference with 'Z' value -2.724 at $p<0.05$. There is no significant difference in Staheli Arch Index on pre-test and post-test between the Kinesio tape group and the Medial Arch Support group ($p>0.05$). There was a significant difference in pre-test and post-test of Kinesio tape in the Visual Analogue Scale with 'Z' value -3.491 at $p<0.05$. Comparison of pre-test and post-test of Medial Arch Support in Visual Analogue Scale with 'Z' value -0.333 at $p>0.05$, thus stating that there is no significant difference. Table 3 shows the comparison of outcome values for Range of motion, Staheli arch index and Visual analogue scale test within the group and between the groups by Mann-Whitney U test. For the range of motion of right plantar flexion on both sides, the 'U' value is 94.500 on right and 81.500 on the left side at $p>0.05$, thus stating that there is no significant difference between the groups. Hence there is a significant difference of dorsiflexion in both groups at the right side with 'U' value is 58.000 at $p<0.05$. Nevertheless, the 'U' value of left side dorsiflexion is 101.500 at $p>0.05$, thus stating that there is no significant difference between the groups. For Staheli Arch Index, the 'U' is 85.000 at $p>0.05$. So, stating that there is no significant difference between the groups. There is a significant difference in the Visual Analogue Scale in both groups with the 'U' value is 30.500 at $p<0.05$. Graph 1 and 2shows the distribution on measures of pre-test and post-test for Range of motion, Staheli arch index and Visual analogue scale test within the group and between Kinesio Taping and Medial Arch Support. The result significantly shows that an improvement in Kinesio Tape than Medial Arch Support.

Graph 2: Improvement in Rompfr, Rompfl, Romdfr, Romdfl, Sai and Vas Measures Between Kinesio Taping and Medial Arch Support

Discussion

This study was done to compare to the effectiveness of Kinesio taping and medial arch support on the flexible flat foot on a random population in AIMST University. The outcome measure used in this study was Range of Motion, Staheli Arch Index, and VAS Scale. Subjects are selected after confirming with the parameter of the arch which measured by Staheli Index Arch.

Plantar Arch Index = A/B

A = Measurement of the support width of the central region to the foot.

B = Measurement of the support width of the heel region to the foot

All 45 participants selected and agreed to take part in this study. However, there were 15 dropouts and a total of 30 participants completed the course of the research study. 12 male and 18 female subjects participated in this research. The reason of subjects for dropouts was declined to participate, due to semester breaks, and a packed schedule. Consents were gained from all participants before the assessment. Each participant undergo pre-test and post-test screening for an assessment of Body Mass Index (BMI), ROM, pain, physical examination, and Staheli Arch Index. The participants divided into two groups by a convenient sampling method. Group A participants will undergo exercises related to strengthening of foot muscles along with non-allergic taping technique while Group B participants will undergo exercises related to the strengthening of foot muscles along with medial arch support. Data of a total of 30 subjects were taken for analysis. The findings of this study were support the hypothesis. This result reflects in agreement with, after applying Kinesio tape, foot pressure, pain and foot arch on the bilateral leg significantly reduced and improved in a range of motion. According to the subject's feedback at the end of the research session, those who applied Kinesio Tape claimed that they feels comfort and better after applied Kinesio Tape, pain was reduced and improvement seen in the ankle movement. Therefore, Kinesio tape was a more effective method than Medial Arch Support to improve muscle tone, range of motion and the foot pronation decreased. Some of these studies are similar to the current study was observed, especially the increase in peroneus longus activity. This study was conducted to compare the effectiveness of taping and arch support on the flexible flat foot on a random population. Weng-Sam Siu et al, stated that using Kinesio tapes that reinforce the transverse arch for static stability and facilitate tibialis posterior for dynamic stability immediately after its application and increase the muscle activity of tibialis anterior during treadmill running in individuals with functional flatfoot, which was similar results of the present study. Joong-San Wang et al stated that the application of Kinesio tape to flexible flat feet was an effective intervention method for immediately reducing abnormally increased foot pressure and tone and stiffness in the lower extremities muscles. Agnieszka Straczynskaa et al stated that the application of Kinesio taping was a statistically significant decrease in pain and improvement in the deviation angle of the calcaneus was identified. Sivachandrian et al stated that the exercise programs significantly improved the angle of the arch foot, navicular height, and medial longitudinal arch. In additional, Smith et al. (Smith, Coates, Leung, & Creaby (2015) compared rigid and elastic anti-pronation taping effect on exercise related leg pain in females. The elastic tape was ranked as the most comfortable condition by a higher percentage of the participants. This implies that the elastic tape, like Kinesio tape, which was intended to provide therapeutic effects, may also provide greater comfort during exercise. Robert Yolo et at stated that taping acts as controlling pronation of the foot by pulling the calcaneus anteriorly and medially, thus limiting hindfoot eversion and restricting the associated talar adduction and plantarflexion. When the subtalar motion is limited, the arch is elevated subsequently reducing the stretch on the plantar aponeurosis. Similarly, the medial arch height is raised as the tape pulls the lateral aspect of the foot medially. According to Park et al. (2015); Tsai, Chang, & Lee (2010) have reported a reduction of pain in patients with plantar fasciitis and hallux valgus after taping. Our flatfoot participants did not have such pain level. Pain scores were not more than 4 (out of 10) due to the acute stage of their condition. These grading was taken before the treatment. Range of motion is defined as the movable range of a joint's potential movement. As for the ankle range of motion, the subject is asked to perform ankle plantar flexion and dorsi flexion. The measurements were taken with the help of goniometer. Quackenbush et al (2008) reported that ankle taping in female athlete's involked significant differences in pre- and post- exercise active range of motion for plantarflexion and Dorsiflexors. In the present study, the taping group showed significant differences in dorsiflexion and plantarflexion at $p<0.05$. This is consistent with prior studies suggesting that,

with taping, the ankle range of motion is greater after exercise than before. Because of the loosened taping during exercise, ankle range of motion increases after exercise. After the treatment session, it was shown that there was a statistically significant reduction in pain and improved in a range of motion in the post-test in Group an after applied Kinesio Tape.

Conclusion

This study was done to compare to the effectiveness of Kinesio taping and medial arch support on the flexible flat foot on a random population aged 18 to 29 years. This conclusion was drawn from the statistics shown in the SPSS after the data analysis was done. There was a statistically significant reduction in pain and improved in a range of motion in the post-test in Group an after applied Kinesio Tape. Thus, the results of the present study concluded that the application of Kinesio tape to flexible flat feet was an effective intervention method for immediately reducing abnormally increased foot pressure and tone and stiffness in the lower extremities muscles and it improved medial longitudinal arch. The study also concluded that taping is effective for 24 hours in the management of flexible flat feet. Having said that, it was statistically found in this study. These findings may have important implications for clinical practice as they will help guide treatment choices for flat foot.

Abstract

Objective: The prevalence of prediabetes is increasing worldwide. According to the International Diabetes Federation in 2016,6.7% of the world's population lived with this condition and estimated to rise to 7.8% in 2040. In general, prediabetes is accompanied by excess body mass index. Therefore, the purpose of this research was to determine the relationship between prediabetes and body mass index of outpatients in the internal medicine polyclinic at Dr. Dody Sarjoto Hospital, Maros Regency, South Sulawesi.

Method: This was an analytical research design with cross sectional approach, involving 143 prediabetes patients. Secondary data were obtained from the record books of the hospital and subjected to Chi Square test.

Result: The highest number of prediabetes cases were within the age range of 40-50 years (58.7%), among female (73.4%), patients with high school education (58.7%), and in 81.1% of patients with family history of DM. Furthermore, the result of the Chi Square test was 0.041, greater than <0.05, indicating a relationship between prediabetes and BMI.

Conclusion: There was a relationship between the cases of prediabetes and BMI of outpatients at dr. Dody Sarjoto Hospital, Maros Regency, South Sulawesi

Introduction

Prediabetes is a health challenge with serious impact and emerging as epidemic in the world, especially in Indonesia. It is a condition characterized with increase in blood glucose known as hyperglycemia, but not high enough to be regarded as diabetes mellitus. The prevalence of prediabetes is increasing every year worldwide, and in 2016, the International Diabetes Federation estimated the adult population with prediabetes to be 6.7%, which was equivalent to 318 million people. It was also estimated that this figure would reach 7.8% in 2040, equivalent to 480 million population of the world.[1] Based on a study, the population of prediabetes in America of people over 20 years old between 1999 and 2010 was 35.5% while the prevalence in UK was 35.5%, 15.5% in China, 14.8% in Spain and 22.4% in Bangladesh.[2] Its prevalence at Indonesia in 2009 was around 10.2% and increased to 36.6% in 2013.[3] According to IDF (2017), Indonesia is the 3rd country with the highest number of prediabetes between the ages of 20 to 79 years. A research showed

that 25% of prediabetes cases within a period of 3-5 years developed into type 2 Diabetes Mellitus (T2DM), about 50% remained as prediabetes, and while 25% reversed to normal blood glucose.[4]

Generally, prediabetes has a great chance of reversing to normal condition, therefore, it could be managed in order to prevent or delay its development into T2DM. One of the best ways of managing it is by avoiding some of the modifiable risk factors such as excess body weight, obesity, lack of physical activity, smoking, alcoholic, hyperlipidemia/dyslipidemia, and high blood pressure. However, the non-modifiable risk factors cannot be avoided by humans and these include age, genetic, and history of diabetes etc.[5] Physiologically, blood glucose are stored in muscle, liver, or fat cells as an energy source, but in insulin resistance condition, glucose are unable to enter these cells, consequently, blood glucose tend to rise but not sufficient to cause diabetes clinically. This condition eventually makes the pancreas unable to secrete insulin as needed, thereby leading to excessive and uncontrolled sugar production in liver, a condition which makes the blood sugar to rise and eventually leads to T2DM.[6]

Diabetes is a metabolic disease characterized by hyperglycemia caused as a result of abnormalities in insulin secretion or action or both.[7]The International Diabetes Federation reported about 382 million DM cases worldwide in 2013 and it was predicted it would rise to 592 million in 2035. Similarly, the World Health Organization (WHO, 2014), reported that 1 million people died as a result of diabetes in year 2000, with a prevalence of around 2%, which then increase to a death of 1.5 million people in 2012 with a prevalence of about 2.7%. Also, 70% of these worldwide deaths due to DM happened in developing countries including Indonesia. According to the results of Basic Health Research (*Riskesdas*) in 2013, the prevalence of diabetes from ages ≥15 years was 6.9% and increased to 10.9% in 2018.[8]

Body mass index (BMI) is an indicator of the level of adiposity in the body, calculated from the body weight (BW) in kilograms divided by height (TB) in meters squared (m^2). It does not directly measure body fat, but shows the body fat measurements such as underweight, normal, overweight and obesity.[9] Underweight increases the risk of infectious diseases while excessive weight i.e, obesity, is an important factor in insulin resistance pathogenesis. BMI is often recommended for evaluating obesity in adults due to the fact it is easier to conduct and inexpensive. BMI level is associated with body fat, which is a risk factor for prediabetes.[10] Obesity is characterized by excessive accumulation of body fat, which increases the risk of hyperglycemia. This condition results in increased secretion of free fatty acids, hormones, and pro-inflammatory substances such as interleukin-6 (IL-6), tumor necrosis factor α (TNFα) which triggers insulin resistance and damage to insulin pancreatic beta cells, which could develop into prediabetes characterized by hyperglycemia.[11] According to a research in South Korea, obesity is 1.5 times at risk of developing into prediabetes.[12] Similarly, the *Riskesdas* data in 2007 showed that obesity significantly increased the possibility of prediabetes by 1.5 times compared with people with normal BMI. The prevalence of obesity according to *Riskesdas* in 2013 was 18.8%, which then increased to 21.8% in 2018.[8] There are various risk factors for obesity, which include genetic, psychological environment, lifestyle, age, sex, economic status, and use of contraception especially the hormonal type. Also, a research showed that obese individuals have 1.63 to 11.58 times greater risk of developing DM compared with non-obese, and the more severe the obesity, the greater the risk of developing DM.[13] Hyperglycemia in overweight and obese people is caused by increase in the free fatty acids which reduce glucose transporter translocation into plasma membrane. This eventually results in insulin resistance in muscle and adipose tissue, initially forming proinsulin with molecules larger than insulin. Usually, proinsulin is stored in the pancreas until it is needed by the body. When secreted into the bloodstream, proinsulin is broken down into 2 parts namely; connecting peptides and active insulin hormones. The main function of the hormones is to reduce glucose levels in the blood. According to Guyton's theory, obesity is a predisposing factor for increased blood sugar. This is because the Langerhans island beta cells are less sensitive to stimulation (insulin resistance) or due to the rising sugar levels and obesity suppresses the number of receptors insulin in cells throughout the body. Therefore, the purpose of this research was to determine the relationship between prediabetes and body mass index (BMI) of outpatients at dr. Dodysarjoto Hospital, Maros Regency, South Sulawesi, Indonesia.

Research Method

This is an analytical descriptive cross sectional study. The research subjects were selected through purposive sampling method, involving all outpatients

treated at Internal Medicine Polyclinic of Dr. Dody Sarjoto Hospital from April 2018 to April 2019. Out of the 2,150 patients sampled during this period, only 143 met both the inclusion and exclusion criteria, hence, were the ones involved in this research. The inclusion criteria include; male and female aged between 18-70 years, fasting blood glucose levels 100-125mg/dl or/and blood glucose levels after 2 hours (post prandial) 140-199mg/dl.

The exclusion criteria are patients with diabetes history and incomplete general data. Secondary data were collected from Dr. Dody Sarjoto Hospital medical record book and the general data were analyzed using SPSS 22 program. The univariate analysis was used to test the normality of the data, as well as the frequency distribution, while bivariate analysis involved the use of Chi-Square Test.

Results

The results of this study are presented in the following table.

Table 1: Characteristics of research respondents.

Characteristics	Frequency	Percentage (%)
Age (Years)		
<28	5	3.5
29 - 39	13	9.1
40 - 50	84	58.7
>51	41	28.7
Gender		
Male	38	26.6
Female	105	73.4
Work		
Yes	62	43.4
No	81	56.6
Education		
D1-D3	21	14.7
S1-S3	28	19.6
Junior High School	10	7.0
Senior High School	84	58.7
DM Family History		
Yes	116	81.1
No	27	18.9
Total	**143**	**100.0**

The highest number of respondents with prediabetes was 84 (58.7%), found between the ages of 40-50 years, while the lowest number of 5 (3.5%) was found at ages <28 years, as shown in Table 1. Also, 81 of the respondents, representing 56.6%, do not work, while the highest number of prediabetes had senior high school as the highest level of education, 84 (58.7%). In addition, there were more respondents, 116 (81.1%), with family history of DM.

Table 2 The data of body mass index.

Body Mass Index	f	%
Normal	6	4.2
Overweight	128	89.5
Obese	9	6.3
Total	143	100.0

Based on Table 2, there were only 6 respondents (4.2%) with normal BMI, majority, 128 people (89.5%) were overweight while 9 people (6.3%), were found to be obese.

Table 3 Chi-Square test.

	Value	Df	Asymp. Sig. (2-sided)	Exact Sig. (2-sided)
Pearson Chi-Square	9.800a	4	.044	.041
Likelihood Ratio	13.460	4	.009	.014
Fisher's Exact Test	9.962			.019
N of Valid Cases	143			

Based on Table 3, the Chi-Square results was 0.041, since this figure <0.05, it means that there is a relationship between prediabetes and body mass index.

Discussion

Prediabetes is a condition characterized by elevated blood sugar above the normal but not sufficient to be recognized as diabetes mellitus. The age range with the highest number of prediabetes was 40-50 years, with 84 (58.7%) people. The high prevalence of prediabetes in this age range was due to the aging process taking place at that point. The production of enzymes associated with insulin is disrupted at this point. Also, there are changes in cell permeability, as well as the response of cell nucleus to insulin, a condition which allows an increase in the blood glucose. There were more cases of prediabetes among women because they generally have less muscle mass, consequently, it is easy to experience insulin resistance within the muscles in moderate to severe levels. Additionally, there were prediabetes cases among patients with no permanent job due to the fact that

they do not perform routine physical activity. Majority of these people just sit at home and watch television, a behavior which increases the risk for prediabetes. The highest number of cases was found among in the high school graduates.

This is possibly due to the fact the largest range of graduated in Indonesia are from the public high schools, hence, more respondents were at this education level. People with family history of DM have a higher risk of coming up with prediabetes. The results of this study support this fact with Table 1 showing 116 (81.1%) prediabetes cases with family history of DM. This is in line with the the results of a multicenter research conducted by Wagner in Germany which showed that family history of DM was significantly associated with the emergence of prediabetes (OR = 1.4 with 95% CI = 1.27: 1.54 p <0.001). It further stated that family history of DM increased the risk of prediabetes by around 40%.[14] In general, there are more obese people with prediabetes compared with individuals with normal body weight. In addition, BMIs above the normal limits have a higher tendencies of coming up with various kinds of complications such as prediabetes, diabetes, hypertension, etc. According to a study, BMI mechanism plays a major role in insulin resistance, as BMI above normal causes peripheral resistance to glucose uptake, thereby decreasing the sensitivity of pancreatic beta cells.[15] Moreover, a research showed that 80% of obese or overweight people experience hyperglycemia[16], while another research conducted in Iraq showed that BMI <25 kg/m^2 had 2.7 times risk of causing hyperglycemia.[17]

Insulin resistance in prediabetes happens in the muscle, liver, and fat tissues. Additionally, the result obtained from the Chi-Square test was 0.041, meaning that there was a relationship between prediabetes and the BMI, as there were more cases among obese patients compared with people with normal body weight. This could be due to the accumulation of excess visceral fat in prediabetes patients which causes insulin resistance in the liver and muscles, and consequently glucose uptake leading to hyperglycemia. The adipose tissue is recognized as an endocrine organ producing several peptides which are both proinflammatory and anti-inflammatory. This inflammatory process causes dysfunction in pancreas causing insulin resistance, and if this condition continues, it leads to increase in glucose levels and impaired lipid metabolism.[1] Under normal conditions of sufficient and sensitive insulin levels, the insulin works on its receptors found on the cell surface, enters the cells and eventually allows glucose to enter the cells, which are used as energy or as energy reserve, with normal blood glucose level the end result.[17] This is not the situation in obese people, as increase in lipopolysaccharides (LPS) mRNA induces TNF-α factors and protein levels, a process leading to inflammatory processes in leptin-1 and PAI-1 obese patients. In general, an increase in TNF-α in fat tissue of obese patients is an indication of insulin resistance.

Furthermore, obesity is a dominant cause of insulin resistance associated with decrease in the number of receptors and the failure of post-receptor to activate the tyrosine kinase, which is a subunit B in the insulin receptor. Activating this complex activates beta-phosphorylase and insulin-mediated action which control blood sugar levels. Consequently, hyperinsulinemia arises due to the failure in the delivery of signals to regulate blood sugar levels. Generally, the risk factors of diabetes include hereditary factors, physical activity, dietary intake, metabolism and hormonal metabolism. Increased glucose and fat usually result in increased transport of fatty acids into adipose and lipogenesis, which is under the influence of insulin. Also, partial oxidation of fatty acids produces ketones which are alternative fuel source for the brain and various organs. Moreover, fat tissues are known not only as storage points for energy reserves but as dynamic network with various functions. This condition of excess fat tissue common in the modern society is also associated with insulin resistance.[18]

Conclusion

Based on the *Chi square* result, 0.041 (<0.05), there is relationship between prediabetes and BMI of outpatient at Dr. Dody Sarjoto Hospital, Maros Regency, South Sulawesi, Indonesia.

Pandemic Corona (Covid-19) and Health Law Protection

Birkah Latif

Associate Professor at Faculty of Law, Health Science, International Law, Hasanuddin University, Jl. Perintis Kemerdekaan KM.10, Tamalanrea Indah, Kota Makassar, Sulawesi Selatan 9024, Indonesia

Abstract

Pandemic Corona (Covid-19), which struck all countries in the world, not only caused anxiety but also the number of victims that were not insignificant. This has caused the state to make efforts to manage health that is categorized as a disaster. Standards for health services also follow the rhythm of the victims that are not small every day. For this reason, it is necessary to examine whether the risk of spreading a pandemic in health is part of legal protection and whether a pandemic is part of disaster mitigation that receives legal protection. The linkage to health protection during the pandemic and law as the basis for policies to be able to implement health decisions and policies, which certainly requires effective and fast treatment.

Keywords: *Pandemic, Corona (Covid-19), disaster, health law.*

Introduction

At the beginning of 2020, which is usually the spirit of countries in starting the economic movement and various other development programs began, suddenly faced with the harsh reality of the emergence of malignant diseases that attack humans not only occur in one continent but simultaneously in all corners of the world.

It was reported from Wuhan that on December 29, 2019 in a hospital in Wuhan, Hubei Province, China the emergence of an acute pneumonia was unknown. The PRC government then informed WHO about the emergence of this disease after going through a verification process.

WHO describes the initial conditions[1]: On 30 December 2019, three bronchoalveolar lavage samples were collected from a patient with pneumonia of unknown etiology – a surveillance definition established following the SARS outbreak of 2002-2003–in Wuhan Jinyintan Hospital. Real-time PCR (RT-PCR) assays on these samples were positive for pan-Betacoronavirus. Using Illumina and nanopore sequencing, the whole genome sequences of the virus were acquired. Bioinformatic analyses indicated that the virus had features typical of the coronavirus family and belonged to the Betacoronavirus2B lineage. Alignment of the full-length genome sequence of the COVID-19 virus and other available genomes of Betacoronavirus showed the closest relationship was with the bat SARS-like coronavirus strain BatCovRaTG13, identity 96%.

The PRC National Health Commission said that: On January 8, 2020 the pathogen from this incident could be identified as the 2019 coronavirus novel (nCoV-2019), and its gene structure was immediately sent to WHO.

Due to the serious condition, WHO then announced[2]: The second meeting of the Emergency Committee convened by the WHO Director-General under the International Health Regulations (IHR) (2005) regarding the outbreak of novel coronavirus 2019 in the People's Republic of China, with exportations to other countries, took place on Thursday, 30 January 2020, from 13:30 to 18:35 Geneva time (CEST).

WHO subsequently established a committee, the Public Health Emergency of International Concern (PHEIC) tasked for:[3]

The Committee's role is to give advice to the Director-General, also provides public health advice or suggests formal Temporary Recommendations as appropriate.

Then on 12 February 2020 the International Committee on Taxonomy of Viruses (ICTV) declared that nCoV-2019 became the official name of severe acute respiratory coronavirus 2 syndrome ((SARS-CoV-2), and on the same day WHO declared SARS-CoV- The 2 official names are corona virus disease 2019 (COVID-19).

With the outbreak of the disease which by WHO is categorized as a pandemic, lead the author to analyze whether the risk of pandemic spreading in the health becomes part of legal protection and whether the pandemic is part of disaster mitigation that gets legal protection.

Discussion

Scope of Pandemic: Definition of Pandemics in the Big Indonesian Dictionary (KBBI) means that it is widespread (about disease) in a region, continent or throughout the world. WHO defines this term as a new pathogen epidemic that spreads easily from person to person throughout the world. A pandemic is when it spreads in several countries or continents and usually affects large numbers of people. Global distribution.

In the current health conditions the world community is experiencing a period of concern with the corona virus pandemic issue. WHO also mentioned: WHO has been assessing this outbreak around the clock and we are deeply concerned both by the alarming levels of spread and severity, and by the alarming levels of inaction. We have therefore made the assessment that COVID-19 can be characterized as a pandemic.[4]

Calling from WHO: Prevention, Preparedness, Public health, Political leadership, And most of all, people. We're in this together, to do the right things with calm and protect the citizens of the world. It's doable.[5]

For this reason, it is hoped that the need of collaborative not only from within the national of country but also unite movement from countries with strategic-preventive-repressive in togetherness, where countries unite in fighting the pandemic. Especially for Indonesia the question arises whether the risk of a pandemic spreading is part of legal protection and whether pandemics have become part of disaster mitigation?

Health Regulations and Epidemic Measures: In Indonesia, indeed, several legal rules for health care have been regulated and more specifically regarding the pandemic contained in the following rules:

Law No. 4 of 1984 concerning Infectious Diseases: This is the legal basis for handling disease outbreaks[6] that have been in force for decades. UU no. 4 of 1984 interpreted outbreaks of infectious diseases as an outbreak of an infectious disease in a society where the number of sufferers increased significantly more than was normal in certain times and regions and could cause havoc. This law not only regulates how to overcome it, but also regulates criminal sanctions for perpetrators of criminal acts. Threatened parties are those who prevent the prevention of communicable diseases.[7]

Government Regulation No. 40 of 1991 concerning Management of Communicable Diseases: This Government Regulation is the implementing regulation of Law No. 4 of 1984, which in essence regulates how prevention efforts[8] are carried out. Valid from July 3, 1991, PP No. 40 of 1991 regulates what the central and regional governments must do if there is an infectious disease outbreak.[9]

Law No. 24 of 2007 concerning Disaster Management: In this Law alluded to non-natural disasters[10] namely disasters caused by events or a series of non-natural events, among others in the form of technological failure, modernization failure, epidemic, and disease outbreaks. UU no. 24 of 2007 is more a regulation that regulates post-event, which is to overcome risks arising from a disaster. The spread of infectious diseases can be categorized as a non-natural disaster. Responsibility for disaster management basically rests with the government, central and regional. This law also regulates the rights and obligations of citizens, as well as the role of businesses.[11]

Law No. 36 of 2009 concerning Health: Entered into force October 13, 2009, Law No. 36 of 2009 specifically regulates infectious diseases in one chapter (Chapter X). Activities that can be carried out are promotive, preventive, curative, and rehabilitative for affected individuals or communities.

Minister of Health Regulation No. 82 of 2014 concerning the Control of Communicable Diseases: Is the implementing regulation of Law No. 36 of 2009 concerning Health. Diseases transmitted to humans based on Minister of Health Regulation can be caused by biological agents, including viruses, bacteria, fungi, and parasites.[12] Steps[13] that can be done are reduction, elimination, and eradication.

Law Number 6 Year 2018 concerning Health Quarantine (State Gazette of the Republic of Indonesia 2018 Number 128, Supplement to the State Gazette of the Republic of Indonesia Number 6236): Public health emergencies[14] themselves are extraordinary public health events marked by the spread of infectious diseases and/or events caused by nuclear radiation, biological pollution, chemical contamination, bioterrorism, and food that pose health hazards and potentially spread across regions or across countries.

Furthermore, Law 6/2018 mandates that the central government and regional governments are responsible for protecting public health from diseases and/or risk factors for public health that have the potential to cause health emergencies through the implementation of public outrage.[15]

Before determining public health emergencies, the central government first determines the types of diseases and risk factors that can cause public health emergencies. In this regulation it is stated that the central government determines and revokes public health emergencies.[16]

Government Regulation in Lieu of Law Number 1 Year 2020 Regarding State Financial Policy and Financial System Stability for Handling Corona Pandemic: Government Regulation in Lieu of Law (Perppu)[17] concerning state financial policies and financial system stability.[18]

There is an additional budget for spending and financing the 2020 state budget for handling Covid-19, the total additional expenditure and financing for the 2020 state budget for handling Covid-19 is Rp405.1 trillion. With regard to the Transfer to Regional and Village Fund Policies, adjustments to Transfer allocations are made Regions and Village Funds include, among others.

1. Adjusting the allocation of Revenue Sharing Funds based on economic development and/or state revenue;
2. Adjusting the allocation of General Allocation Funds per region based on certain criteria determined by the Minister
3. Finance;
4. Increase/decrease the allocation of Special Transfer Funds, transfer of allocations between Physical budget fields or adjustments to the use of Special Transfer Funds due to certain conditions that require an urgent budget; and/or
5. Adjusting the Village Fund budget ceiling.
6. In addition, there are arrangements regarding the prioritization of the use of the Village Fund, which can be used, among others, for direct cash assistance to the poor population in the village and activities to handle the 2019 Corona Virus Disease pandemic (covid-19).

Government Regulation Number 21 Year 2020 concerning Large-Scale Social Restrictions in the Context of Accelerating Handling of Corona Virus Disease 2019 (COVID-19): The PP 21 of 2020 concerning Large-Scale Social Restrictions in the framework of Accelerating Handling of Corona Virus Disease (COVID-19)[19] is certainly decided with much consideration according to the culture of the Indonesian state. Lockdown policy as applied in many countries, India for example causes chaos and surprising social problems. But the key to this is self-limitation and the movement of individual citizens to stay at home, limiting the frequency and number of mass gatherings to later conquer this pandemic coronavirus.

Presidential Decree No. 11 of 2020 concerning Determination of Corona Virus Disease 2019 (COVID-19) Public Health Emergency: Presidential Decree No. 11 of 2020 concerning Determination of Corona Virus Disease 2019 (COVID-19) Public Health Emergency is taken by considering[20]

Article 4 paragraph (1) of the 1945 Constitution of the Republic of Indonesia; Law Number 6 of 2018 concerning Health Quarantine (State Gazette of the Republic of Indonesia of 2018 Number 128, Supplement to the State Gazette of the Republic of Indonesia Number 6236);

Government policy

The role of the government in terms of medic and non-medic:

1. Mass rapid test with large coverage of residents

suspected of being exposed to the Covid-19 corona virus. Rapid testing involves all parties, from government hospitals, SOEs, the TNI-Polri, to the private sector, research institutions and universities that can also be involved.

2. Providing availability of medical devices and stopping exports of medical devices. The government ensures the availability of medical devices to prevent the transmission of the Covid-19 corona virus, such as masks and hand sanitizers. One of the ways taken is to stop the export of masks, hand sanitizers, or other medical devices needed to prevent corona from being stopped for a while.
3. Food stock

   Ensuring the availability of Indonesian food stock (logistical affairs agency (Bulog) for the community during the Covid-19 pandemic.
4. Work, study and worship policies from home
5. Involvement of religious leaders and appeals for not going home on Muslim Celebration Day (Eid Al-Fitr).

   President Jokowi requested that religious institutions and figures be involved in helping the government prevent the spread of the corona virus which caused Covid-19 disease.[21]
8. Incentives for medical personnel

   The President instructed the Minister of Finance to formulate incentives for health workers who handle Covid-19 patients.
7. Incentives for small businesses

   President Jokowi is aware that social distancing policies to avoid the spread of the Covid-19 corona virus can have an impact on the business world.

Therefore, Jokowi asked the Coordinating Minister for the Economy AirlanggaHartarto to formulate incentives for the business world, particularly micro, small and medium enterprises (MSMEs).

Strategies and mechanisms of the Ministry of Health of the

Republic of Indonesia: In dealing with the pandemic covid-19, it is necessary to study how the mechanism of health protection in Indonesia and its implementation strategy.

Establishment of the Covid-19 Task Force by the Government of Indonesia:

In Indonesia, the response to disasters has been anticipated by forming ad hoc bodies such as:

1. The National Committee for Avian Flu Control and Pandemic Preparedness in Indonesia
2. BRR (Aceh-Nias Rehabilitation and Reconstruction Agency) after the 2004 Tsunami
3. Mitigation plans for example in DKI Jakarta Flood Disaster Mitigation Plan.

In its implementation, disaster management is generally included in the provisions of Law No. 24 of 2007 concerning Disaster Management with technical implementation through the National Disaster Management Agency in regulation No. 4 of 2008 concerning Guidelines for the Preparation of Disaster Management Plans, in the introduction stated that Indonesia's broad demographic and natural conditions tend to be affected by very high disasters and varying in types:

Indonesia, which consists of a group of islands, has a very high potential for disasters and also varies greatly in terms of types of disasters. These natural conditions and the diversity of population and culture in Indonesia create the risk of natural disasters, human-made disasters and complex emergencies, although on the other hand they are also rich in natural resources

The types of disasters that can arise are: In general, the risks of natural disasters include disasters caused by geological factors (earthquakes, tsunamis and volcanic eruptions), disasters caused by hydrometeorology (floods, landslides, drought, typhoon angina), disasters due to biological factors (outbreaks of human diseases, plant/livestock diseases, pests, pests plants) as well as technological failures (industrial accidents, transportation accidents, nuclear radiation, chemical pollution). Disasters caused by human activities are related to conflicts between people due to the struggle for limited resources, ideological, religious and political reasons. While complex emergencies are a combination of disaster situations in a conflict area.

In dealing with such disaster conditions, integrated and directed preparation is needed: The complexity of the disaster problem requires a careful arrangement or planning in its handling, so that it can be carried out in a directed and integrated manner. The countermeasures that have been carried out so far have not been based on systematic and planned steps, so that overlapping often occurs and there are even important measures that are not addressed.

In the implementation of disaster management, so that each activity in each stage can run in a directed direction, then a specific plan is prepared at each stage of disaster management.

At the stage of a disaster in a situation where a disaster does not occur, a Disaster Management Plan (Disaster Management Plan) is prepared, which is a general and comprehensive plan that covers all stages/ areas of disaster work. Specifically for certain disaster prevention and mitigation efforts there are plans called mitigation plans,

At the stage of a disaster in a situation where there is a potential for disaster, a preparedness plan is prepared to deal with an emergency based on a single hazard scenario (single hazard) then a plan called a Contingency Plan is prepared.

When an Emergency Response is carried out an Operational Plan which is the operationalization/ activation of the Emergency Plan or Contingency Plan that has been prepared previously.

During the Recovery Stage, a Recovery Plan is prepared, which includes rehabilitation and reconstruction plans carried out in the aftermath of a disaster. Meanwhile, if a disaster has not yet occurred, then in anticipation of future disasters the preparation of instructions/guidelines for the post-disaster management mechanism will be carried out.

The pandemic disaster management policy that was declared as a non-natural disaster was then followed up with a special team namely the Task Force created because certain conditions had occurred with the presence of COVID-19 transmission in Indonesia, which needs to be anticipated. In order to accelerate the handling of COVID-19, quick, precise, focused, integrated, and synergic steps are needed between ministries/agencies and local governments.

The legal standing of this team is Presidential Decree (Keppres) No. 7 of 2020 concerning the Task Force for the Acceleration of Corona Virus Handling. The Task Force for the Acceleration of Handling

COVID-19 is under and is responsible to the president. The Head of the National Disaster Management Agency Lieutenant General Doni Monardo was appointed as the Chairperson.

In accordance with the provisions of the Presidential Decree, the Task Force also aims to accelerate the handling of the corona virus through synergy between ministries/institutions and local governments.

The contents of Presidential Decree (Keppres) No. 7 of 2020 contains the Coordinating Minister for Law and Legal Affairs and the Minister of Health designated as Deputy Director, Minister of Finance as secretary with a number of Ministries/Institutions as directors. However, this Presidential Decree was later amended by the presence of KEPPRES Presidential Decree (Keppres) No. 9 of 2020 with the following composition:

KEPPRES Number 7 Year 2020	KEPPRES Number 9 of 2020
The steering committee consists of 27 elements which include: 19 ministers and institutional elements such as the Head of the National Intelligence Agency (BIN), the Head of BPOM, the Chief of Staff of the President, the Head of LKPP, the Commander of the TNI, the National Police Chief, the Head of the BPKP, and the Governor of Indonesia	**Steering member becomes 33 elements:** 33 ministers and institutional elements such as the Head of the National Intelligence Agency (BIN), the Head of BPOM, the Chief of Staff of the President, the Head of LKPP, the Commander of the TNI, the National Police Chief, the Head of the BPKP, and the Governor of Indonesia

Preparation of hospital mechanisms: The Ministry of Health's government regulations have indeed revised the guidelines for the prevention and control of the Corona or Covid-19 virus, including the addition of categories of asymptomatic people (OTG) categories. This term is certainly not many people know about it.

The term OTG is used to categorize those who are asymptomatic and who have a risk of contracting from people who are confirmed positive for Covid-19, but who have close contact.[20]

"Close contact is someone who has physical contact or is in a room/visit, within a radius of 1 meter with PDP (Patient under Supervision) or Covid-19 confirmed case, within 2 days before a symptom case arises and up to 14 days after a symptom case arises, "wrote the Ministry of Health in the document.

During this time the public only knows a variety of medical terms that are used to categorize patient status, such as people in monitoring (ODP) and patients under surveillance (PDP).

The three criteria for someone who is potentially an OTG due to close contact, namely:[21]

Health workers, who inspect, treat, deliver and clean the room in the case treatment area (Corona) without using personal protective equipment (PPE) according to the standard.

People who are in the same room with the case within 2 days before the case symptoms arise and up to 14 days after the cases symptoms occur.

People traveling together (radius of 1 meter) with any type of conveyance/vehicle in the 2 days before the case of symptoms develops and up to 14 days after cases of symptoms appear.

In the Regulation of the Minister of Defense of the Republic of Indonesia Number 39 Year 2014 Regarding Disaster Management at the Hospital of the Ministry of Defense and the Indonesian National Army it is stated that:[21]

The implementation of Disaster Management is a series of efforts that include the establishment of disaster risk policies, prevention activities, emergency response, and rehabilitation.

It is also regulated in Article 1 point 10 regarding:

Hospital Disaster Management Plan is a planning activity from the Hospital to deal with disaster events, both planning for disasters that occur inside the Hospital (Internal Hospital Disaster Plan) and Hospital planning in dealing with disasters that occur outside the Hospital (External Hospital Disaster

All accredited hospitals in Indonesia must have a disaster management plan for a hospital or Hospital

Disaster Plan (HDP). However, because the value for HDP is only 20 percent and can pass without making plans, it is not uncommon for hospitals to only make documents and not socialize them to all staff. Furthermore, hospitals often do not make disaster threats a culture in hospitals.[20] Therefore, in the event of an internal disaster or the arrival of an external victim, or sending a team to the disaster area or experiencing a natural disaster, the hospital experiences difficulties in HDP application.[20]

Said by Lucky Tjahjono[20]: Health crises arising from disasters require coordinated handling from various parties both cross-program and cross-sectoral related in handling health crises in hospitals due to disasters. By integrating and coordinating the handling of the health crisis starting from the efforts of prevention, mitigation, preparedness, emergency response to the recovery of the health crisis in the Hospital due to the disaster by the various parties involved, it is expected that the impacts arising from the disaster can be minimized.

In addition, hospitals must be able to apply the concept of planned disaster management. Where hospitals should follow the procedure mentioned in Minister of Health Regulation 75 of 2019 on Health Crisis Management, the aim[20] is to provide guidance to Health Crisis Management actors at the regional and national levels, so that a coordinated, planned, integrated, and comprehensive health crisis management system is established to provide protection to the community from threats, risks and impacts of health problems.

Minister of Health Regulation No. 75 of 2019 concerning Health Crisis Management in it regulates the implementation of Health Crisis Management at each stage of the Health Crisis namely pre-crisis health, emergency response and post-crisis health. Health Crisis is an event or series of events that result in fatalities, injuries/illnesses, displacement, and/or the presence of potential hazards that have an impact on public health that requires quick responses beyond normal habits and inadequate health capacity.[21]

Disaster situations make vulnerable groups such as pregnant women, infants, children and the elderly vulnerable to disease. In these circumstances the risk and transmission of the disease increases. The hospital has a key role in handling health especially with pandemic conditions. WHO states:[1]

Hospitals and other healthcare facilities play a critical role in national and local responses to emergencies, such as communicable disease epidemics

Hospital readiness is needed which leads to networking in the health sector[1]: To ensure that the hospital is at all times in a state of preparedness to participate fully, efficiently and effectively in the coordinated health-sector response to an emergency, such as a communicable disease epidemic

In the global disaster by Covid-19, it was stated that[21]: By observing regional outbreaks in the context of Italy's case growth, we can start to model and anticipate both what the ultimate capacity to provide care will be and when that capacity will be exceeded.

That in handling cases, observation and planning are needed in dealing with the problem in our respective countries. The problem often faced by hospitals is that they already have SK COVID-19 task handling units and their duties and functions, but do not yet have an internal communication channel and an external communication channel. For example, the logistics sector is already included in the ICS and has a clear function assignment, but when there is a problem of lack of PPE, the logistics sector does not know where to coordinate, whether to directly ask external parties or through the internal commander first. This communication flow is important to be understood by the ICS team to facilitate systematic coordination between fields (internal) and outside the team (external). Thus all information needs and reporting activities can be met properly.

Management in handling a pandemic should be[1]: To ensure that the hospital has established the mechanisms and procedures including those for more strategic all-hazards emergency risk assessment and specific epidemic event risk assessment, prevention, preparedness, response and recovery that are needed for overall coordination of the hospital's epidemic risk management activities.

In following management it will be able to take steps in handling more leverage. The concept of handling the COVID-19 pandemic is basically the same as the concept of disaster management. The difference is only in the basic principle of handling because of differences in the nature of the causative agent. It is time for the hospital to activate ICS which has been formed to handle the COVID-19 pandemic. ICS that is formed can be said to be running if it has fulfilled 3 functions, namely

what doing what (division of tasks), communication (communication channel), and what if (backup plan).

Wang CJ stated[21]: Taiwan have been successful at combating the virus through aggressive testing and containment measures. South Korea, while initially inundated with patients from a rapidly spreading cluster, has successfully mitigated spread (at least temporarily) with minimal associated mortality. These examples provide encouragement that a well-executed public health response can minimize the potential for operational crises. The common themes in success have been massive testing, adaptive policy recommendations for different regions, and communication by public officials that is constant, transparent, and honest. The public needs to trust public officials and see the good and bad news every day.

Joseph J. Cavallo emphasize that: Actions taken now by society and health care systems will determine whether history regards 2020 as a great public health achievement or an epic failure of our public health and health care infrastructure.

Eric Toner[22]: Because it will take considerable time to fully understand the epidemiology of COVID-19, it is reasonable to begin preparations using a model we have studied extensively for decades and that seems similar to COVID-19—pandemic influenza. The threat of a novel influenza pandemic has stimulated international, national, and local planning and preparedness efforts for years. In the event of a 1918-scale flu pandemic, hospitals would be flooded with sick patients seeking care.

Conclusion

In the study of data relating to regulations and policies on health and regarding outbreaks of disease (pandemic) there are legal instruments and their applications.

In the real risk of pandemic spread if legal interpretation is used and also see the legal regulation has become part of the legal protection itself and applies everywhere. As a country that upholds the welfare state, Indonesia in particular is inseparable from the protective ties to its people. By the way the law has stated that *Salus populi suprema lex*, which means that people's salvation is the highest law, then in a legitimate manner, society must be saved. In the study of normative-positive legal rules, there are many rules that regulate and mention disaster mitigation. Even though in the regulations and legal basis, it is not specifically mentioned for its type but has been included in the general classification that disasters include non-natural disasters that include plague and/or pandemic. Concerning the issue of pandemics being part of disaster mitigation has been decomposed from the highest regulations to the implementing regulations, which contain definitions to the operational and technical implementation. Indonesia has also included these rules in existing health policies (health stakeholders including hospitals as the spearhead of medicinal treatment). We realize this condition is not perfect, there are still shortcomings, especially for hospitals that must include later in the Hospital Emergency Management Plan During the COVID-19 Epidemic, for pandemic outbreaks other than dengue fever and malaria. Cross-sectorial cooperation in a pandemic will be very helpful and provide hope that the storm from this pandemic will end soon.

Abstract

Covid-19 spreads from one person to another person through close contact in the form of droplets to respiration track. The physiological changes that happen to the body system is primarily on respiration and immune system. Such changes give higher possibility on pregnant mothers to be infected by covid-19. In order to decrease the infection risk, national policy suggests to omit hospital visit which is not important and changes it into distance care or virtual visit using phone or video call. Quality Antenatal Care (ANC) service is a service provided to pregnant mothers according to the service standard. Quality service is formed from service quality dimension. This research was carried out using analytical survey through cross sectional approach. The research population was all pregnant mothers in the working area of Public Health Center of Tangerang City chosen through total sampling. The data were collected using questionnaire (google form). Research finding resulted that during Covid-19 pandemics, there was 72.2% of the subjects who obtained suitable Antenatal Care. The research concluded that service quality of ANC during Covid-19 pandemics was in accordance with the service guidelines established by the government.

Keywords: *Service Quality, Antenatal Care Scope, Covid 19, public health care center.*

Introduction

Data regarding the effect of Covid-19 on pregnant mothers is still limited. However, information regarding diseases related to Covid-19 indicates that children are rarely exposed to it (Chavez, Long, Koyfman, & Liang, 2020)[3]. In 2 reports issued, there were 18 assessments done on Covid-19 disease, in which all of them occurred during the third trimester. Fetal distress and premature birth also seen in several cases, the two assessments were cesarean delivery and there was no proof indicating infection on womb. (Meliala, 2020)[10].

T. Indrayani
Assistant Professor of Health Science, Universitas Nasional, Jakarta, Indonesia
e-mail: trianaindrayani@civitas.unas.ac.id

Physiology changes on immunity and respiratory system can cause pregnant mothers to be more susceptible to Covid-19 infection. Up to now, there is no effective vaccine found yet. Thus, it is suggested that pregnant mothers have to refrain from unnecessary travel, avoid crowd, public transportation and contact with sick people as well as always maintain personal and social cleanliness (Liang & Acharya, 2020)[8].

In order to decrease the risk of infection, pregnant mother who does not have any particular worries regarding her pregnancy does not need to seek for pregnancy care, instead they can find online material to support the pregnancy. As an example, a midwife has started a series of YouTube video to guide pregnant mothers in passing weeks before and after giving births (Furuta, M., & Furuta, M. 2020)[5]. It also includes maintaining social distancing as well as often washing hands using soap and running water for 20 seconds (Poon et al., 2020)[12].

Social distance is the best protection mechanism thus the visit for the second trimester through tele health is recommended to protect the patients and service provider health (Laupacis, 2020)[10].

Midwife needs to be contacted before visiting the clinic so that they will come without any guide, in this case the health provider needs to be informed to apply the right self-protection procedure (Boelig, Saccone, Bellussi, & Berghella, 2020)[2,5]. The planning of individual labor and team-based approach through multispecialty consultation is used (Rasmussen, Smulian, Lednicky, Wen, & Jamieson, 2020)[15].

The quality of ANC care can be seen based on the factors affecting its effectiveness, compliance and sustainability of the care (Nwaeze, Enabor, Oluwasola, & Aimakhu, 2013)[11,14]. Quality service is formed from the service quality dimensions including reliability, responsiveness, assurance, empathy and tangible (physical appearance of the service) (Yuwono, Hartati, & Winarko, 2019)[18].

During the covid-19 pandemics in Indonesia, the Antenatal Care provision in either hospital, public health center,or independent midwife practice must follow the guidelines established by the Ministry of Health of the Republic of Indonesia. The guideline explains that the pregnant mothers need to participate in pregnant mothers online class, pregnancy examination in the second trimester need to be done through tele communication or postponed expect there is dangerous symptoms, pregnancy examination is done through appointment so that they do not need to wait for long, health worker needs to wear protective equipment level 1 which are head cover, medical mask, face shield, handscoon, working clothes and shoes (Enfagrow & Care)[4].

Method

The current research was done through analytical survey of cross sectional approach. The population involved in this research was all pregnant mothers in the working area of Public Health Center of Tangerang City. The total of the samples was 115 pregnant mothers chosen through total sampling. The inclusion criteria proposed were pregnant mothers who were involved in the WhatsApp group during the data collection. This research was carried out in March 2020.

Result

Table 1. The Scope of Antenatal Care Provision

The Scope of ANC Provision	Frequency	Percentage %
Inappropriate	32	27.8
Appropriate	83	72/2
Total	**115**	**100**

Based on Table 1, it is indicated that among the 115 respondents, those who obtained inappropriate antenatal care was 32 respondents (27.8%), while the remaining 83 respondents (72.2%) obtained appropriate antenatal care.

Table 2. Quality of Antenatal Care Service

Quality of ANC Service	Frequency	Percentage %
Good	113	98.3
Poor	2	1.7
Total	**115**	**100**

Table 2 informs that among 115 respondents, those who considered the antenatal care service as good were 113 respondents (98.3%), while the other 2 respondents (1.7%) stated that the antenatal care service provided was poor.

Table 3. Service Quality on the Scope of Antenatal Care Provision

Total	**113**	**98.3**	**2**	**1.7**	**115**	**100**	

Discussion

Based on the research result presented in Table 3, it indicates that among 115 respondents, those who obtained inappropriate antenatal care service were 32 respondents (27.8%).

Antenatal care is health service performed by professional worker for pregnant mothers during their pregnancy period, according to the minimum standard of antenatal service (Singh et al., 2019)[17].

According to the researchers' analysis, there were more respondents who considered the Antenatal Care service as appropriate, compared to those who considered as inappropriate. This is because the midwives have performed the service according to the standard established by the government during Covid-19 pandemics in which standard examination is still done (examination of body weight and blood pressure, measurement of upper arm circumference, high fundal examination of the uterus, examination of fetal heart rate and provision of vitamin of blood booster). However, there were also midwives who did not perform the examination in accordance with the scope of Antenatal Care service.

Based on the research result presented in Table 4

1. **Relationship between Tangible and Service Quality on the Scope of Antenatal Care Provision:** This research was in line with the research conducted by Firdausi in the working area of Kabila Public Health Center of Bone Balango District obtaining p value of 0.00< 0.05(Ramadhani, 2014)[14]. Consumers' satisfaction regarding a product depends on the direct proof obtained from the availability of equipment completeness, capacity of product quality and comfortable facility (Razak, 2019)[16].

The researchers assumed that pregnant mothers' good satisfaction on tangible dimension is related to the service provided by midwives that has been in

accordance with the standard of Antenatal Care service and Operational Standard of Service during Covid-19 pandemics. Midwives have provided service by giving distance in the waiting room and providing hand sanitizer to wash hands before entering the waiting room.

2. **The Relationship of Reliability and Service Quality on the Scope of Antenatal Care Provision:** Reliability is one of the dimensions which consist of uncomplicated procedure in accepting patients quickly, accurately and on time starting from the service to the treatment (Berliana & Amelia, 2018)[1].

The researchers analyzed that pregnant mothers considered the service given by the midwives as fast and accurate in responding to the pregnant mothers' need and complaint. Compliance and reliability of the midwives in meeting the service standard is one of the factors affecting the pregnant mothers' satisfaction on antenatal care service such as using the examination equipment as usual (weighting the body weight, measuring the blood pressure, examining the fetal heart rate and providing counselling). However, there were still many midwives who did not wear complete Personal Protective Equipment (PPE) during the pandemics due to the equipment which was difficult and expensive to obtain in the market.

3. **Relationship between Responsiveness and Service Quality on the Scope of Antenatal Care Provision:** Nurmawati (2010) stated that the pregnant mothers who considered the responsiveness dimention as in accordance with the scope of service werw 69 (86%) people, starting that good relationship between human will create good relationship (Indrayani & Sari, 2020)[6]. Fast service can be distinguished between the patients' service who where provided by special room in order to obtain fast service (Berliana & Amelia, 2018)[1].

According to the researchers' analysis, the high appropriateness of this dimension was affected by the fast response given, especially on the complaint experienced by the pregnant mothers and provision of information regarding Covid-19 prevention that must be done by pregnant mothers.

4. **Relationship between Assurance and Service Quality on the Scope of Antenatal Care Provision:** The current research result is in accordance with the result of research done by Firdausi (2014) in which as many as 71 respondents (89%) felt the availability of assurance, friendly environment, in this case is friendly service as the stage to improve the quality of public health facilities (Nair & Panda, 2011)[10,17]

The research also assumed that assurance is factor determining the service quality, because through the assurance, patients can feel safe during the examination and satisfied by the information provided as well as assured regarding the privacy by the polite service given, so that worries on Covid-19 infection can be overcome.

Relationship between Empathy and Service Quality on the Scope of Antenatal Care Provision

Current research is in line with the research performed by Yuniarti (2015) stating that there was relationship between empathy and patients' quality by p value of 0.000. This research also in accordance with research carried out by Nurani (2012) saying that by giving health counselling, screening and follow-up to pregnant mothers adjusts the visit time which is one of the actions to prevent Covid-19 (Qiao, 2020)[13].

Empathy given by the midwives during Covid-19 pandemics was analysed as good in which the midwives have given easiness for the patients in examining their pregnancy. Although the control schedule was made based on appointment, all of the examination can be implemented well.

Conclusion

Based on the research that has been done, it can be concluded that:

1. Based on the exposure of Antenatal Care, it indicated that 115 respondents have obtained appropriate Antenatal Care during Covid-19 pandemics by 72.2% of respondents.
2. Based on the service quality, among 115 respondents, it was stated that the five indicators have relationship with the service quality.
3. There was relationship between tangible, responsiveness, assurance and empathyon ANC service provision which is according to Covid-19 guidelines for pregnant mothers in Public Health Center of Tangerang City.

The Effectiveness and Safety of Convalescent Plasma as a Therapy for COVID-19 Patients: A Literature Review

Tri Setyawati[1], Virgiana[2], Rosa Dwi Wahyuni[3], Sumarni[3], Rosmala Nur[3]

[1]Assistant Professor of Biochemistry, Department of Biochemistry, Faculty of Medicine,Tadulako University Indonesia,94118, [2]Assistant Professor of Medicine, Medical Profession Program, Faculty of Medicine, Universitas Tadulako-Palu, Indonesia, 94118, [3]Assistant Professor of Public Health, Student Doctor Program, Departement of Public Health, Faculty of Public Health Hasanuddin University Indonesia, [4]Assistant Professor of Public Health, Student Doctor Program, Departement of Public Health, Faculty of Public Health Hasanuddin University Indonesia, [5]Assistant Professor of Public Health, Departement of Public Health, Faculty of Public Health, Tadulako University Indonesia, 94118

Abstract

COVID-19 is a new disease caused by SARS-CoV-2 with an increasing number of cases. until now, no specific vaccine or antiviral therapy regimen has yet been found. A therapy that has been known for approximately a century ago called convalescent plasma therapy has been discussed again as an effective and safe therapy for COVID-19 patients. Conduct a literature review of scientific studies related to the effectiveness and safety of convalescent plasma as a therapy for COVID-19 patients. Convalescent plasma has proven to be effective because it can improve the clinical condition felt by patient, prevent the entry of viruses into cells and inhibit the virus replication. This therapy is also proven to have no harmful effects, so it is safe to be performed by paying attention to certain things such as conditions that must be fulfilled by the donors.

Keywords: *COVID-19, SARS-CoV-2, Convalescent Plasma, plasma, virus, therapy*

Introduction

In Wuhan (China), at the end of 2019, there was an outbreak of the corona virus that had never been identified in humans(1). WHO officially labeled this kind of virus as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and the resulting disease as coronavirus disease (COVID-19)(2). Infected by COVID-19, a person will show a number of symptoms such as fever, cough, rapid breathing and difficulty breathing. In severe cases, it causes pneumonia, severe acute respiratory syndrome and the worst possibility, death(1).

Coresponding Author:
Virgiana
Assistant Professor of Medicine, Medical Profession Program, Faculty of Medicine, Universitas Tadulako-Palu, Indonesia, 94118
e-mail: anggivirgiana@gmail.com

WHO affirmed that on May 10, 2020 there were 3,925,815 people worldwide infected by COVID-19 and 274,488 people reported dead(2). COVID-19 is currently a major concern throughout the world(3). The number of infected cases keeps increasing, but specific vaccines or antiviral therapy regimens have not been found yet (4–6). Treatment only focuses on supportive care in the form of oxygen administration, ventilation, fluid therapy, low-dose corticosteroid combination therapy, antivirals and atomized inhalation of interferon (4).

Convalescent plasma therapy has been utilized since a century ago and is now re-discussed as an effective therapy for COVID-19 patients(7,8). The convalescent plasma is a blood plasma obtained from a person who has been declared cured of the infection process and has antibodies against certain pathogens. This plasma can be transfused to patients with varying degrees of severity of infection as a relative treatment(8).

Convalescent plasma has been used in a variety of previous infectious diseases, such as influenza,

cytomegalovirus infections, Middle East Respiratory Syndrome (MERS-CoV), Severe Acute Respiratory Syndrome (SARS-Cov), H1N1 - H5N1 avian flu and Ebola[9–11]. The United States Food and Drug Administration (FDA) has now approved the use of convalescent plasma as a therapy for critical COVID-19 patients. However, the use of this therapy follows the usual system of new drug investigations[12].

Based on the aforementioned issues, the main focus of this paper is to conduct a review of previous studies related to the effectiveness and safety of convalescent plasma as a therapy in COVID-19 patients.

Method

Some international journal databases such as Pubmed, Proquest and the Indonesian Scientific Journal are sources of literature search conducted through Google Scholar. The literature search aims to find a lot of information related to convalescent plasma therapy and COVID-19. It is done using the keywords "convalescent plasma" and "COVID-19".

Results and Discussion

Efforts to create the SARS-CoV-2 vaccine and COVID-19 treatment have now been carried out by many scientific laboratories. However, referring to previous therapeutic experience of infectious diseases, a convalescent plasma therapy might be an effective therapeutic option in the treatment of COVID-19[6].

A good result of convalescent plasma therapy has been demonstrated by a study conducted at Wuhan Huoshenshan Hospital on 6 patients who were confirmed to be positive for COVID-19 with different clinical, laboratory and radiological symptoms. The study was carried out based on the results of a Reverse Transcription-Polymerase Chain Reaction (RT-PCR) throat swab in male and female patients with an age range of 28 - 75 years who had confirmed COVID-19. They had a variety of main conditions ranging from fever, shortness of breath, recurrent infections of COVID-19, to those with comorbidities with Sjogren's Syndrome. Convalescent therapy was given to each patient after more than 4 weeks from the initial complaint that appeared. The therapy was given 1-3 times with a dose of 200 ml for 30 minutes each time of transfusion. Evaluation results showed that this therapy could reduce the clinical symptoms felt by the patient, improve lung conditions evidenced by a gradual reduction in consolidation and ground glass opacity occured in the lungs, clear SARS-CoV-2 which could lead to a double increase in titers of IgM and IgG antibodies against SARS-CoV-2 in patients receiving the therapy[13].

Another study was conducted on 4 male and female patients who were critically ill due to SARS-Cov-2 infection with an age range of 31-73 years. Each patient had comorbidities including hypertension, chronic obstructive pulmonary disease (COPD), chronic kidney disease and pregnancy. Patients obtained treatment in the ICU, experienced acute respiratory distress syndrome (ARDS), respiratory failure, septic shock and dysfunction and even multiple organ failure. Each patient was given 1-8 times convalescent plasma therapy with a volume of 200-400 ml each. The results indicated that the convalescent plasma therapy had a good effect on the patients' condition. This therapy improved their clinical condition, radiological picture and laboratory picture by which they no longer needed therapy for COVID-19 management. The duration required between administration of convalescent plasma therapy with a negative RT-PCR throat swab was in the range of 3 to 22 days[14].

There was also a research conducted at Shenzhen Third People's Hospital in China on the use of convalescent plasma therapy for COVID-19 patients. The study was conducted in 5 critical patients who were characterized by the following conditions: respiratory failure requiring mechanical ventilation, shock identified by vasopressor therapy and elevated lactate levels (> 2 mmol/L) despite adequate fluid resuscitation, or organ failure. The amount of plasma given to each patient was two consecutive transfusions of 200 - 250 ml with a total plasma of 400 ml. After conducting the convalescent plasma therapy, the patients' clinical condition improved, which was indicated by a decrease in body temperature, an increase in PAO_2/FIO_2 and chest radiology results showed a gradual improvement. Laboratory results showed a decrease in the number of viruses; some viruses become negative and there was a decrease in the number of inflammatory biomarkers (C-reactive protein, procalcitonin and IL-6). Four patients who had received mechanical ventilation and ECMO no longer needed 9-day respiratory assistance after the plasma transfusion [15].

Similar study was also carried out in three different hospitals in Wuhan on 10 patients with severe COVID-19. Each patient received a 200 ml convalescent plasma

therapy which was transfused within 4 hours. This therapy had a good effect on COVID-19. All symptoms in these 10 patients, especially fever, cough, shortness of breath and chest pain disappeared or, in other words, most of their condition improved within 1 to 3 days after the transfusion was performed. Antibody titer against SARS-CoV-2 increased in 5 patients and had a constant level in 4 other patients. The amount of SARS-CoV-2 RNA in each patient decreased and was not detected after 2-6 days of convalescent plasma therapy[16].

In Korea, a study on the effectiveness of convalescent plasma therapy was also conducted in two COVID-19 patients with acute respiratory distress syndrome (ARDS). The study was conducted on days 7 and 22 after the initial appearance of symptoms in each patient. Positive effects were shown after the administration of the therapy including improvement of clinical conditions, chest X-ray results accompanied by an increase in PaO_2/FiO_2, reduction in the number of inflammatory biomarkers and SARS-CoV-2 RNA showing negative results on days 20 and 26 after administration of therapy[17].

In addition, a study conducted on 21 COVID-19 patients obtaining intensive care in Henan Province of China showed that 6 patients given 300 ml convalescent plasma therapy had viral clearance and a longer survival rate than patients without plasma therapy[18].

Based on the aforementioned results of studies, the convalescent plasma therapy was effective for COVID-19 patients. It has been mentioned in the literature that antibodies mediated by the humoral response are very important for preventing or treating viral infections. Some parts of the antibody reduce the amount of virus by binding the epitope to the external surface of the virus particle, thus it prevents the entry of the virus into the cell and also prevents the replication of the virus[19].

The research stated that no harmful effects appeared after the plasma therapy was carried out[16,20]. However, one of the patients showed reddish spots on the face that easily disappeared after getting the therapy[20]. To avoid the harmful effects of therapy, it must be ensured that the plasma donor has completely healed. Here are some conditions that have to be fulfilled by the donors: 1) Free of fever for at least three days; 2) Reduction of respiratory symptoms; 3) Negative SARS-CoV-2 RT-PCR in two consecutive tests (one day interval between tests); 4) Anti-SARS-CoV-2 is positive, while HIV, HBV, HCV and other respiratory viruses are negative; and 5) Plasma should be taken after three weeks of disease onset[13,15,20].

Conclusion

This study established a conclusion based on the results of the research that had been carried out in various places with clinical symptoms, the results of radiological examinations and the results of various laboratory examinations. It concluded that therapy using convalescent plasma was proven effective since it could minimize the clinical symptoms felt by patients, prevent the entry of viruses into cells and inhibit viral replication. This therapy was also proven to have no harmful effects by which it was safe to do by paying attention to certain things such as conditions that needed to be fulfilled by donors.

Abstract

SARS-CoV-2 is a new type of corona virus that has been identified as a cause of COVID-19 cases. This disease is transmitted quickly, causes a global pandemic and can affect all ages, including children. In children, cases are still rare and hard to be found. Because the prevalence of events in children tends to be smaller than in adults, information about the clinical characteristics of COVID-19 infection in children is still lacking. The aim of this research is to find out the clinical characteristics of COVID-19 infections in children. Conducting a literature review of various scientific studies related to the clinical characteristics of COVID-19 infection in children. The most common clinical symptoms found in pediatric patients with COVID-19 infection are coughing, fever and gastrointestinal symptoms where these symptoms usually tend to be mild to moderate and often the symptoms are not specific or asymptomatic. Laboratory results are generally normal but the CT-Scan results show suspicion towards pneumonia in the majority cases of children.

Keywords: *Clinical characteristics, COVID-19, Children.*

Introduction

A new type of corona virus has been identified as the cause of a group of pneumonia cases detected in Wuhan City in early 2020. WHO officially named this disease as coronavirus 2019 (COVID-19) and the International Coronavirus Study Group (CSG) decided to name the virus SARS-CoV-2.[1]

At 26 April 2020, there were 2,804,796 total confirmed positive cases worldwide with 193,710 fatal cases (6.90%). Based on this, there are studies that use data based on a certain time span. The study took data from 149,760 laboratory confirmed cases in the United States from 12 February to 02 April 2020. The cases were analyzed based on known age. The results obtained were among 149,082 (99.6%) cases, 2,572 (1.7%) were children aged <18 years.[2,3]

Based on the most recent case reports, 90% of the 2,143 children diagnosed through laboratory examinations or clinical symptoms of COVID-19 infection are reported to be asymptomatic, mild or moderate. The remaining 5.2% are heavily infected and 0.6% are in critical condition. Children and adolescents infected with SARS-CoV-2 generally only experience mild symptoms and radiological manifestations. Children rarely experience severe cases of infection or are in a critical condition.[4,5]

Therefore, based on these data it can be said that cases of COVID-19 infection among children are still quite rare and symptoms tend to be milder or absent,

so this article review needs to be done to increase anticipation regarding the clinical characteristics of COVID-19 infection in children.

Method

The method used in compiling this article review is use research journals related to COVID-19 infection in children. The journals used in the study of literature are obtained through a database of international journal providers Elsevier and the Scientific Journal of Indonesia through Google Scholar. Journal searches are performed using the keywords "*COVID-19*" and "*child*".

Result and Discussion

Coronavirus (CoVs) is a group of RNA viruses with a single, encapsulated strain. This virus can mutate quickly and zoonoses (risk of spreading from animals to humans). One example of this virus is SARS-CoV which appeared in 2002 and causes severe acute respiratory syndrome. SARS-CoV-2 which currently appears is a new type of corona virus causing COVID-19 outbreaks in China and various other countries, causing a global pandemic.[6]

This virus spreads through droplets when infected patients cough, talk loudly or sneeze. Contact with the mouth, nose or conjunctiva of the eye through contaminated hands is also a source of transmission. Close contact with patients infected with SARS-CoV-2 is one of the ways in which infections occur in children. In addition, it has been reported that SARS-CoV-2 can also be transmitted via aerosols, the fecal-oral route and from mother to baby. This virus can still live in feces after a few weeks leading to transmission of oral-stool. Thus, because live virus strains can be isolated from feces, this indicates the potential for infection from bodily waste.[7,8,9,10]

Although this virus spreads very quickly, the cases in children are much lower compared to adults. One reason that may cause cases of COVID-19 in children tends to be lower because children have less outdoor activity and do less international travel so that the chance of contacting the virus is smaller.[11,(12)]

According to national guidelines, the diagnosis of COVID-19 is confirmed using RT-PCR with specimens taken from nasopharyngeal swabs and detection of lesions by chest CT-Scan. Intake of nasopharyngeal swabs are performed on all patients, including children.[13]

The severity of COVID-19 is classified based on clinical symptoms, laboratory testing and chest X-ray imaging, including asymptomatic infections, mild, moderate, severe and critical cases. The diagnostic criteria are as follows:

1. **Asymptomatic:** Without clinical symptoms and signs, chest imaging is normal while the 2019-nCoV nucleic acid test shows positive results.
2. **Mild:** Symptoms of acute upper respiratory tract infections including fever, fatigue, myalgia, cough, sore throat, runny nose and sneezing. In some cases there is no fever, but often there are gastrointestinal symptoms
3. **Medium:** With pneumonia, fever and cough are common, mostly dry cough followed by productive cough. Some may have wheezing and wet or dry crackle. Some cases may not have clinical signs and symptoms, but chest CT shows subclinical lung lesions.
4. **Severe:** Early respiratory symptoms such as fever and cough, can be accompanied by gastrointestinal symptoms such as diarrhea. Dyspnea occurs by central cyanosis and decrease in oxygen saturation is followed by other manifestations of hypoxia
5. **Critical:** Children can quickly develop into acute respiratory distress syndrome (ARDS) or respiratory failure and may also experience shock, myocardial injury or heart failure, acute kidney injury, encephalopathy and coagulation dysfunction. Organ dysfunction can be life threatening.[14,(15)]

Based on the results of the Chang TH et al study, analyzes conducted in all age groups of children (neonates-adolescents) showed the majority of patients had mild to moderate infections (98%) with more than half (59%) patients who had symptoms of fever and 46% had symptoms cough. Only 12% of patients have gastrointestinal symptoms. About 26% of patients have no specific symptoms. On the results of laboratory tests, the Chang TH et al study showed lymphopenia in 32% of cases. Some children (9%) even experience severe lymphopenia. Radiological examination results on 3 children showed consolidation and ground glass opacity. In 27% of cases there were no lesions in the lungs.

Chen J et al results showed that among the 12 pediatric patients infected with COVID-19, the main symptom most commonly experienced was coughing (75%) followed by fever (58.3%) and then 4 patients

reported having diarrhea (33.3 %). On laboratory examination, most patients (11/12) had normal white blood cell levels and 2 patients had lymphopenia. Dynamic changes from the laboratory that included WBC, the results of leucosyte and platelet counts occurred in 3 patients. Data collected from days 8-14 of the 3 patients showed normal laboratory results.

In the study of Xiaoxia L et al, the most common complaint experienced by pediatric patients at the Children's Hospital of Wuhan was coughing (48.5%). After that followed by pharyngeal erythema (46.2%) then fever with a range of 37.5oC (41.5%). From the results obtained, 32.1% of pediatric patients suffer from fever above 38oC with the majority temperature ranges ranging from 38.1 oC - 39 oC. Other symptoms were diarrhea (8.8%), fatigue (7.6%), rhinorrhea (7.6%) and vomiting (6.4%). In addition, 4 out of 171 children (2.3%) are known to have decreased oxygen saturation to below 92% and 26.7% of children have tachypnea. 42.1% of children also reported experiencing tachycardia while 27 other children (15.8%) were reported asymptomatic. Investigations showed that the CT scan results of 56 patients (32.7%) showed ground glass opacity and local spot images in 32 people (18.7%). Bilateral shading was also seen in 21 children (12.3%) and interstitial abnormalities occurred in two children (1.2%).

In the study of Su et al found that among 9 pediatric patients, 2 children had a fever in the range of 37.4-38.5 oC (22.2%) and 1 child had a cough (11.2%) and 6 others did not symptomatic (66.7%). In addition, based on the results of laboratory tests, 8/9 (88.9%) children have normal levels of white blood cells or decreased levels of white blood cells that are consistent with the characteristics of viral infections. Six children (66.7%) showed an increase in CKMB. ALT, AST and liver and kidney tests are within normal limits. The results of radiological examination found bronchitis in two children (22.2%) and one person with bronchial pneumonia (11.1%). One boy who was older than his twin showed pulmonary consolidation and ground glass opacity on the first day of hospitalization but the lesions disappeared after five days of treatment. In five other children (55.6%) no abnormal radiological features were found.

In the study of Sun et al at the Children's Hospital of Wuhan in pediatric patients with severe COVID-19 infection, the most common symptom was polypneu (8/8), followed by fever (6/8), cough (6/8)), phlegm (4/8), diarrhea (3/8), muscle fatigue/pain (1/8), headache (1/8) and constipation (1/8). The results of pulmonary auscultation examination showed the presence of rales in the left or right lobe in 5 patients (5/8) while in 3 other people there were rales (3/8). For the CT scan results showed there were six patients with bilateral pneumonia and two patients with unilateral pneumonia. CT scan images also include many features such as spotting (7/8), *ground glass opacity* (6/8), pleural effusion (1/8) and *white-lung like image*s (1/8). Patients with severe COVID-19 infection, septic shock and multiple organ dysfunction syndrome are the most common complications in critically ill patients.

In the study of Du et al several differences were found in clinical features between adult patients and pediatric patients. The findings show that the most common clinical symptoms in children are fever and dry cough but when compared with adults, these symptoms tend to be less common in children. In addition, other reports show that a decrease in lymphocyte counts is one of the more common clinical features. But in pediatric patients, there is no significant reduction in lymphocyte levels. On the other hand, the number of neutrophils in pediatric patients actually decreases so that it can be stated that lymphocyte levels cannot be an indicator of diagnosis of pediatric cases.

In the study of Du et al, also found that an increase in LDH is more common in pediatric patients than adult patients so that children are more likely to suffer heart muscle damage. In contrast, elevated levels of CRP and IL-6 are seen in adults, but not in children. For the results of chest X-ray examination, the majority of children and adult patients found abnormalities in the form of pneumonia and often bilateral. However, pneumonia in adult patients is more severe than in children. Even among patients who are not asymptomatic, 62.5% of cases have pneumonia. Therefore, lung damage caused by SARS-CoV-2 remains relatively clear.

In this study it was suggested that the pathogenesis of SARS-CoV-2 is closely related to the interaction of viruses with angiotensin-converting enzyme 2 (ACE2) cell surface receptors. The number of ACE2 receptors in children is lower than in adults so this is likely the main reason why children experience fewer symptoms and organ dysfunction. In short it can be said that most cases of COVID-19 infection in children are classified as mild.

Management for adult patients and children is

generally not much different. However, in severe but non-emergency cases, administering oxygen to younger pediatric patients is recommended using nasal prong (nasal prong) or nasal cannula to make it more acceptable. In addition, in adult patients with a critical condition (septic shock), norpinephrine is considered a first-line treatment. Epinephrine or vasopressin can be given afterwards to reach the MAP target. Whereas in pediatric patients, epinephrine is considered as a first-line treatment while norepinephrine is only additional if shock still occurs even though the dose of epinephrine given is optimal.[22,23]

Conclusion

The conclusions of the many journals that have been reviewed as intended are to find out the clinical characteristics of COVID-19 infection in pediatrics. The authors conclude that the clinical characteristics of pediatric patients with COVID-19 infection include clinical symptoms and examination results. The most common clinical symptoms found in pediatric patients with COVID-19 infection are coughing, fever and gastrointestinal symptoms where these symptoms usually tend to be mild to moderate and often the symptoms are not specific or asymptomatic. For the investigation itself, it is generally obtained the results of a normal leukocyte level, but the results of the CT-scan of the majority of pediatric patients show spots, consolidation, ground glass opacity which indicates suspicion toward pneumonia.

Tobacco Smoke and Pregnancy Outcome: Literature Review

Haerani Harun[1], Anwar Daud[2], Veni Hadju[3], Muh Syafar[4], Ridwan Amiruddin[5], Rahma[6], Abdul Faris[1]

[1]Associate Professor, Student of Doctoral Program, Faculty of Public Health Hasanuddin University, Makassar, Indonesia, [2]Lecturer, Department of Environmental Health Faculty of Public Health Hasanuddin University, Makassar, Indonesia, [3]Associate Professor, Department of Nutritional Sciences Faculty of Public Health Hasanuddin University, Makassar, Indonesia, [4]Associate Professor, Department of Health Promotion Faculty of Public Health Hasanuddin University, Makassar, Indonesia, [5]Professor, Department of Epidemiology, Faculty of Public Health Hasanuddin University, Makassar, Indonesia, [6]Lecturer, Faculty of Ushuluddin, Islamic Institute of Datokarama, Palu Indonesia, [7]Lecturer, Faculty of Public Health, Tadulako University, Palu, Indonesia

Abstract

Pregnant women have a risk for tobacco smoke both actively and passively. Various effects of tobacco smoke on pregnancy have been investigated. Pregnant women are usually exposed to enviromental tobacco smoke (ETS) in various places with different duration of time. Cigarette smoke has a severe effect not only on pregnant women but also on the fetus. This is a literature review. Various references were collected from online database including reports, journals, mostly in the last 10 years. The journals were mostly from the scholarly journals. The articles were screened according to the research objectives. The keywords used are tobacco smoke, environmental tobacco smoke and pregnancy outcome. Tobacco smoke can effect the immunity, hormonal and metabolic system of the pregnant woman, therefore disturbing the growth of the fetus. Tobacco smoke also known to increase the risk of premature birth and reduce gestational age. Tobacco smoke cause several problems in newborn such as respiration distress, low birth weight (LBW), neural disorder, sudden infant death syndrome (SIDS) and congenital anomaly.

The effect of tobacco smoke, actively of passively, have worse outcome for the pregnant women and their babies.

Keyword: *Pregnancy Outcome, tobacco smoke, ETS, LBW, preterm birth.*

Introduction

Smoking pregnant women have an increased risk of having an ectopic pregnancy, spontaneous abortion and other complications leading to pregnancy complications as well as the placenta. The fetus also has the risk of exposure to tobacco smoke, more than thousands of types of hazardous chemicals, especially nicotine, tar and carbon monoxide can have an effect on the fetus and cause unwanted disorders or abnormalities[1].

Environmental tobacco smoke (ETS) is a complex mixture consisting of most of the smoke emitted from the smoker's body, the smoke produced by burning cigarettes and the surrounding air[2].Exposure of ETS in pregnant women causes increased levels of carbon monoxyde(CO), nicotine and cotinin in maternal serum or urine, in the fetus and in amniotic fluid. The effect of ETS on pregnant women can occur from the first semester to the third semester. Pregnant women are usually exposed to ETS in various places with different duration of time. Places that have the potential to become ETS exposure locations include at home, at work and the outside environment [3.]

The effect of exposure to cigarette smoke on secondary smokers has not been widely studied in developing countries even though the prevalence of smokers is higher in developing countries than in developed countries. The increasing number of smokers in the world causes ETS exposure to secondary smokers become a concern for the global health. Environmental conditions such as population density make the ETS effect on health increased. Research in developing countries has found that ETS exposure in pregnant women is associated with poor pregnancy outcomes[3].

Tobacco smoke and pregnancy: One effect of the cigarette smoke exposure on pregnant women is its effect on the mother's immune system. In pregnancy changes occur in the mother's immune system to prevent rejection of the fetus. Exposure to ETS can cause changes in the immune system of pregnant women. Changes include an increase in activated leukocytes and a decrease in the percentage of regulator T lymphocyte cells (Treg cells). Smoking during pregnancy also affects the function balance between Th1 cells (T helper lymphocytes) and Th2 cells, causing an increase in the production of cytokines, proinflammatory chemokines and Th1 growth factors. In addition, the percentage of macrophages and NK cell residues is higher in smokers in the first semester [4]

Smoking is also associated with physiological changes in hormones during pregnancy. In smoking mothers there are a decrease of estrogen, globulin bindingsex hormone and human chorionic gonadotropin (hCG) compared to non-smokers. Nicotine as the main component of cigarettes has a substantial impact on the hormones of pregnant women, nicotine causes excessive stimulation of the acetylcholine receptors, releasing vasoactive catecholamines. The activation of nicotine receptors causes the release of acetylcholine, dopamine, serotonin, growth hormones and adrenocorticotropic hormones and glutamate, these hormones significantly influence fetal growth. Smoking is also associated with changes in metabolism during pregnancy. Some reports say that there is a strong relationship between smoking and the incidence of diabetes mellitus and disruption of insulin sensitivity, which can also have an effect on fetal metabolism[4].

Tobacco smoke exposure can also effect the fetus. Exposure to nicotine in pregnant women can cause vascular placental vasoconstriction, decrease placental blood flow and reduce trophoblast invasion which results in inhibition of good placental circularization leading to placental hypoxia causes disruption of placental invasion. Placenta previa is a form of placental invasion disorder[4]. Nicotine can cause a significant decrease in the mitotic potential of cytotrophoblast tissue in vitro. This effect is also found in smoker women. This effect can explain the mechanism of impaired placental development during the early phases of pregnancy due to placental ischemia which can cause fetal death[5.] Low placental weight strongly related with LBW [6].

Beside nicotine and cotinin, CO levels are also the found highest in smokers. The presence of CO in the body causes oxygen binding to hemoglobin decrease due to the higher affinity of hemoglobin for CO. CO Exposure tothe fetus prevents the release of oxygen and then converted to carboxyhemoglobin. The result is a decrease in tissue oxygenation through competitive inhibition with oxyhemoglobin. Prolonged CO exposure in pregnant women can cause significant permanent damage to the brain of a fetus which sensitive to hypoxia. Nicotine is also considered to have a bad effect due to the stimulation of nicotine cholinergic receptors and their neuroteratogenicity effects.[4,7,8]Kadmiun, the other components found in cigarettes are embryotoxic and tetarogenic in animals. Increased cadmium levels in maternal and placental blood are inversely correlate to zinc levels in placental cord blood, suggesting that cadmium interferes with zinc transfer to the fetus and causes impaired fetal growth.[4]Nicotine also interferes with the micro RNA which is important for the maturation of fetal stem cells.[9]

The effects of tobacco smok on the fetus are considered to be multifactorial, including indirect effects such as poor nutritional status associated with anorexiagenic effects of nicotine exposure and CO. Placental blood flow decrease is associated with the vasoconstrictive effect of catecholamines released from adrenals and nerve cells after nicotine exposure. The direct effects of nicotine on the nicotinic acetylcholine receptors that occur during the formation of the fetal brain are also factors that may contribute.[10]

Tobacco Smoke and Preterm Birth: The rate of preterm birth is quite high around the world.In Europe rates of preterm births are reported between 5 - 9%, while in developing countries and the United States the rate of preterm births reaches 12%. The cause of preterm birth is often difficult to determine. Some risk factors associated with preterm birth include excessive distension of the uterus, low economic status and smoking[11].

Smoking is known as a risk of spontaneous and elective preterm birth, but has a stronger relationship with spontaneous preterm birth. Passive smoking in pregnancy also has a risk of preterm birth both spontaneous and elective 5. Elective preterm birth may be associated with cigarette-related obstetric complications such as placenta previa, placental abruption and impaired fetal growth. Research shows that smoking during pregnancy

increases the risk of preterm birth by 25% [11]. The exposure of ETS also specifically has an influence on preterm birth[12,13].

Active smoker mothers have been accepted as a risk for preterm birth, for around 14% of preterm births. One mechanism that links cigarette exposure with preterm birth is the CYP1A1 genotype and GST (glutathione S-transferase). Abnormalities in these genes make mothers more vulnerable to exposure to hazardous substances such as cigarette smoke.[14] Cotinin levels as anindicator of cigarette exposure are also strongly related to preterm birth.[4] The danger of non-smoking tobacco is also seen in the research of Munmun et al. Which shows that non-smoking tobacco (chewed and swallowed) increases the risk of preterm birth.[15]

There are four mechanisms proposed by Goldstein et al in 1964 to explain the relationship between smoking and preterm birth: (1) Decreased maternal appetite caused by smoking leading to a decrease in nutrition for the fetus, (2) vasoconstriction caused by smoking results in decreased blood supply to the fetus, reduced fetal nutritional supply and slowing the release of catabolism results, 3) cigarettes may have a direct effect of toxins on the fetus and 4) an increase in fetal CO levels causes reduced oxygen transport capacity and teratogenic properties.[11,16]

The mechanism of smoking effect on preterm birth is currently believed to be likely caused by various effects that play a simultaneous role. CO levels in cigarettes are about 4% of the volume, after dilution of air in elveoli CO levels in smokers are 400-500 ppm. A room filled with cigarette smoke, CO levels can reach 100 ppm, causing the risk of CO exposure to non-smokers in the room. In blood CO is bound to hemoglobin and forms carboxyhemoglobin, because its affinity is about 200 times of oxygen, hemoglobin binds stronger with CO than oxygen. The binding of CO to hemoglobin causes the oxygen affinity of hemoglobin to increase, so that the remaining oxygen bound to hemoglobin is difficult to release. Carbon monoxide can cross the placental blood barrier. Carboxyhemoglobin levels in the fetus are usually higher than the levels in the mother. Increased levels of carboxyhemoglobin in the fetus cause fetal hypoxia. With decreased oxygen delivery to cells, CO also has an effect on the intercellular process by interfering with the work of cytochrome enzymes.[11]

Research on rhesus monkeys shows that nicotine administration does not cause changes in oxygen partial pressure so that the fetus also does not experience changes in oxygen pressure. Fetal hypoxia in this study was caused by decreased placental blood flow. Other studies on sheep have also shown that nicotine causes an increase in catecholamines and decreases uterine blood flow. Although data from studies in monkeys and sheep show that nicotine decreases uterine blood flow, research data in humans are very limited.[11]

Tobacco smoke can also increase the risk of preterm rupture of placental membranes through several mechanisms, 1) tobacco smoking decreases immunity and becomes a predisposing factor for infection, 2) tobacco smoking decreases copper levels and ascorbic acid in the blood,leading to a decrease in the elasticity of the placental membranes and increase the risk of rupture. Both of these mechanisms have the potential to cause preterm birth[11]

Prostagladin has been known to trigger labor. Prostaglandin levels such as F2-isoprostane as a marker of oxidative stress are found in the amniotic membrane and amniotic fluid in smokers. F2-isoprostane levels increased 3 times compared to non-smokers. Increased F2-isoprostane levels is considered asa mechanism that associated smoking and preterm birth. Smoking is also considered to increase the sensitivity of the uterus to the contractile hormone. Research by Egawa et al in mice shows that inhalation of cigarette smoke increases the contractile activity and sensitivity of myometrium to oxytosis.[11,17]Cadmium found in tobacco smoke interacts with calcium and effects myometrial activity. Cadmium may modulate the function of the oxytocin receptors in the myometrium. Increased levels of cadmium in pregnant women are found to be associated with an increased risk of preterm birth.[11,18]Another condition associated with preterm birth is necrotizing-enterocolitis (NEC). The study of Ding et al in smoking pregnant women showed an increased risk of infant death by NEC in the preterm newborn. Death in neonates by NEC is difficult to prevent with a mortality rate of 15-20%.[19]

Spontanious Abortion: Spontaneous abortion or miscarriage is one of the most common pregnancy complications, about 12-26% of known pregnancies. Generally the literature on the relationship between smoking and abortion does not show any consistency although some studies have concluded that smoking can cause abortion. A meta-analysis study by Pineles et al. Showed the relative risk of abortion during pregnancy

is 1.32. The risk of abortion increases with the number of cigarettes. One cigarette per day increases the risk of abortion by 1%. Secondary smokers have an 11% increased risk of abortion.[20]

Tobacco Smoke Effect on Newborn: Various studies provide an overview of the effects of cigarette smoke on fetal growth and development during pregnancy and infant growth and development after birth

Respiratory Disorder: Based on several studies children who are exposed to cigarette smoke can experience lung growth disorders and are more prone to lung infections and asthma. Exposure to cigarette smoke in pregnant women can also affect the newborn.[1]Smoking during pregnancy can cause the newborn's lungs failed to reach maximum function and continues with decreased lung function. Preterm births in most smokers also cause disruption of lung maturation. Diseases caused by these infants include wheezing, bronchitis, hospitalization due to lung infections and asthma in children.[21]

Generally, children who are exposed to nicotine during pregnancy also experience exposure to cigarette smoke in childhood. This raises the question whether the increased risk of asthma is caused by exposure to prenatal or post natal cigarette smoke. Research by Pattenden et al showed that exposure to cigarette smoke during pregnancy without post natal exposure still shows an association with an increased risk of asthma.[22,23]

Immune factors are also considered to play a role in impaired lung development in fetuses exposed to cigarette smoke. In animal models, there is a change in immune cell phenotype after exposure to cigarette smoke/nicotine. Wang's study et al showed a decrease in Th1 cytokine production after pre-natal and post-natal cigarette smoke exposure associated with increased Th1 immune cell recruitment to the lung parenchyma. By adjusting for risk factors for infection, secondary smokers have an immune system which tends to Th2 leading to an allergic phenotype, small airway inflammation and asthma-like symptoms. Exposure to cigarette smoke pre natal and post natal also shows an imbalance of Th1/Th2 causes susceptibility of airway reactivation.[24]

The mechanism of exposure to nicotine causes various pathological conditions in the lungs is not yet fully understood, but based on some data it was found that nicotine causes various anomalies in the lungs. Histological studies in animals show goblet cell hypertrophy after nicotine exposure and it is associated with asthma in the community.[22,25,26]

Low Birth Weight: Low birth weight babies are the variables most widely studied the effect of smoking mothers during pregnancy or exposure to cigarette smoke in pregnant women on pregnancy outcomes. Data shows that LBW is more common in smokers (12.4%) compared to nonsmokers (7.7%). Women who smoke have a 1.5 to 3.5 times greater risk of giving birth to LBW and the risk increases along with the cigarette consumption.[1]

The physical environment has an important role in determining the weight of babies born and their health in the future. Research in Jordan shows that exposure to ETS in non-smokers pregnant women causes an increase in LBW. Increased ETS exposure increases the risk of LBW infants. All ETS exposure in the home, office and outside environment has the potential to reduce the weight of newborn. It was also found that second and third semester exposures were the most vulnerable time of exposure causing LBW. LBW infants tend to be more at risk for neurological problems including cerebral palsy, seizures, severe mental retardation, respiratory diseases and other morbidity.[3]

It has been ascertained which component of cigarettes affects the flow of uterine blood and primarily affects the birth weight of the baby.[4] Lee et al study showed that exposure to ETS in pregnant women also has the potential to cause LBW and the effect of smoking on LBW from active smokers has the same mechanism as the effect of smoking on LBW in secondary smokers. The risk of small infants according to pregnancy is also increased in the group of mothers with high ETS exposure compared with mothers with low ETS exposure[27]

Behaviour and Neural Disorder: Nicotine exposure to the fetus can affect fetal brain development [10]. A study in Finland shows that heavy nicotine exposure causedthe infant born with attention deficit/ hyperactivity disorder (AHDH5 or attention deficit/ hyperactive disorders.[28]Fetuses exposed to tobacco smoke during pregnancy ware found to have a risk of cardiac autonomic abnormalities during sleep especially in preterm babies. Changes in autonomic activity are at risk of causing neurological and cardiological complications[29]

Research on nicotine exposure to lung development in the fetus is mostly done in animals. Perinatal nicotine exposure in mice causes an increase of airway reactivity.

Nicotine also causes an increase in smooth muscle volume in the distal bronchi and hyperreactive airway in sheep.[21]

Sudden infant death syndrome (SIDS): One of the most severe complications of nicotine exposure in pregnancy is sudden infant death syndrome or SIDS. The cause of SIDS is not clearly known in infants less than one year old suddenly die without definite explanation even after a thorough investigation. Exposure to nicotine is known to be a risk factor for SIDS, but the mechanism of nicotine exposure that causes infant death is unclear and is still being debated. But some animal studies provide some clues.[22,30,31]

Research by Cohen et al in rats shows that nicotine exposure causes disruption of catecholamine synthesis in newborn mice. The study also showed that the mice exposed to prenatal nicotine had impaired response to induced hypoxia. Other studies have shown that mice exposed to nicotine during pregnancy have a risk of death after exposed to hypoxic conditions and have disruption of catecholamine release from adrenal medulla. Human and mouse responses to hypoxia include the release of catecholamines from the adrenal medulla to maintain cardiovascular function. Disorders of catecholamine release in neonates exposed to nicotine during pregnancy may cause an increased risk of SIDS.[22,32]

Congenital Anomaly: The effects of tobacco smoke on infanstcongenital anomalies have been investigated. Exposure to tobacco smoke is known to be associated with fetal heart defects including atrial septal defects, atrioventricular septal defects, transposition of large arteries, craniosynostotic cleft palate and gastroschisis.[4,33,34] Exposure to ETS in pregnancy could also affects the abnormalities of the fetus. Research by Hoyt et al. shows that exposure to mothers as secondary smokers is associated with anencephaly and craniorachischisis, spina bifida, palatoschisis (cleft palate), labioschisis (cleft lip) with and without palatoschisis, agenesis or bilateral renal hypoplasia.[35]

Other studies have also shown an association of ETS exposure in pregnancy with anorectal atresia,[36]neural tube defect,[37]and limb abnormalities [38]Meta-analysis study by Salmasi et al on ETS exposed mothers showed a slight increase risk to have a smaller babies, have a congenital anomaly and tends to have smaller head[39]

Conclusion

Tobacco smoke effect the immunity, hormonal and metabolic system in pregnant women. The substance found in tobacco smoke were found to be the cause of some pregnancy complication leading to poor pregnancy outcome such as preterm birth, spontaneous abortion and adverse effect on tha infants. The infants could suffer respiratory disorder, behavior and neural disorder, SIDS and another congenital anomaly. The effect of tobacco smoke, actively of passively, associated with poor outcome for the pregnant women and their babies.
