Correlation Between Oxygen Saturation, Uric Acid and Creatinine Level to Maternal Outcome of a Woman with Severe Preeclampsia

Fadlia Pratiwi Suyuthi[1], Maisuri T. Chalid[1], Samrichard Rambulangi[1], Deviana S. Riu[1], Eddy Tiro[1], Firdaus Kasim[2]

[1]Researcher, [2]Lecturer in Biostatistics and Community Medicine, Departement of Obstetrics and Gynecology, Hasanuddin University, Makassar, Indonesia

Abstract

The aims of the research is to measurecorrelation between oxygen saturation, uric acid and creatinin level to maternal outcomes of a woman with severe preeclampsia. The research is observational with cross sectional cross design. The amount of samples is counted by using categorical correlative analysis uncoupled and the sample taking is using total sampling technique which collected 135 women sample with severe preeclampsia in Wahidin Sudirohusodo General Hospital Makassar. The data is analyzed by using SPSS 21. The result of this research shows oxygen saturation (p=0.021) the uric acid has (p=0.006) association with complication on severe preeclampsia. Oxygen saturation (p=0.000) and uric acid (p=0.028) also has the association with the mortality on severe preeclampsia. Creatinine has no relation with the complication (p= 0.56) and mortality (p=0.358) on severe preeclampsia. The logistic regression analysis shows that oxygen saturation (OR=5.443; p=0.016) and uric acid (OR=4.333; p=0.004)has the relation with the complication on severe saturation. This research concludes that oxygen saturation and uric acid has relation with the complication and mortality on severe preeclampsia.

Keywords: *Severe Preeclampsia, Oxygen Saturation, Creatinine, Uric Acid.*

Introduction

The number of maternal death in Indonesia is still very high, which is 305 per 100,000 life birth in 2015 based on the data showed by Indonesia Republic Minister of Health. This findings is still far from the target planned in the 5th Millenium Development Goals (MDGs) for 2015 which is 102 per 100.000 life birth (Wibowo dkk, 2016)[1].

Until today, preeclampsia and eclampsia still become Obstetric service issue and the mother and baby mortality beside bleeding and infection. The number of preeclampsia case is around 5-10% of the whole pregnancy cases with each country gaining different number of it. In 2015 the World Health Organization (WHO) estimated 303,000 maternal death in the whole wide world. According to the MDGs, the number of maternal death is decreasing 43% since 1990 (Primadi dkk, 2015). World Health Organization estimates that preeclampsia cases are seven times higher in developing countries compare to ones in developer countries. The preeclampsia prevalence in developer countries is 1.3%-6%, while in developing countries is 1.8%-18%. There are 128.273 and around 5,3% preeclampsia incidents in Indonesia and there has not been any indication of the incidents decreasing in the past two decades (Wibowo dkk, 2016; Primadi dkk, 2015). The data is compiled by fetomaternal Division of Wahidin Sudirohusodo General Hospital Makassar, which shows there were 175 severe preeclampsia cases in 2016.

There are several indicators to notify maternal outcomes complication on preeclampsia, which are from oxygen saturation, uric acid and creatinine. <93% oxygen saturation is one of the high risk factors of maternal complication from respiration and non respiration system (Alexandra et al., 2011).

The purpose of this research is to rate the association

of oxygen saturation, uric acid and creatinine level in maternal outcomes of patients with severe preeclampsia.

Methodology

The research is and observational research and cross sectional design. The amount of samples is counted by using categorical correlative analysis uncoupled and the sample taking is using total sampling technique which collected 135 women sample. The samples are pregnant women with severe preeclampsia diagnosis admitted at Dr. Wahidin Sudirohusodo General Hospital Makassar during the period of the research with included and excluded criteria. The included criteria in this research are pregnant women diagnosed with severe preeclampsia who are willing to take part in the research. The excluded criteria are subject with complication before oxygen saturation, uric acid and creatinine test and have history of kidney disorders, cardiopulmonary and metabolic disease. The procedure in the this research is by taking blood samples in order to examine the uric acid level and the creatinine in the laboratory and also to check the oxygen saturation by using pulse oxymetry attaching informed consent signed by the subjects. The data analysis consists of descriptive analysis and hypothesis test. In descriptive analysis, nominal and ordinal data is stated in frequency and percentage distribution. The hypothesis test is using Chi square for free and bound categorical scale. To identify the confounding variable on the outcomes, Chi square test is performed to indicates the rate of the risk. The amount of influence is stated based on the magnitude of risk which is know as Relative Risk (RR) for bivariate analysis. The rate of RR > 1 and the range of trust is not 1, which means the variable is considered to be risk factor. The boundary limits is when $p < 0.5$ with the interval of trust as 95%. The data analysis is conducted by using SPSS program for Windows.

Results

From the research, there are 135 women samples with severe preeclampsia in Dr. Wahidin Sudirohusodo General Hospital Makassar. Some common characteristic are researched suc as gravidity, educational background, occupation, age, gestational age and maternal outcomes. Table 1 shows there no significant differences between the groups of primigravida and multigravida and their relation to mortality and morbidity on severe preeclampsia with percentage 42,2% and 57,8%.

Most of the research correspondents have low educational background (65,2%). Most respondents of the research have steady job, 75 people (55,6%). This reasearch shows that no correlation between occupation incidents on severe preeclampsia.

Most of the respondents of the research are diagnosed with severe preeclampsia at the gestational age of <34 weeks, 85 people (63%). The severe preeclampsia incidents in this research tend to happens to the high risk age group, with the percentage of 59,3%, 80 people.

Table 1. Characteristics of Research Subjects

Characteristics	n	%
Gravidity		
Primigravida	57	42.2
Multigravida	78	57.8
Working Women		
Well Educated	47	34.8
Lower Educational Background	88	65.2
Occupation		
Employed	75	55.6
Unemployed	60	44.4
Gestational Age		
<34 weeks	85	63.0
>34 weeks	50	37.0
Age		
Low risk	55	40.7
High risk	80	59.3
Total	135	100

Table 2. Correlation between oxygen saturation, uric acid and creatinine towards complication incident of severe preeclampsia

Variable	Complication	Without Complication	p
SpO_2			
Normal	18 (78.3%)	106 (94.6%)	0.021*
Abnormal	5 (21.7%)	6 (5.4%)	

Variable	Complication	Without Complication	p
Creatinine			
Normal	10 (43.5%)	59 (52.7%)	0.565**
Abnormal	13 (56.5%)	53 (47.3%)	
Uric Acid			
Normal	7 (30.4%)	72 (64.3%)	0.006**
Abnormal	16 (69.6%)	40 (35.7%)	

*Fisher's Exact Test, **Continuity Correction

Table 2 shows correlation between SpO2, creatinine, uric acid and the existence of any complication what so ever to patients with severe preeclampsia. The level of SpO2 indicates significant association of complication on severe preeclampsia with the rate of p=0.021. The creatinine level does not show any significant association on the complication incident to severe preeclampsia with the rate of p=0.565. On the other hand, uric acid shows significant association with the complication on severe preeclampsia. Severe preeclampsia complication tends to happens to respondents with abnormal level of uric acid (69,6%). This indicates that uric acid has significant association to severe preeclampsia complication incident (p=0.006).

Table 3. Correlation between oxygen saturation level, creatinine, uric acid, to severe preeclampsia mortality

Variable	Life	Died	p
SpO_2			
Normal	124 (94.7%)	0 (0%)	0.000*
Abnormal	7 (5.3%)	4 (100%)	
Creatinine			
Normal	68 (51.9%)	1 (25,0%)	0.358*
Abnormal	63 (48.1%)	3 (75,0%)	
Uric Acid			
Normal	79 (60.3%)	0 (0%)	0.028*
Abnormal	52 (39.7%)	4 (100%)	

*Fisher's Exact Test

The data in table 3 shows correlation between the level of SpO2, creatinine and uric acid towards the incident of mortality to severe preeclampsia patients. The severe preeclampsia patients who finally died had abnormal SpO2 level. On a contrary, only 7 respondents (5%) with severe preeclampsia who survive have abnormal SpO2 level. Correlation between SpO2 level with mortality incident on severe preeclampsia shows significant relation with the rate of p>0.05 (p=0.000).

Creatinine shows no significant association on severe preeclampsia mortality (p=0.358). There are 68 People (51,9%) who survive from the group of severe preeclampsia with normal creatinine level. That number does not show much difference from the group severe preeclampsia who survive with abnormal creatinine level, which is 48,1%. The uric acid has significant relation with mortality incident on severe preeclampsia with the rate of p=0.028. All the death case over severe preeclampsia have abnormal uric acid level. The surviving severe preeclampsia patients dominantly have abnormal uric acid level (60,3%).

Table 4. The effect of oxygen saturation and uric acid towards severe preeclampsia morbidity

Variable	p*	OR
SpO_2	0.016	5.443
Uric Acid	0.004	4.333

*Logistic regression analysis

Table 4 show the logistic regression analysis from the oxygen saturation and uric acid level variable to predict the complication on severe preeclampsia cases. The data in the Table shows the level of SpO2 (OR=5.443; p=0.016) and uric acid (OR=4.333; p=0.004) has significant predictive rate over severe preeclampsia case.

Table 5. The effect of oxygen saturation and uric acid towards severe preeclampsia mortality

Variable	p	OR
SpO_2	0.995	0.000
Asam Urat	0.996	0.000

*Logistic regression analysis

The data in table 5 shows the effect between oxygen saturation and uric acid towards the incident of mortality to severe preeclampsia case. The data also shows that oxygen saturation and uric acid have no significant effects towards severe preeclampsia mortality (p=0.995).

The aims of this research is to identify the association of SpO2, creatinine and uric acid towards the incident of complication on severe preeclampsia patients.

Primigravida is one of the risk factors on preeclampsia cases. It suspected that the case may show because the incompetency of the immune system during first pregnancy between maternal and fetoplacenta tissue (Grum et al., 2017). Our research has shown that there is no significant difference between the groups of primigravida and multigravida with the incidents of morbidity and mortality on severe preeclampsia cases.

Luo et al (2007), in his systematic study shows that the primipara has 2,4 times tendency to experience severe preeclampsia compare to the ones in multipara group. This is different from the study that stated severe preeclampsia cases are more to be found in multipara. Immune system maldaptation suspected as a factor taht may contribute to the high incidence of preeclampsia in primigarvida (Luo,Z. C., *et. al*, 2007)

This research also shows that from 135 severe preeclampsia samples, only 4 people (3,0%) of them died. Curiel-Belsara et al (2011) in the research shows that the rate of mortality on severe preeclampsia reaches 1,5% and tend to happens to multipara. This also indicates that severe preeclampsia has lover mortality number but has more complication cases (17%) (Curiel-Belsara et al., 2011).

Early onset preeclampsia is the condition where the preeclampsia incident happens on the 34th week of gestational age. Late onset preeclampsia is one of the terminologies used when the preeclampsia develops after the 34th week of gestational age (Raymond & Peterson, 2011). Wojtowicz et al (2019), in their research show that early onset preeclampsia tend to experience more severe complication compare to late onset preeclampsia. In our research, we have come across different statement, where are no significant differences between early onset preeclampsia and late onset preeclampsia towards severe morbidity and mortality incident.

Sari et al (2019), in their research shows that severe preeclampsia tend to happens more on the high risk age group. Grum et al (2017), shows that there are no significant differences between age and severe preeclampsia incidents. It is similar to the research we have conducted where most of the severe preeclampsia patients come from high risk group, which is < 20 years of age or > 35 years of age. Von Dadelszen et al (2011), in their research show that there no relation between age with complication incidents on preeclampsia cases. The result is similar to our research, where there are no significant differences found between the age group and mortality and morbidity happens to severe preeclampsia cases.

The oxygen saturation in the research shows that there is significant association that triggers the complication on severe preeclampsia (p=0.021). This suits to the research conducted by Millman et al (2011), that stated that oxygen saturation is able to act as main preeclampsia predictor if it is combined with the accompaniment complaints such as difficult to breathe or chest pain (AUC ROC 0.73; 95% CI 0.67-0.78). Von Dadelszen et al (2011), shows that level of SpO2 <90% also acts as predictor on severe preeclampsia complication.

Creatinine level is one of the parameters used to measure the renal function on patients with severe preeclampsia. Vyakaranam et al (2015), in the research shows that creatinine with 80% sensitivity and 77,4% to measure the renal damage that happens to preeclampsia patients by using 0,7mg/dl limitation. The creatinine level on patients with severe preeclampsia have higher average rate, which is 0.94 mg/dl ± 0.26 SD. Our research has failed to indicates the significant relation between the level of creatinine and the complication incident on severe preeclampsia cases. This is probably caused by the Method od study.

Manjareeka & Nanda (2012), in their research shows that the level pf uric acid on patients with severe preeclampsia have higher rate compare to the normal group. The research shows that the level of uric acid has no relation with the increase blood pressure of preeclampsia patients. On a contrary, the level of uric acid can work as the reflection of kidney function and as free radical scavenging which can be more protective on preeclampsia patients. The research that we have conducted shows higher level of uric acid found on severe preeclampsia patients with complications. This may also support the previous researches which explains that uric acid may has protective role in damaging the organ on severe preeclampsia.

At first, uric acid might decrease at the first trimester with the rate of 3 mg/dl, this happens for the uricosuria effect from the estrogen and the increase of renal blood stream. Uric acid level will be higher related to worse maternal and fetal outcomes. The average uric acid rate on severe preeclampsia patients is 7.88 ± 3.11 mg/dl higher compare to normal group (Kumar & Singh, 2019). The research suits the research we have done where most of the severe preeclampsia patients have complications (69,6%) and die (100%) have abnormal uric acid level.

Conclusion

Based on the result and the discussion of the research, it can be concludes that oxygen saturation and uric acid level have significant correlation with severe preeclampsia mortality and morbidity, while creatinine level has no significant correlation on severe preeclampsia mortality and morbidity incidents. Oxygen saturation and level of uric acid are together have significant effect on the morbidity incident. But it shows no significant effect on severe preeclampsia mortality incidents.

Marriage Tradition of Indigenious Community of Baduy and The Covid-19 Prevention

Farida Patittingi[1], Desti Novita[2], Kahar Lahae[1]

[1]Faculty of Law Hasanuddin University, [2]Attorney General of the Republic of Indonesia

Abstract

Baduy is a group of people who are still primitive, because they still survive with the principles of a long life full of local wisdom, including in conducting marriage rituals. However, the problem with marital procedures is contrary to positive law in Indonesia. In addition, the marriage ceremony conducted by the Baduy indigenous people involves many people which is also contrary to government policies regarding social distancing in handling the Covid-19 outbreak. The purpose of this study is (1) to analyze the marital status carried out by the Baduy community in positive law in Indonesia, (2) to analyze the efforts of the Baduy community to prevent the spread of covid-19 in the midst of procuring a marriage ritual that involves many people. The method in this paper uses normative juridical research and uses three sources of legal material, namely primary, secondary and tertiary. Data analysis was performed descriptively qualitative. The results showed that (1) the legality of the marriage of the Baduy community certainly had no legality and this marriage was not recognized by the state, (2) the marriage ceremony of the Baduy community could still be carried out as usual, bearing in mind that this community was very closed with the outside world long before the Covid-19 pandemic, but this clearly cannot be applied in outside Baduy communities which incidentally still open access for outsiders to visit

Keywords: *Baduy, Covid-19,Indegenious People, Marriage, Tradition.*

Introduction

Baduy indigenous people are a group of people who adhere to their customs, rituals and religion. Baduy community name is actually urang kenekes. They are an Indonesian people who live in the Kendeng Mountains in Lebak Regency, Banten, West Java. In their belief, Baduy people first worshiped supernatural beings, that is, spirits, supernatural spirits that were considered to be the ancestors of the givers of life and death. That spirit is what animates everything. As the sole holder of power called Batara Tunggal. The place where the supernatural creature lives is near the springs of the Ciujung River and the Cisemet River. The shrine is worshiped and is called the Arca Domas. This place of worship is now strictly forbidden to outsiders.

Baduy community trust which is very thick towards spirits makes them have their own traditional ceremonies. The traditional ceremony is used in a variety of memorials and activities, including in marital activities. Usually in the traditional ceremony, the Palawari on the women's side by Ambu, the Baduy tribe calls for the mothers to wear black Kemben traditional clothes and bring rice cone. Then, gather in one of the houses of the people to do rituals and prayers led by Pu'un or the king of Baduy Dalam. Pu'un is the supreme leader of adat as well as adat and religious government. Not only that, after the ritual, the customary leaders or leaders of the Baduy tribe gather in a bale or hall to perform the ratification of the surrogate pair and are led by Pu'un (https://cnnbanten.id : 1). The traditional marriage ritual carried out by the Baduy community is sacred and involves many people.

The ritual has become a natural thing and a normal routine conducted by the Baduy people. However, the problem now is that Indonesia is facing a Covid-19 pandemic outbreak, which in order to overcome the outbreak the government issued a policy on social distancing that must be obeyed by all people to avoid the spread of Covid-19. This regulation clearly contradicts the traditional rituals performed by the Baduy tribe, which involve many people and cause crowds.

Marriage is basically legal, if done according to each religion or belief. Legitimate marriage if done according to State law according to Article 2 (1) of Law no. 1/1974. The intended religious and religious law is not only the law found in the book, but also all the legal provisions (which are still valid for each group). Both of which have preceded this National marriage law. (see Article 66).

The marriage is generally based on mutual liking, but there are marriages that although the bride and groom already like each other, but the marriage is carried out with no outright or underhand marriage or marriages siri or marriage siri, namely marriages that are conducted based on religious or customary rules customs and are not recorded at the marriage registrar's office, not recorded at the KUA for those who are Muslim or in the Civil Registry Office (KCS) for those who are not Muslim. The term siri comes from the Arabic sirran, israr which means secret. Siri marriages, according to the meaning of the word, marriages that are carried out in secret or secret (Yunus, 2009 : 34).

Likewise what happens to the customary law of Baduy people, where a marriage is valid if an orderly procedure has been carried out according to the law of belief, the marriage has been considered valid according to customary law and in the marriage there are traditional rituals that must be carried out by both partners. Customary marriage rituals carried out by Baduy people are based on the beliefs they profess, that is to spirits or supernatural spirits, which beliefs have not been recognized in Indonesian law because they conflict with the provisions of the Almighty God.

Hazairin argues that customary law is not statutory law although as a law it has received temporary recognition in the transitional rules of Article II of the 1945 Constitution. Legislation is always in written form (written law), whereas customary law is not written law. So what is the fate of marriage law according to customary law if it has to do with religious or religious law. Provisions of customary law that conflict with the provisions of religious law or with statutory provisions in the field of religious law. The religion in question is any religion or belief in the belief in the Almighty, if he has legal provisions in the field of marriage. The beliefs that are still held in small groups here and there lie outside the scope of national marriage laws should enter into religion before they do marriages according to the 1974 national marriage law (Zarin, 2014 : 24).

The registration of marriage is affirmed by the state in legislation (Article 2 paragraph 2 of the UUP), which aims to benefit citizens. Because with a siri marriage for men who are not responsible, it will be easy not to do what is their duty to his wife and children, easily getting divorced at will.

As one of the consequences of a legal marriage will result in legal consequences, such as the rights and obligations of husband and wife, marital property, mutual relations between parents and children (nasab), child care obligations (hadhanah) and inheritance. One result of a legal marriage, a child born from such marriage is a legitimate child, has a perfect civil relationship with both parents, as stipulated in Article 42 of the UUP Article 99 of the Presidential Instruction. Number 1 of 1991 concerning Compilation of Islamic Law. Civil relations in question include the right of nasab (lineage) of children connected to the father (in Islam), the right of fulfillment of the livelihood of parents to children, the right of care and education (hadhanah), the right to inherit each other, the right of marriage guardianship for fathers over daughters and other civil rights.

Then the problem in this paper is related to the legal status of marriages committed by the Baduy community. This is because in conducting marriages, Baduy people use their own customary law and are not familiar with the registration of marriage in the office of the marriage registrar, both KUA and KCS. For this reason, the first problem statement raised was how is marriage in the Baduy indigenous community when viewed in positive law in Indonesia? In addition, in conducting marriages, Baduy indigenous people perform traditional rituals or ceremonies that involve large numbers of people and cause crowds, which is against the social distancing policy that is being intensified by the government in its efforts to deal with the spread of the Covid-19 virus. So what about the efforts of the Baduy indigenous people in preventing the spread of Covid-19 in the midst of procuring a marriage ritual that involves many people

Research Method

The type of research used is normative juridical research (legal research) or library law research, namely research conducted by examining mere library materials or secondary data (Soekanto & Mamudji, 2011 : 3).This research was conducted by reviewing cases based on applicable laws and regulations and based on other secondary data obtained.

Result and Discussion

Baduy Indigenous Marriage Rituals: Marriage is a natural law that must occur and be carried out by every human being without exception. This is a perception of the people in the Baduy. A remote tribe located in the foothills of the Kendeng mountains, Kanekes village, Leuwidamar District, Rangkasbitung Regency, Banten has its own unique wedding culture. The Baduy marriage system is the Monogamy marriage. Which means that a Baduy man cannot have more than one wife and a polygamy marriage is a taboo subject. Marriage of the first son (sister) of one lineage to the last daughter (sister) of another lineage. A younger sibling cannot have a marriage before his brother has a marriage (ngarunghal). Furthermore, in practice, there is no difference between Bedouin cousins and cousins between cousins so that there is a tendency for marriages to occur in the closest family, which can occur up to fourth level cousins. In Baduy,they called it, baraya (Badruzaman, 2020 : 35)[2].

In a marriage in Baduy is a process that is not a joke among Baduy residents, because after marriage the married couple inevitably have to be able to meet their own needs. Therefore, before the customary marriage takes place there is a series of traditional processes that must be undertaken by the bridegroom. The process before the marriage consists of bobogohan (the introduction of a mate), marriage proposal and marriage contract.

Bobogohan is a time of introduction between men and women who will get married or married. Men visit women, their future wife. However, the arrival of this man must not be alone. He must come with his male friends. Because in Baduy, unmarried men and women cannot be seen together. In addition, men must help their future in-laws work in the fields. The woman's parents will assess the work of her future daughter-in-law, if it is appropriate to accompany her daughter later. In Baduy, new families must support themselves by working in the fields. However, not all prospective brides undergo bobogohan. Children who are arranged for marriage are often notified and brought together on the day of the wedding ceremony. In the belief of Baduy indigenous people, children cannot refuse arranged marriages by their parents, because they will accept the law of karma. The atmosphere of the Bobogohan program is usually accompanied by a musical instrument playing that is carried by the men. The Baduy call marriage as a harmonious pillar, meaning that marriage must be done, because if not then he will violate his nature as a human being. After the agreement of the two parties to get married, then the application stage was conducted.

The next stage is applications that go through three processes, namely applications submitted from male families to female families. The first application was submitted to express the desire to propose a daughter (expressing the seriousness of the man to the woman). After eight months, the second application was submitted. The second proposal is proof of the seriousness of the family of a man marrying a daughter of the family.After five months, a third application is submitted and if marriage is approved, it can be held immediately (Halwany, 2020 : 3)[4].

All three applications must be passed by every Baduy resident who will hold a marriage, especially in Inner Baduy. For Outer Baduy, the number of applications can be less than three times. During this application period, the male proposal may still be rejected.

After all the processes are gone through, a wedding ceremony is held that can only be held in the fifth month, kanem, katujuh. This calendar is based on pikukuh. Pikukuh which means rules and teachings that must be carried out by the Baduy community, these rules regulate what is permissible and what is prohibited in the Baduy tribe which has been outlined by the ancestors of the Baduy community.

In general, the bride and groom's wedding procession will say the shahada (like the consent of the Kabul), witnessed by Naib as the leader. The registration of marriage by KUA did not apply in Baduy, it was hindered by the belief they believed in. In Baduy, a marriage ceremony and a reception for the bride and groom were held at the Balai Adat, led by Pu'un to legalize the marriage. In the provisions of the marriage system the Baduy people do not recognize polygamy and divorce. They are only allowed to remarry if one of them has died (Halwany, 2020 : 4).

The Baduy people have always held fast to all the provisions and rules set by Pu'un (Head of Custom). Adherence to these provisions is an absolute guide to living life together. In addition, driven by strong conviction, almost the entire Baduy Outer and Inner Baduy people have never opposed or rejected the rules applied by the Pu'un. By living life according to the customs and rules set by the Head of Indigenous people

there, a community with a very peaceful and prosperous society is created. Their lives are essentially the same as other people's lives. The only difference is that there are so many traditional rules that they must obey.

- **Marriage of Baduy Indigenous Peoples Judging from Positive Law:** The Baduy community is a tribe that has a very strong principle. We can see this in the marriage of the Baduy community. Baduy people are very strong in regulating marriages. For the Baduy community, marriage is a natural law that must be implemented, which is usually referred to by Baduy Marriage as a "harmonious pillar", namely that marriage must be carried out so that they do not violate their nature as humans.

Marriage as mentioned in Law No. 1 of 1974 in Article 1 Paragraph 2 which reads "marriage is a bond of birth and heart between a man and a woman as husband and wife with the aim of forming a happy and eternal family based on a Godhead. In carrying out a marriage, the most important thing that must be fulfilled is the harmony and marriage conditions. Pillars of marriage are part of the nature of sustainability. If one of the Pillars is not fulfilled, then the marriage is invalid alias canceled. The condition of marriage is something that must exist when marriage takes place (Asnawi, 2004 : 50)[1].

Aside from the Pillars and Marriage Terms, another more important thing is related to marriage administration. Because the administration of this marriage has an impact on the recording of the marriage. Recorded marriage is a form of written evidence of marriage. Regarding the provisions on marriage registration have been regulated in Article 2 of Law no. 1/1974 which states:

1. Marriage is legal, if it is done according to the law of each religion and its beliefs.
2. Each marriage is recorded according to applicable laws and regulations

Marriage registration is an administration activity of marriages conducted by Marriage Registration Employees (PPN) domiciled in the Office of Religious Affairs (KUA) within the scope of the territory of the two brides' candidates to hold marriages that are Muslim and in the Civil Registry Office (KCS) for non-Islamrecorded according to applicable laws and regulations (Mardani, 2016)[5,3].

The importance of marriage registration is very influential for family life, community life and state life. So that marriages that are not registered can have a negative impact, namely the marriage does not have any legal force in protecting the rights and fulfillment of the obligations of each party, both husband and wife (Mardani, 2016)[5]

If in the future a violation is committed by one of the parties, the injured party cannot claim any legal rights. Actors who are absent from their obligations, legally do not have an obligation to account for what has been done to their partners. Because the bond established in the marriage is not in accordance with the provisions of the marriage law in force in Indonesia and the marriage is considered illegal before the law. Therefore, marriages that are carried out without being registered and registered by the Registrar of Marriage, then the marriage has the potential to cause harm and neglect of obligations in the marriage bond.

As we know, the Baduy people adhere to the Sundanese wiwitan religion. This Sundanese wiwitan belief is a belief in the worship of the forces of nature and ancestral spirits (animism and dynamism) held by traditional societies. Every Baduy must have a Sundanese religion. However, as for those who are Muslim, it is a Baduy community that converted to Islam.

Regarding the legality of the marriage of the Baduy people, of course there is no legality and this marriage is not recognized by the state, because this marriage is only carried out in front of the headman which is carried out based on adat. This marriage was not registered at the civil registry office in accordance with the provisions on marriage registration as regulated in Article 2 of Law 1/1974 and Law Number.22 year 1946 jo Law Number 32 year 1954.

- **Baduy Community Efforts in Preventing the Spread of Covid-19 in the Middle of Marriage Procurement that Involves Many People:** The Baduy Dalam tribe in Lebak Regency, Banten, has their own way to ward off the spread of the corona virus or Covid-19. Even with this method, it has been proven that no Baduy people have been infected by the deadly virus. Baduy Traditional Elder who is also the Head of Kanekes Village, Leuwidamar District, Lebak Regency, Jaro Saija, stated that in order to ward off the corona virus, his party carried out the Kawalu ritual for approximately 3 months(Puji & Setyo : 2020)[6].

To prevent transmission, during the ritual the residents are prohibited from going outside the area, especially Jakarta, Tangerang, Bekasi, Depok and Bogor which have now been designated as red zones. While those who are overseas are asked to go home immediately. Those who return to their hometowns are first required to check their health at the local health center. In addition, the promotion of clean living in order to avoid the Corona virus in accordance with instructions from the Health Office and traditional rules in Baduy.

In addition, efforts are being made to temporarily close traditional tourism objects in Baduy, Kanekes Village, Lewidamar District. The decision was the result of deliberations with traditional institutions, the Village Consultative Body (BPD) and representatives of handicraft entrepreneurs. This is expected to make the Covid-19 virus not spread to baduy tribal communities, both inside and outside (Soekanto, Soerjono & Sri Mamudji. 2011)[7].

Related to the traditional Baduy tribal wedding ceremony that involved many people in the midst of the pandemic of the 19th plague, this should have received attention. Previously we separated first between the Baduy tribe and the outside Baduy tribe. According to the opinion of the writer, the marriage ceremony in the Baduy tribe is no problem if it is still held as usual. This is because, the indigenous Baduy tribe is indeed very closed and only government visits are allowed to enter the area. In addition, people are also not permitted to go outside the area. In addition, the ritual ritual of kawula has also been held.(Yunus, M. 2009)[8]

However, the condition is different from the baduy tribe community outside, where this area can still be visited by outsiders even though they have to go through a series of health procedures first. In baduy society outside it would be nice if the marriage ceremony for the time being did not need to involve many people, as would be done in the tradition of the Baduy. This was done to break the spread of the Covid-19 virus in the Baduy community itself.**(**Zarin. 2014**)**[10]

Conclusion

Baduy indigenous marriages are conducted traditionally and based on the belief they believe makes the marriage is not recorded at the office of the registrar of marriage, both KUA and KCS. This is indeed legally customary, but for the legality issue of the marriage of the Baduy people there is certainly no legality and this marriage is not recognized by the state.

Furthermore, for the problem of the marriage ceremony of the Baduy indigenous people which involves many people, it should be addressed wisely. In dealing with this problem, it is first separated between the outer Baduy tribe and the inner Baduy tribe. In the Baduy tribe in the marriage ceremony in the Baduy tribe there is no problem if it is still carried out as usual. This is because, the Baduy indigenous tribe very closed so there is no circulation of people in and out. On the other hand, outside Baduy tribal communities cannot be applied as such because these communities still open outside community visits. Customary marriage ceremonies to outside Baduy tribal communities should be limited in terms of the number of people as will be applied in the Seba Baduy tradition.

Abstract

The spread and transmission of the virus is very fast and widespread has become a concern of all people in the world to prevent the transmission and overcoming of COVID-19. This paper aims to analyze the legal aspects in overcoming COVID-19 transmission through the application of learning from home, both for schools and colleges. The research is a normative-legal research with statute, case and conceptual approaches. The results show that the attention of the government is more focused on economic and health issues and does not provide a balanced portion of education. Implementation of schooling or lectures from home is currently only regulated in a Ministerial Circular so that it is only a suggestion. Therefore, in order to be able to realize the protection and fulfillment of the right to education during Covid-19 pandemic, the government should issue legislation that becomes a reference for education providers and for the community so that their right to education is still granted under any circumstances.

Keywords: *COVID-19; Constitutional Rights; Right to Health; Right to Education.*

Introduction

Protection of the citizen's rights in a rule of law is a must. The fulfillment of this right is an obligation and responsibility of the State to protect and fulfill rights in all situations and conditions.[1] Looking to case law regarding civil commitment, many scholars and some lower courts have concluded that isolation and quarantine are constitutional only when the government can show by clear and compelling evidence that they are the least restrictive means of protecting the public's health.[2] But one this condition that faced by the world including Indonesia is pandemic Corona Virus Disease 2019 or known as Covid-19. The spread and transmission of the virus is very fast and widespread has become a concern of all people in the world and every country taking rapid steps in order to prevent the transmission and overcoming of Covid-19.

Until now, after 4 months since the first-transmission was announced by the President of the Republic of Indonesia, the curve of increasing the number of positive or reactive viruses continues to grow even in some areas experiencing a very significant increase. Then, prevention of covid-19 transmission was addressed by the government with the issuance of various regulations on all aspects of community life even in some areas that have imposed large-scale social restrictions (hereinafter abbreviated as PSBB – *Pembatasan Sosial Skala Besar*) although the effectiveness of this step cannot yet be said to be effective in the prevention and overcoming of Covid-19.

The aspect of community life that is strongly affected by the spread of Covid-19 is education.[2] Since March, schools and campuses have closed so that the entire learning process is done online or online-learning. Certainly, this is a new thing for most Indonesian people, especially among people who have not or rarely come into contact with technology and informatics. Various complaints from the public regarding the implementation of education from home (school/online-lectures) were not uncommon, ranging from difficulties in understanding learning method to the difficulties of funding related to this system.

The government policy to implement learning from home is carried out in the presence of a circular from the Ministry of Education and followed up by each local government. Online learning solutions is one of the government efforts to provide protection and fulfillment of the community right to health, but on the other hand, various difficulties

faced by the community related to the complexity and additional costs because online learning is the duty of the State to take solutions and attitudes that can provide a balance between the protection and fulfillment of the right to health and education.[3]

Beginning in June 2020, when it began to spread the discourse to re-open education and stopping online-learning system, protests from the community also arose because of fears if schools and campuses became new clusters in the transmission of Covid-19. However, on the other hand there were also circles people who have started to not feel at home with online-learning because it causes various complications and difficulties.

The government's policy to implement learning from home is carried out in the presence of a circular from the Ministry of Education and followed up by each local government. Online learning solutions is one of the government efforts to provide protection and fulfillment of the community' right to health, but on the other hand, various difficulties faced by the community related to the complexity and additional costs because online learning is the duty of the state to take solutions and attitudes that can provide a balance between the protection and fulfillment of the right to health with the right to education. This is interesting for the author to do a study related to legal aspects in overcoming Covid-19 transmission through the application of learning from home both for schools and colleges.

Method

The research is a normative-legal research conducted by examining library materials or secondary data consisting of primary, secondary and tertiary legal materials. The materials are arranged systematically, reviewed then drawn a conclusion in relation to the problem under study. It is carried out by examining library materials or secondary data.

- **Guarding Right to Health and Education: The Constitutional and Human Rights Dimensions:** The discourse on the rule of law began to develop as ideas emerged about the theory of natural law, which grew in Europe in the seventeenth to eighteenth centuries. In general, in the theory of the rule of law, there are 2 (two)types of conceptions about the rule of law, which consist of the concept of the rule of law in the sense of *rechtsstaat* and in the sense of the rule of law. The term *rechtsstaat* is known in Continental-European countries, this understanding was developed among others by Immanuel Kant, Paul Laband, Julius Stahl and Fichte. Whereas, the rule of law was developed in Anglo-Saxon countries, adherents of the common law as pioneered by A.V. Dicey in England. However, basically the two conceptions have one similar purpose, namely the existence of protection of human rights and respect for the dignity of man.[5]

The protection of human rights in a rule of law is carried out among others by establishing a constitution which is a binding basic law based on the highest authority or the principle of sovereignty adopted in a country and in the environment of democratic countries, the people are the holder of sovereignty that determines the enactment of a constitution.[6] Constitutionalism today is considered a necessary understanding for every modern country. This was stated among others by C.J. Friedrich, in essence, that the general agreement or consensus among the majority of the people regarding the idealized building pertains to the State. The organization of the state is needed by members of the political community so that their shared interests can be protected or promoted through the establishment and use of mechanisms called the State.[7] The consensus that guarantees the establishment of constitutionalism in modern times is generally understood to rely on 3 (three) consensus, as follows:[8]

1. Consensus on general goals or ideals (the general goals of society or general acceptance of the same philosophy of government).
2. Consensus on the rule of law as the basis of government or State administration (the basis of government).
3. Consensus on the form of institutions and constitutional procedures (the form of institutions and procedures).

In the view of Frans Magnis Suseno, the rule of law is State authority that must be exercised on the basis of good and fair law which is the basis of all State actions and the law itself must be good because it is in accordance with what is expected by society from the law and is fair because of the intent the basis of all law is justice characterized by (1) legal certainty, (2) demands for equal treatment (3) democratic legitimacy and (4) demands for reason.[9] The ideals of the Indonesian rule of law can be clearly seen from the goals of the Indonesian state contained in the Fourth Paragraph of the 1945 Constitution of the Republic of Indonesia, which is to

protect all Indonesians and all over Indonesia, promote public welfare, educate the nation' life and participate in carrying out world order. These four objectives are affirmed without prioritizing their fulfillment so that the duty of the state in realizing protection is equal and equal to the State's duty in realizing prosperity and intellectual life of the nation.

The protection and fulfillment of the right to health and education is one of the tasks of the State which cannot be ignored under any circumstances. The right to healthas stipulated in Article 28H paragraph (1) which reads "*every person has the right to live in prosperity physically and mentally, to live and to have a good and healthy living environment and the right to obtain health services*." Normatively, the 1945 Constitution does not state that the right to health is a human right or part of human rights. However, because Article 28H is in a chapter or articles regulating human rights, the material is considered human rights or part of human rights.[10] The Indonesian Constitution has affirmed that the right to health is a fundamental right for humans. The basic philosophy of guaranteeing the right to health as a human right is *theraison d'etre* of human dignity. Health is a fundamental right of every human being. Therefore, every individual, family and community have the right to obtain protection for their health and the government is responsible for regulating and protecting so that the community is fulfilled the right to live healthy.[11]

The right to health as a fundamental right that demands state responsibility in its fulfillment is reinforced in the declaration made by WHO and UNICEF known as *Almaata* declaration, namely the important WHO and UNICEF Declaration of Almaata adopted at the International Conference on Primary Health Care in 1978. The conference reaffirms the right to health which is part of human rights, where the fulfillment of the right to health is the responsibility of the State and the goals of the whole world which must also be supported by various sectors.[13]

In the literature, there are several terms used in referring to the right to health, namely: *human right to health*, *right to health*, or *the right to attainable standard to health*. In addition, there are also other terms such as *right to health*, *rights to health care*, *right to health protection* and in broad terms *health rights*. In other words, the mention of the right to health still varies between one author and another, so the term has not been generally agreed upon.[12]

Right to health does not always mean the right for everyone to be healthy and not sick, or the obligation of the government to provide expensive health care facilities that are beyond the government' capacity. But this right is more demanding that the government and public officials can make policies and work plans that lead to the availability and affordability of health service facilities for all in all possibilities and as much as possible in a relatively short time. Article 12 Paragraph (1) of *the International Covenant on Economic, Social and Cultural Right* (ICESCR), the right to health is explained as "the right of everyone to enjoy the highest standards that can be achieved for physical and mental health" does not cover the area of health services.

The regulation of human rights in the constitution has shown that human rights are constitutional content that has the power to bind all parties, including state and regional government officials, executive, legislative and judiciary in the fulfillment of human rights and this is not only the responsibility of state administrators and government, however, is the responsibility of all people and all citizens even though responsibility for the implementation of human rights rests with the government, including the main responsibility in fulfilling the right to education.[14]

- **Reality of Right Protection to Health and Education in COVID-19 Pandemic:** The right to health and education are rights that must be protected and fulfilled by the State under any conditions including during the Covid-19 pandemic. For the fulfillment of the right to health, during the Covid-19 pandemic, the government has issued several regulations, namely:

1. Perppu No. 1 of 2020 concerning State Financial Policy and Financial System Stability for Handling CoronaVirus Disease 2019 (Covid-19) Pandemic.
2. Presidential Instruction No. 4 of 2020 concerning re-focusing activities, budget reallocation and procurement of goods and services in the context of accelerating the handling of Corona Virus Disease 2019 (Covid-19).
3. Presidential Decree No. 11 of 2020 concerning Stipulation of Community Health Emergency of Covid-19.
4. Presidential Decree No. 12 of 2020 concerning the Stipulation of non-natural disasters the Corona Virus Disease 2019 (Covid-19) as a national disaster.

5. Government Regulation No. 21 of 2020 concerning Large-Scale Social Restrictions in the Acceleration of Handling Corona Virus Disease (Covid-19) was established in Jakarta on March 31, 2020 by President Joko Widodo.
6. Presidential Decree No. 7 of 2020 concerning the Task Force for the Acceleration of Corona Virus Disease 2019.
7. Presidential Decree No. 9 of 2020 concerning Amendment to Presidential Decree No. 7 of 2020 concerning Task Force for the Acceleration of Handling Corona Virus Disease 2019 (Covid-19).

In addition to the rules above, the relevant ministries also issued regulations and adopted policies in the context of overcoming Covid-19 transmission, including:

1. Regulation of the Minister of Trade No. 23 of 2020 concerning Provisional Prohibition of Antiseptic Exports, Mask Raw Materials, Personal Protective Equipment and Masks.
2. Regulation of the Minister of Law and Human Rights No. 11 of 2020 concerning Provisional Prohibition of Foreigners Enter the Unitary Territory of the Republic of Indonesia.
3. Regulation of the Minister of Finance No. 23/ PMK.03/2020 concerning Income Taxpayers Affected by Corona Virus Outbreak.
4. Regulation of Financial Service Authority No. 11/ POJK.03/2020 concerning the National Economic Stimulus as a Countercyclical Policy on the Impact of Covid-19 Pandemic.
5. Regulation of the Minister of Health No. 9 of 2020 concerning Large-Scale Social Restriction Guidelines in the Accelerating of Handling Corona Virus Diseases 2019 (Covid-19)

The State is a central actor who holds the main responsibility in implementing policies based on international law or international treaties where the right to health is protected.[15] In carrying out these efforts the state must take strategic steps in the fulfillment of the right to health, by involving all stakeholders in the health sector both from the government and from the private sector. In this case the right to health as a human right legally gives birth to a relationship between an individual and the state, where state obligations relating to human rights must refer to three principles namely respect, protect and fulfill rights for health which is part of human rights.[16] This became the main reason so that in the Covid-19 pandemic, the government issued several regulations, namely:

(a) PerppuNo. 1 of 2020 concerning State Financial Policy and Financial System Stability for Handling the Corona Virus Disease 2019 (Covid-19) Pandemic
(b) Presidential Instruction No. 4 of 2020 concerning re-focusing activities, budget reallocation and procurement of goods and services in the context of accelerating the handling of Corona Virus Disease 2019 (Covid-19).
(c) Presidential Decree No. 11 of 2020 concerning Determination of the Public Health Emergency Covid-19.
(d) Presidential Decree No. 12 of 2020 concerning the Stipulation of non-natural disasters the Corona Virus Disease 2019 (Covid-19) as a national disaster.
(e) Government Regulation No. 21 of 2020 concerning Large-Scale Social Restrictions in the Acceleration of Handling Corona Virus Disease (Covid-19) was established in Jakarta on March 31, 2020 by President Joko Widodo.
(f) Presidential Decree No. 7 of 2020 concerning the Task Force for the Acceleration of Corona Virus Disease 2019.
(g) Presidential Decree No. 9 of 2020 concerning Amendment to Presidential Decree No. 7 of 2020 concerning Task Force for the Acceleration of Handling Corona Virus Disease 2019 (Covid-19).

As described above it can be seen that a number of regulations related to health have been issued but for the right to education it is only regulated in a circular of the Minister of Education so that it appears that the government' priority is on regulations related to health. UNICEF, WHO and IFRC in COVID-19 Prevention and Control in Schools in March 2020 states that in a situation of faster virus transmission, schools must be closed but the education process must continue to run through online-learning activities using various media. This is based on UNESCO data that 1.5 billion students and 63 million teachers at the elementary to secondary level in 191 countries affected by the Covid-19 pandemic and become extraordinary because it has never happened before.

The education world experienced a very significant change because there was a change in the way of learning from face-to-face learning to online learning and digital transformation which is considered the safest way in deciding the spread of the Covid-19 outbreak.

The government' policies related to online or online learning in general provide new experience for all stakeholders related to education and with this policy the government expects that the right to education remains protected even though it is under the Covid-19 pandemic. However, the realization of these government policies cannot be avoided from various barriers that require an effort to arrange the ideal method and mechanisms in overcoming various problems in learning this online method. The reality of Indonesian society shows that information technology does not touch all levels of society. Online learning cannot be done if the school or parents do not have sufficient capital to access the tools. This learning will not occur when teachers and students alike do not have computers, cellphones, or adequate quotas and internet networks. Many complaints both from educators, students and parents related to the implementation of learning from home. Many educators have complained about the limited availability of technological facilities, operational capabilities and internet network limitations in some areas.

To conduct a good learning process, there are basic elements that must be fulfilled, namely curriculum, human resources, teachers, lecturers and staff of teaching facilities and infrastructure. In the atmosphere of the Covid-19 pandemic, there is a need for regulations that can provide regulation and become guidelines for the world of education in conducting teaching and learning processes so that they do not lose the right to education. This regulation must be able to answer all obstacles faced by the community in obtaining their right to education during the Covid-19 pandemic. This regulation not only regulates the procedures but also regulates funding problems in the implementation of education from home because it cannot be denied that the implementation of online learning method requires large costs so that the rules related to the budget and funding must be set forth in the legislation that guides and guides the implementation of certain tasks.

Conclusion

Education is a right that must be protected and fulfilled by the State including during Covid-19 pandemic. Today, the attention of the government is more focused on economic and health issues and does not provide a balanced portion of education. Implementation of schooling or lectures from home is currently only regulated in a Ministerial Circular so that it is only a suggestion. Therefore, in order to be able to realize the protection and fulfillment of the right to education during Covid-19 pandemic, the government should issue legislation that becomes a reference for education providers and for the community so that their right to education is still granted under any circumstances.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

Abstract

The aim of this study is to determine the medical tourism awareness of health workers in public hospitals in South Eastern Anatolian Region. The study was carried out between January-March 2020 and 392 health workers participated in the study. The reliability value of scale, used in the study, was counted as very high (0.921). The medical tourism awareness of health workers in the study was found as low in general (2.89). In the sub-dimensions of scale, the awareness of health workers was found as low. When the sub-dimensions of medical tourism awareness scale used in the study analysed, it was found out that health workers are generally unsure at sub-dimensions of institutional competence (2.83), the effects of medical tourism (2.73), the problems of medical tourism (3.11), medical tourism potential of city (2.83) and medical tourism practices of public hospitals (2.84). According to the results of correlation analysis between sub-dimensions, a positive relationship between all sub-dimensions was determined.

Keywords: *Health, Medical tourism, Health tourism.*

Introduction

Health tourism, which began to be frequently spoken in recent years and regarded as an export opportunity by several countries, is referred as an important foreign exchange inflow for Turkey that attains the high quality in the delivery of health care. Thermal tourism services, which were previously tried to be provided only in thermal facilities, started to spread in health care services later and was referred as medical tourism (MT). Especially, private hospitals and intermediary institutions, had the opportunity to both earn higher income and develop themselves in terms of institutional and labour force and export in health care services by seeing the opportunity in the health tourism and using available health resources.By making health tourism in Turkey a government policy since 2006, a department within Ministry of Health was established and tourism policies regarding the Ministry was started to be developed. New steps have been taken towards especially MT and private sector has been encouraged in this regard.

Today, people make great efforts to stay healthy and increase their life quality. With this effort, individuals who want to get cheaper, more quality and out-of-turn health service travel to abroad. Travels of those people have led a new and different field as a MT to arise in the tourism sector (Connel, 2006, p. 1093)[6]. MT is defined as "trips which are made to abroad by a tourist for treatment and rehabilitative health services" (Pollard, 2010)[9].MT means "benefitting from cross border health opportunities to get affordable services which are not available or do not have long waits in one's home country" (Carrera and Bridges, 2006)[5]. According to (Yun Yu and Gyou Ko2012:80), MT is to travel to overseas countries for treatment and care. (Lee and Spisto 2007:1)[8]defined MT as "travelling to another country in order for tourist to feel better or get treatment". According to (Khan and Alam 2014:258)[7], it istravelling of someone to another country which is made to get healthy again in cases like dental treatment and organ transplantation.

Factors that motivate tourists to made MT to receive treatment in another country are; shorter waiting periods than those of their countries, decrease in cost, private treatments, more quality care, the charm of new and

different, non-covered treatment, high-level technology, desire to be treated in the countries having scientifically medical activity all around the world (Woodman 2009, Ministry of Health 2012:13)[13]

In terms of medical tourism, our country has important touristic destinations, critical labour force potential with young population and trainability and several advantages by providing appropriate conditions to treat patients more quality and economically in a positive environment and most of the health institutions are at a level that can compete with the West (Eriş, 2019)[3]. In addition, insufficient publicity, inadequacy in terms of human rights, negative image, the lack of coordination with foreign insurance companies, not giving adequately weight to marketing strategies and marketing researches, the lack of coordination between Ministries and sectors are among the disadvantages (Tengilimoğlu, 2005:92)[11].

The aim of this study is to determine the medical tourism awareness of health workers, in public hospitals in South Eastern Anatolian Region.

Material and Method

Population and Sample: The population of study consists of approximately 15.000 workers in the public and university hospitals in the city centre of Şanlıurfa, Gaziantep, Batman, Diyarbakır, Adıyaman, Mardin and Siirt. With simple random sampling method, the size of sample was determined as 377.

Data Collection Method: Two method as face to face interview and drop off/pick up method were used to collect data. The study was carried out in January, February and March 2020. During the conducting of questionnaire, 392 questionnaires, filled out by voluntary participants, were included in the assessment and analysed was made. The questionnaire, created in the study named "A Research on Health Care Worker's Awareness of Health Tourism: Example of Ahi Evran University Education and Research Hospital Workers" carried out by Acar and Turan (2016)[1], was taken as reference. In the questionnaire, created to be used for data collection, there are 27 statements and participants are asked to give answers according to 5-Likert scale.

The Analysis of Study Data and The Assessment of Study Findings: Data collected in the study was analysed with SPSS 20 package programme. In order to determine the demographic and personal features of hospital workers, which constitutes of sample group, the analysis of frequency, percentage distributions were made; correlation analysis was made to determine the arithmetic means of answers given by health workers to the statements in the scale and their standard deviation and relationships between sub-dimensions of the scale.

Findings: Finding obtained are presented in this chapter of the study.

Table 1: The Reliability Analysis Findings for Scale and Sub-dimensions

Scale and Sub-dimensions	The number of statements	Cronbach's Alpha
The Scale of MT	27	0.921
Institutional Competence	11	0.914
The Effects of MT	5	0.687
The Problems of MT	3	0.720
MT Potential of City	4	0.657
MT Practices of Public Hospitals	4	0.715

The findings of reliability analysis of scale and its sub-dimensions in the study were shown in Table 1. According to the findings, the reliability of scale and sub-dimensions are found as sufficient or very high.

Table 2 The Frequency Distribution of Demographic Information of Hospital Workers in the Study

		Number	Percentage
Sex	Male	200	51.0
	Female	192	49.0
Age	18-25	67	17.1
	26-40	174	44.4
	41-65	151	38.5

		Number	Percentage
Education	High School	65	16.6
	Two-year Degree	99	25.3
	Undergraduate	166	42.3
	Graduate/Postgraduate	62	15.8
Job	Doctor	57	14.5
	Nurse	143	36.5
	Other Health Workers	145	37.0
Department	Administrative Personnel	49	12
	Medical Department	318	81.1
	Administrative Department	74	18.9
City	Diyarbakır	65	16.6
	Urfa	75	19.1
	Antep	58	14.8
	Batman	46	11.7
	Siirt	56	14.3
	Adıyaman	45	11.5
	Mardin	47	12.0
	Total	392	100

The distribution of frequency for the demographic information of hospital workers that participated in the study are shown in Table 2. It was find out that hospital workers work in 7 cities, Şanlıurfa, Diyarbakır, Gaziantep, Batman, Siirt, Adıyaman and Mardin, located in South Eastern Anatolian Region, 51% of them are male, 44.4% of them are at 26-40 age group, 42,3% of them have bachelor's degree, 37% of them are in the other health workers group and 81.1% of them work in a medical department.

When Table 3 analysed, hospital workers state that they are unsure regarding the medical tourism awareness in general. When the sub-dimensions of medical tourism awareness scale, used in the study, analysed, they state that hospital workers are generally unsure at dimensions of institutional competence (2.83), the effects of medical tourism (2.73), the problems of medical tourism (3.11), medical tourism potential of city (2.83) and medical tourism practices of public hospitals (2.84). According to the results of correlation analysis between sub-dimensions, a positive relationship between all sub-dimensions was determined.

Table 3. The Means of Answers given to MT Awareness

	Mean	Std. D.
Institutional Competence	2.83	0.909
The Effects of MT	2.73	0.928
The Problems of MT	3.11	1.089
MT Potential of City	2.83	0.961
MT Practices of Public Hospitals	2.82	0.936
The Scale of Medical Tourism Awareness Total	2.84	0.741

Table 4 Correlations of Sub-dimensions of Medical Tourism Scale

		Institutional Competence	The Effects of MT	The Problems of MT	MT Potential of City	MT Practices of Public Hospitals
Institutional Competence	Cor. coeff.	1	,478**	,265**	,541**	,673**
	p		,000	,000	,000	,000
The Effects of MT	Cor. coeff.		1	,371**	,501**	,525**
	p			,000	,000	,000
The Problems of MT	Cor. coeff.			1,000	,432**	,394**
	p				,000	,000
MT Potential of City	Cor. coeff.				1,000	,618**
	p					,000
MT Practices of Public Hospitals	Cor. coeff.					1,000
	p					

**Shows the significant relationship for p<0,01

The correlation relationships between the sub-dimensions of medical tourism scale are shown in Table 4. When the table analysed, it is seen that there are positive relationships between all sub-dimensions of medical tourism scale. When the sub-dimensions, in which the positive relationship is highest, analysed, it seen that it is between “MT practices of public hospitals” and “institutional competence” (.673). The lowest positive relationship was found between “the problems of MT” and “institutional competence” (.265).

Conclusion and Suggestions

MT has become a field that comes to prominence within the health tourism in recent year. MT which especially draws the attention of private hospitals, is a field on which public and university hospitals should put emphasis.

In this study, it is aimed to determine the MT awareness of hospital workers in the public hospitals in South Eastern Anatolian Region. According to the data obtained from the study, it was found out that 392 hospital workers that participated in the study are unsure (2.84) regarding the scale, used in the study, in general. Hospital workers did not present a positive or negative opinion because they could not be sure regarding the statements in the scale in general and they stated that they are unsure generally. In addition, it is predicted that they did not present a certain opinion regarding the scales in the studybecause hospital workers do not have adequate information on medical tourism.

When the sub-dimensions of scale in the study analysed respectively, hospital workers are unsure regarding all sub-dimensions. At the first sub-dimension of scale, institutional competence, hospital workers stated that they are unsure regarding both general dimension (2.83) and the means of answers given to statements. Hospital workers stated that they disagree with the statements, “This Hospital follows the scientific publications and practices” (2.60) and “This Hospital is proper for health tourism in terms of technological equipment” (2.60), the means of answers give to the statement, “This Hospital is appropriate for medical tourism practices in general” (2.70), was found as low in general and they stated they are unsure regarding the statement. Generally, it was found out that hospital workers are unsure about whether the hospital they work for is institutionally adequate for medical tourism.

At the effects of medical tourism sub-dimension, the second sub-dimension of scale, it is seen that hospital workers are unsure in general (2.83) and according to the answers given to the statements. When the statements of the effects of medical tourism sub-dimension analysed one by one, hospital workers stated that they are generally unsure regarding the statements, “Foreign patients are the source of income for our hospital” (2.65) and “Foreign patients enable our city

to develop economically" (2.69). There is not a certain opinion regarding the other statements of the effects of medical tourism sub-dimension. In general, they have doubts regarding the effects because they do not know the medical tourism.

At the problems of medical tourism sub-dimension, another sub-dimension of the scale, it was found out that hospital workers are generally unsure (3.11). When the means of answers given to the 3 statements of the problems of medical tourism sub-dimension analysed, it is seen that they are unsure regarding all three statements.

At the sub-dimension of medical tourism potential of city, another sub-dimension of scale, it was found out that hospital workers are generally unsure (2.83). Although hospital workers stated that they disagree with the statement, "This city has adequate reserves in terms of thermal springs" (2.58), they stated that they are unsure regarding other three statements.

At the sub-dimension of medical tourism practices of public hospitals, another sub-dimension of scale, it was found out that hospital workers are generally unsure (2.823). Although hospital workers stated that they disagree with the statement, "Foreign patients can prevent us from giving adequate attention and care to native patients" (2.52), they stated that they are unsure regarding other three statements.

When the correlation relationships between all sub-dimensions of medical tourism scale analysed, it is seen that there is a positive relationship between all sub-dimensions of medical tourism scale. It can be said that sub-dimensions of scale have positive effects on each other. It is seen thata positive increase in one of the sub-dimensions would cause a positive increase in other sub-dimensions.

When the literature review analysed, it is seen that there are limited studies regarding the medical tourism awareness of health workers. As a result of the study, carried out by (Acar and Turan 2016)[1], they found out that health workers are unsure regarding the medical tourism potential of city in which they work and the medical tourism practices of hospital for which they work. They obtained results which are similarasour study. In a study regarding the medical tourism perceptions of doctors that work in a university hospital, carried out by (Erdoğan 2018)[2], it was found out that doctors are unsure regarding the medical tourism potential of both their hospital and Isparta. In a study regarding the medical tourism awareness of health workers, carried out by (Dökme et al. 2018)[4], it was found out that health workers are highly anxious about the providing of health services in their hospitals.

In conclusion, it is the seen that the medical tourism perceptions of health workers in their city and hospital are low. That the managers of public hospitals, especially Ministry of Health, primarily give trainings to health workers about medical tourism and make hospitals ready for medical tourism would be helpful.

Two authors collaborated at all stages of this research. Ethical approval was obtained from Harran University Social and Human Sciences Ethics Committee.

Evaluation of the Results to Digestive Endoscopy Patients in Azadi Teaching Hospitalin Kirkukcity

Rebaz Ismael Ali[1], Marghoob Hussein Yaas[2]

[1]Lecturer, Faculty of Medicine, College of Nursing, University of Kirkuk ,College of Nursing,
[2]College of Nursing-University of Al-Kitab, University of Al-Kitab, Altun Kupri, Iraq

Abstract

Background: Esophagogastroduodenoscopy (EGD)endoscopic findings, such as esophagitis, bleeding, ulcer and malignancy, represent a public health problem.

Aims: To evaluate patients results after doing digestive endoscopy and to determine the, characteristics and results of endoscopy among patients in Kirkuk city hospitals.

Methodology: The samples purposively collected from the patients who referred for Esophagogastroduod endoscopy unit in Azadi teaching hospital in Kirkuk city for period from one September 2016 to the 12th September 2018. The study sampled consist of (70) patients with digestive diseases were selected (male & female). A questionnaire was developed for purposive of study & included 2 parts were demographic data, endoscopy characteristics. The data were arranged for, age,gender, residence and the results of the procedure.

Results: The age group (20-29) years was represent (31.4%) of the sample, the female represent (64.3%) from the sample, the residence (70.0 %) were living in urban and the frequency of endoscopy is majority of the sample (72.9%) were scheduled for two time.

Conclusion: The study showed highest percentage endoscopic finding gastritis and cancer for indication and repeated vomiting for complication.

Recommendation: The study recommended promote best health practices and early nursing management optimized for the endoscopy of G.I.T disease to reduce damage and prevent complications.

Keyward: *Evaluation, Digestive Endoscopy.*

Introduction

Philipp Bozzini was the first one who developed endoscope technology in 1806 in German Mainz utilizing "for the examinations of the canals and cavities of the human body"[(1)]. At the beginning of the eighteenth century a flexible fibrotic type of endoscope and since that became as part of standard practice in medicine and Gastrointestinal tract endoscope which is characterized by easiness and safety with a highly valuable assistance method in diagnostic and therapeutic. Further to the that low in cost and mortality[(2)]. Aforementioned technology can be used to examine gastrointestinal (GI) symptoms such as difficulty swallowing, abdominal pain, nausea, vomiting and hemorrhage. Another utilizing is diagnosed by taking a biopsy investigating GI system for inflammation, bleeding, anemia, tumors and bleeding. The third use can be used for treatment expanding narrowed esophageal, bleeding vessel cauterization and cutting off an extra or a foreign bodies removing[(3)]. Peptic ulcer (duodenal and viscus ulcer) is common in men and prevalence is distended with age with a top prevalence of twenty eight point eight% in five the last decade of life[(4)]. The examination of endoscopic is vital, evaluating and managing higher and lower canal issues. Organic process disorders are very frequent inside the normal population [(5)]. The function of endoscopy in bleeding peptic ulcer disorder is critical. It is a positive device in diagnosis, prognostication and medical aid of harm ulceration. The desires of excellent endoscopy – receipt of an accurately indicated procedure, a right diagnosis and excellent care have to be done with the minimal threat to the patient

and take place in a properly – geared up facility staffed through true education and in a position endoscopists[6]. Bleeding is the 1st danger of issues after an endoscopy is expanded if the technique involves casting off a piece of tissue for trying out (biopsy) or treating a digestive device problem. The second danger is the infection in most endoscopies that consist of an examination and biopsy and risk of contamination is low and in the end danger is tearing of the gastrointestinal tract. The risk will increase if the extra procedures such as dilation to widen esophagus, are carried out[5].

Methodology

Design: To descriptive design was applied in the present study to achieve the objectives was from one September 2016 to the 12th September 2018.

Sampling: A Purposive sampling of (70)sample selected from the patients were attended hospital according to following criteria:Patient who done the endoscopy in any part of GIT system, where, male and female with ages ranged between (10- 60 and over).

Setting: The present study was conducted at azadi teaching hospital which receiving large number of patient who have GIT endoscopy done for them for diagnosis or treatment.

Tools: A questionnaire was adopted and developed for the purpose of the study, it comprises of (2) parts, part (I) included demographic characteristic of patients which consists of (9) items. It includes (age, gender, residence, marital status, educational Level, occupation, smoking, NSAID, number of endoscopy). Part (II) endoscopy characteristics. This part was concerned with the patients characteristics about endoscopy. It comprised of(36)items . That's classified as the following: Endoscopic organ site use, Indication of endoscopy, Reason of endoscopy, Result of endoscopic and Complication after GIT endoscopy. All items were measured by using 3-likert scale option were used in the rating scale as(Always, Sometime, Never) . The data were collected through the utilization of constructed questionnaire, interview technique with the patients in hospital. The data Was collected between (21thNovember in 2016 to 29th March in 2017).

Data Analysis: Data were analyzed by using descriptive statistics, which include Descriptive statistical method (Frequency, percentages and Mean of score) and Inferential statistical method (ANOVA), by using; Statistical Package for Social Science (SPSS) version (23) is used for data analysis at (P.value ≤ 0.05).

Table (1) indicates the socio-demographic characteristics of the whole study sample. The it shows that the highest percentage of age groups is between (20-29 years) and constituted (31.4 %) and according to gender, the high percent was of females and constituted (64.3%). With regard to residence, (70.0%) of patients were living in urban areas, most of the patients were married and constituted (65.7%). (24.3 %) of the sample were primary school,As regard to occupation, (41.4 %) patients were housewives. With relation to smoking, the majority of the subjects (64.3%) were smokers. The high percent in ibuprofen and constituted of (42.9%), were NSAID. Finally, in respect to the frequency of endoscopy, the majority of the sample (72.9%) were scheduled for two time.

Table (2) Mean of scores for objects of patients' endoscopy concerning the organ site use of endoscopy.

Endoscopic Organ site Use	Always		Sometime		Never		MS
	f	%	f	%	f	%	**1.7286**
Esophagus	15	21.4	21	30.0	34	48.6	2.8429

Hypertension	4	6.7	22	36.7	34	56.7	1.4857
Emphysema	5	7.1	19	27.1	46	65.7	1.4143
Allergy	1	1.4	18	25.7	51	72.9	1.2857

Table (6) indicates that the mean of score was highly significant in items(1-2) and moderately significant in items (4) and low significant in items (3-5-6-7-8).

Table (7) statistical Differences between Gender, Smoking, NSAID, Number of endoscopy and Associated with Results to Digestive Endoscopy.

Categories	S.O.V	Sum of Squares	df	Mean Square	F	Sig.
Gender	Between Groups	11.048	31	.356	2.696	S.
	Within Groups	5.024	38	.132		
	Total	**16.071**	**69**			
Smoking	Between Groups	7.810	31	.252	1.159	N.S
	Within Groups	8.262	38	.217		
	Total	**16.071**	**69**			
NSAID	Between Groups	55.152	31	1.779	.776	S.
	Within Groups	87.148	38	2.293		
	Total	**142.300**	**69**			
Number of endoscopy	Between Groups	14.471	31	.467	1.570	S.
	Within Groups	11.300	38	.297		
	Total	**25.771**	**69**			

Table(7)demonstrates that there is a significant difference in gender, NSAIDs, number of endoscopy and no significant of smoking in respect to the patient's digestive endoscopy at $P < 0.05$.

Discussion

Table (1) indicates the socio-demographic characteristics of the whole study sample. The it shows that the highest percentage of age groups is between (20-29 years) and constituted (25.7%)

The explanation of this result the young age in our country face several issues like security situation and no gift of utilized there for the young age became additional nerve-racking and suffer from completely different issues like Gastro enteric issues. Mentioned that over seventieth of all ulceration cases occur in people between the ages of (25 and 64) years(7).

According to gender, the high percent was of women and constituted (64.3%). Interpret of this end result related to pregnant may reasongastro esophageal reflexes disorder,also can also related to use of contraceptive medication. Also the women additionally appear to have slower emptying of meals from the belly than men. This can also be necessary in explaining why women have a tendencyto trip nausea and bloating more regularly than men. Also supported this result when they noted that the incidence of duodenal ulcer in male to female is 2 – 3: 1 whilst in gastric ulcer are 1:1.(8)

With regard to residence, (70.0%) of patients were living in urban areas.Because the clinics place in center of governoratein this manner we obtain most of them beginning urban area. Also the results appears most the patients were married and constituted (65.7%). (24.3 %) of the sample were primary school, As regard to occupation, (41.4%) patients were housewife. Mentioned that occupation has been related to the progress of peptic ulcer (PU) (7). With relation to smoking, the majority of the subjects (64.3%) were smokers. The high percent in Ibuprofenand constituted of (42.9 %), were NSAID. Finally, in respect to the frequency of endoscopy, the majority of the sample (72.9%) were scheduled for two time.

Table (2) Mean of scores for items of patients' endoscopy regarding the organ site use of endoscopy. Table (2) indicates that the mean of score was highly significant in items(2-stomach) and moderately significant in items (3 Duodenum) and low significant in items (1- esophagus and 4-colon), Declarethe Peptic ulcer extra common happens with endoscopy and come out in 20% - 40% of people who live in industrialized countries and merely about 15%-25% of these people in fact have an ulcer (9).

Table (3) Mean of scores for items of patients' endoscopy regarding the indication of endoscopyand shows the mean of score was moderately significant in items (1-infection, 5-spasm and obstruction, 6 life style

events). Mention to the majority patients alluded for endoscopy complain of symptoms that come below the general heading of indigestion (10)

Table (4) indicates that the mean of score was highly significant in items (2-chronic constipation). Interpret of this result related to the constipation consider a big problems there for when patients suffer from this problems will try to find the main cause for this problems by endoscopy. Is disagreement with our learn and reveal that every the patients with a finding of esophageal tumor were properly referred but 10 absent of 70 patients with a diagnosis of gastric cancer, all elderly more than 50 years, had unfortunate indication for EGD (research of primitive cancer in patients by way of adenocarcinoma metastases) (11)

Table (5) about results of endoscopic and shows that the mean of score was moderately significant in items (2-gastritis and 10-gastro dudenitis) . Mention that thegrades of endoscopic analyze as oesophagitis, metaplastic epithelium in the gullet, hiatal hernia or imperfect sphincter closure, soreillness, erosive or nodular gastritis and cancer. In expansion, the worked abdomen was scored (12)

Table (6) indicates of complications of endoscopy and shows that the mean of score was highly significant in items (1-poor appetite and 2-vomiting). Account so as to complications of esophagogastroduodenoscopy (EGD) is connected by a 0.1% occurrence of complications. The largelyimortant of these complications are perforation thenhemor- rhage. Desire, Mallory-Weiss tears and former “minor” complications such since retroesophageal swelling have too beendepicted (13).

Table(7) illustrate that around is a significant difference in sexual category, NSAIDs, number of endoscopy and no significant of smoking in accept to the patient’s digestive endoscopy on $P < 0.05$. Recover that the main pathology (tumour, ulcer, or stricture) was found by endoscopy in 787/3815 (21%) patients through digestive disorder. Age, male sex, hemorrhage and anemia were found to be significant but vulnerable independent indicators of endoscopic result. A multivariate prediction regulation based on these factors had bad predictive accuracy (c statistic=0.62). Using a simplified prediction rule of age >45 years before the attendance of some “alarm” symptom, affectability was 87% and specificity was 26%. Rising or declining the age reduce bad did not significantly advance the prognostic truth (14).

Conclusion

Further than one quarter of the study test their age ranging beginning (20 – 29) years. Although height percentage in married status who had investigative and therapeutic endoscopes among too much voltage, food preparation and anxiety at home. One third of studies patient’s smoker followed over half of studies sample taking NSAIDs. The more I have done them Endoscopy they are two-off due to the early diagnosis of the sickness. The study showed elevated percentage of endoscopic finding site in stomach and duodenum.

Recommendation:

1. Promote best health practices and early nursing management optimized for the endoscopy of G.I.T disease to reduce damage and prevent complications.
2. Availability of endoscopic facilities at all hospitals in city and make it accessible to all population and thus enables earlier diagnosis of digestive tract diseases.
3. Expansion of the service with endoscopic, more relevant accessories and diagnosis and facilitate therapeutic measures.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

Non Genetic Study for Autism Child in Related to Age And Sex of Autism Child, Parental and Maternal age And Degree of Relative and Family History with the Disease or Any Other Psychological Disorder in Anbar Governorate

Raida Noori Hamid[1], Shakir Mahmood Ali[2], Shaimaa Hamid Mudher[1]

[1]Lecturer, [2]Ass. Lecturer, College of Dentistry, University of Anbar, Iraq

Abstract

Aims of this study were find the relation of the non-genetic factors related to the parents of the autism child, the child himself and the family history in specific points because there is no perfect causes for the autism., the autism child including the age of mother during delivery of these child, the degree of kinds hip between the parents, the sex of the child. The information taking from 80 children present in institute of the Virgin Mary for Autism & Balsam institute for Autistic patients, from both sex, the age of them between 3-16 years who suffer from Autism. Data collected we distributed forms to autistic families for the purpose of taking the information we needed. There is no significance relation between parental or maternal age and autism, male greater than female, family history not effects on the presence or not of autistic disorder.

Keywords: *Autism, non genetic factors, Anbar governorate.*

Introduction

The autism is defined as a severe social problem which marked by difficult communicated with environment or the surrounding people, in the speaking, the repetitive and the behavioral limitations and an strong and over response to any events in the surrounding [(1)]. The autism is considered as a chronic disorder that could be occurred at early childhood, that divided into three types of disturbances in behaviorwhich are: the social irritability, a speakingproblems and a repetitive form of the behavior [(2)]. It is also explained as a clinical problems which appear as delayed in development or deviation in the way of development.[(3)]. In 1990s the reported cases of autism were increased until in 2000s.this result of increasing in number change The numbers of the reported cases of the autism increased dramatically in the 1990s and in the early 2000s.these increasing in number belong to change in the practices of diagnosis,the patterns referral,the time of the diagnosis and the social awareness[(4)].

The outward appearances of the autistic children may not indicate as a disorder. The diagnosis of the state occur by taking all the information of the patient t, any neurological or physical disturbances. There are many possible causes for autism belong to before the delivery period which are include disturbance of respiratory system, anemia, the mother taking large amount of drug during pregnancy of autistic children, or the occurrence of bleeding after the 1 st trimester and the amniotic fluid defect[(5)].autism also have a genetic change in spite of there is no one know the number of gene that affected[(6)].

The common cause of the autisimanomalies of the chromosome 15 and the chromosome 17q21,numerical and formal abnormalities of the sex chromosomes, are the common cause of the autisim.[(7)] for ASDs the environment also play a role in the development of the disorders . the possible causes for autism spectrum disorder as an environmental factor are radiation and mercury[(8)]. The studies which talked about consider the MMR vaccination as one causes for autism,another study provide a strong refuse for these hypothesis [(9)] the mixing of DPT and MMR vaccines may affect the immune system of children that enhance the autistic biomedical cascade [(10)]. The are many studies suggest the family factors such as the education level, age of child and parents while the age of parents related to many

disorder or health problems such as cancer of childhood period, schizophrenia, death of fetus, however,the relation of parental age and autim still not clear [11].

Another articles study that congenital malformations have appositive relation with low birth weight(<2, 500 g), fetus birth less than 37 weeks the low birth boys according to gender related study say that it is increased risk of autism greater than low birth weight girls (<2,500 g) [12]. When there are many differences between The monozygotic twins this will enhance the non-geneticeffects of the autism [13]. Because of there are many limitations in the studies made before or after the birth for the risk factor in autism this proved the relation between them still unknown [14].

The aim of the study: To find the relation between the non-genetic factors related to the parents of autism child, the child himself and the family history in specific points because there is no perfect causes for the autism.

Research Methodology

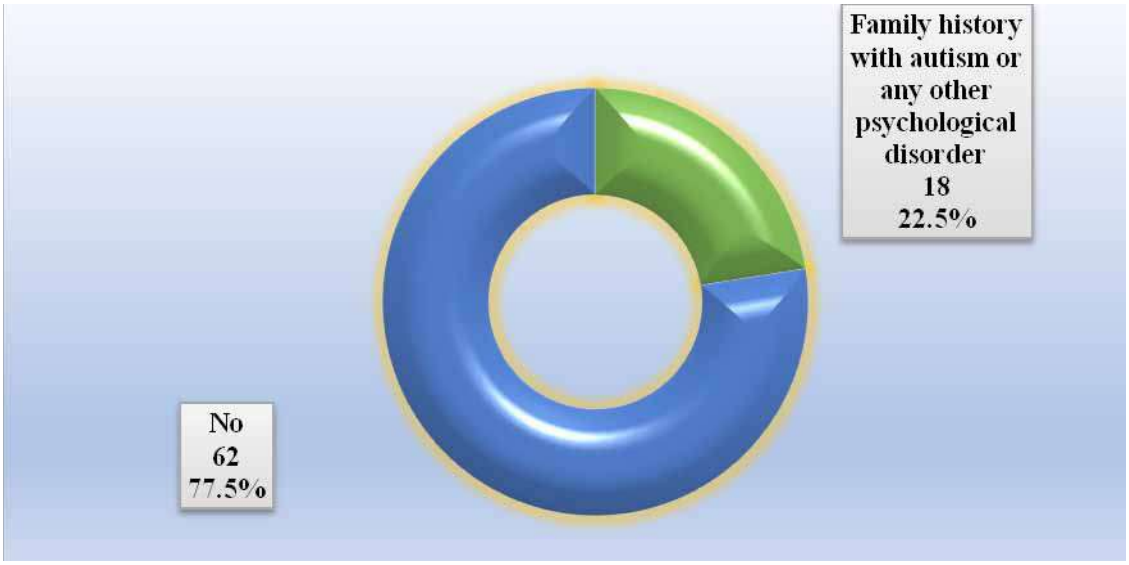
The information taking from 80 children present in institute of the Virgin Mary for Autism & Balsam institute for Autistic patients, from both sex, the age of them between 3_16 years who suffer from Autism. Data collected we distributed forms to autistic families for the purpose of taking the information we needed. The sample was divided firstly on the base of age of the autistic child into three groups which are under the age of 5 years, between 5-9 years and above 10 years. In addition the sample divided on the base of sex into two groups which are male and female. In this study the age of parents(father and mother) was taken at the day of the child birth. In addition to that the relative degree was taken for the parents of the autism children (relative or not). Family history with autism or any other psychological disorder was taken.

Results

Statistical package of SPSS-25 (Statistical Packages for Social Sciences- version 25) was used to do analysis for the data.Mean, percentage,frequency,percentage,standard deviation and range are used in presenting the data . Pearson Chi-square test (□2-test) with application of Yate's correction or Fisher Exact test were measure the significance of difference of different percentages (qualitative data). Statistical significance was considered whenever the P value was equal or less than 0.05.

The male was 67 (83.8%) and the female was 13 (16.3). the age was 7 (8.8%) under the age of 5 years and 50 (62.5%) between 5 and 9 years and 23 (28.7) above 10 years old.

		No	**%**
Age of autistic child (years)	<5y	7	8.8
	5---9y	50	62.5
	=>10y	23	28.7
	Mean±SD (Range)	8.0±2.7 (3-15)	
Sex of autistic child	Male	67	83.8
	Female	13	16.3



In this study the age of mother and father was taken at the day of the child birth and it found that the mother age was less than 20 year for 7 child (8.8%), 20-29 years for 46 child (57.5%), 30-39 years for 25 child (31.3%) and more than 40 years for 2 child (2.5%). The fathers were 20-29 years for 31 children (38.8%), 30-39 years for 42 children (52.5%), more than 40 years for 7 children (8.8%).

		No	**%**

Discussions

Among all the professionals there is agreement that the autism is one of the most difficult and puzzling diseases. It is considered as a neuro developmental disorder and characterized by the impaired of social interaction; its prevalence has increased in recent years[15].

In our study the high percentage of patients was between the ages 5-9 years which was 62.5%, while under the age 5 years the percentage was 8.8% and above the age 10 years it was 28.7% and this findings are in disagreement with the findings of Farida El-Baz et al [16] who found 46% of the cases was at the age of 1.5 years and 4% at the age of 4 years. and also in reverse to the findings of Gray and Tonge[17] who found high percent of autism children at the age of 1-2.5 years. In contrast our findings were in agreement with the findings of Paul et al. [18] who reported that the average age of identifications is 5.7 years. This study showed that the percentage of the males was more than the females (males 83.8%, females 16.3) and this was in agreement with the study of Farida El-Baz et al [16] who found that the percentage of the males was 71.3% and the females was 28.7% and this was also consistent with the study of Itzchak et al [19] in which the males was 81% and the females was 19%. Regarding the maternal and paternal age of the autism children at the birth our study showed the high percentage was the age of 20-29 years of the mothers (57.5%) followed by the age of 30-39 years (31.3%) while for the fathers the high percentage was at the age 30-39 years (52.5%) followed by the age of 20-29 years (38.8%) and this was in disagreement with the study of Kolevzon et al [8] who found that the risk of the autism increased with the advanced age of both father and mother. While the study of Marissa et al [20] showed that increased maternal age, regardless the paternal age, may associated with greater risk of autism. Our study dealt with the consanguinity of the father and mother of the autistic children and showed that 67.5% of them are not relative and 32.5% of them are relative and this findings was in agreement with the findings of Farida El-Baz et al [16] in their study who found that 87% of the parents of the autistic children was non consanguineous while Muhle et al [21] showed that the families of the autistic individuals tend to show a set of cognitive disorders which are not seen in the other family groups. This study showed the percentage of 77.5% of the autistic children were with no family history with autism or any other psychological disorder in contrast 22.5% of them were with a history of family autism or psychological disorder and this was in reverse to the findings of SherllyXie et al[22] in their study who suggested that the family history mental or neurological disorders was associated with the increased risk of autism and also Bilder D et al. [23] showed in their study the family history of autism was found in 16% of the cases versus 1%of the controlled cases.

Conclusions

There is no significance relation between parental or maternal age and autism, male greater than female, family history not effects on the presence or not of autistic disorder.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Indonesia.

Conflict of Interest: The authors declare that they have no conflict of interest.

Parent's Knowledge upon Nutritional Status of Primary School Children toward Low-Income Households in Al-Hilla City, Iraq

Abdulmahdi A. Hasan

Associate Professor, Assist proof, faculty of Psychiatric Mental Health Nursing, PhD College of Nursing, Babylon University Hillah, PO Box: 4 Iraq

Abstract

Background: Nutrition has a main impact on the health promotion of school-age children, it is crucial that the rising energy demands that come with this age are met daily with high nutritional value foods. School-age children get a well-balanced diet, an average of 2400 calories per day required to meet growth needs, as the child's size grows, as well as the amount of food required

Method: Descriptive design study was used and get the stated objectives the period of one month (from the first of January, 2020 to the first of February, 2020).

Results: The data analysis was indicated that the largest percentage of gender is female (97%); all of them are in the fifth class and 32% of mothers and 31% of fathers are graduated from primary school, most of them from urban area 86%.

Conclusion: All of the children were in the 5th class—most children with normal weight**.** Most children have breakfast daily. Most of the children have three meals daily. Most mothers choose easy to prepare food for her child. There is no a relationship between education of the mother and eating breakfast. However, there are a relationship between monthly income and eating fruits .

Introduction

Anthropometrics may be responsive measures of infant and child health, growth and development which it one most widely accessible, cheap and non-invasive approach used to measure human body size, proportion and composition[(1)]. The ultimate goal of the nutritional assessment, according to WHO in 2013 to improve human health[(2)].

Corresponding Author:

e-mail: drmustafasalah7@gmail.com

To ensure optimum work capacity, normal reproductive performance, adequate immune reactions and resistance to infections, sufficient food and nutrition are important for proper growth and physical development. An inadequate diet can cause severe forms of malnutrition in children, deficiencies in vitamin A and disorders of iodine deficiency, also World Health Organization, in 2013 has proposed various anthropometry-based indices to determine the school-aged children's nutritional status. Body mass index (BMI) has now been well developed as the most important predictor for adolescent nutritional status[(3)]. Several research has looked at adolescent nutritional status from different parts of the world[(4)].

Children's nutritional status plays a crucial role in their wellbeing, with malnutrition accounting for (45%) of all deaths among children under five years of age and

stunting development among another 165 million[5]. With the positive success of various programs for child protection, more children reach school age (ages 6-12)[6]. Unfortunately, minimal attention was paid to school-age children's health and nutritional status, especially in developed countries with a greater focus on enhancing their access to education[7].

However, undernourished and obese school children may struggle to meet their maximum cognitive potential with an eventual decline in school academic achievement and later in adulthood, low job ability[8],[9],[10]. Hundreds of millions of children in urban areas of the world are growing up in the midst of poverty and deprivation, with the rising incidence and complications of childhood malnutrition [11]. Some socio-demographic features such as age, gender and order of birth have also been found to affect their health and nutritional status[12].

Methodology

This part will present the methodology of the current study and all numerous stages that passed through, from the beginning of its approval and ending with the analysis of its collected data.

Design of the study: A descriptive design study was used to get the stated objectives the period of one month (from the first of January, 2020 to the first of February, 2020).

Administrative and Ethical Arrangements: Before the gathering of the data and formal administrative permissions, the researcher was obtained to conduct the study.

1. The researcher obtains ethical approval from the Ethical Researcher Committee, University of Babylon/Faculty of Nursing.
2. The Central Statistical Organization has approved the study tool.

Ethical considerations: This study was accepted by the Faculty Nursing/University of Babylon. Several strategies were utilized to protect the responder's rights, who agreed to participate in this study. Next, verbal, oral consent of samples was obtained before the questionnaire was administered. The samples were told of the study intent and that they were entitled to refuse to participate. It has also been told the samples that they should refrain from answering any questions and can terminate at any time.

The setting of the study: The study was conducted in Altatbiqat primary school and 14 tmmuz primary school at Hilla city center.

Population and sampling plan: This quantitative study using a descriptive correlational design to assess Parent's Knowledge upon Nutritional Status of Primary School Children toward low-income households in Al-Hilla city. A convenience sample of (n=100) consenting parents. Data were selected through the period of one month (from the first of January, 2020 to the first of February, 2020).

The Instrument of the study: The questionnaire that is used in this study contains two parts as the following:

Part 1/A. Includes the Child's demographic information, which consists of (4) items that include age, class, Gender, number of brothers.

Part 1/B. Knowledge of Parent demographic information, which is consisted (educational level of mother and educational level of a father, monthly income, number of family members and Residence).

Part 2: Feeding Aspect According B.M.I consist of (6 Items).

Part 3: Food Choosing for Parents consist of (17 Items).

Rating and scoring:

The study instrument is rated on: A three-level Likert scale was used for knowledge items to measure the responses (Important, Kind of important and Not Important) and all statements are scored as 3= Important, 2= Kind of important and 1= Not Important, 3 represents the high -value scale.

The validity of the questionnaire: A preliminary copy of the questionnaire was sent to (10) experts. Responses from the expert suggested that slight changes needed to be made to some items. This adjustment was made according to their recommendations, few items needed to be omitted and others were added according to expert notice.

Statistical Data Analysis: Various statistical method were used to interpret and test the study findings using the Statistical Package of Social Sciences (SPSS) version 25 and Microsoft Excel (2016). All continuous

quantitative variables and the generated overall knowledge scores were tasted for normality distribution and all were followed by the statistical normal distribution.

Results

Table (1): Nutritional Status, according to B.M.I.

Variables	Group	Frequency	Percentage
Weight	Less than normal	15	15
	Normal	83	83
	Obese	2	2
	Excessive obesity	0	0
	Total	100	100
High	Normal	84	84
	Tall	10	10
	Short	6	6
	Total	100	100
Is he/she have breakfast?	Yes	93	93
	No	7	7
	Total	100	100
Is breakfast at home or at school?	Home	91	91
	School	9	9
	Total	100	100
Is he/she have any fruits daily?	Yes	87	87
	No	13	13
	Total	100	100
Number of meals daily	Less than three	5	5
	Three	82	82
	More than three	13	13
	Total	100	100

Table (3) indicated that most of the sample with normal weight of 83% and tall 84%.

Table (2): Point of view about food choices by parents(total score)

	Group	F.	%
Point of view about food choices by parents	Not Important	16	16
	Kind of important	21	21
	Important	63	63

F :Frequency % :Percentage

Table (3) shows that most families about 63% point of view about food choices that Important.

Table (3): Relationship between some variables in present study

Demographic data	Rating	F	%	P-Value
Relationship between Education of mother and eating breakfast for child	Do not read and write	8	8	X^2 =5.895 N.S=.435 Df=6
	Write read and	17	17	
	Primary school	31	31	
	Middle school	16	16	
	High school	10	10	
	Institute	8	8	
	Bachelor and more	10	10	
Monthly income and eating fruits	Enough	26	26	X^2 =8.954 Sig=.01 Df=2
	Not enough	34	34	
	Kind of enough	40	40	

F : Frequency % :Percentage X^2: chi-square-test. sig: significant df :degree of freedom, N.S: not significant

The table (4) shows the relationship between some variables in the present study. Regarding education of mother and eating breakfast for child this table reveals that is no relationship them. (P-value = 0.435) at the ($p \leq 0.05$) level of significance. In respect, monthly income and eating fruits the result shows that relationship between them. (P-value = 0.01) at the ($p \leq 0.05$) level of significance.

Discussion

School-age children are unable to meet their needs with the necessary nutrients that lead to building a fully developed body because unhealthy lifestyle neglects low-income households to their needs. Nevertheless, our study children's nutritional status was especially optimal, in line with the other researchers[13],[14].

Many studies were done in Islamabad and Abbottabad showed gross malnutrition in school children[15],[16]. In the present study, most of the children, 83% were in optimal nutritional status and had sound skeletal growth despite their society and economic status. These results are in disagreement with the results of Fisher and Birch[17]. They indicated that parents influence the development of children's eating habits, not only through the foods that they make available to children, but also through their eating patterns, mealtime activity and child-feeding activities. Child-feeding habits of parents are correlated with eating patterns of children, including different eating styles, food intake and preferences and energy intake control.

In this study, there was no a relationship between having breakfast for children and the educational level of mothers. This result disagrees with Al-Shookri in Oman, who revealed that there was a positive correlation between children's dietary food intake scores and the mothers' level of education which nutritional knowledge was due to dietary intake, which the importance of the fact that nutrition-related education and information for mothers can improve their off spring's dietary intake[18]. Finally, the data analysis was showed that relationship between monthly income of father and eating fruits.

Conclusions

1. All of the children were in the 5th class.
2. Most of children with normal weight**.**
3. Most of children have breakfast daily.
4. Most of the children have three meals daily
5. Most of mother choose easy to prepare food for her child.
6. Most of mother choose rich protein food for her child.
7. Families' ability to provide and choose suitable and healthy food for their child its good.
8. Recommendations
9. The study recommends the following:
10. Nutritional programs training for teachers and parent

11. Create a nutritional assessment database based on school policy at all primary schools in Hilla City.
12. Supply of material for calculating height and weight in schools.
13. Group Calculator by using a measurement system to control on BMI.
14. Making a health education pyramidal food guide.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in Iraq.

Conflict of Interest: The authors declare that they have no conflict of interest.

Right to Health Protection in the Former-Soviet Constitutions: Constitutional and Legal Analysis

Maksakova Ruslana[1], Yurii Viktorovych Kyrychenko[2], Maryna Leonydovna Smoliarova[3]

[1]Professor, Faculty of Doctor of Science of Law, Head of the Department of Constitutional, Administrative and Labor Law, [2]Associate Professor, Department of Political Science and Law, [3]Associate Professor, Department of Constitutional, Administrative and Labor Law, Zaporizhzhia Polytechnic National University, Zhukovs'koho St, 64, Zaporizhzhia, Zaporizhia Oblast1,2,3

Abstract

The constitutional framework for legal aid to available health care therefore determines one of the strategic areas of policy of democratic, social and law-governing states (former Soviet states). This determines the relevance of studies of resistance to constitutional and legal regulation of the health system formed as a result of changes in the skin and radical structure of social structure in previous USSR states. The article contains the constitutional and legal analysis of the right to health protection in the former-Soviet constitutions by reviewing the constitutional healthcare provisions and specifying the groups of qualified bearers of right to health protection and variety of rights as the healthcare system elements. The studies are to be continued, as well as the review and summary of information about constitutional and legal regulation of the right to health protection in the former-Soviet states are needed.

Keywords: *Health, healthcare, right to health protection, Constitution, former-Soviet states.*

Introduction

The public welfare directly depends on the health status of the population that is conditioned by availability of the medical assistance, medical supplies, as a whole and its services, in particular. That is why the constitutional framework of the legal support of the available healthcare set forth one of the strategic areas in the state policies of the democratic, social and law-governed states (the former-Soviet states constitute themselves as such). This determines the relevance of study of contradictory features of the constitutional and legal regulation of the healthcare systems in the former USSR states formed as a result of the accelerated and radical formation changes in the social structure.

Method

To prepare the article, the following general scientific and special study method were used: analysis, synthesis, information search, structured system analysis, dogmatic, comparative legal.

Results and Discussion

The similar topics were studied by S.V. Agievets, K. Bendukidze, A.O. Dichko, L.V. Zhylskaya, O. A. Kovalenko, N. P. Kryzina, V.S. Lysenko, V.M. Oleynik, V. Petrovsky, V.V. Puchkova, F. S. Reder, S.A. Rudy, S.G. Stetsenko, M. Taner, A. Urushadze, M. A. Shevchenko, L.Z. Shupa, et al. The studies are to be continued, as well as the review and summary of information about constitutional and legal regulation of the right to health protection in the former-Soviet states are needed.

There are broad and narrow definitions of the term "right to health protection" in the scientific literature. Broadly, this is a collection of legal norms regulating the relations of the population health protection in socio-economic, healthcare and other spheres of the state life. Narrowly, this is an intersectoral legal institution directly aimed at health protection (Agievets SV 2012)[1].

The constitutional lawmaking of the states-the union republics of the former USSR in the past - is distinguished by inert continuity of the lawmaking aimed at sectoral

regulation of the social sphere, including the right to health protection. The statements on the guaranteed free medical aid are contained in the most of the new Constitutions of the CIS members and others.

That is why, to guarantee the constitutionally objectified right to health protection, its international legal recognition, documentation, as well as provision and preservation of the implementation mechanisms are of critical importance and have been realized since H2 XX century in view of the lawmaking process of the UNO and WHO and other subjects of the international legal relations.

The principle of priority and rule of the international law embodied in the Constitutions of the former-Soviet states provides for the required state obligation on the guaranteed safeguards for the human and civil rights to the available healthcare and excludes any avoidance of its fulfilment that is motivated by explanations regarding insufficient capacities of the national economy.

The mandatory legislative regulation of the available right to healthcare by all the former-Soviet states is determined by their UN membership as the parties to the Covenant on Economic, Social and Cultural Rights of 1966. The Covenant Preamble sets forth the regulation of the UN charter binding the states "to promote universal respect for and observance of, human rights and freedoms" (Agievets, S. 2002)[2]

Substantiating the above provisions, L.V. Zhilskaya fairly points out the unlawful interpretation of the principle of "the gradual implementation of obligations" embodied in the Covenant as ensuring these rights only when the state achieves a certain economic development level, whereas according to the above obligation, all the member states, irrespective of the degree of their national welfare, must undertake the immediate steps to exercise economic, social and cultural rights not postponing them for an indefinite period (Zhilskaya LV. 2005)[3].

Clause 1, Article 12, of the Covenant contains a mandatory provision for the member states regarding recognition of the right of everyone to the highest achievable level of physical and mental health specified in cl. 2 of this Article: «*a*) the provision for the reduction of the stillbirth-rate and of infant mortality and for the healthy development of the child; *b*) the improvement of all aspects of environmental and industrial hygiene; *c*) the prevention, treatment and control of epidemic, endemic, occupational and other diseases; *d*) the creation of conditions which would assure to all medical service and medical attention in the event of sickness" (**Agievets, S. 2002)** [2.]

The mentioned provision in brief or in detailed wording is reflected in the Constitutions of all the former-Soviet states, at this, the detailed wording assumes the presence of a system of the state guarantees for ensuring the maximum possible level of mental and physical health.

The healthcare issues are highlighted in Articles 37, 41, 42 of the Constitution of the Russian Federation. The basic scope of the right to health protection, including the medical aid, is included in cl. 1, Art. 41, providing the relevant right to everybody, that is not only to the citizens. At the same time, the medical aid guarantees consisting in the free medical aid provision by the state and municipal healthcare institutions out of the relevant budget, insurance contributions, other revenues, are addressed to the citizens only. Cl. 2 of Art. 41 provides for financing the federal programs on health protection and promotion, undertaking the measures to develop the state, municipal and private healthcare systems. But at the same time, the activity facilitating the health promotion by developing the physical training and sports, establishing the ecological and sanitary and epidemiological welfare is only "encouraged". Consequently, ensuring the natural human right to health and medical aid is not guaranteed by Art. 41 of the Russian Constitution in contrast to the legal rights of a citizen. This contradicts the provision of cl. 1 of Art. 17 concerning recognition and guarantee of the human and civil rights and freedoms in the Russian Federation pursuant to the general principles and norms of the international law and this Constitution. Nevertheless, cl. 3 of Art. 41 establishes the responsibility of the state, in the persons of officials of the state system, for life and health of people. The sanction for suppression by such officials of the life and health threatening facts and circumstances attracts a legal responsibility as provided by the Federal Law. At the same time, cl. 3 of Art. 37 grants to everyone the right to work in the conditions meeting the safety and hygiene requirements and Art. 42 - the right to favourable environment and reliable information on its state that is substantiated by the restorative justice norm on compensation of damage caused to health and property by an environmental offence (The Constitution of the Russian Federation 1993)[4].

Notwithstanding that cl. 3 of the Constitution of Ukraine of June 28, 1996 recognizes the human life and health as the highest social value, such contradiction is also present in the wording of the human right to health protection in cl. 49 of the Constitution declaring the right of everyone to health protection, medical aid and medical insurance to be provided by the state funding of the relevant socio-economic, medical-sanitary and health improvement and prevention programs. At the same time, the assessment criteria of the proper level of the medical services - their efficiency and availability, embodied in para. 3 of this Article refer not to everyone but only "all citizens". The free medical aid must be provided by the state and municipal healthcare institutions and the state shall "promote" the development of such institutions of all legal forms of organization. At this, the state guarantee is contained in the norm prohibiting the reduction of the network of the state and municipal healthcare institutions, although the current implementation of the medical reform in Ukraine actually transforms this guarantee into the declaration. According to para. 4 of Art. 49, the state shall take care of developing the physical training and sports, ensuring the sanitary and epidemiological welfare. Art. 50 contains a natural human right to the life and health safe environment that simultaneously provides for compensation of damage caused by infringement and a guarantee for free and available information with the right of its distribution and prohibition of its classification (The Constitution of Ukraine. 1996)[5].

The Constitution of the Republic of Belarus of 1994 (as amended and supplemented, adopted at the National Referendums on November 24, 1996 and October 17, 2004) clearly restricts a range of subjects having the guaranteed right to health protection with its citizens. The guarantees embodied in Art. 45 include free treatment in the state healthcare institutions, available medical services, development of the physical training and sports, environmental improvement activities, opportunity to use the recreational institutions, labour protection improvement; and those in Art. 47 include the right to social security in old-age, in case of disease, disability, loss of earning capacity. and only the norm stated in Art. 46 grants the right to favourable environment and compensation of damage caused by breach of this right of everyone (The Constitution of the Republic of Belarus 1994)[6].

The specific feature of Art. 37 of the Constitution of Georgia of August 24, 1995 as amended on October 15, 2010 is the interpretation of health insurance as the available means of the medical aid being a right of everyone. At the same time, the free medical aid is limited by the legally established "specific conditions". The state control covers all healthcare organizations, pharmaceutical production and trade. All people have the right to harmful environment, use the natural and cultural environment. The environmental conservation and protection and sustainable use pursuant to the ecological and economic interests of the society constitute the common obligation of "all" and the state (The Constitution of Georgia. 2005 Aug 24., Kryzina NP,KOO. 2016)[7, 8].

The Constitution of the Republic of Armenia of July 05, 1995 as amended on December 06, 2015, Art. 85, very briefly declares the right of everyone to health protection according to the law, thus restricting the list and procedure of the basic free medical services not mentioning the medical aid and guarantees (The Constitution of the Republic of Armenia. 1995) [9].

The Constitution of the Republic of Azerbaijan of November 12, 1995 (as amended and supplemented on 25/07/2016) and vice versa, Art. 41 more meaningfully sets forth the right to health protection and medical aid covering everyone, binding the state to undertake necessary measures to develop all kinds of healthcare on the basis of various kinds of ownership, guarantee the sanitary and epidemiological welfare, create the opportunities for various forms of the medical insurance. In the given wording, the right to health protection and right to medical aid are considered as individual interconnected varieties of healthcare rights. The state provides for development of all kinds of healthcare in various forms of organization, guarantees the sanitary and epidemiological welfare, creates the opportunities for various forms of medical insurance. Similarly to the Russian Constitution, the officials concealing the facts and events that create danger for health and life shall be brought to the responsibility as provided by the law(The Constitution of the Republic of Azerbaijan. 1995 Nov 12.) [10.]

The Constitution of the Republic of Moldova of July 29, 1994, Art. 36, briefly and without details, guarantees the right to health protection, declares the minimum level of the free state medical supplies and refers to the organic act establishing the national healthcare system structure and facilities intended for physical and mental health protection (The Constitution of Georgia 2005

Aug 24, The Constitution of the Republic of Azerbaijan. 1995 Nov 12)[8],[11].

The Constitution of the Republic of Kazakhstan (adopted at the National Referendum on August 30, 1995) (as amended and supplemented as of 23/03/2019 г.), Art. 29, grants the right to health protection and statutory guaranteed scope of the free medical aid to the citizens only. The medical aid can be paid not only at the private health care centers and when provided by the persons engaged in the private medical practice, but also at the state medical institutions on the basis and in a manner provided by the law (The Constitution of the Republic of Moldova. 1994 July 29)[12].

According to Art. 47 of the Constitution of the Kyrgyz Republic of June 27, 2010, the right to health protection, the state-created conditions for medical services and measures to develop the state, municipal and private healthcare sectors shall cover all people. But it does not specify the scope of subjects of the right to free medical services, as well as medical services on favourable conditions in the scope of state guarantees provided by the law. Similarly, to Russia and Azerbaijan, there exists the legal responsibility of the officials for concealing the health and life-threatening facts and events (The Constitution of the Kyrgyz Republic. 2010 June 27.)[13].

The Constitution of the Republic of Uzbekistan of December 08, 1992, is limited by the right of everyone to the qualified medical services declared in Art. 40 (The Constitution of the Republic of Uzbekistan1992 Dec 8.)[14].

The Constitution of Turkmenistan of May 18, 1992, as amended and supplemented on December 27, 1995, Art. 52, stipulates the right of "each person" to health protection, including free use of services of the state healthcare institutions. Along with the paid medical services, it also embodies the alternative medicine on the basis and in a manner provided by the law. Art. 53 grant to every person the right to life and health favourable environment, reliable information on its state and compensation of damage caused to health and property by an environmental offence or natural disasters (The Constitution of Turkmenistan. amended and supplemented. 1992 May 18) [15].

According to the Constitution of the Republic of Tajikistan (as revised by Referendums on 26/09/1999, 22/06/2003, 22/05/2016), Art. 38, the right to health protection cover everyone and the free medical aid shall be provided by the state institutions as legally provided. This also refers to the other forms of the medical aid. The measures to improve the environment, create and develop the mass sports, physical training and tourism are the responsibility of the state (The Constitution of Turkmenistan. 1992 May 18) [16].

The Constitution of the Republic of Lithuania of October 25, 1992, Art. 53, binds the state to take care of the people's health and guarantee the medical aid and services to a person in case of disease. But the law establishes the procedure of free medical aid provided at the state healthcare institutions for the citizens only. The state encourages the physical training and promotes or the sports. The environmental protection against harmful impacts is a common responsibility of "each person" and the state (The Constitution of the Republic of Lithuania. 1992 Oct 25) [17].

The Constitution of the Republic of Latvia adopted at the general meeting of the Constitutional Assembly of Latvia on February 15, 1922, revised on 22/07/2014, cl. 111 of Chapter VIII, is limited by the statement of the state health protection and guarantee of minimum medical aid to everyone and cl. 115 – by the statement of right of everyone to live in the favourable environment by providing the information on the state of the environment and taking care of its protection and improvement (Kryzina NP,KOO. 2016 No.2. 2018, The Constitution of the Republic of Estonia. 1992 June 28.)[18, 19].

The Constitution of the Republic of Estonia of June 28, 1992, is distinguished by the major social right to health protection as provided by cl. 28 stating that everyone has the right to health protection. A citizen of Estonia has a priority right to the public support in old age, in case of disability, loss of breadwinner, poverty. Its kinds, size, provisions and procedure are established by the law. Simultaneously, if not contradicting to the law, such support can be provided to foreign citizens and stateless persons coming to Estonia (Kryzina NP,KOO 2018, Dichko GO. 1993 July 16)[8,18]

The considered constitutional and legal provisions of the former-Soviet states concerning the right to health protection make it possible to conclude on the following:

1. The guaranteed free medical aid (maintenance, services) is present in the most of the post-Soviet constitutions as a result of inertia of the Soviet

constitutional system.

2. The priority of the international right is one of the principles of the state of law and the most important factor for the required fulfilment by the former-Soviet states of their constitutionally acceptable international liabilities on guaranteeing the right to health protection and implementing the complex measures to ensure availability and efficiency of the healthcare system.

3. The constitutional provisions on free medical aid (maintenance, services) is embodied as the relation with the paid aid in various ratios, but a common feature of the post-Soviet constitutions is a statutory restriction of the free-of-charge basis and a trend to its minimization.

4. The scope of subjects - the qualified bearers of the right to health protection - is represented in all constitutions by two main groups: all individuals having the natural human rights and citizens having the legal rights. At this, the absolute majority of the constitutions provide the free medical aid (maintenance, services) for the citizen only.

5. In all post-Soviet constitutions, the right to health protection is related to the right to health living environment that is ensured by common responsibilities on its conservation and protection by a human, citizen and state. Simultaneously, there is the human and civil right to compensation of damage caused by violations in the sphere of natural management. At this, there is the constitutionally accepted legal responsibility of officials for concealing the information concerning any danger to life and health.

6. A number of constitutions include the rights to improvement of occupational hygiene and labour protection, physical training and sports, use of recreational facilities demonstrating these states striving for achievement of the ecological and sanitary and epidemiological welfare, maximum possible level of mental and physical health of population.

Ethical Clearance: The Research Ethical Committee at scientific research by ethical approval of both environmental and health and higher education and scientific research ministries in turkey.

Conflict of Interest: The authors declare that they have no conflict of interest.

Abstract

The environment in labor can have a great effect on the fears and anxieties experienced by the mother. Anxiety can inhibit cervical dilatation, so that the perception of pain increases. Cortisol is secreted in response to tension and anxiety, it affects the progress of cervical dilatation. The increasing concentration of cortisol during pregnancy and continue to rise until labor. Anxiety is usually associated with increased pain during labor and modification of labor pain can be done through psychological and physiological mechanisms. One way to modify psychological labor pain is by setting the delivery environment. The purpose of this study was to analyze the effect of the setting of the labor environment on the progress of labor.

The results showed the average delivery progress (cm/hour) in the treatment group 1.38 (0.43) and the control group 1.23 (0.52), obtained p = 0.058, this indicates there was no difference in labor progress in both study groups. Based on the statistical test results of the effect of the setting of the delivery environment on the progress of labor, the p value = 0.015 shows that there is an influence of the delivery environment setting on the progress of labor and the RR value of 3.67 (IK = 1.14-11.84), which means that the mother gives birth in a Independent Midwifery Practice (IMP) who did not manage the delivery environment had a risk of having a cervical opening < 1 cm/hour by 3.67 times compared to mothers giving birth at the IMP who did the setting of the delivery environment.

The conclusion of this research is that there is a positive influence of the delivery environment to the progress of labor.

Keywords: *Labor progress, labor environment, childbirt, cortisol, cervical dilatation.*

Introduction

Childbirth is an amazing event that can be experienced and remembered in every woman's life. Birth will change a woman's life and the care given has the potential to affect both physically and emotionally in the short and long term. The goal of caring for women during childbirth is to create positive experiences for a woman and her family while maintaining physical and psychological health (Susilowati E. 2014, Iravani M, Zarean E, Bahrami M. 2015).[1,2]

The environment in labor room can have a great effect on the fears and anxieties experienced by the mother (Munro J, Jokinen M. 2012).[3] Anxiety is usually associated with pain that increases during labor and can be in either modify labor pain through psychological and mechanisms of physiological.(Lowe NK 2002)[4] One way to modify labor pain psychologically is by regulating the labor environment.

Fear and pain cause stress which results in adrenaline expenditure. This results in vasoconstriction and reduced vascularization to the uterus, resulting in a decrease in uterine contractions which will cause prolonged labor. This is less beneficial for the mother and fetus in the mother's uterus (Reck C, Zimmer K, Dubber S, Zipser

B, Schlehe B, Gawlik S. 2013)[5] Stress during labor can also reduce the amplitude and frequency of uterine contractions and thus, labor will last long and allow for *caesarean section* (SC).(Namazi M, Akbari SAA, Mojab F, Talebi A, Majd HA, Jannesari S. 2014).[6]

It also can increase adrenaline so that blood vessel constriction occurs so that oxygen supply to the fetus decreases. Decreased blood flow also causes weakening of uterine contractions and results in prolonged labor.[5] hormones, such as catecholamines, cortisol, epinephrine and beta-endorphins, whichare secreted in response to tension and anxiety, are involved inthe progression of cervical dilatation. It is affecting the muscles of the uterus and reduce the strength of the contract of the of the uterus and efficiency in the delivery so eventually will prolonged labor, increasing pain and trigger anxiety. (Masoudi Z, Akbarzadeh M, Vaziri F, Zare N, Ramzi M. 2014).[7]

Method

Population and Sample: Subjects in this study were all women in the Independent Midwifery Practice (IMP)who met the inclusion criteria, were not included in the exclusion criteria and were willing to participate in the study by signing the informed consent sheet after explanation.

Inclusion and Exclusion Criteria: The inclusion criteria in this study were primigravida, latent parturient phase with gestational age 37-4 0 weeks, normal pelvic size, estimated fetal weight of 2500-4000 grams, single fetus, head presentation, desired and or planned pregnancy, mother accompanied during pregnancy, mother who has an anxiety score ≤ 59 . Exclusion criteria were premature rupture of membranes, blind and deaf, mothers who had attended pregnancy exercises and yoga.

Research Design: This study is a quasi-experimental study with a non equivalent control group design. The research subjects were divided into two groups namely the treatment group and the control group. In the treatment group of the Midwifery Practice (IMP), maternity interventions were given in the form of labor environment settings which included lighting arrangements, wall color arrangement, arrangement of medical equipment, use of natural scenery, use of music, furniture arrangement, temperature regulation and using plants to neutralize fishy odors the labor environment, while the control group using environmentally deliveries already exist.

This research was carried out simultaneously with members of the research team in developing the delivery environment. Data collection was performed in the treatment group and the control group. The treatment group was given an intervention in the form of childbirth at the Independent Midwifery Practice (IMP) that had done the delivery environment. The maternity control group at IMP is in accordance with the existing delivery environment.

Measurement Result

The main outcome to be measured in this study is the difference in labor progress (cervical opening) in the intervention and control groups. Other results that will be measured in this study are anxiety scores, pain scores and cortisol levels, gestational age and birth weight .

Research Flow: In the Independent Midwifery Practice (IMP) which is made as an intervention group, the delivery environment will be arranged in accordance with the draft delivery arrangements that have been made and the Independent Midwifery Practice (IMP) which is used as a control group using the existing delivery environment. This study requires examination of cortisol levels in maternal, so the researcher collaborates with the Laboratory of the Faculty of Medicine Unpad to examine cortisol levels. Examination of cortisol levels is done once, namely in the latent phase, blood samples are taken for examination of cortisol levels carried out by midwives. Then to obtain the inclusion criteria anxiety score ≤ 59 performed an anxiety score assessment by other researchers. Furthermore, the measurement of labor progress (cervical dilatation) starts from the opening of 3 cm to the opening of 10 cm, is checked every 4 hours and the average opening (cm/hour) is assessed .

Research Instrument: The instruments used in this study were partographs and observation sheets to assess the progress of labor.

Location and time of research: This research was conducted at the Independent Midwifery Practice (BPM) of West Bandung Regency and Cimahi in July-September 2016.

Ethical Aspect: The ethical aspects considered include (Wirakusumah FF, Satari MH. 2011)[8]

1. The principle of respecting human dignity and respect (*Respect for person)*

In this principle, research subjects are given information about the research to be carried out including: procedures, benefits, volunteerism, confidentiality of data, inconvenience and compensation as well as officers who can be contacted if there is anything that needs to be discussed in connection with research. The research subject is free to determine its participation in following the course of the study, it must be stated in writing by signing the consent form (*informed concent)* as respondents.

2. The principle of benefits and no harm *(Beneficence)*

The advantage of this research that can be felt directly by respondents is obtaining the comfort of giving birth in a room that has been arranged so that labor is expected to run smoothly.

3. The principle of *justice*

Researchers always be honest, careful, professional, humane. Researchers also always pay attention to the factors of accuracy, equality, accuracy, intimacy, psychological and religious feelings of respondents.

Results

In the study of the effect of the setting of the delivery environment on the progress of labor the characteristics of the subjects can be seen in the following table:

Table 1 Characteristics of research subjects

Characteristics	Group		Value of p
	Treatment	Control	
	(n = 30)	(n = 30)	
Mother's age (years)			0.812 *
Average	22.90	22.70	
Median	23.00	22.50	
Range	17-29	17-32	
Gestational age (weeks)			0.317 **
Average	38.33	38.03	
Median	38	38	
Range	37-40	37-40	
Birth weight (gram)			0.215 **
Average	2,925	3,040	
Median	3,000	3,000	
Range	2,500-3,400	2,500-3,500	

Note: * T test is not paired, ** Mann-Whitney Test

Based on table 1 it can be seen that the statistical test results obtained on maternal age characteristics p value = 0.812, gestational age values p= 0.317 and birth weight (BW) obtained p value = 0.215 it indicates that there is no significant difference between the characteristics mothers in the treatment group and in the control group, so that both of these research groups were considered homogeneous.

Differences in cortisol levels (µg/dl) and pain in the two study groups can be seen in the table below:

Table 2 Differences in Cortisol and Pain Levels in the Treatment and Control Groups

Cortisol (µg/dl)	Group		Value of p
	Treatment	Control	
	n = 30	n = 30	
Cortisol			0.988 *
Average	371,201	429,125	
Median	361,211	334,185	
Range	140,000-579,856	160,050-895,831	
Pain			0.109 *
Average	4.97	5.67	
Median	5	6	
Range	3-7	2-10	

Explanation: * Mann-Whitney

From table 2 it can be seen that the statistical test results obtained cortisol values (µg/dl) p = 0.988 and pain values obtained p = 0.109 it shows that there is no significant difference between the treatment group and the control group, so both of these research groups are considered homogeneous.

To analyze the comparison of the progress of labor in the treatment group and the control group can be seen in the following table:

Table 3 Comparison of Progress in Labor in the Treatment and Control Groups

Variable	Group		Value of p
	Treatment	Control	
	(n = 30)	(n = 30)	
Labor Progress (cm/hour)			0.05 8 *
Average	1.38	1.23	
Median	1,2	1.08	
Range	0.8-2, 3	0.5-2.3	

Note: * Mann-Whitney test (one- sided test)

From table 3 it can be seen that the results of statistical tests for the progress of labor (cm/hour) in the treatment group and the control group obtained p = 0.058, so this shows that there was no difference in labor progress in the two study groups.

To analyze the effect of the setting of the delivery environment on the progress of labor the following calculation results are obtained:

Table 4 The influenced of Labor Environment Settings on the Progress of Labor

Group	Cervical Opening				RR (95% IK)	Value of p
	< 1 cm/hour		≥ 1 cm/hour			
	n = 30	%	n = 30	%		
Control	11	36.7	19	63.3	3.67(1.14-11.84)	0.015 *
Treatment	3	1 0	27	90		

Note: *Test two proportions (one party)

From table 4.4 the statistical test results show that in the control group subjects who had cervical opening < 1 cm/hour were 11 (36.7%) and in the treatment group were 3 (10%), whereas in the control group subjects who had cervical opening ≥ 1 cm/hour was 19 (63.3%) and in the treatment group was 27 (90%). The difference in the proportion of labor progress in the two groups was found to be p = 0.015, so this shows that there is an influence of the delivery environment on the progress of labor. Furthermore, by calculating the relative risk of the relationship between treatment with the progress of labor obtained RR = 3.67 (IK = 1.14-11.84), meaning that mothers who give birth at Independent Midwifery Practice (IMP) who do not do labor settings have a risk to have cervical opening < 1 cm/hour 3.67 times compared to mothers who gave birth at Independent Midwifery Practice (IMP) who carried out the delivery environment.

Discussion

The environment in the process of childbirth can have a great effect on the fears and anxieties experienced by the mother, such as an unfamiliar environment, then the existence of medical interventions and the existence of negative thoughts such as childbirth which is always followed by pain and then the mother is afraid of the condition of the baby being born. Anxiety is usually associated with pain that increases during labor and childbirth pain can be modified through psychological and physiological mechanisms. (Lowe NK.2002).[4]

The environment is the biggest factor influencing the healing process in medical facilities that is equal to 40%. The physical environment affects 94% of the ease or difficulty of giving birth.[9,10] A physical environment has an influence on human thoughts, feelings and behavior. As a built environment, space is a stimulus (stimulation from outside) that is able to be responded by the human sensory system (vision, hearing, taste, smell and touch), which psychologically has the potential to form perceptions that indirectly affect emotional and human behavior. (Sari SM. 20030)[11]

Pain during labor can be caused by uterine contractions and cervical opening (stretching down the uterus). According to control theory, there is a relationship between pain and psychological problems such as anxiety.[12] The environment in labor can have a great effect on the fears and anxieties experienced by the mother. (Munro J, Jokinen M. 2012)[3]

Simultaneously, the hypothalamus-pituitary-adrenal (HPA) axis and *the sympathetic nervous system* (SNS) organize various circumstances psychological (eg: emotional processing) and physiological (eg: hormonal endocrine activation and cardiovascular) process to ensure that the maintenance of homeostasis of the organism that is being challenged to stress. (Thoma MV, Marca RL, Brönnimann R, Finkel L, Ehlert U, Nater UM. 2013)[13] At the same time, the perception of the injury will enable (HPA) axis, where corticotropin releasinghormone (CRH) produced in the hypothalamus into the bloodstream, causing the release of adrenocorticotropic hormone (ACTH) and other substances. ACTH then activates the adrenal cortex to release cortisol.(Melzack R. 1999)[14] During labor an increase in CRH levels stimulates an increase in myometrial prostaglandin receptors, prostaglandin release, oxytocin, fetal cortisol and beta-endorphins. (Dixon L, Skinner J, Foureur M. 2013)[15]

The speed of the opening of the cervix itself is influenced by various factors, namely the strength and weakness of uterine contractions will affect the process of cervical opening. To be able to perform contractions oxytocin hormone secretion is needed. Oxytocin is a hormone produced in the hypothalamus and is transported through the axoplasmic flow to the posterior pituitary which, if given the right stimulation,

will be released into the blood. This hormone is named oxytocin based on its physiological effects, namely the acceleration of labor by stimulating contraction of the uterine smooth muscle.(Lestari I, Abadi A, Purnomo W. 2012)[9]

A major proposition from the gate control theory is that to reduce pain affects the center of the brain that serves attention, cognition and emotion which activates nerve impulses to close the " gate" located in the dorsal horn of the spinal column. A second proposition from gate control theory is that pain is a sensory interaction, motivation and a component of middle control.[17] The presence of pain interferes with the brain's homeostatic regulatory system, resulting in stress and requires a complex program to restore homeostasis.(Newburn M, Singh D 2003)[10]

The pain causes stress which results in adrenaline expenditure. This results in vasoconstriction and reduced vascularisation to the uterus, resulting in a decrease in uterine contractions which will cause prolonged labor.[5] Oxytocin also reduces stress by way of centralized activate the parasympathetic nervous system, which gives the effect of calm and healing; and by reducing activity in the sympathetic nervous system which reduces fear, stress and stress hormones and increases socialization.(Buckley SJ. 2015)[18]

Increased anxiety and pain increase catecholamine release and alpha receptor stimulation by the sympathetic nervous system, which in turn causes vasoconstriction, increased muscle tension and decreased uterine blood flow, increased blood pressure, loss of uterine contractions, slowed labor progress and increased metabolism and oxygen consumption to mother. [4, 19] Stress during labor can also reduce the amplitude and frequency of uterine contractions and thus, labor will last for a long time and allow for *caesarean section* (SC).(Namazi M, Akbari SAA, Mojab F, Talebi A, Majd HA, Jannesari S. 2014)[6]

Lighting can be used creatively and seriously to create a birth space that is calming and relaxing. [1] At the beginning of labor, catecholamines (stress hormones) have the potential to stop labor. When a woman feels very afraid of pain, is in the hospital, labor can fail to progress.(Lothian JA. 2004)[20] Darkness stimulates the body to produce melatonin, which then increases oxytocin production. Found a link between lighting arrangements with oxytocin production. The presence of oxytocin affects the production of endorphins.(Gedey S. 2014)[21] Expending endorphins can make mothers feel relaxed.

A causal relationship between an increase in nocturnal endogenous melatonin and a decrease in core temperature. On the other hand, melatonin secretion is usually suppressed by bright light and thus, endogenous melatonin levels are almost zero during the day.(Kondo N, Taylor NA, Shibasaki M, Aoki K, Muhamed AMC. 2009)[22]

Color can affect the human soul strongly or can affect human emotions. Color can also affect one's mood.(Darmaprawira S. 2002).[23] The use of color in the delivery room must be considered because it can stimulate the neocortex to release endorphins. Bright colors must be avoided because it can stimulate the neocortex. (Stenglin M, Foureur MJ. 2013)[24] The neocortex provokes the release of adrenaline and inhibits the physiology of birth.(Jenkinson B, Josey N, Kruske S. 2014) [25] Penyimpanan equipment deliveries in wardrobes can create peace for the mother and reducing the clinical atmosphere.[25] Labor equipment should be stored and kept away from the view of maternity so that the mother does not experience anxiety.(NTC Policy Briefing 2011)[26] The use of natural elements can also help reduce stress and pain felt during labor, for example by exposure to natural scenes.[27]

In addition to lighting arrangements, the color/use of wall paint, the arrangement of medical equipment and the use of natural elements, it is also important to note the importance of the arrangement of furniture. Furniture influences the atmosphere of the delivery room. Minimalist furniture and arrangement is very important to note, given the importance of sufficient space for mobility in the delivery room.(Jenkinson B, Josey N, Kruske S.)[25] The existence of restrictions on mobility contributes to increased stress and tension. (Manizheh P, Leila P. 2009)[28]

The use of music in the labor room can also help mothers to deal with pain that is good to increase stimulation and pain threshold. (Gedey S. 2014)[21] Music provides a pleasant sensory stimulus, causing endorphin release. In addition, music therapy is also a cognitive process that can stimulate the control system through the production mechanism of endorphins, so that with the stimulation of the descending control, the "gate" area will close the transmission of pain to the brain.

Music therapy has vibration and harmony that can be used according to the listener so it will feel comfortable. In addition, because the vibrations of music produce vibrations or the delivery of air to the ear, the vestibular organ (balance tool) also gets the impact of music so that it relaxes.(Malehere NS. 2013, Dwirahayu Y. 2014)[29, 30]

Adding new odors in the labor environment to change odorous substances into substances that are less stimulating. (Suma'mur. 1996)[31] Like adding plants in the labor environment that can neutralize fishy odors in the labor environment.

Improve the physical environment, increase women's expectations and confidence. Women believe that the birth environment can affect the ease or difficulty of labor and the facilities provided can affect opportunities for normal birth or risks that require emergency surgery. (Newburn M, Singh D. 2003).[10]

Conclusion

The conclusion of this research is that there is a positive influence of the delivery environment to the progress of labor.

Abstract

A procedure for the quantitative determination of framycetin sulfate in the drug 'Framex' (nasal spray) 8000 IU/ml has been developed, using spectrophotometry (SF) method. The developed method has been validated using the following indicators: specificity, correctness, linearity, repeatability and intralaboratory accuracy. It has been found that the developed methodology is valid for all characteristics and can be used for the quantitative determination of framycetin sulfate in the substances and composition of medicinal products.

Keywords: *Framycetin sulfate, validation, spectrophotometry, framex, antibiotic, aminoglycosides.*

Introduction

On the current pharmaceutical market, there are very few drugs with antibacterial activity, that can be used for children under 1 year old. These include the drug 'Framex' (produced by Aseptica, Uzbekistan)[1]. The nasal spray composition is based on the antibiotic of the aminoglycoside series of the topical bactericidal action of framycetin. 1 ml of the drug contains 8000 units of framycetin[2].

It is a common fact that aminoglycosides are highly active against most gram-negative and gram-positive microorganisms - pathogens of upper respiratory tract infections. However, systemic antibacterial drugs of these groups have a side ototoxic effect, which makes it impossible to use their antimicrobial potential in bacterial infections of the nasal cavity, nasopharynx and paranasal sinuses in children. The indicated side effects can not be expected with the local administration of these drugs, since, according to the results of clinical studies, the level of their systemic absorption during topical use is extremely low[1].

One of the urgent problems of pharmaceutical chemistry is the development and validation of theroutine analysis method for the quantitative determination of the active pharmaceutical ingredient in substances and finished medicinal products. The developed method are designed to minimize the consumption of solvents and reagents, the duration of the analysis, and to obtain the most accurate result. Validation of an analytical method is an experimental proof that the method is suitable for solving the proposed problems[2].

In our work, we used the drug 'Framex' (nasal spray) containing 8000 IU/ml of framycetin sulfate. The pharmacologically active ingredient of the drug is framycetin sulfate[3]. In its chemical structure, it is 2-deoxy-4-O-(2,6-diamino-2,6-dideoxy-α-D-glucopyranosyl)-5-O-[3-O-(2,6-diamino-2,6-dideoxy-β-L-idopyranosyl)-β-D-ribofuranosyl]-D-streptamine sulfate. The chemical structure of framycetin sulfate allows its staining using basic conditions (pH=9-10)[4].

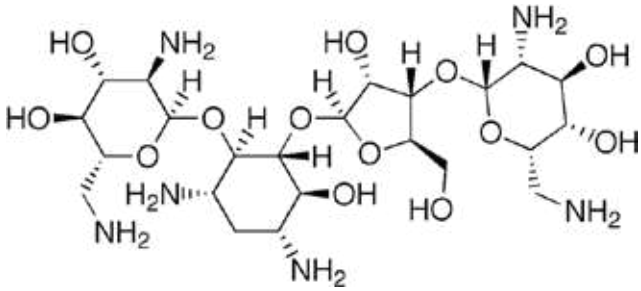

Fig. 1. Structural formula of framycetin

The aim of this work is to develop and validate the SF method for the quantitative determination of framycetin sulfate in substances and the drug 'Framex' (nasal spray).

Materials and Method. In our study, we used class A measuring glassware, an CY 224 CITIZEN analytical balance (India), a 'UV-1800' UV spectrophotometer (manufactured by Shimadzu Corporation, Japan) (wavelength range from 190 to 1100 nm, relative accuracy less than 0.1%)

The specificity of the method is determined by comparing the values of the active ingredient in the analysis of the solvent (form), the active ingredient and the pharmaceutical product.

The linearity of the method is determined by at least 5 different dilutions of the test solution in the range of application of at least 80-120% of the concentration of the analyte in the test solution[5].

Repeatability is carried out using tests of at least 6 prepared samples at 100% concentration of the active ingredient in the test solution.

The correctness of the method determines the response of the active ingredient in placebo[6]. The placebo concentration is 100% of the weigh indicated in the control method. The active ingredient is added to the model mixture in accordance with the required concentration level (lower limit - max. 80, 100%; upper limit - min. 120%)[7].

The object of the study was the drug 'Framex' (the content of framycetin sulfate - 12.5 mg/ml), the corresponding MPhM (manufacturer's pharmacopoeial monograph)is 42 Уз-26491354-2019. Solutions of 80% (0.40 mg/ml), 90% (0.45 mg/ml), 100% (0.50 mg/ml), 110% (0.55 mg/ml), 120% (0.60 mg/ml) were prepared. The substance of framycetin sulfate 'Suzhou Pharmaceutical Technology CO., LTD' (China) (content of active ingredientis 654 IU/mg) was used as a working standard sample (WSS). A WSS solution of framycetin sulfate with concentrations of 0.5 mg/ml was prepared. We prepared WSS, test and blank solutions. All three flasks were simultaneously placed in a water bath for 15 minutes at a temperature of 70-80 ^{0}C. Then, the flasks were removed, cooled to room temperature and water was added, in order to bring the total volume of solution to the mark. The optical density of the obtained solutions was measured on a spectrophotometer at a wavelength of 564 nm in a cuvette with a layer thickness of 10 mm, using a blank solution as a compensation solution[8].

Results and Discussion

The obtained solutions were measured using a spectrophotometer under the optimized conditions given in the article. The obtained spectra confirm that the measurement conditions are optimized and the absorption spectrum of the test solution prepared for quantitative determination in the region from 200 to 700 nm corresponds to the spectrum of the WSS solution of framycetin sulfate and has maxima at a wavelength of 252 nm (3), 401 nm (2) and 564 nm (1).

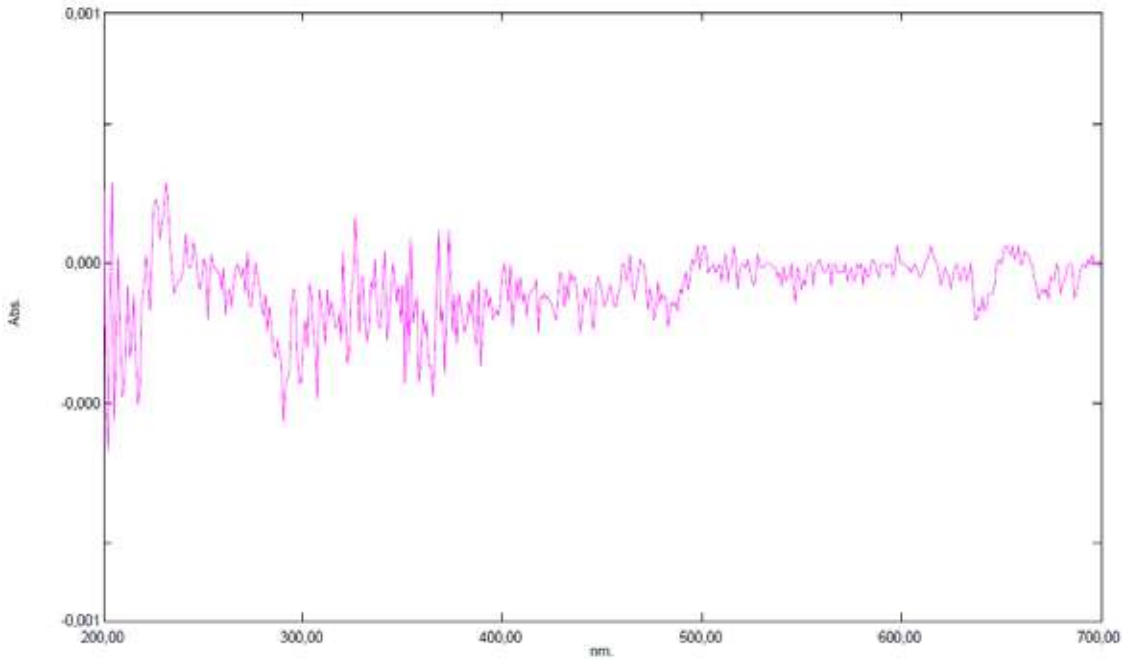

Fig. 2. Absorption spectrum of the blank solution

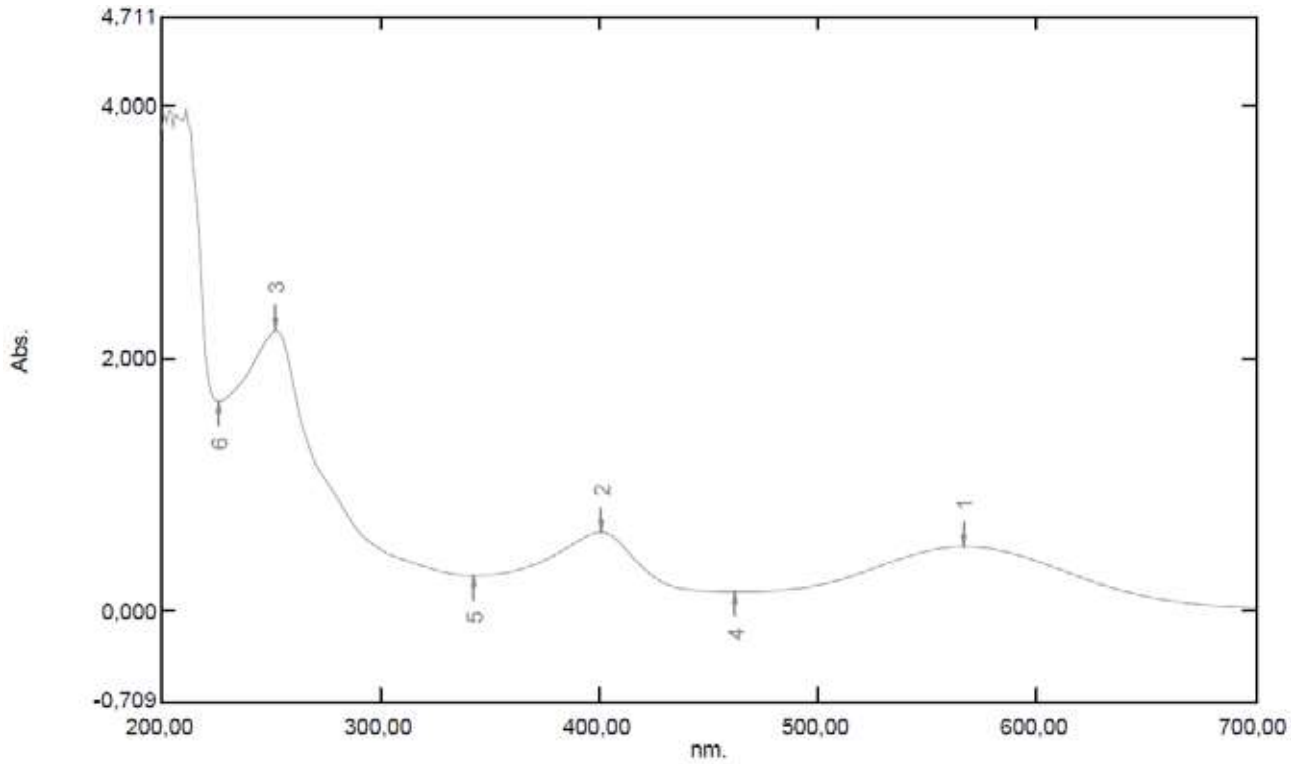

Fig. 3. WSS absorption spectrum of framycetin sulfate (C=0.50 mg/ml).

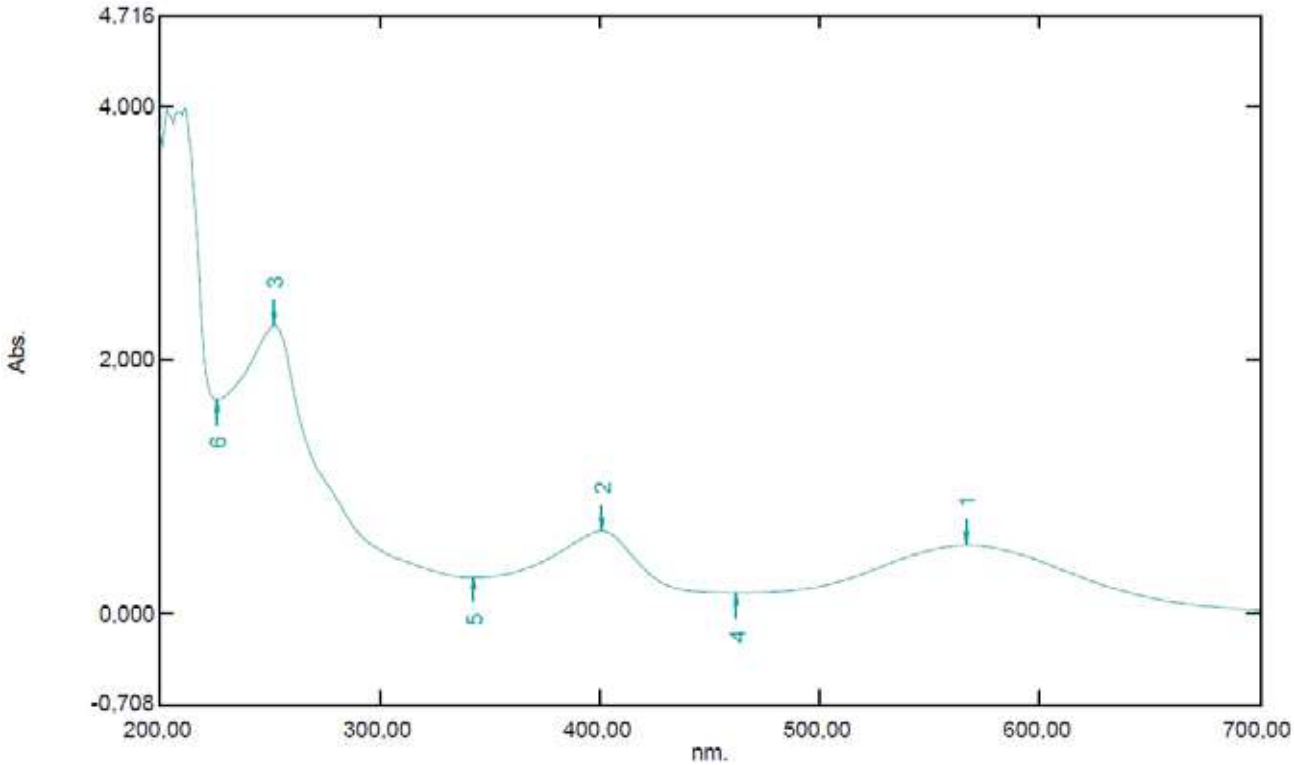

Fig. 4. Absorption spectrum of the test solution (C=0.50 mg/ml).

Fig. 1-3 shows that, under optimized conditions, the maximum values of the WSS and test solutions are identical. The developed technique indicates that the conditions for preparing samples and measuring spectra for determining the quantitative content of framycetin sulfate are specific.

Specificity. The blank solution, standard solution and pharmaceutical product were measured. The optical density of the samples was measured at a wavelength of 564 nm.

Assessment criteria: neither solvents nor reagents used for sample preparation should distort the result.

Linearity. We prepared and measured solutions of the drug with an active ingredient concentration in the range from 80 to 120%: 2 solutions with an active ingredient concentration of 80%, 2 solutions with an active ingredient concentration of 90%, 2 solutions with an active ingredient concentration of 100%, 2 solutions with a concentration active ingredient of 110% and 2 solutions with an active ingredient concentration of 120%. The linearity results are shown in Table 2.

Based on the obtained data, a dependence of optical density on the concentration of framycetin sulfate in solution can be found. The program also draws a trend line and determines the regression equation.

Table 1: Results of linear dependence of optical density on the concentration of framycetin sulfate

No.	Concentration level, %	X (Weigh of drug in mg/ml)	Y (Optical density, A.U.)
1	80	0.4012	0.283
2	80	0.4007	0.281
3	90	0.4501	0.315
4	90	0.4509	0.316
5	100	0.5006	0.352
6	100	0.5000	0.350
7	110	0.5499	0.386
8	110	0.5504	0.388
9	120	0.5993	0.421
10	120	0.6001	0.423
Average		0.5003	0.352

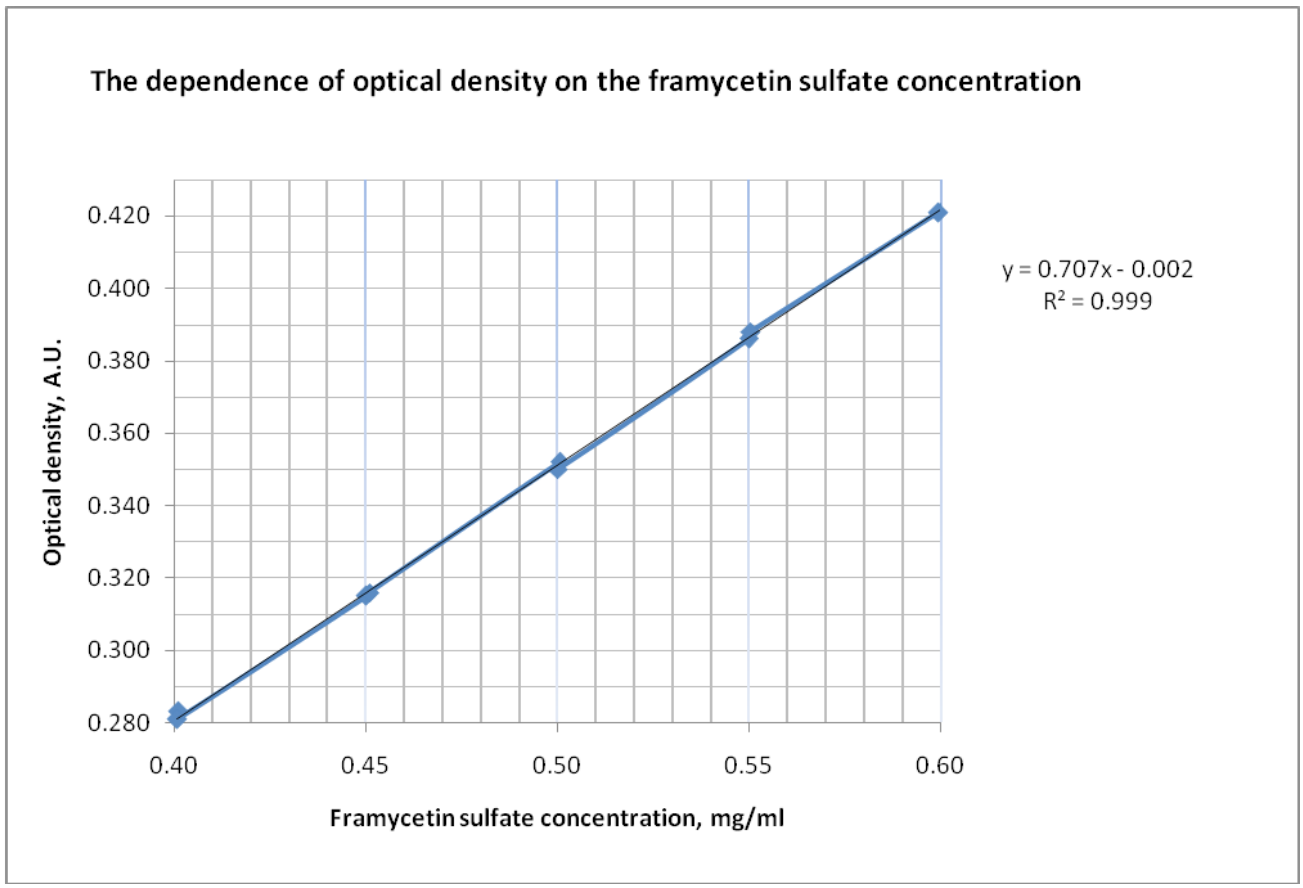

Fig. 5. Graph of the linear dependence of the optical density on the concentration of framycetin sulfate.

Criteria for assessing the linearity: correlation coefficient ≥ 0.99.

Correctness. We prepared and measured drug solutions with an active ingredient concentration in the range from 80 to 120%: 3 solutions with an active ingredient concentration of 80%, 3 solutions with an active ingredient concentration of 90%, 3 solutions with an active ingredient concentration of 100%, 3 solutions with a concentration active ingredient of 110% and 3 solutions with an active ingredient concentration of 120%. The correctness results are shown in Table 2.

Table 2: Results of determining correctness for the developed methodology

Concentration level, %	Optical density, A.U.	Specific content of framycetin sulfate, IU/ml	Specified content of framycetin sulfate, IU/ml	Response, %
80%	0.283	6493.4	6400.0	101.46
80%	0.281	6447.5	6400.0	100.74
80%	0.280	6424.6	6400.0	100.38
90%	0.315	7227.7	7200.0	100.38
90%	0.316	7250.6	7200.0	100.70
90%	0.314	7204.7	7200.0	100.07
100%	0.350	8030.7	8000.0	100.38
100%	0.352	8076.6	8000.0	100.96
100%	0.353	8099.6	8000.0	101.24
110%	0.386	8856.8	8800.0	100.64
110%	0.388	8902.6	8800.0	101.17
110%	0.386	8856.8	8800.0	100.64
120%	0.421	9659.8	9600.0	100.62
120%	0.423	9705.7	9600.0	101.10
120%	0.422	9682.8	9600.0	100.86
Average				100.76

We performed statistical processing of the obtained t_{kp} data, calculated the average value, the common standard deviation, the coefficient of variation, and the relative confidence interval. The results are shown in Table 3.

Table 3. Results of static processing of correctness determination

Statistical characteristic, %	Results
Average value	100.76
Standard deviation	0.3789
Coefficient of variation	0.3761
Lower limit of the confidence interval (P=95%)	100.55
Upper limit of the confidence interval (P=95%)	100.97

Criteria foraccessing correctness: average value 97.5-102.5%, coefficient of variation ≤ 2.0 %, confidence interval should include 100%.

Repeatability. For the study, 6 solutions of the drug at 100% concentration of the active ingredient were prepared. The analysis was carried out on an interday basis for each sample, by two different analysts, using different measuring glassware. The repeatability results are shown in Tables 5 and 6:

Table 4. The results of the determination of repeatability obtained by the chemist-1 (n≥6; P=0,95)

Sample No.	Optical density, A.U.	Specific content of framycetin sulfate, IU/ml	X_i-X_{cp}	$(X_i-X_{cp})^2$
1	0.352	8076.6	7.6483	58.4968
2	0.352	8076.6	7.6483	58.4968
3	0.351	8053.7	-15.2966	233.9872
4	0.352	8076.6	7.6483	58.4968
5	0.351	8053.7	-15.2966	233.9872
6	0.352	8076.6	7.6483	58.4968
Average		8069.0		

Table 5. The results of the determination of repeatability obtained by the chemist-2 (n≥6; P=0,95)

Sample No.	Optical density, A.U.	Specific content of framycetin sulfate, IU/ml	X_i-X_{cp}	$(X_i-X_{cp})^2$
1	0.350	8030.7	-15.2966	233.9872
2	0.351	8053.7	7.6483	58.4968
3	0.351	8053.7	7.6483	58.4968
4	0.350	8030.7	-15.2966	233.9872
5	0.351	8053.7	7.6483	58.4968
6	0.351	8053.7	7.6483	58.4968
Average		8046.0		

We performed statistical processing of the obtained t_{kp} data, calculated a single standard deviation relative confidence interval. The results are shown in Table 6.

Table 6. The results of static processing of the definition of repeatability

Statistical characteristic, %	Results of Chemist-1	Results of Chemist-2
Lowest value, IU/ml	8053.7	8030.7
Highest value, IU/ml	8076.6	8053.7
Average value	8069.0	8046.0
Standard deviation	90.6228	90.6228
Coefficient of variation	1.1231	1.1263
Lower limit of the confidence interval (P=95%)	99.67	100.58
Upper limit of the confidence interval (P=95%)	102.05	100.58
t_{kp} (95% and N1+N2-k=10) 2.228	1.43	
F(95% f1=N1-1;f2=N2-1) 5.05	1.00	

Criteria for accessing repeatability and ruggedness: coefficient of variation ≤1.5% (n≥6), confidence interval F(5%,5,5): ≤ 5,05, t(5%,10): ≤ 2,228.

Conclusions

The method of quantitative determination of framycetin sulfate in the drug 'Framex' has been developed and validated using SF method. Based on the results of the intra-laboratory experiment, it has been found that the metrological characteristics of validation parameters as correctness, specificity, repeatability, linearity and ruggedness do not exceed the validation criteria. The stability of the method can be reproduced in the laboratory. The deviation of a single value is 100.7% with a confidence probability of 95%.

Comprehensive Integrated Assessment of Health, Lifestyle and Medical Services for Children at the Age of their First Year

Ilshod Isayev

PhD, Teaching Assistant, Department of Public Health, Organization and Management of Health Care, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Abstract

Introduction: Children are the main value of any society, which plays a huge role in its development and prosperity. Meanwhile, they are the most vulnerable sector that have to be protected from negative physical and mental factors as well as diseases. A wide range of factors can affect the health of children, especially in their first year of life. Deep knowledge on those triggers may help to reduce the risk of developing different pathological conditions among them.

Materials and Method: An integrated analysis and risk assessment of different pathologies in 767 outpatient children under 1 year were cunducted. A survey of the parents of those children was also conducted. The objectivity of the information obtained is guaranteed by the directed application of the method and techniques used in public health and healthcare, namely, medical-statistical analysis, sociological, psychological and expert analysis.

Results: Many childrenhad a low risk of developing chronic diseases, including those with a hereditary predisposition and had a IIB health group, these are children with background of conditions and risk factors that can cause the formation of a chronic pathology. The third group of healthy children was represented by children with chronic pathology in the stage of compensation, the number of such babies was small (5.9±0.85%), as well as healthy babies with I (6.0±0.86%) and II A (4.2±0.72%) by health groups. Furthermore, more than half of the children of the first year of life had a normal functional state of the body. However, in 43% of cases, the functional state was impaired, which is manifested by the presence of various pathological conditions.

Conclusion: Comprehensive integrated approach and using evidence-based medicine principles for studying the medical conditions in children under 1 year-old can be valuable and help us to obtain reliable data on the health conditions and affecting risk factors.

Keywords: *Children of the first year of life, functional state, health group, medical care, evidence-based medicine.*

Introduction

Maintaining the health of a child is an essential part of the task of ensuring the health of a nation, which reduces the creation of necessary set of conditions and an overall improvement in the quality of life, politically and legally constituting one of the foundations of national security (De Jong et al, 2017)[8]. In general, we are talking about a set of special measures that protect the health of children, their development, starting from birth. Children are the main value of society, contributing to its development and prosperity, but at the same time they are the most vulnerable part, which needs protection from diseases, physical and mental factors.

Recent decades have determined the need for a transition to more modern, cost-effective and effective preventive technologies for maintaining and optimizing the health of the child population, especially children from birth to 1 year. Among all age groups, special attention should be paid to young children, since it is during this period that risk factors can be realized and

various chronic pathologies can form (Da Cunha et al, 2016)[7]. A variety of factors can influence the health of a child in its first year of life, the knowing those triggers may help to reduce the risk of developing different pathological conditions.

During the last few years, many studies have been published in the literature that reflect this topic of issues. Perinatal damage to the central nervous system (CNS) is the most frequently detected pathology in children of the first year of their life (Sovetkhan et al, 2019)[3].There is evidence of a relationship between central nervous system prenatal damage and somatic pathologies, as well as the negative impact of prenatal injuries of central nervous system on neuropsychic development and mental health of children (Dvorkina et al, 2015)[2].

Rickets is the most common background disease in young children (TT C, 2016)[6]. However, due to several reasons, the diagnosis of rickets is not always established by local pediatricians. Yerenkov et al. (2016) suggests using ultrasonic densitometry in order to increase the efficiency of diagnosis of rickets in young children.

Another common background disease is iron deficiency anemia (IDA) among children (Dvorkina et al, 2015)[2]. Ivanova et al. proved that there was a link of between iron deficiency anemia with a slowdown of psychomotor development in children of the first year of life. It has been proven that anemia with its untimely and inadequate treatment can irreversibly affect cognitive functions (Peterkova et al, 2016).

An electrocardiographic study is widely implemented in diagnostic algorithms for assessing the health status of young children. When studying the state of the cardiovascular system in children of the first year of life, Kharlamova et al. detected posthypoxic cardiopathy in 76.4% of children, however, in half of them, it's the symptoms extinguished by the age of one month (Bezler & Galitsa, 2015)[1]. Congenital heart defects are also diagnosed frequently in the early neonatal period (Peterkova et al, 2016)[3]. An echocardiographic examination of 1012 children in the first half of life indicates a high incidence of minor cardiac abnormalities, in particular, additional trabeculae in the cavity of the left ventricle. In the study of Kuleshova et al (2014), a high frequency of functional disorders of the digestive tract, especially in children in the first half of life was proved. The health of children in their first year of life largely depends on the type of feeding. Kashin et al. (2005), analyzing the physical development of children of the first year of life depending on the type of feeding, showed that children who were on early artificial feeding had higher weight growth rates by the end of the first year of life. However, in the group of babies who were breast-fed for a long time, a mesosomatic body type (85.3%) with harmonious development (84.1%) was more often observed. Similar data was presented by other authors (Puzankova et al, 2015; Savchenko et al, 2015). (De Jong M CATJvWM. 2017;Atyasova et al 2005)[8] showed that infants who were breast-fed are 1.8 times more likely to be diagnosed with dystrophy, 2 times more likely to have deficiency anemia, and 1.7 times more purulent-septic diseases compared to breastfed babies[1].

Legonkova et al. (2011)[10] conducted a multicenter open comparative prospective study, which aimed to study the health status of children who were on different types of feeding. As a result of long-term observation, it was shown that children receiving breast milk had higher rates of physical and neuropsychic development, a lower incidence of acute respiratory diseases and atopic dermatitis.

Clinical examination is a dynamic monitoring of the level of development and the state of health (of children) with the aim of early diagnosis of initial deviations, timely correction as well as providing the conditions necessary for an optimal state of health and development (Bezler & Galitsa, 2015)[1].

The main methodological principles of dispensary observation in the first year of life are as follows: 1) continuous coverage of children living in the polyclinic service area, the unity of the preventive and medical work of the district doctor; 2) differentiated monitoring of children and preventive, improving, curative measures, depending on the individual characteristics of the child; 3) the leading role of the district children's clinic (or district central hospitals) in the follow-up with the wide involvement of advisory centers; continuity between institutions of various profiles in the examination and management of children; 4) a prognostic approach in assessing the capabilities of the immediate and distant level of health and development of the child; 5) the introduction of new non-traumatic method of preclinical diagnosis and computer monitoring (integrated automated systems) of medical examinations and the dynamics of children's health indicators.Thus, the only way to improve the health of young children, reduce their morbidity and disability is to fully strengthen the

state pediatric service and its central link responsible for medical examination - children's district polyclinics - with the widest participation of specialists from research institutes and departments of pediatrics in medical examinations of the pediatric population, pediatric centers.

Purpose of the study is to develop recommendations for improving the treatment and preventive care for children in their first year of life based on a comprehensive study of their health status and lifestyle.

Materials and Method

To achieve this goal, it is necessary to identify the risk factors for morbidity and mortality in children of the first year of life. It is also need to be identified the combinations of risk factors that are most unfavorable from the point of view of the development of morbidity and the occurrence of a "death case" in children of the first year of life. As for the interaction of risk factors with each other, as well as with factors that favorably affect the child's body, these issues have been studied extremely insufficiently. An increase in the incidence of the disease, an increase in the proportion of children often ill in the structure of the incidence of children in many countries, are attributed by most authors to changes in the conditions and lifestyle of families. The study of the interaction of health and lifestyle with the use of multivariate analysis can make a significant contribution to the development and improvement of the primary and secondary prevention of children. The approaches to choosing an object of study for studying the lifestyle on the health of children in their first year of life can be different, and each approach, in our opinion, has a number of advantages and disadvantages. The elimination of these shortcomings can be promoted by a combination of separate approaches, each of which involves solving a separate problem. An integrated approach to the selection of the object of study, in our opinion, makes it possible to obtain more informative data. In this article we will consider some approaches to the selection of the object of socio-hygienic research, the influence of the lifestyle of the development of diseases and the occurrence of a "death case" of children of the first year of life. First of all, it is necessary to decide which group of children should be examined to identify risk factors for children's health. Risk factors for disease, death act on the body until the moment when an accurate diagnosis is made or the causes of death are identified.

From our point of view, their identification can be approached in two ways: by conducting a retrospective study using the analytical method and by prospectively studying risk groups selected taking into account known factors. The first of these approaches is used more often and is technically simple. In this case, the examined group of children (patients - often ill) is formed with a confirmed, specified and final diagnosis or cause of death. A control group may be - health of children (who have never been ill for a year) of the same age and gender.

To characterize the choice of research base, from our point of view, is essential. The volume (n) and sampling method (cluster, stratified, random mechanical, randomized) were determined. The second approach to the selection of the object of study is based on known risk factors for morbidity and causes of death in children of the first year of life. Since the number of these factors is very significant, it is necessary to consider which of them should be relied upon in the selection of the studied group of children to study the influence of lifestyle, diagnosis on morbidity, or causes of death of children. For example: rest and nutrition of pregnant women, body weight at birth, the nature of feeding, may themselves be the result of a particular lifestyle and, therefore, are not suitable for the selection of the studied group.

Study Population: Based on the foregoing, 767 outpatient records of children under 1 year were analyzed. A survey of the parents of those children was also conducted. The objectivity of the information obtained is guaranteed by the directed application of the method and techniques used in public health and healthcare, namely, medical-statistical analysis, sociological, psychological and expert analysis.

In our opinion, for the selection of the examined group in order to prospectively study the impact of lifestyle on children's health, it is possible to use factors such as the mother's age (up to 20 years), the body weight of the child at birth (up to 1,500 grams), the sex of the child, the order of birth a child.

In this case, control groups are selected in accordance with which of the factors is taken as the basis for the choice of the examined group. So in the control group can include healthy children born to mothers whose age was 21-24 years old, born from 2-3 pregnancies, with a body weight at birth of 3000-3499 gr. So, the control group should correspond to the subject - by age, gender,

place of residence, examination of children in family clinics. In the study, it should be kept in mind that often male children born from mothers up to 20 years old, from the first birth, with low birth weight, who were breastfed, are ill. One of the criteria for children's health is the assessment of ontogenesis features.

In the study, the risk group selected by such factors as the age of the matter, gender, the child's birth order, and body weight of the child at birth should be used to compare the lifestyle of children who are often ill and who have never been ill during the study period, and observation should be carried out from their birth and during the first year of life.

Statistical Analysis: For statistical processing and analysis of the obtained data, personal computers of the Intel Centrino type (Core2 Duo) and Microsoft Office 2007 packages were used.

Results

In order to evaluate ontogenesis, genealogical, biological, and social anamnesis were collected, and the burden coefficient of the genealogical anamnesis in children of the first year of life was calculated and gained the results as follow (Table 1).

Table 1: The structure of the genealogical history in children of the first year of life by burden ratio (M±t, %)

Burden coefficient	Children under the study n = 767
Low	58,03±1,80***
Moderate	41,97±2,73
Significant	-
High	-

Note: *** - p <0.001

The table shows that most children had a low risk of developing chronic diseases, including those with a hereditary predisposition.

As a result of a comprehensive assessment of the health status of children in the first year of life, a health group was determined (Table 2).

Most of the children under one year old had a IIB health group, these are children with background of conditions and risk factors that can cause the formation of a chronic pathology. The third group of healthy children was represented by children with chronic pathology in the stage of compensation, the number of such babies was small (5.9 ± 0.85%), as well as healthy babies with I (6.0 ± 0.86%) and II A (4.2 ± 0.72%) by health groups.

Table 2: The health group of children aged 1 year (M±t, %)

Healthy group	Children under the study n = 767
I (1)	6,0±0,86
IIA (2)	4,2±0,72
IIБ (3)	83,9±1,32***
III (4)	5,9±0,85
IV (5)	-
V (6)	-

Note: *** - p1-3, 2-3, 4-3 <0.001

The level of the functional state of the body of children is reflected in the table. 3.

Table 3: The functional level of children in their first year of life (M±t, %)

Functional condition level	Children under the study n = 767
Normal	56,9±1,80***
Poor	43,1±1,80
Worse	-

Note: *** - p <0.001

The table shows that more than half of the children of the first year of life had a normal functional state of the body. However, in 43% of cases, the functional state was impaired, which is manifested by the presence of various pathological conditions. So, small abnormalities of the development of the heart (false chord, open oval window) and pyeloectasia were found in 63.1 ± 1.76% of infants. Perinatal damage to the central nervous system was diagnosed in 65.1 ± 1.72% of children, possibly due to a deterioration in the health status of expectant mothers and the pathological course of pregnancy. Almost every fifth child of the first year of life has atopic dermatitis (19.6 ± 1.43%) and iron deficiency anemia (21.3 ± 1.48%). Rickets was diagnosed in 10.3 ± 1.10% of infants, dystrophy by type of malnutrition - in 7.6 ± 0.95%. 5.5 ± 0.82% of children in the first year of life were observed by an infectious disease specialist for intrauterine infection. Only 7.2 ± 0.93% of children under one year-old did not have background diseases. All this raises questions about the additional search for risk factors for the development of these diseases and the improvement of preventive measures.

Thus, as a result of a comprehensive study of the health status of children of the first year of life living in Tashkent, it was found that the IIB health group prevails (83.9 ± 1.32%), most children have a low risk of developing chronic diseases, including with a hereditary predisposition (58.3%), a good level of resistance (87.3%) and the normal functional state of the body (56.9%).

However, the presence of babies with a retardation in neuropsychic development (36.0%), congenital malformations (63.1%) and weight loss (8.0%) pose new challenges for the outpatient service in terms of strengthening pedagogical and psychological support for families with small children, more effective interaction with obstetric care services and improvement of medical check-ups for children in their first year of life.

The number of children with the first health group during the year ranged from 0 to 3%. Upon discharge from the maternity hospital 2A, a sufficiently large number of newborns had a health group ($p < 0.01$). Subsequently, in the process of neonatal screening and clarification of the anamnesis, the number of children with a 2A group of health significantly decreased, without significant differences (Fig. 1).

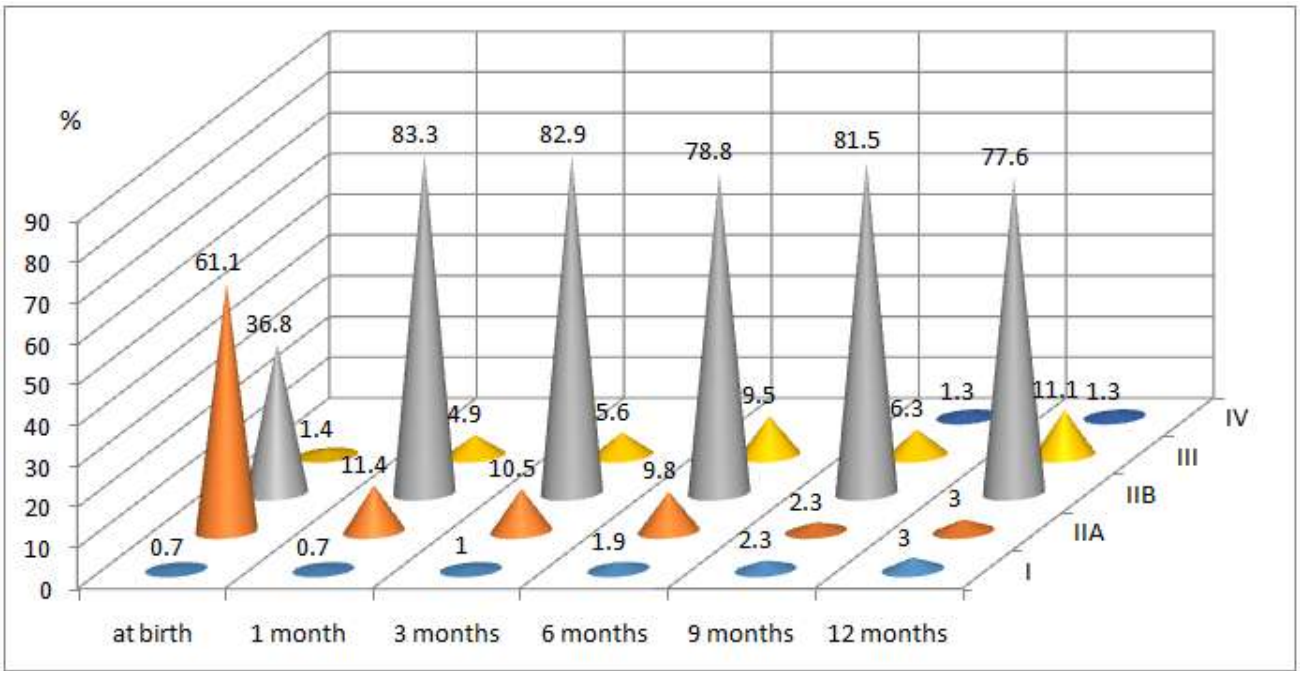

Fig. 1. Dynamics of monitoring children depending on the health group during the first year of life

The number of children with the third group of health did not exceed 13%. At the age of 12 months, children with chronic pathology in the compensation stage were found in 11.1% of cases. The fourth group of health was observed in one baby (1.3%).

Discussion

Analysis of scientific and medical publications on the topic of the study indicates that children in their first year of life, their state of health, taking into account the importance of socio-hygienic factors, are a fairly common object of scientific research. However, to date, a comprehensive study of the health status of children of the first year of life has not been carried out taking into account indicators of the physical development of morbidity and mortality, health levels of children have not been developed and determined, taking into account complex factors, assessment tables of physical development have not been studied and developed, and children's health has not been established taking into account the leading factors of lifestyle and the quality of medical care. Treatment and prophylactic and organizational and methodological measures have not been developed to improve the health status and differentiated medical care of children in their first year of life, taking into account a set of factors affecting their health.

The literature mentions a significant number of risk factors for children's health, the identification of which is carried out mainly by comparing the frequency of the studied symptoms in the group of patients and healthy children (Bezler & Galitsa, 2015; Sovetkhan et al, 2019)[1,3]. In this case, the question arises about the specificity of individual factors, which to date cannot be considered resolved (Dvorkina et al, 2015; and Peterkova et al, 2016)[2,3].

On the basis of the data obtained, it was established that the family history had a low coefficient of burden. The adaptation period in the maternity ward in newborns proceeded, as a rule, without pathology ($p < 0.05$). Most of the newborns discharged from the hospital had II A health group ($p < 0.01$).The number of children with the first group of health during the year was insignificant (0.7%), group II A in the process of neonatal screening and clarification of the anamnesis significantly decreased from 61.1% upon discharge to 7% at 12 months of a child's life. Number children from group IIB by the end of 12 months of life increased almost 2 times ($P < 0.05$) from indicators at birth. A similar picture was noted for the III group of health ($P < 0.05$).

However, in this case, the influence of lifestyle cannot be ruled out, therefore it is advisable to conduct a comparative study of the influence of several complex lifestyle factors in children of the first year of life, to eliminate the influence of previously known risk factors for morbidity and mortality in children. A comparison of the risk factors for morbidity and mortality of children and their interaction as a cause and effect for various approaches to the selection of an object, the study will allow us to determine with sufficient accuracy the most significant factors and their unfavorable combinations, and to develop recommendations on this basis for the primary prevention of children's morbidity and secondary prevention of causes death of children. Prevention is carried out by the family in which the child lives and primary health care institutions (SP, SVP, Central District Hospital, Central City Hospital, etc.), each of which contributes to this great business in accordance with its capabilities.

In order to develop specific recommendations for the family and medical institutions for the formation and upbringing of a healthy child, it is necessary not only to identify risk factors for children's health, but also to carefully study the contingent of sick children and the features of the work of outpatient and inpatient facilities, the relationship, and the continuity in their conduct primary and secondary prevention of morbidity in children.

Conclusion

Thus, a comprehensive integrated approach and using evidence-based medicine principles for studying the medical condition of children under 1 year-old in conjunction with their lifestyle factors will make it feasible to obtain the most reliable data on the state of health and affecting risk factors. Moreover, this method helps us to develop evidence-based recommendations for primary and secondary prevention of diseases that cause of postnatal death.

Study Limitations: The study was conducted on children living in Uzbekistan. Therefore, some of the results and outcomes of the study are specific for locals only. Thus, if needed, further researches can be conducted worldwide or in certain areas.

Acknowledgements: We are grateful to the authority of Tashkent Pediatric Medical Institute for the cooperation in our research. The parents of the participants kindly gave full written permission for this report.

Ethical Approval: The ethical approval for the study was granted by the Committee of Ethical Approval for Researches under the Ministry of Health of the Republic of Uzbekistan.

Consent: Written informed consent was obtained from all participants' parents of the research for publication of this paper and any accompanying information related to this study. A copy of the written consent is available for review by the authors.

Conflict of Interest: The authors declare that they have no competing interests.

Funding: No funding sources to declare.

Walkability Index Based on Pedestrian Needs in the Losari Beach area of Makassar City

Susy Asteria Irafany[1], Shirly Wunas[2], Slamet Trisutomo[3], Arifuddin Akil[4], Mimi Arifin[5], Abd. Rachman Rasyid[6]

Urban Management, Graduate School Hasanuddin University, Makassar-90245, Indonesia

Abstract

Walkability Indexis the result of measuring the comfort level of pedestrian paths which will be a benchmark for developing pedestrian paths that are feasible for everyone. Jpedestrian paths (sidewalks) can be said to be feasible if they can meet pedestrian needs based on several criteria such as accessibility, circulation, safety, security, beauty, cleanliness, noise, shade, and connectivity. The purpose of this study is to obtain a pedestrian comfort index based on pedestrian needs in the Losari Beach Area and Fort Rotterdam. To produce this comfort index, it is necessary to identify the factors and measure the level of comfort based on pedestrian needs, and to determine the priority of pedestrian needs..The pedestrian path available in this area is known as "Bundaratta", located in the recreation/natural tourism area (Losari Beach) and cultural tourism (Fort Rotterdam) people of Makassar City. With the function of the land as a recreation area, a comfortable pedestrian path is urgently needed by local and foreign tourists to enjoy and reach the existing facilities around the area. This research is a quantitative descriptive study, using a Likert scale to obtain a level of comfort and the Analytical Hierarchy Process (AHP) to obtain priority for the comfort factor. The results showed that the pedestrian comfort index along Losari Beach to Fort Rotterdam is 60.20 and it is in the comfortable category, but it still needs some repairs and improvements in several location segments so that this pedestrian lane falls into the category that is truly comfortable and even very comfortable. for its users.

Keywords: *Comfort index, pedestrian path, pedestrian need.*

Introduction

The term pedestrian or pedestrian comes from the Latin word pedesterpedestris, namely people who walk or pedestrians. Pedestrian also comes from the Greek word pedos which means foot so that pedestrian can be interpreted as a pedestrian or person walking, Pedestrian is also defined as the movement or circulation or movement of people or humans from one place to the origin to another as a destination (destination) by foot(Rubenstein, 1992)[1]. Another definition of a pedestrian is a person who dominantly uses feet (walking) and/or one part of the body (for example with hands for people who do not have legs) to move from one place to another and not in a state of using a vehicle. (Pattisinai, 2013)[2].

Broadly speaking, the motivation of a person in walking, like pedestrians using the sidewalk, divided into 2 (two) types of pedestrians, namely functional pedestrians and optional pedestrians (Gatoet Wardianto, 2017)[3]. Functional pedestrian activities are routine every day or periodically and occur throughout the year, such as walking to school, to work, shopping for daily necessities which are classified as necessary activities, namely compulsory activities. Meanwhile, functional pedestrian activities are optional (optional), such as taking walks, recreation/excursions in historical areas, shopping tours, culinary tours[4], walking for health purposes and even taking walks without a specific purpose or other social activities[5].

Losari Beach area is a natural recreation/tourism area, as well as Fort Rotterdam which is a recreation/ cultural tourism area in Makassar. Pedestrian activity in the area is optional (optional). Very busy at certain times, especially on weekends or holidays. Local and foreign tourists will enjoy the natural beauty of the Losari beach and see the historical buildings of Fort Rotterdam. These

places can be reached by foot along the pedestrian path "Bundaratta"[6].

A. Pedestrian Need Concept: Alfonso (2005)[7], states that pedestrian activity is based on 5 (five) factors of human needs, namely the feasibility factor, the accessibility factor, the safety factor, the comfort factor and the pleasurability factor. The feasibility of a pedestrian path (sidewalk) can be measured from the level of fulfillment of pedestrian needs based on 8 (eight) criteria, namely mobility, accessibility, continuity, connectivity, safety, comfort, security and beauty(Gatoet Wardianto, 2017)[8]. On the other hand, Fruin (1979)[9], states that facility planning for pedestrians (sidewalks)[10] must pay attention to 7 (seven) main targets, namely safety, security, security, convenience, continuity, comfort, system integration (system coherence)[11], and the level of congestion (level of service/LOS). The seven factors are interrelated and influence each other[12].

Proper pedestrian paths or sidewalks must be able to meet pedestrians' needs, not just for walking, but also for leisure, walking, (strolling), and interacting with other pedestrians. (Gatoet Wardianto, 2017)[13]. A well-designed built environment without the presence of pedestrians is not an active social place with a high level of community. This will cause loss of vitality and livability in the area(Rafiemanzelat, Emadi, & Kamali, 2017)[14].

B. Pedestrian Comfort Concept: Sander and Mc Cormick (1993)[15] describes the concept of comfort as a condition of one's feelings towards something and is very dependent on the person experiencing the situation[16]. In other words, comfort is the fulfillment of conditions or conditions that a person wants to stimulate which is received and caused by environmental conditions around him[17]. The desired condition or condition depends on the perception of each individual. The environmental quality of the pedestrian path will affect a person's level of comfort when walking so that in planning it is necessary to consider the human scale, good design, materials, space for walking and a good surface for walking are determinants of pedestrian comfort. (Zakaria & Ujang, 2015)[18].

The word "index" itself according to the Big Indonesian Dictionary (KBBI) from linguistics means the ratio between two certain linguistic elements that may be a measure of a certain characteristic; pointer[19]; If it is related to comfort, it can be defined that the Walkability Index is a list of measures based on the standards referred to to assess a person's comfort level[20], in this case pedestrians, to environmental conditions around the pedestrian path[21]. One of the indicators can be referenced from several studies related to pedestrian comfort on pedestrian paths that produce standards for measuring comfort levels, such as the Global Walkability Index (GWI)[22].(Habibian & Hosseinzadeh, 2018)[23]

Comfort is the main requirement in planning pedestrian or sidewalk facilities by considering pedestrian path conditions related to pavement quality, size, cleanliness, weather, availability of city facilities, circulation, even though the surrounding climatic conditions will affect them on foot.(Corazza, Mascio, & Moretti, 2016).[24]

Here are some of the factors on pedestrian needs that will affect the comfort of walking based on the opinions of several experts and researchers:

(a) Mobility, is a pedestrian requirement related to the space for pedestrians to easily carry out their activities. Pedestrian mobility is determined by the following factors: the track surface, the track width and the absence of obstructions along the sidewalk(Gatoet Wardianto, 2017)[24]. Dimensions (width) of pedestrian paths that are not optimal, uneven surfaces are a major barrier for elderly pedestrians (elderly people) because they are related to where and their safety (Strohmeier, 2016)[16]. Likewise halya with aand permanent obstructions in the form of trees and the placement of city facilities, as well as temporary barriers in the form of several peddlers, motorbike parking, pedicabs and others that will affect pedestrian comfort(Erna & Leksono, 2016)[25]

(b) Accessibility, is the need for pedestrians to access/ reach the desired destination points without obstacles and barriers. Accessibility is the key in making pedestrian paths walkable or pedestrian friendlyfeet, (Rafiemanzelat et al., 2017). Thus, the pedestrian path is easily accessible to everyone, including those with special needs, such as wheelchair users, blind people or the elderly (Zakaria & Ujang, 2015).

(c) Continuity, is the need for pedestrians to be able to carry out walking activities in a sustainable manner, not cut into pieces or stop. The available sidewalk network must ensure the continuity of movement for pedestrians(Gatoet Wardianto, 2017).

(d) Connectivity, is the complete integration of pedestrian paths with transportation modes so that a person can navigate the entire system easily (Bhattacharyya & Mitra, 2013). The unavailability of access to public transportation and the lack of connection of pedestrians and pedestrians is an obstacle to pedestrian mobility (Strohmeier, 2016)

(e) Safety, is the need for pedestrians to avoid traffic accidents. The use of traffic control signals or by pedestrian traffic light signals will create a safe zone between cars and pedestrians, thereby reducing the risk of conflicts and accidents. (Dorohin, Zelikov, & Denisov, 2018). Especially at crossings and road junctions, these control signals are needed to ensure pedestrian safety Elderly(Kim, 2019). The existence of information signs is very useful for pedestrians to provide an overview of the availability/direction of facilities in the area being traversed (Koh Puay Ping & Wong, 2013)

(f) Convenience is a pedestrian need related to climate and weather conditions (heat, sun, wind and rain) as well as the physical conditions of the pedestrian path. Protection can be done by placing trees, shelters, benches or other objects in certain locations that can be used to sit if pedestrians feel tired or just to enjoy the view(Gatoet Wardianto, 2017).

(g) Security is a need for pedestrians to avoid fear of crime that can threaten their lives. The CPTED (Crime Prevention Through Environmental Design) concept is a concept that was built in a certain way to reduce or prevent crime or crime.(Gatoet Wardianto, 2017). Adequate lighting arrangements are also an important factor for attracting visual interest and preventing nighttime crime.(Bhattacharyya & Mitra, 2013)

(h) Beauty is the need for pedestrians to get a pleasant physical atmosphere or environment when doing their activities on foot on the pedestrian path.Trees and parks along the pedestrian path, as well as the scenery around it is what attracts pedestrians. (Koh Puay Ping & Wong, 2013). In this case the role of architects and urban designers in designing streetscapes will be able to refresh and rejuvenate tired pedestrians.(Bhattacharyya & Mitra, 2013).

(i) Circulation is rotation or circulation. This is closely related to the dimensions of the pedestrian path. Comfort can be reduced due to poor circulation, such as the absence of a clear division of space for the circulation of humans and motorized vehicles. Pedestrian circulation is closely related to the dimensions of roads and pedestrian paths, the place of origin of circulation and the exact destination of pedestrian circulation, the purpose of travel, the time of day and the volume of pedestrians.(Ashadi., Rifka H., 2012).

(j) Nature or Climate Style, is a natural condition and climate that occurs at one time. Condition Weather such as rain, wind and temperature have a significant impact on pedestrian behavior as this will influence people's interest in walking(Arana et al., 2014).Modification of city infrastructure, in this case pedestrian paths in accordance with local climatic conditions, will attract pedestrians to continue walking in all seasons and throughout the day.(Shaaban & Muley, 2016). The existence of a shelter such as a gazebo or sheter and vegetation in addition to having aesthetic qualities, plays an important role in urban sustainability, because it has a positive influence on climate and pollution prevention.(Lamour, Morelli, & Marins, 2019).

(k) Fragrance or smell,Bad smells or odors are generated by untreated trash cans, open drainage (gutters) around and odors from motor vehicle exhausts. This unpleasant odor will be smelled by pedestrian path users so that it will reduce pedestrian comfortHygiene and maintenance factors are related to the presence of garbage, or maybe the pungent odor it causes will affect a person walkingi(Erna & Leksono, 2016)

(l) Noise, Noise is unwanted noise in a certain level and time and can cause disturbances to human health and environmental comfort. The permissible noise level for urban areas, especially for trade and service areas and for recreation, ranges from 65 - 70 dB.To minimize, plants are needed as a barrier around the pedestrian path.The arrangement of plants on the sidewalk (on the side of the road) is adjusted to the width of the land, starting from the shoulder of the road to the channel threshold or the Rumija limit. This can reduce the amount of air pollution or noise(Natalia Tanan & Gede Budi Suprayoga, 2015).

(m) Shape,The shape of the pedestrian path design must be adjusted to human standards in order to create a sense of comfort. Wide sidewalks, free from obstacles, freedom of walking, with good quality

coating, green and leafy to provide safety and comfort to users(Lamour et al., 2019). Research results from R. Projadi, Sangkertadi and RC Tarore (2014) revealed that there are 4 (four) physical characteristics of the pesedrian lane that will affect pedestrian comfort, namely shape, dimensions, color and texture.

(n) Cleanliness,is a state free from dirt, including something clean in addition to adding to the attractiveness of the location, it also adds to the feeling of comfort because it is free from garbage and eliminates the unpleasant odors it causes. among them, dust, trash, and odors. Something clean that will add attractiveness as well as convenience for pedestrians (Feybe G. Kaliongga., Veronica A. Kumurur., 2014). It is necessary to arrange and place trash bins on the pedestrian path, the number and distance of every 20 meters at meeting points such as intersections with the size adjusted to the needs. The materials used are materials with high durability such as metal and printed concrete(Ministry of PUPR, 2018)

(o) Lighting, Sufficient lighting for pedestrian paths is a means to increase security against criminal threats in order to create comfort on pedestrian paths (Feybe G. Kaliongga., Veronica A. Kumurur., 2014). Lighting is needed for safety, comfort and aesthetics(Muhammad Muslihun, 2013). The location of the lighting on the pedestrian path is placed every 10 meters with a maximum height of 4 meters, and the materials used are materials with high durability such as metal & printed concrete. (Ministry of PUPR, 2018).

(p) Supporting Elements,Pedestrian path design is no longer oriented to the aspect of beauty alone, but rather focuses on the comfort felt by pedestrians. For this reason, complementary elements of pedestrian paths are needed, including paving, lights, signs, sculptures (vocal points), bollards, benches, shade plants, telephones, kiosks, shelters and canopies, clocks, trash cans, stops and utilities. (Rubenstein, 1992).

This study will use the following variables:

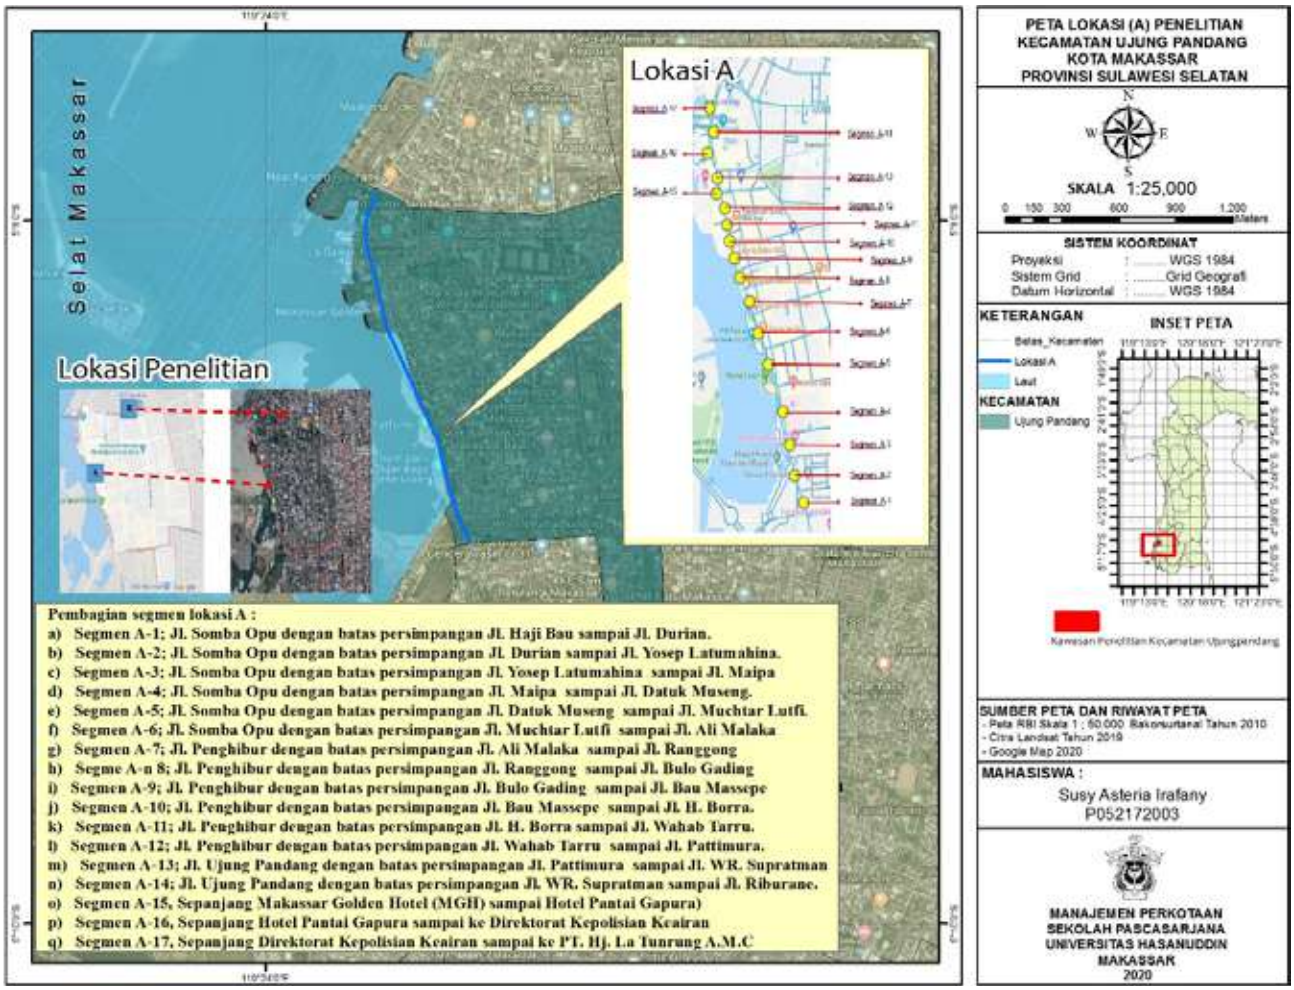

Table 1. Variables and sub-variables for determining the pedestrian lane comfort index

Variable	Sub Variable	Source
Accessibility	• Facilities for pedestrians with special needs • Ramp and Marka	Untermann (1984), R. Judge (2002), Alfonso (2005), Rubenstein (1992) and G. Wardianto (2017)
Beauty	• Pedestrian path material • Garden/Flower Pot • Seat	
Circulation	• Pedestrian path dimensions • The existence of obstructions on the pedestrian path	Untermann (1984) and R. Judge (2002)
Shade	• Shelter/shelter • Vegetation/shade plants	
Cleanliness	• The quantity and quality of bins • Cleanliness level	
Security	• Security systems (CCTV, security posts) • Pedestrian path lighting	Untermann (1984) R. Judge (2002), Alfonso (2005) and Krambeck (2006)
Safety	• Differences in the level of the pedestrian path and the road body • Availability of markers and signs/signals for pedestrian paths • Pedestrian path conditions • Material surface texture • The crossing	Krambeck (2006), Rubenstein (1992) and G. Wardianto (2017)
Noise	Noise canceling facilities	R. Hakim, 2002
Connectivity	Continuity of pedestrian paths Facilities move between modes of transportation	G. Wardianto (2017)

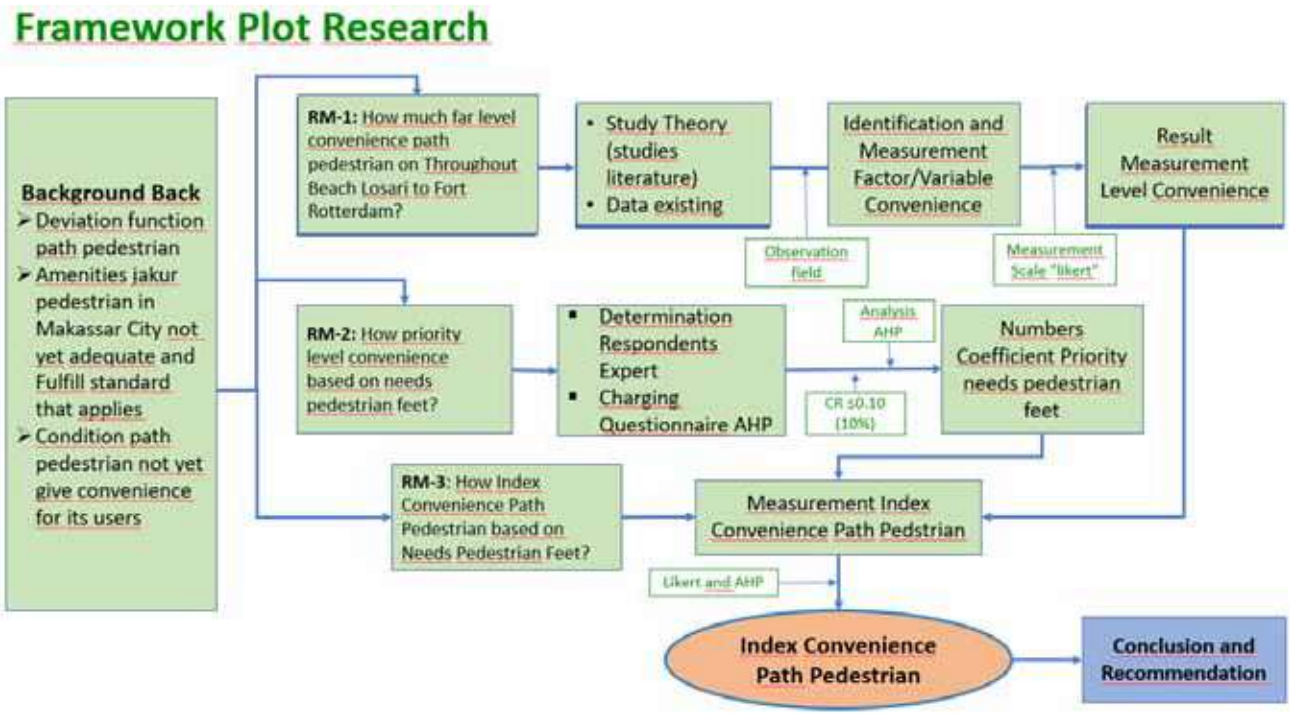
A. Research Method



Research Sites: The object of this research is the pedestrian path along Losari Beach to Fort Rotterdam, Makassar City. As for asite selection welds. This is based on the consideration that natural and cultural recreation areas are quite dense with pedestrian activities. This pedestrian path is long enough so that to obtain more valid data, the pedestrian path is divided into 17 (seventeen) pedestrian lane segments.

Source: Author, 2020

Figure 1. Segment Division of Research Sites

Data Collection and Analysis Techniques: This type of research is a quantitative descriptive study with the Analytical Hierarchy Process (AHP) analysis technique. Primarydata collection techniques are carried out through direct observation in the field, structured interviews using a questionnaire and documentation in the form of recorded images/photographs related to the research location. All data related to variables/sub variables will be assessed based on a Likert scale (0 - 5) to obtain a level of comfort. Whereas for priority determination, the variable assessment was assessed by 7 (seven) expert respondents and the data obtained would be processedusing the Analytical Hierarchy Process (AHP) method and the results will be tested for the level of consistency with limitsThe maximum value of Consistency Ratio ≤ 0.1 or 10%. Walkability Index is obtained by multiplying the AHP weighting coefficient with the results of measuring the comfort level of each variable.

Figure 2. Research Framework

B. Research Results and Discussion:

Measurement of Pedestrian Path Comfort Level: The comfort level of the pedestrian path along Losari Beach to the Fort Rotterdam is measured using variables/sub variables that are measured/assessed as referred to from several applicable regulations (Ministerial Regulations, Ministerial Circular, Decree, Guidebook, etc.). Variables/sub variables are measured using a Likert scale with a score of 1 to 5, where a score of 1 indicates a very bad/very uncomfortable condition, a score of 2 indicates a bad/uncomfortable condition, a score of 3 indicates a fairly good/comfortable condition, a score of 4 indicates a good condition./comfortable and a score of 5 indicates very good condition/very comfortable. The Likert scale obtained is converted into a value at intervals of 0 to 100 to show the results of the index calculation.

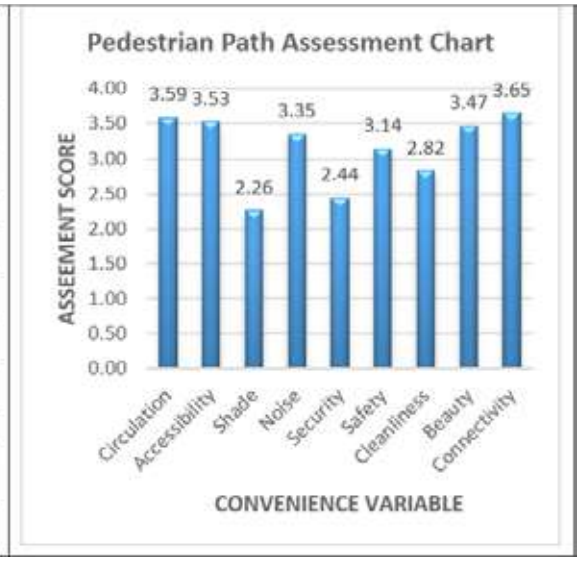

Table 2. Likert Scale and Value Conversion

Likert scale (0-5)	Value conversion (0-100)	Information
1	0 to <20	Very bad/very uncomfortable
2	20 to <40	Bad/uncomfortable
3	40 to <60	Good enough/comfortable enough

7	Cleanliness	2.82
8	Beauty	3.47
9	Connectivity	3.65
Average		**3.14**

Source: Author's Analysis, 2020

The table and graph above shows that the average value of the pedestrian paths on the pedestrian path along Losari Beach to Fort Rotterdam is 3.14 and is included in the quite good/quite comfortable category.

The lowest score can be seen in the shade variable: 2.26 (bad/uncomfortable). The sub variable that is very influential on the assessment of this variable is the availability of shelter facilities such as shelters (covered seats) which are not available in every segment of the location. Roofed shelters are only found at bus stops on segments A-5 and A-17 and they are not utilized optimally. This shelter can also be used by pedestrians as a place to change the mode of transportation. The lowest average score below 3.00 is also found in the safety and cleanliness variables. For security factors, security facilities are needed in the form of CCTV facilities that can reach the pedestrian paths at this location. Likewise, the provision of special lighting facilities for pedestrian paths. What is currently available is a street lamp whose illumination level cannot provide optimal lighting for the pedestrian path. Pedestrian lane special lights also function as aesthetic ornaments that beautify pedestrian paths. The existence of security officers can also be empowered to help control the security of pedestrian paths. For the hygiene variable, almost all pedestrian path segments in this location do not provide special trash cans to accommodate pedestrian trash. Based on the prevailing standards, these bins are placed at a distance of about 20 meters and at meeting points (eg intersections). This is necessary to ensure the cleanliness of the pedestrian path. Pedestrian lane special lights also function as aesthetic ornaments that beautify pedestrian paths. The existence of security officers can also be empowered to help control the security of pedestrian paths. For the hygiene variable, almost all pedestrian path segments in this location do not provide special trash cans to accommodate pedestrian trash. Figure 2. Pedestrian Path Condition

The variable average score (3.14) with an interval of 3.00 - <4.00 is in the quite comfortable category, but that does not mean that it does not require improvement but needs to be improved; For safety variables, the surface of the pedestrian paths, especially in segment A-17, needs to be physically repaired because around 50% of the pedestrian paths are damaged (holes) so that it can endanger pedestrian safety. Pedestrian signs (prohibited signs, warning signs, command signs and directional signs) are also not available at this location. Likewise, the pedestrian lane is very minimal, making it difficult for pedestrians to move places because they have to cross a fairly dense vehicle lane. This crossing route is not visible in the Losari beach area, even though there are many pedestrian activities only in the Fort Rotterdam area. For noise variables, plants that are able to reduce noise from motorized vehicles are needed on the road around the pedestrian path. The variables of accessibility and circulation are closely related to the ease of access to reach the pedestrian path and the freedom to move pedestrians on the pedestrian path without any obstacles. Arrangement of supporting facilities such as placing lighting lamps, aesthetic accessories (seats, flower pots, etc.) need to be rearranged so that they do not interfere with pedestrian access and circulation. Connectivity between pedestrian lanes also needs to be considered, especially the connectivity of pedestrians and the available pedestrian paths.

Prioritizing Pedestrian Needs: The determination of priority scale uses the AHP (Analytical Hierarchy Process) method based on 9 factors of pedestrian comfort. To obtain the priority scale, an AHP questionnaire was compiled which will be filled in by experts, namely people do not have to be experts in the field of pedestrian paths, but understand the problems to be studied. Resource persons or informants who become expertists and meet the consistency test requirements come from government elements as many as 3 people, 2 academics, city observers and 1 person each using the pedestrian path.

To obtain an assessment matrix from several respondents, the mean measurement was carried out based on 9 (nine) variables using the Geometric Mean formula.

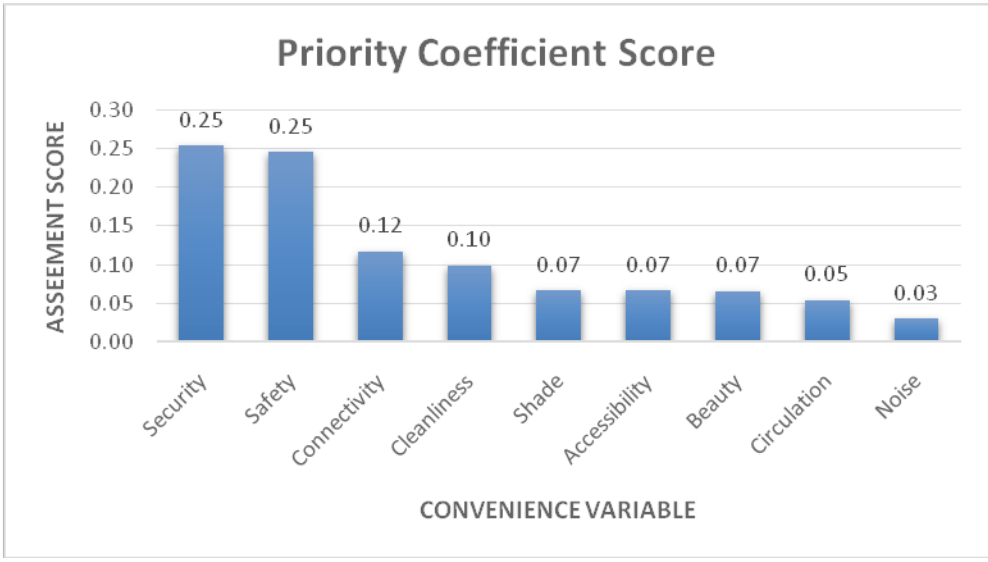
The formula for the Geometric Mean is as follows:

$$GM = \sqrt[n]{X1 \times X2 \times X3 \times \ldots xXn}$$

Where: GM = Geometric Mean

X1, X2, X3,…, Xn = Weight of the assessment of variables 1, 2, .., n

n = Number n (order)



Based on the Geometric Mean formula, the average measurement results are obtained and then the eigen values are calculated to obtain the Priority Vector which is then re-tested for the validity of the data (level of consistency) using the Consistency Ratio (CR) formula as follows:

$$CR = CI/IR$$

Where: CR = Consistency Ratio (requirement CR ≤ 0.1)
CI = Consistency Index ((λ max-n)/(n-1))
IR = Index Random Consistency

Based on the formula above, the calculation of the Consistency Ratio (CR) is 0.015 (consistent, CR ≤ 0.1)

Based on the Analytical Hierarchy Process (AHP) data, which is derived from geometric mean data, the data on the priority order of the pedestrian comfort factors are obtained as follows:

Source: Author's analysis, 2020

Figure 5. Priority sequence graph based on AHP at location A

According to respondents from several experts, the priority needs of pedestrians that really need to be considered in the development of pedestrian paths in this location are the safety and security factors. As a recreation/cultural tourism area, there will be many pedestrians using this pedestrian path, so that the safety and security factors for pedestrians are things that need to be the priority of development so as to provide a sense of comfort for pedestrian lane users. Provision of security facilities (CCTV/security posts/security guards) and lighting needs special attention. Meanwhile, to ensure the safety of pedestrians on pedestrian paths, it is necessary to pay attention to the existence of ramps that are according to standards, availability and placement of markers and signs/signals for pedestrian paths as well as textures and materials used by pedestrian paths. The connectivity factor between pedestrian lanes and transportation mode facilities also needs to be considered in maintaining the continuity of the use of pedestrian paths in Makassar City. This is related to the physical ability of pedestrians and the mileage that pedestrians can travel so that facilities are needed to change modes of transportation to vehicles or public transportation.

Measurement of Pedestrian Track Comfort Index in Makassar City: Measurement of the pedestrian comfort index at each research location uses the results of the assessment of the comfort level of the pedestrian paths obtained from field data by taking into account the priority coefficient from the results of data processing Analytical Hierarchy Process (AHP). To calculate the pedestrian comfort index, the researcher will add up

the multiplication of the comfort level value (column 4) with the priority coefficient (column 3) of each variable. The index numbers obtained for each location will be converted to values 0–100.

Table 4. Walkability Index

Influence Variable	Priority Coefficient	Priority Level (%)	Comfort Level (Scale 1 - 5)
(1)	(2)	(3)	(4)
Circulation	0.0545	5.45	3.59
Accessibility	0.0665	6.65	3.53
Shade	0.0673	6.73	2.26
Noise	0.0306	3.06	3.35
Security	0.2534	25.34	2.44
Safety	0.2454	24.54	3.14
Cleanliness	0.0990	9.90	2.82
Beauty	0.0659	6.59	3.47
Connectivity	0.1174	11.74	3.65
Location Convenience Index A (conversion values 0-100)		**60.20 (Convenient)**	

Source: Author's analysis, 2020

Table above shows that the Walkability Index at location A is 60.20 and is included in the comfortable category (interval 60 to <80). Based on columns (3) and (4), it shows that the security variable has a major priority in improving pedestrian paths at this location, which is 25.34%. Field conditions indicate that the level of comfort is included in the uncomfortable category (2.44) due to the lack of availability of security systems (CCTV, security posts and security guards) which are able to reach all areas of the pedestrian path and the unavailability of lighting specifically intended for pedestrian paths.

Likewise, the safety factor is the second priority (24.54%) in the development of pedestrian paths at this location. Based on the results of the assessment of the level of comfort for each location segment, it shows that the safety sub-variables, namely the availability of markers and pedestrian paths/signs are not available. Likewise, the availability of zebra crossing facilities is inadequate, only available around SombaOpu Fortress, even though these facilities are urgently needed by pedestrians to ensure the safety and security of pedestrians.

The connectivity factor occupies the third priority in improving pedestrian pathways (11.74%), even though it is in the quite comfortable category (3.65). Connectivity between pedestrian lanes and transportation modes is important in improving pedestrian pathways at location A. The existence of 2 (two) bus stops as a place to change the mode of transportation at this location needs to be optimized for use so as to be able to increase pedestrian comfort. Cleanliness and shade factors also need special attention because they are included in the uncomfortable category with the fourth and fifth level of development priority. In this case, the availability of trash and shelter facilities needs to be a concern in providing a sense of comfort to pedestrians.

The pedestrian path accessibility factor at location A is quite comfortable because it is easy to access by normal pedestrians and those with special needs, only need to be equipped with road markings such as a zebra crossover. Other factors such as beauty, circulation and noise which are categorized as comfortable enough, need to be maintained even if the comfort needs to be increased by completing facilities that are not yet available.

C. Conclusions and Recommendations

The conclusions from the results of this study are as follows:

1. The results showed that the pedestrian path along Losari Beach to Fort Rotterdam was in the quite good/quite comfortable category (score 3.14). Improvement needs to be done, starting from providing several facilities to physical development in several location segments

2. The priority of pedestrian needs on pedestrian paths in this location places security, safety and connectivity as the main priority in the development of pedestrian paths in Makassar City. The improvement and development of these three factors need serious handling in order to create a pedestrian path that is comfortable for everyone without exception.

The recommendations of this study are addressed to the Makassar City Government or to further researchers in the following:

1. In developing pedestrian nets in Makassar City, factors such as security, safety and connectivity have become top priorities in addressing one of the increasingly complex challenges of urban development while still paying attention to other supporting factors.
2. Further researchers are advised to carry out more in-depth and detailed research on the priority needs of pedestrians that have been obtained in this study.

Abstract

Transient ischemic attacks (TIA), as precursors of cerebral strokes, occupy an important place among all forms of cerebrovascular insufficiency. Regarding epidemiology of transient ischemic attacks (TIA), there are no accurate data in most countries. In the United States, up to 5 million adult citizens per year suffer from these episodes, many TIA remain undiagnosed. These episodes of a sudden and short-term neurological deficit have long been considered as benign and harmless. Most general practitioners and patients misunderstand or insufficiently understand TIA's nature and significance, perhaps, this is the reason of insufficient medical interest, lack of statistical data on this nosological unit. Transient ischemic attacks (TIA) are clinically defined as rapidly developing focal and sometimes diffuse (cerebral) dysfunctions of the brain that are caused by local ischemia and last no longer than a day[1]. Over the past two decades, many views on TIA have changed significantly, approaches to the diagnosis and treatment of patients have become much more intense and aggressive. Modern knowledge about TIA is of paramount importance both for proper organization of patient care and educational programs among the population; their importance can hardly be overestimated.

Keywords: *Transient ischemic attack, Cardiomagnyl, ischemic stroke, prevention.*

Introduction

Transient ischemic attacks (TIA), as precursors of cerebral strokes, occupy an important place among all forms of cerebrovascular insufficiency. Regarding epidemiology of transient ischemic attacks (TIA), there are no accurate data in most countries. In the United States, up to 5 million adult citizens per year suffer from these episodes, many TIA remain undiagnosed. These episodes of a sudden and short-term neurological deficit have long been considered as benign and harmless. Most general practitioners and patients misunderstand or insufficiently understand TIA's nature and significance, perhaps, this is the reason of insufficient medical interest, lack of statistical data on this nosological unit. Transient ischemic attacks (TIA) are clinically defined as rapidly developing focal and sometimes diffuse (cerebral) dysfunctions of the brain that are caused by local ischemia and last no longer than a day [1]. Over the past two decades, many views on TIA have changed significantly, approaches to the diagnosis and treatment of patients have become much more intense and aggressive. Modern knowledge about TIA is of paramount importance both for proper organization of patient care and educational programs among the population; their importance can hardly be overestimated. TIA shall be considered an urgent situation for the following reasons: • first - the risk of ischemic stroke development after TIA is rather high; • second - effective secondary prevention is available. In this respect, early and reliable diagnosis of TIA is utterly important, allowing correct treatment of this pathology. In TIA diagnostics, ultrasonic Doppler examination and computer tomography are used in most

cases. Usually, TIA is an acute episode in the general clinical picture of chronic progressive cerebral ischemia, neuroimaging method also make it possible to detect dyscirculatory encephalopathy signs. Atherosclerosis is defined as the most common cause of TIA in Western Europe and America in 80-90% of cases. Atherosclerotic multiple lesions are more common than isolated ones. According to Spiridonov A.A. (1996), pathology of only one carotid artery occurs in 51.7% of cases. The lesion of one vertebral artery was observed in 38% of cases. The incidence of multiple BCA lesions ranges from 50 to 93.8%. BCA lesion in 33% of cases is located intracranially, or in the zone, inaccessible for direct surgical revision. Other 67% were extracranial, 52% of these were located in CCA bifurcation area, 20% in the area of vertebral artery mouths and 9% in the area of the main branches of the aortic arch.Pathological deformations of carotid and vertebral arteries takes the second place in the structure of TIA causes. The reasons for development of pathological deformations have not yet been determined. Most authors believe that they result from congenital (embryogenesis disorder) or acquired factors (weakening of the artery wall elastic structure, atherosclerotic artery lesions, age-related anatomical changes in the cervical spine), or functional adaptive mechanisms aimed at pulse wave reduction (with arterial hypertension) and blood flow uniformity.

The aortic arch syndrome (AAS) is another cause of BCA lesion. It is observed in approximately 10-15% of patients and is a polyetiological autoimmune vasculitis with a primary lesion of the aorta and main arteries of the elastic type. AAS affects people aged from 10 to 40 years, more often women[7,9,15]. AAS is characterized by multiple lesions of the aortic arch branches, often symmetrical, for example, two carotid and two subclavian arteries. Most often, the subclavian artery is occluded and almost twice as often - the left subclavian artery. Most often, a subclavian artery is occluded and almost twice as often - a left subclavian artery.

In 5-10% of cases, TIA is caused by relatively rare diseases, causing lesion (blockage or narrowing) of the BCA and resulting local brain ischemia. Acute and blunt vascular injuries with arterial thrombosis, BCA dissection, BCA fibromuscular dysplasia, as well as extravasal vascular compression.

Dissection of pre-cerebral and, less commonly, cerebral arteries is the cause of about 2% of TIA cases, it is more typical for young women. BCA and VA dissection can occur due to trauma, unsuccessful manipulation of the cervical spine or developmental abnormalities. A hematoma, formed under the intimal artery, causes its lumen narrowing and can cause thrombosis or embolism.

The clinical picture of TIA is very diverse, but with this pathology there are no clear pathognomonic symptoms, their presence would help clinicians in diagnositics nd timely selection of treatment tactics for detected lesions, including surgical revision of pathology. If TIA is located in the carotid pool, then, as a rule, transient paresis or paralysis is observed. With TIA in the vertebral-basilar pool, the main clinical symptom is dizziness.

The purpose of our work was to study method of ultrasonic Doppler examination and computer tomography for TIA diagnosis. The study included 76 patients (47 men and 29 women, aged from 45 to 80 years (mean age 62.3 ± 5.1 years) Control group (15 patients) included practically healthy individuals of the same age, with no signs of cerebrovascular insufficiency.

TIA etiological factors in our observations were as follows: cerebral atherosclerosis 68.42% (52 patients) and a combination of cerebral atherosclerosis and hypertension 31.57% (24 patients). The course of hypertension in our observations was malignant with average indices of blood pressure of 170 ± 6.4 mm Hg and frequent increases in systolic blood pressure over 220 mm Hg, worsening the picture of cerebrovascular insufficiency.

In the clinical picture, outside TIA, cerebral complaints to headaches, dizziness, which intensified at head turn and change of the body position, sleep disturbances, performance impairment and memory problems prevailed. In the presence of diffuse focal symptoms in the form of tendon anisoreflexia, oral automatism symptoms, pathological stop signs, most of our patients (80.2%) were diagnosed with dyscirculatory encephalopathy. It should be noted,that in most patients, clinical symptoms spoke for dyscirculatory encephalopathy, primarily, in the vertebral-basilar pool. In the latter case, there was vertebral-basilar insufficiency of II or III degree, which was also determined by the method of ultrasonic Doppler examination and computer tomography. The study of cerebral hemodynamics and main artery of the head was performed using ultrasonic Doppler examination on VAZOSKAN device, manufactured by Sonicaid (England) using sensors with

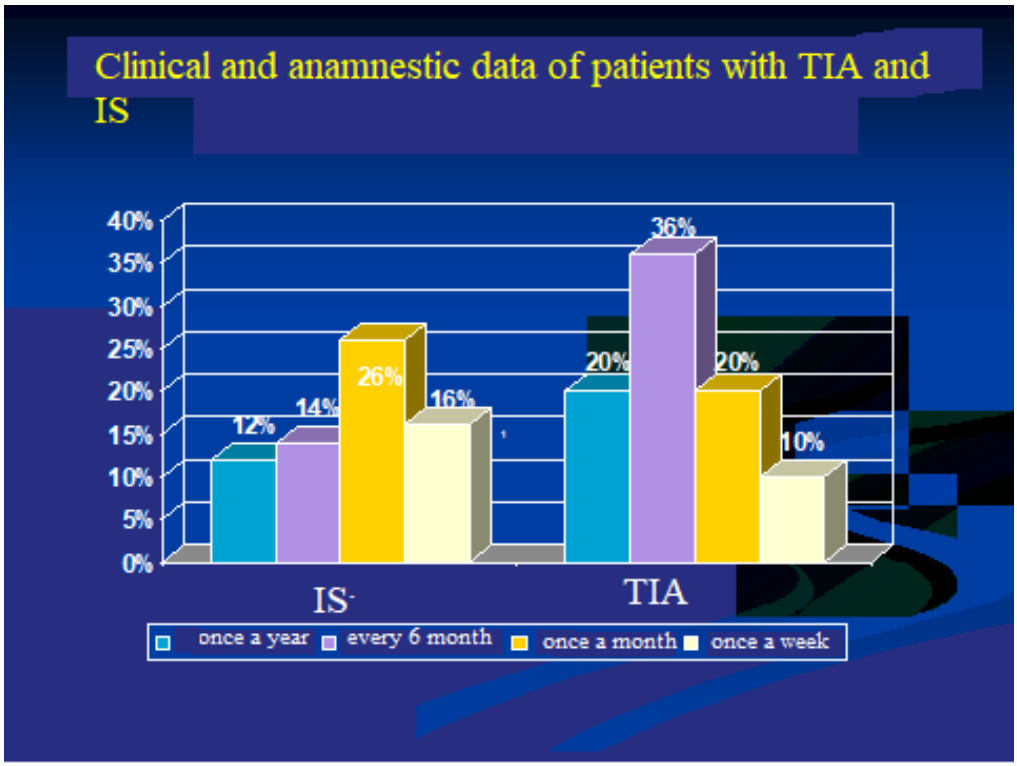
a frequency of 2.4.8 MHz and diameters of 14, 10 and 6 mm. The studies were performed in the city diagnostic centre.

According to Spiridonov A.A. (1996), pathology of only one carotid artery occurs in 51.7% of cases causes TIA development. The lesion of one vertebral artery was observed in 38% of cases. The incidence of multiple BCA lesions ranges from 50 to 93.8%. To determine the role of occlusive lesions in TIA development, ultrasonic Doppler examination was performed. The study of cerebral hemodynamics and main artery of the head was performed using ultrasonic Doppler examination on VAZOSKAN device, manufactured by Sonicaid (England) using sensors with a frequency of 2.4.8 MHz and diameters of 14, 10 and 6 mm.

Magnetic resonance imaging studies were performed in Radiology Department of the 3rd clinic of Tashkent Medical Academy using Magnetom Open Viva (Siemens) device with a magnetic field strength of 0.2 Tesla in coronary and transverse projections using a common flexible RF coil for the patient in a neutral position on his back.

Results

The patients' condition upon admission in most cases 80% (32 patients) was regarded by us as moderate. It is important to note that in most cases, the severity of patient's condition was due to a number of neurological symptoms, but not impairment of consciousness. For description of transient disorders, the following aspects were evaluated: TIA duration and incidence, probable vascular pool, morbidity, prevalence of focal or cerebral symptoms. Moreover, in most of our observations, TIA were predominantly focal over cerebral. Anamnestic data of patients with TIA are shown in Fig. 1.



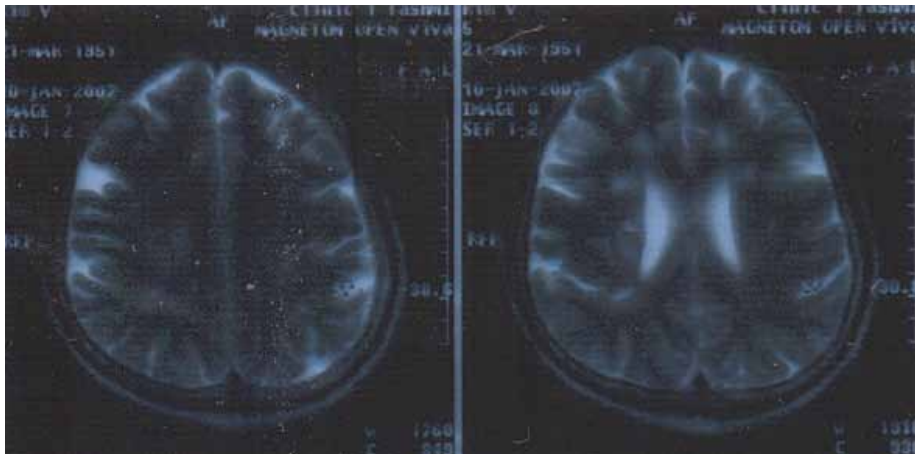


Figure 1. Clinical and anamnestic data of patients with TIA and ishemic stroke (IS).

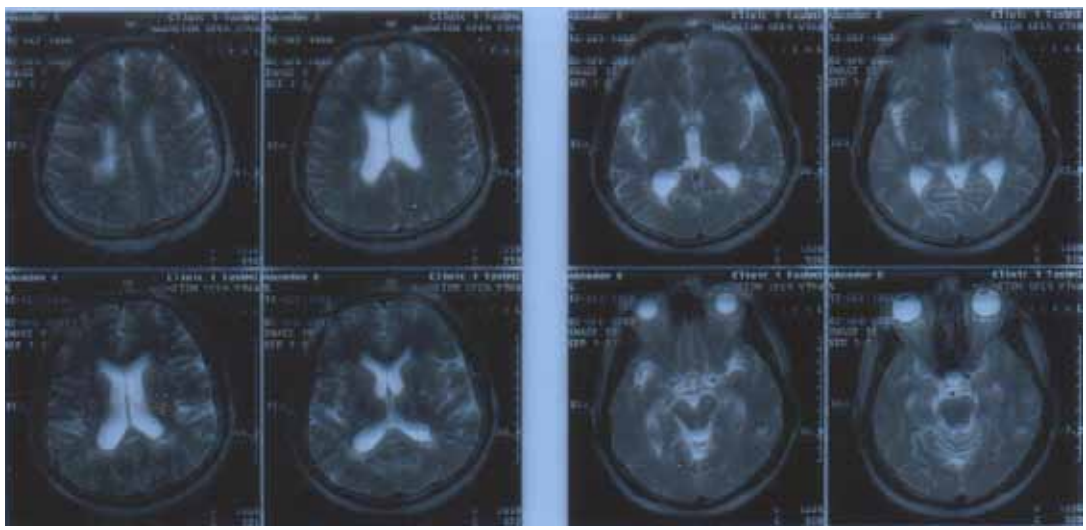
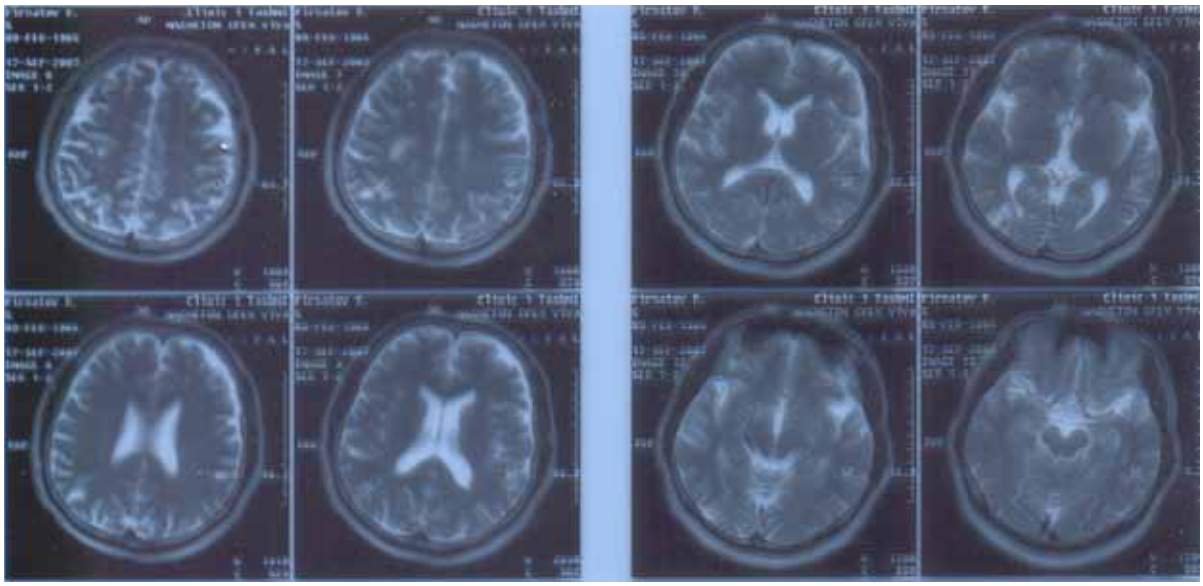
As can be seen in Fig. 1, IS most often developed in patients with TIA incidence once a week or once a month. The highest risk of IS development was observed at a TIA incidence of once a week and reached 33.3%. The duration of TIA in this group of patients was up to 10-16 hours (according to anamnestic data). Based on clinical and anamnestic studies, we analysed the dependence of the risk of stroke development on the incidence of previous TIA in 18 patients who had a stroke against TIA (Fig. 2). In all cases, the stroke vascular pool coincided



with the TIA localization. Besides, as presented data show, the incidence of stroke and TIA coincided when they were localized in the right carotid system (31% and 37%, respectively). At the same time, TIA in the left carotid system were observed 3 times less often (18%) than strokes in the same pool (55%). In contrast, TIA in vertebral-basilar pool were observed 3 times more often than strokes in the same vascular pool. The obtained results can be explained by anatomical features of the vascular pool structure, as well as by compensatory characteristics of these vascular pools.

The MRI studies revealed the dependence of TIA clinical picture the severity of brain atrophy. To determine the latter, based on MR images, we calculated indices of the lateral and third ventricles. Our studies showed that in the group of patients with frequent TIA (more than 2-3 times per month), indices of lateral ventricles were 1.3 and were much higher than in patients with TIA 1 time in 6 months or 1 year (0.8). Besides, dependence of MRI indices on the degree of dyscirculatory encephalopathy and etiological factors, caused cerebrovascular insufficiency.



Multiple foci of reduced density no larger than 1 cm were found on MR images in the periventricular zone.

The number of the above foci also depended on the TIA incidence. Besides, in the group of patients with TIA incidence of more than 2-3 times a week, an expansion of subarachnoid space and sylvian fissures was observed, showing probable external brain atrophy and the state of cerebral hemodynamics. Typically, the cause of TIA in the latter case was a combination of arterial hypertension and cerebral atherosclerosis.

In patients with TIA on the background of cerebral atherosclerosis, we revealed only the expansion of sylvian fissures and subarachnoid space, with indices of lateral ventricles not significantly different from those of the control group.

Thus, as our studies showed, the clinical picture of TIA is characterized by various symptoms and diagnosis complexity, considering its retrospective character. The incidence, duration and vascular pool of TIA are correlated with the risk of cerebral stroke. The clinical picture of TIA is also largely determined by the brain condition, in particular, the severity of its atrophy. The latter, depending on the etiological factor, manifests itself in the form of predominantly external or internal forms. The number of foci of reduced density in the periventricular zone is also directly dependent on TIA incidence.

Results of Transurethral Correction of Stenotic Developmental Abnormalities of Ureterovesical Junction in Children

Makhmudjon Aliev[1], Akmal Rakhmatullaev[1], Bilim Terebaev[1]

[1]*Associate Professor, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

Abstract

Purpose: Improving the results of treatment of stenotic developmental abnormalities of the ureterovesical junction (SDA UVJ) in children.

Materials and Method: Treatment analyzed included 88 pediatric patients (125 ureters) with SDA UVJ, aged 3 months - 15 years.

Results: Endoscopic stenting has been performed using antireflux stents, with subsequent bladder drainage using a urinary catheter. We have also developed an inverted V-shaped ureterocele incision. The UVJ control calibration has been performed using calibration catheters. If the UVJ diameter did not correspond to the age norm, the second stage of treatment was carried out by dilating with conical bouges or by UVJ balloon dilating. Transient complications developed in the immediate postoperative period have been successfully eliminated using conservative measures, in all cases.

Conclusions: The study results imply the effectiveness of endoscopic method in correcting SDA UVJ in children.

Keywords: *Obstructive megaureter, stenotic developmental abnormalities of ureterovesicular junction, endoscopic treatment, children.*

Introduction

The endosurgical treatment of patients with UVJ abnormalities have not almost been used in pediatrics, due to the lack of differential diagnostic criteria for various forms[8] of this disease or indications for such an intervention [14].

Studying the urodynamic disturbance mechanisms led us to the fact that the existing open surgical procedure of patients with stenotic anomalies had to be reconcepted, and the list of indications for endosurgical interventions[7] - expanded. The technique of transurethral ureteroplasty for UVJ stenotic anomalies, using bouginage or balloon dilatation of UVJ with ureteral stenting and ureterocele incision[13], had been previously recognized as effective. For the first time in pediatrics, this approach to the treatment of obstructive megaureter was described by N.V. Dorasvely in his work (1990), which presented two cases of successful endoscopic ureteroplasty using a Fogerty balloon dilator[10]. However, the discrepancies in the results of these interventions performed in younger children still remain[12].

Endosurgical method of treating children with UVJ developmental abnormalities have an increasing number of its supporters[1]. However, insufficiently studied mechanisms of urodynamic disturbance reduce the positive results of such interventions[2]. Forms of UVJ developmental anomalies are diverse, while in children, functional anomalies predominate[6]. All this explains why the differentiated treatment strategy has been chosen for pediatric patients[8].

The aim of this study is to improve the results of treatment of SDA UVJ in children.

Materials and Method

The treatment analyzed included 88 pediatric patients (125 ureters) with SDA UVJ, aged 3 months - 15 years. The research was carried out in the Department

of Intermediate Level Pediatric Surgery (Head of the Department - prof. M.M. Aliev) of TashPMI (Rector - prof. B.T. Daminov), and in the Department of Pediatric Surgery (2014-2019) of the Republican Specialized Scientific and Practical Medical Center of Pediatrics (Director - prof. D.I. Ahmedova).

Indications for endoscopic transurethral correction of organic stenotic anomalies (SA) of UVJ have been determined based on the nature of functional disorders - mild, moderate or severe - according to our diagnostic research algorithm.

3 types of endoscopic correction of UVJ have been performed in 88 patients (125 ureters) with SA (Table 1).

Table 1: The nature of endoscopic interventions performed in children with SA UVJ

Types of UVJ anomalies	Endoscopic method of treatment			Total
	UVJ bouginage**	UVJ balloon dilatation**	Ureterocele incision	
OSA*	8 (11)	21 (29)	16 (18)	53 (66)
FSA*	21 (35)	22 (32)	-	35 (59)
Total	29 (46)	43 (61)	16 (18)	88 (125)

Note: The number of ureters is provided within brackets. * - SA - stenotic anomalies; O - organic; F - functional. ** - UVJ bouginage and balloon dilatation have been performed with mandatory stenting of the lower third of the ureter.

As shown in Table 1, in our practice, we preferred UVJ balloon dilatation with stenting of the lower third of the ureter. In 16 children (18 ureters), the ureterocele incision was performed only with its intravesical form.

During examination cystoscopy, the ureterocele opening was catheterized with a flexible conductor to a depth of 8-10 cm. The ureterocele opening bouginage was performed consecutively using conical bouges Biorad Medisys PVT (India) 6-8-10-12 Fr, along the entire UVJ, under triple video+Carm+ultrasound control. Bouginage up to 6 Fr was carried out for children under the age of 3 years, up to 8 Fr - for children from 4 to 7 years, and up to 12 Fr - for children over 7 years.

Balloon dilatation was performed using a balloon catheter manufactured by Biorad Medisys PVT (India). Balloon catheter was passed over using a flexible conductor, UVJ dilatation up to 6Fr with a pressure of up to 2 Atm/bar was performed for children under the age of 3 years, up to 8Fr with a pressure of up to 3 Atm/bar - for children from 4 to 7 years, and up to 10Fr with a pressure of up to 4 Atm/bar - for children over 7 years. The abundant flow of turbid urine with the failure of a bouge or balloon was considered as an efficacy criterion for dilation (P. Puri et al. 1991).

Results

After bouginage or dilatation, a polyurethane stent with a diameter of 4-10 Fr of the same manufacturer was installed in the lower third of the ureter at one end and into the bladder cavity at the other end. Then, it was passed through the conductor using a 'pusher' (Fig. 1). Stents were placed in the ureter for a period of 20-30 days.

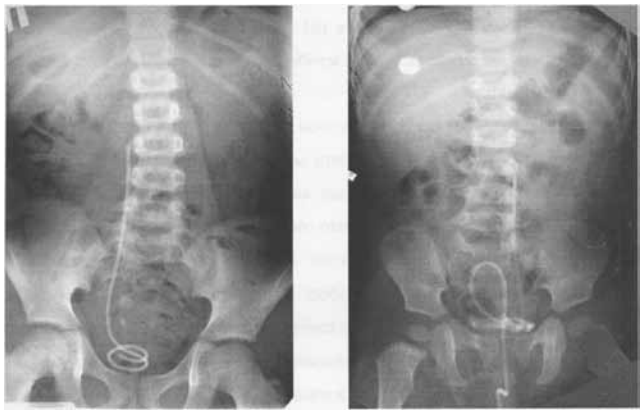

Figure 1. Plain urography. Normal position of the 'low' stent.

During primary stenting of the ureter, the diameter of the stent did not largely exceed 5-6 Fr. With repeated stenting (7 cases), its diameter was 8-10 Fr. After 20-30 days, when the stent was removed, it was determined by cystoscopy whether it is necessary to replace the stent. With that, UVJ control air-blast calibration was performed using calibration catheters. If the UVJ diameter did not meet the age norm, the second stage of treatment included dilating using conical bouges or UVJ

balloon dilating. Then, the larger stent was installed for a period of 20-30 days.

Outcome of treatment in children using double J (JJ) stenting has been more successful than that through high derivative urine using percutaneous puncture nephrostomy. Indications for percutaneous puncture nephrostomy have been determined by pronounced deviation of the ureter and a sharp decrease in its contractility in case of insufficient derivation of urine from the lower ureter. Based on the foregoing, a modification of stents has been developed, that promoted improved drainage of the upper urinary tract. For this purpose, so-called 'low stents' were used. After endosurgical intervention, they were inserted up to the middle third of the ureter or the first knee-shaped bend. In this way, appropriate urinary drainage from all parts of the collecting system was ensured. A thin line from the distal end of the 'low' stent was withdrawn through the external urethral opening, which made it possible to remove the stent without additional instrumental interventions. Endoscopic stenting was performed with antireflux stents Biorad Medisys PVT (India) with the subsequent drainage of the bladder - on the first or the second day - with a Foley 8-12 Fr urethral catheter. The drainage time was determined depending on the age of the child and the urethra diameter.

Discussion

For ureterocele incision, we used endoscopic equipment manufactured by KARL STORZ (Germany): an electrochemical resectoscope 10 CH with loop-shaped electrodes and a hook-shaped cold knife. During ureterocele incision - transverse or semi-lunar - the ureterocele upper wall contracted between the two fixation points (Waldeyer's ring and the proximal urethra), and the free edge of the artifical opening was moved in the proximal direction, as a result of which the opening became U-shaped. The submucous ureteral segment was shortened inversely in proportion to the length of the discission, which could not ensure a tight closure of its walls in the area of the opening.

Taking into account this disadvantage of the conventional method above, we have developed an inverted V-shaped ureterocele incision. In this case, the contracting upper wall of the ureterocele, while retaining both fixation points, does not displace the proximal border of the articular opening, since it does not have free edges oriented perpendicular to the axis of the ureter. Due to this, the length of the submucosal part of the ureter remains unchanged and depends only on the length of the incision performed. After contraction, the upper and lower walls of the ureterocele close tightly, which improves antireflux function. The incision was short, its length did not exceed the length of the working part of the electrode and the hook of the cold knife (3 mm). The intervention was completed by draining the bladder with a Foley 8-12 Fr urethral catheter, at the first or the second day.

UVJ endosurgical intervention was always carried out against the background of antibacterial prophylaxis, 1-2 days before the intervention, depending on the results of common urine and bacterial urine culture tests, determining the sensitivity of the flora to antibiotics.

After surgery, patients stayed in the hospital within 2.06±0.49 days, on average (1-3 days). Upon discharge, patients were advised to maintain an increased fluid intake and take uroseptics and antihistamines, in order to prevent sensitization to stent material. Recommendations had to be observed for the entire period of 20-30 days before the removal of the stent and the subsequent transition from the inpatient to outpatient setting. The dynamics of emptying the lower third of the ureter and the pyelocaliceal system was evaluated through ultrasound, which was performed every 10 days for 1 month. The tendency to a decrease in the diameter of the lower third of the ureter within 2 weeks largely indicated the reversibility of changes in the enlarged ureter. On the 20th-30rd day after ureteral stenting, patients were re-hospitalized, in order to remove or replace the stent. A control excretory urography was performed with 1 or 2 images, depending on the initial state of the upper urinary tract (UUT). After ureterocele incision, the mycystic cystography was performed, in order to extend the study materials.

Transient complications (ureter atony, hemorrhagic cystitis, exacerbation of pyelonephritis, dysuria) developed in the immediate postoperative period have been eliminated by conservative measures, in all patients. Such measures consisted of antibacterial, anti-inflammatory therapy and physiotherapeutic procedures that stimulated ureter contractibility (Table 2).

Table 2: Complications of the immediate period after endoscopic correction for UVJ stenotic abnormalities in children

Method of endoscopic correction	Types of complications			
	Leukocyturia (FOV)	Proteinuria (g/l)	Atony of the ureter (urine discharge/min)	Dysuria
UVJ bouginage n=17	19,3±1,25	0,18±0,9	1,83±0,06	7 (33,3%)
Balloon dilatation UVJn=27	17,1±0,69	0,05±0,1	1,55±0,07	8 (33,3%)
Ureterocele incision n=11	28,3±0,52	0,07±0,07	1,9±0,05	4 (50%)

Note: $P < 0.05$.

As can be seen from Table 2, the most frequently observed complications of the immediate postoperative period were exacerbation of pyelonephritis and transient urodynamic abnormalities. Infusion and antibacterial therapy led to normalization of body temperature, urine tests and elimination of dysuria.

Excretory urography has been performed in 29 patients (46 ureters), in order to evaluate the results of UVJ endoscopic augmentation with low stenting within 1-3 months after the treatment. Of the 46 cases of examination of kidneys and ureters, in 35 cases (76.1%) a decrease in the degree of enlargement of UUT was recorded, by an average of 47.5±1.1% (Fig. 2, 3, 4), in 9 cases (19.6%) - no changes, and in 2 cases (4.3%) - an increase in the UUT size.

Figure 2. Patient A., 7 years. Excretory urography. III grade megaureter on the left. Before the UVJ bouginage with low stenting on the left.

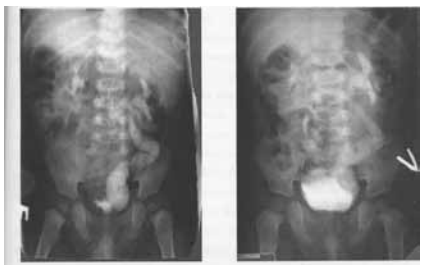

Figure 3. The same patient Excretory urography 1 month after UVJ bouginage with low stenting on the left.

Figure 4. The same patient Excretory urography 3 months after repeated UVJ bouginage with replacement of the low stent on the left after 30 days.

In order to evaluate the results of UVJ endoscopic balloon dilatation with low ureter stenting, within 1-3 months after treatment, excretory urography results have been studied in 43 patients (61 ureters). Of the 61 cases of examination of kidneys and ureters, in 54 cases (88.5%) a decrease in the degree of UUT enlargement was recorded, by an average of 58.4±1.2% (Fig. 5, 6), in 5 cases (8.2%) - no changes, and in 2 cases (3.3%) - an increase in UUT size.

Excretory urography has showed the following results of endoscopic surgery using the modified method of inverted V-shaped ureterocele incision. In 16 patients (18 ureters) a decrease in ureterocele lumen was observed by an average of 68.3%, in 14 ureters (77.8%) - by 57.8% ($p<0.05$) (Fig. 8), in 1 (5.5%) - without reducing UUT size. In 3 cases (16.6%), the vesicoureteral reflux has been observed (Fig. 6, 7), and in 1 case - urethenosis (Fig. 8).

Fig. 5. Patient V., 5 years. Excretory urography. II grade megaureter on the right, III grade megaureter on the left. Before UVJ balloon dilatation

Fig. 6. The same patient Excretory urography after 3 months. Positive result.

Fig. 6. Patient S., 6 years Excretory urography. Intrauterine ureterocele on the right.

Fig. 7. The same patient Cystography. Unsatisfactory result. Vesicoureteral reflux on the right.

Fig. 8. Patient F., 4 years. Excretory urography. Ureter and ureterocele lumen reduction.

After analyzing the results of the UVJ dilatation with low stenting, we have identified the following reasons for unsatisfactory indicators: 1) stent prolapse into the bladder lumen (Fig. 9.) 2) stent migration into the ureter lumen (1 case) 3) accumulation of salts on the stent surface and its obstruction, which contributed to the exacerbation of pyelonephritis (1 case). When dissecting the ureterocele in a modified way, the fusion of the edges of the incision and the excessive ureterocele tissue dissected have been revealed, which caused vesicoureteral reflux.

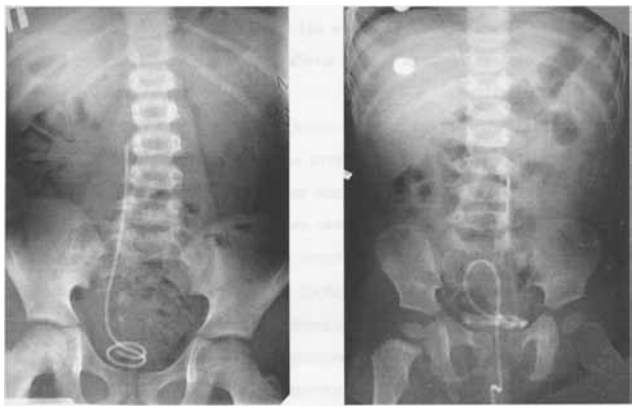

Figure 9. Patient P., 3 years. Plain urography. Stent prolapses into the bladder.

In order to study positive urodynamics after endoscopic correction in SA UVJ within 1-3 months, we used the following special research method: ultrasound of the ureter-cystic urinary discharge (UCUD) using pulse-wave dopplerometry and transformational echopieloscopy (TEC) with diuretic load (Table 3). In patients with positive urodynamics, with pulse-wave dopplerometry of the ureter-bladder discharge of urine, the frequency, duration and maximum speed of UCUD were close to normal values. Analysis of transformational echopieloscopy has showed that the more pronounced the initial dilatation of the ureter, the less its expansion at the time of examination.

The maximum expansion of the distal ureter (35-40% of the initial size) was observed at 5-8 minutes of the examination, and the restoration of the original size usually occurred at 35-45 minutes. During the study period, the expansion of the ureter in this group of patients did not exceed 1.5 cm in diameter, which indicated that its wall tone is preserved.

Table 3: Positive urodynamics in the immediate period after endoscopic correction in children with SA UVJ.

Method of endoscopic correction	The number of ureters	UCUD Doppler ultrasound			TEP		
		Frequency of discharge per 1 min.	T_c (sec)	V_{max} (m/s)	T_{max} (min)	P_{max} (%)	T_i (min)
UVJ bouginage	46	1,93±0,56	1,56±0,18	0,31±0,04	7,3±0,78	39,2±0,46	44,2±0,89
UVJ balloon dilatation	61	2,9±0,2	1,8±0,4	0,34±0,03	5,8±1,1	36,5±3,6	41,1±0,78
Ureterocele incision	18	2,4±0,36	1,2±0,1	0,33±0,02	6,4±0,44	35,8±0,37	37,6±0,69

Note: T_c - duration of one urine discharge; V_{max} - maximum speed of urine discharge; T_{max} – time of maximum expansion of renal collecting system (min); P_{max} – maximum expansion of renal collecting system (%); T_i - the restoration (reduction) time of the size of renal collecting system to its initial values (min.);- $P<0.01$

Conclusions

The obtained results have showed the effectiveness of endoscopic method for the correction of UVJ stenotic anomalies in children. The revealed causes of conservatively reversed complications and unsatisfactory results have mainly depended on the severity of urinary infection and have made it possible to improve the conservative treatment of children with AS UVJ.

Epidemiological Characteristic of Aphthous Stomatitis and Real Clinical Practice of Management of Patients in Uzbekistan

D.M. Alimova[1], O.E. Bekjanova[2]

[1]PhD, MD, Department of Therapeutic Dentistry, Tashkent State Dental Institute, Tashkent, Uzbekistan, [2]MD, Professor, Head of the Department of Therapeutic Dentistry, Tashkent State Dental Institute, Tashkent, Uzbekistan

Abstract

Introduction: The article provides an epidemiological description for patients with chronic recurrent aphthous stomatitis (RAS) and the frequency of their reversal in the general structure of diseases of the oral mucosa from 2014 to 2018. The structure of clinical forms of RAS in the Republic of Uzbekistan (ICD-10) was taken. The study of the dynamics of frequency and debut of various clinical forms of RAS, the gender characteristics of RAS has led to the need for the introduction of modern standards for examination, treatment, and prevention of the disease. The goal of the research is to study the frequency of occurrence of RAS, as well as the real clinical practice of managing patients in the Republic of Uzbekistan and its compliance with existing recommendations.

Materials and Method: Patients' medical records and records of the patients' consultation journal for five years of work (from 2014 to 2018) were studied.

Results: Taking into account the gender and age characteristics of patients with RAS will determine the real clinical picture and prevalence of this disease, increase the ability of monitoring, medical examination and providing timely specialized care, allowing to prevent the progression and maintain the working capacity of patients with this pathology of OCR.

Conclusion: The frequency of RAS at the general reception for diseases of OCR is 6.22 ± 0.42%; in the general structure of the disease, the fibrinous form prevails 3.46%; the incidence of necrotic periadenitis is 3.15%; herpetiform aphthous stomatitis is recorded in 2.25% of patients and 1.25% - a symptom in Behcet's disease. The debut of RAS falls on the age period of 18-34 years (62.50%), which indicates a negative trend of "rejuvenation" of this pathology. For effective treatment and rehabilitation of patients suffering from RAS, it is necessary to conduct a comprehensive examination attracting internists, an appointment of means of immunomodulating therapy and means effectively correcting the most important homeostatic mechanisms in humans.

Keywords: *The fibrinous form of chronic recurrent aphthous stomatitis, Setton's aphthae, herpetiform aphthous stomatitis, symptom in Behcet's disease.*

Introduction

Chronic recurrent aphthous stomatitis is one of the most common diseases of the oral mucosa, characterized by recurrent rash of aphthae and a prolonged course with periodic manifestations[12]. Recurrent aphthous stomatitis (RAS) is a disorder characterized by recurrent ulcers on the oral mucosa in the absence of other symptoms. RAS presents several pathological conditions with similar clinical manifestations. According to the international classification of diseases (ICD-10), RAS refers to ICD-10: K12.0 ICD-10/K00-K93 CLASS XI Diseases of the digestive system/K00-K14 Diseases of the oral cavity, salivary glands and jaw/K12 Stomatitis and related lesions[13].

Six clinical forms (fibrinous, necrotic, glandular, scarring, deforming and lichenoid) of ASD have been

distinguished since 1978, based on the analysis of clinical and morphological manifestations. According to foreign authors, ASD is characterized by three main manifestations: small aphthae (Mikulich aphthosis), located mainly on the mucous membrane of the lips, cheeks, the bottom of the oral cavity, large aphthae (necrotic periadenitis of oral mucosa, or Sutton's disease) and herpetiform ulcers – multiple aphthae of round forms[14].

According to various authors, the prevalence of RAS in the overall structure of the pathology of OCR ranges from 1.27 per 1000 population to 8.68 ± 0.62%. Recurrent aphthous stomatitis (RAS) occurred among the population of Sverdlovsk region, in 6.9% cases. Large aphthae, up to 1 cm in diameter, very painful, epithelizing for a long time (up to 5 weeks), the so-called Setton`s aphthae, were diagnosed in 12% of patients with RAS[7]. According to the WHO, RAS occurs in 20% of the population, and adults at the age from 20 to 40 suffer from recurrent chronic aphthous stomatitis[4].

In general, it was determined that the prevalence of RAS had a tendency to increase, which is due to the global aging of the population, an increase in the pathology of OCR, an increase in somatic pathology, and uncontrolled use of immunomodulators and medications with antibacterial properties[10].

In everyday clinical practice, patients, applying for dental care with mucosal diseases present one of the most difficult problems due to difficulties in diagnosis and treatment. The official reports of the dental service of the Republic of Uzbekistan do not include indicators of the incidence of chronic aphthous stomatitis[4]. However, there is an urgent need for studying the prevalence of gender-related morbidity indicators, the age limits for the debut of pathologies belonging to this group of diseases. Information on the epidemiology of aphthous stomatitis in the country should stimulate the development of modern method of diagnosis, therapy and rehabilitation of patients with a similar pathology[10].

Information about the prevalence and characteristics of the clinical course of the disease is necessary for planning the activity of a medical organization and its management; planning of therapeutic and preventive measures; establishing health indicators and the prognosis of morbidity[12]. Knowledge of the prevalence and intensity of dental diseases is the basis for developing the need for medical personnel and resources.

The goal of the research is to study the frequency of occurrence of RAS, as well as the real clinical practice of managing patients in the Republic of Uzbekistan and its compliance with existing recommendations.

Materials and Method

We studied the medical records of patients who applied for dental care for the treatment of diseases of the oral mucosa at the dental clinic of Tashkent State Dental Institute TSDI for five years of activity (from 2014 to 2018).

We used the classification of RAS proposed by WHO for identifying the disease: 1. The fibrinous form of RAS (Mikulich aphthosis); 2. Necrotic periadenitis (Setton's aphthae) (recurring scarring deep aphthae, deforming aphthae, creeping aphthae); 3. Herpetiform aphthous stomatitis; 4. Symptom in Behcet's disease.

When studying the history of development of the disease, the emphasis was on identifying the preclinical stage of the disease, the onset of the disease, the duration of the disease, the stage of the disease at the time of diagnosis, the first symptoms, the dynamics of the signs of the disease, previously conducted treatment, its effectiveness, drugs prescribed for treatment, their tolerability, the presence of allergic reactions.

Data about patients were recorded in the Unified Card, designed for this purpose.

The control sample in this series of activity amounted to 40 healthy individuals of the corresponding gender, age and ethnic composition who underwent a complete dental examination.

Results

208 patients applied for treatment of the aphthous stomatitis from 2014 to 2018, thus, the frequency of RAS in the total frequency of RAS treatment complaints was 6.22 ± 0.42%. It should be noted that over the entire sampling period, the frequency of RAS in the overall structure of the RAS diseases did not undergo significant differences and ranged from 5.32 ± 0.42% (2014) to 7.62 ± 1.05% (2016) (table 1). Thus, for the diseases that make up the group of aphthous mouth ulcers over the past 5 years, the peak of visits was in 2016-2017, which in general can be described as a negative trend in morbidity increase.

Table 1. Dynamics of the appealing frequency regarding RAS in the general structure of OCR diseases

Diseases	Years					
	2014	2015	2016	2017	2018	Total
RAS	32 / 5,22 ± 0,90	38 / 5,32 ± 0,87	47 / 7,52 ± 1,05	49 / 7,11 ± 0,97	42 / 5,97 ± 0,89	208 / 6,22 ± 0,42
Total with OCR disease	612 / 100,0	714 / 100,0	625 / 100,0	689 / 100,0	703 / 100,0	3343 / 100,0

Note: In the numerator – the number of patients; In the denominator, in % of the total number of patients.

The unit weight of the registered clinical forms (within the framework of ICD-10) within the group of aphthous lesions of the oral cavity is presented in Table 2.

Table 2. The structure of clinical forms of RAS in the Republic of Uzbekistan (ICD-10)

No.	Clinical Form	Abs	%
1.	Fibrinous Form, Mikulich Aphthosis	115	55,29±3,45
2.	Necrotic Periadenitis (Setton's Aphthae) (Recurrent, Deep Aphthae, Deforming Aphthae, Creeping Aphthae)	61	29,33±3,15
3.	Herpetiform Aphthous Stomatitis	25	12,02±2,25
4.	Symptom in Behcet's Disease	7	3,36±1,25
5.	**Total**	**208/100,0**	

Table 2 shows that the mainly fibrinous form of the disease (Mikulich aphthosis) is recorded, the proportion of which in the general structure of the diseases was 55.29 ± 3.45%; a significant proportion – 29.33 ± 3.15% was occupied by severe periadenitis (Setton's aphthae, recurrent, deep aphthae, deforming aphthae, creeping aphthae); 12.02 ± 2.25% in the total structure of RAS accounted for herpetiform lesions and the proportion of Behcet's syndrome was the smallest – 3.36 ± 1.25% (table 2).

It should be noted that the established trend towards a higher incidence of fibrinous disease was recorded throughout the study period. Throughout the entire period of research, a traditionally high unit weight of severe periadenitis was noted (table 3).

Table 3. Dynamics of frequency of various clinical forms of RAS

Clinical course of RAS	Years				
	2014	2015	2016	2017	2018
Fibrinous form	20 / 62,5±8,56	26 / 68,21 ± 7,56	20 / 42,55 ± 7,21	23 / 46,94 ± 7,13	26 / 61,90 ± 7,49
Setton's aphthae	6 / 18,75±6,90	10 / 26,32 ± 7,14	17 / 36,17 ± 7,13	18 / 36,73 ± 6,88	10 / 23,81 ± 6,579
Herpetiform aphthous stomatitis	5 / 15,62±6,42	1 / 2,63 ± 2,60	8 / 17,02 ± 5,48	6 / 12,24 ± 4,64	5 / 11,90 ± 5,01
Symptom in Behcet's disease	1 / 39,25±3,08	1 / 2,63 ± 2,60	2 / 4,26 ± 2,71	2 / 4,08 ± 2,80	1 / 2,38 ± 2,5

Clinical course of RAS	Years				
	2014	2015	2016	2017	2018
Total	32 / 100,0	38 / 100,0	47 / 100,0	49 / 100,0	42 / 100,0

Note: In the numerator – the number of patients; In the denominator, in % of the total number of patients.

Clinic development debut among patients with various clinical forms was registered at age from 18 to 24 – 23.08 ± 2.92%; from 25 to 34 – 39.42 ± 3.39; from 34 to 44 – 23.56 ± 2.94%; from 45 to 54 – 9.61 ± 2.04%. According to archival data, in 4.33% ± 1.41 (9) patients, the disease manifested at the age of more than 55 years, which corresponds to global data. The results obtained indicate a negative trend of "rejuvenation" of this pathology. At the same time, in 62.50 ± 2.34% of patients, clinical manifestations of the disease formed in the age period of 18 – 34 years (table 4).

Table 4. Debut of various clinical forms of RAS

Age groups, years	Clinical course				Total
	Fibrinous	Setton's aphthae	Herpetiform aphthous stomatitis	Symptom in Behcet's disease	
18 -24	20 / 17,39±3,53	15 / 24,59 ± 5,51	10 / 40,0 ± 9,80	3 / 42,86 ± 18,70	48 / 23,80 ± 2,92
25-34	45 / 39,13±4,54	21 / 34,42 ± 6,08	12 / 48,0 ± 9,99	4 / 57,14 ± 18,70	82 / 39,42 ± 3,39
35-44	32 / 27,82±	15 / 24,59 ± 5,51	2 / 8,0 ± 5,43	— / — / —	49 / 23,56 ± 2,94
45-54	12 / 10,43±4,8	7 / 11,47 ± 4,08	1 / 4,0 ± 3,92	— / — / —	20 / 9,61 ± 2,04

Total:	115 / 100,0	61 / 100,0	25 / 100,0	7 / 100,0	208 / 100,0

Note: In the numerator – the number of patients; In the denominator, in % of the total number of patients.

In the analysis of gender differences, it was determined that chronic recurrent aphthous stomatitis is mainly registered among women: over the past 5 years, the frequency of women reporting about RAS was 68.75 ± 3.21% against the corresponding frequency among men – 31.21 ± 3.21%. This trend continued throughout the studied period (Table 5).

Table 5. Gender characteristic of RAS

Gender	Clinical course				Total
	Fibrinous	Setton's aphthae	Herpetiform aphthous stomatitis	Symptom in Behcet's disease	
Men	33 28,70±4,22	21 34,43 ± 6,08	10 40,0 ± 9,80	1 14,28 ± 13,30	65 35,25 ± 3,21
Women	82 71,30±4,22	40 65,57 ± 6,08	15 60,0 ± 9,80	4 57,14 ± 18,70	143 68,75 ± 3,21
Total	115 100,0	61 100,0	25 100,0	7 100,0	208 100,0

Seasonal occurrence of exacerbations was noted, chronic recurrent aphthous stomatitis, as a rule, manifested in spring-autumn period (table 6). Moreover, in 23.08 ± 2.92% of patients, the onset of the disease occurred in autumn period of the year; in 36.54 ± 3.34% in winter; in 25.96 ± 3.03% in spring, and only in 14.42 ± 2.43% the onset of the disease occurred in summer season (figure 1).

Table 6. Distribution of patients with RAS by seasons of the year

Clinical course of RAS	Seasons			
	Autumn	Winter	Spring	Summer
Fibrinous form	26 22,61 ± 6,03	42 36,52 ± 5,52	31 26,96 ± 6,04	16 13,91 ± 6,32
Setton's aphthae	14 22,95 ± 6,07	20 32,78 ± 5,38	17 27,87 ± 6,10	10 16,39 ± 6,76
Herpetiform aphthous stomatitis	6 24,0 ± 6,16	11 44,0 ± 5,69	5 20,0 ± 5,49	3 12,0 ± 5,93

Total	48 100,0	76 100,0	54 100,0	30 100,0

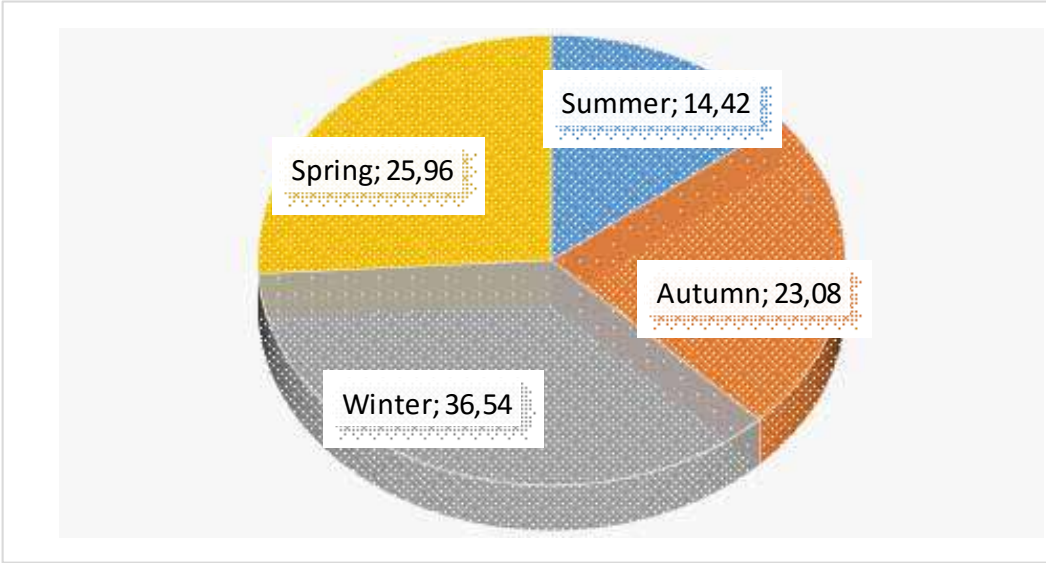

Fig. 1. Distribution of patients with RAS by seasons (in % of the total number of the diseased)

Discussion

Analysis of the duration of the disease at the time of treatment showed that in most patients the disease lasted 3-5 years, the maximum duration at the time of treatment was registered in a more severe form (Setton's aphthae, necrotic periadenitis, deforming aphthae), the average disease duration was 6.88 ± 0.28 year; with a fibrinous form, the disease lasted 3.44 ± 0.17 year and with herpetiform aphthous stomatitis and a symptom in Behcet's disease, 2.84 ± 0.11 and 4.46 ± 0.21 year, respectively.

Analysis of the completeness of the diagnosis, quality of treatment and prevention of RAS revealed the following:

When collecting an anamnesis, as a rule, data on the patient's profession and the presence of occupational hazards and bad habits (smoking, consuming nasvai (a type of non-smoking tobacco product), alcoholism, etc.) were ignored; the nature of nutrition and the use of products that can cause allergic reactions was not taken into account); the history of allergy was not taken into account, the hereditary burden and the presence of RAS among relatives of the first and second lines of kinship were not found out, information about the transferred and concomitant diseases was ignored.

When collecting the anamnesis of only 140 (67.31%) patients, the time of the onset of the first symptoms, the presence of pathology in the past, the nature of the previous treatment and its results were specified. Data on intolerance to drugs and materials, stress that can trigger this exacerbation, acute condition/disease or exacerbation of a chronic disease that developed less than 6 months before seeking dental care, as well as work involving contact with occupational hazards, were obtained from 122 (58.65%) patients.

Incomplete implementation of diagnostic procedures is noted at the stage of diagnosing the disease. A visual examination with a full description of the elements of the lesion was performed in 108 (51.92%) patients, palpation of the organs of the oral cavity, external examinations of the maxillofacial part, and palpation of the maxillofacial part were not performed in any patient, as well as the degree of opening of the mouth and restriction of mobility of the lower jaw is also not determined.

The oral cavity using additional tools is not examined. Carious cavities are not investigated using a dental probe and periodontal pockets using a periodontal probe. Occlusion and degree of pathological tooth mobility are not determined, as well as the diagnosis of the state of the dentofacial system using method and means of beam imaging. Histological examination of the oral tissue preparation and a biopsy of the oral mucosa was not implemented. Determination of oral hygiene and periodontal indices was carried out only in 54 (25.96%) patients.

At present, the importance of the immune system and disturbances in the microbiocenosis of the most important biotopes of the body in the severity of the clinical course of diseases of OCR is not questioned. In this connection, special attention was paid to the study and prescription of drugs for immunity and intestinal microbiocenosis.

When diagnosing the disease, only 45 (21.63%) patients underwent consultative examination and were prescribed examination and treatment by a general practitioner (gastroenterologist, dermatologist, endocrinologist, occupational therapist, neuropathologist), somewhat more often, consultation with an orthopedic dentist was assigned in 63 (30.29%) patients.

It is obvious that the prognosis of RAS and the relapse rate largely depend on the timeliness and accuracy of the diagnosis. The selected sample based on the results of archival data, the diagnosis of chronic recurrent aphthous stomatitis was carried out on the basis of:

– only anamnesis and objective examination data – in 108 (51.92%) patients;
– anamnesis, objective examination, assessment of dental status data – in 54 (25.96%) patients;
– data of anamnesis, objective examination, assessment of dental status, consultative examination by a physician (gastroenterologist, dermatologist, endocrinologist, occupational therapist, neuropathologist) – in 45 (21.63%) patients;
– data of anamnesis, objective examination, assessment of dental status, assessment of the immune status, study of intestinal microbiocenosis, consultative examination by a physician (gastroenterologist, dermatologist, endocrinologist, occupational therapist, neurologist) – in 30 (14.42%) patients.

In the study of the non-pharmacological assistance provided, it was found that oral sanitation with the implementation of professional oral hygiene was carried out only in 59 (28.36) patients; teaching patients the oral hygiene with carrying out controlled toothbrushing – in 81 (38.94%) patients; removal of odontolith, grinding of sharp edges of teeth, replacement of metal fillings and prostheses from dissimilar metals, orthopedic correction, polishing of dentures and elimination of galvanosis – in 45 (21.63%) patients.

In the overwhelming majority of cases, drug therapy in 200 (96.15%) patients consisted of applying painkillers – 1-2% lidocaine solution, 1-2% trimecaine, cleaning the surface of aphthae from fibrinous or necrotic plaque using proteolytic enzymes: trypsin and chymotrypsin, as well as antiseptic treatment with antiseptic solutions: 0.05% chlorhexidine solution, 1% hydrogen peroxide solution, 0.01% miramistin solution, etc. Subsequently, epithelizing therapy with ointments carotoline, solcoseryl, actovegin and cholisal gel was prescribed.

Prescription of dietary therapy was established in 153 (73.56%) patients. It should be noted that there were no prescriptions in the treatment regimens, including sedative and antihistamines, nonspecific hypersensitizing therapy, metabolic correction drugs (calcium preparations, vitamin therapy), drugs that correct microcirculatory disorders and metabolic trophic processes that normalize the lipoperoxidation process, as well as specific hyposensitizing therapy.

Quite rarely, immunomodulating therapy was registered in 102 (49.04%) patients.

Taking into account the gender and age characteristics of patients with RAS at a dental appointment for OCR diseases allowed to determine the real clinical picture and prevalence of this disease, to increase the possibilities of monitoring, clinical examination and provision of timely specialized care to prevent the progression and preserve the working capacity of patients with this OCR disease.

Conclusion

1. The frequency of RAS at the general reception for diseases of OCR is 6.22 ± 0.42%; in the general structure of the disease, the fibrinous form prevails 55,29 ± 3,46%; the incidence of necrotic periadenitis – 29,33 ± 3,15%; herpetiform aphthous stomatitis is registered among 12,02 ± 2,25% patients and symptom in Behcet's disease among 3.36 ± 1.25%.
2. The debut of RAS falls on the age period of 18-34 years (62.50%), which indicates a negative trend of "rejuvenation" of this pathology. Women morbidity prevails in the general structure of the disease – 68.75 ± 3.21%.
3. For adequate treatment of RAS, it is necessary to introduce modern standards for the examination, treatment and prevention of the disease.

The results of the study can be used in practical work for predicting the risk of the onset and development of OCR diseases among the population, as well as for improving therapeutic and preventive measures. For the effective treatment and rehabilitation of patients suffering from RAS, it is necessary to conduct a comprehensive examination with participation of internists, the appointment of the immunomodulating therapy and agents that effectively correct the most important homeostatic mechanisms of the body.

Abstract

In this study, we present the results of treatment of 224 patients with idiopathic thrombocytopenic purpura (ITP). In this study, we present the comparative results of treatment with inhalation and traditional method by glucocorticoid hormones and splenectomy (SE). It was established that the usage of glucocorticosteroid hormones in the manner of cold doses inhalation was more effective in 87, (2%) of patients in comparison with traditional method of treatment – 75,(7%) and in this way the remission of disease approaches on 6,3 days earlier. For the treatment of these patients we used splenectomyand created new approach to the operation. This method, which was executed in the early post operational period, was more effective in 96, (9 %) of cases compared with traditional approach.

Keywords: *Thrombocytopenia, glucocorticoids, splenectomy, complications, prophylaxis, hormone inhalation.*

Introduction

Idiopathic thrombocytopenic purpura (ITP) is one of the common forms of hemorrhagic diathesis[1]. It is known that the basis of the pathogenesis of ITP is an autoimmune process from any cause which result in the synthesis of antiplatelet autoantibodies with an antimegakaryocytic orientation occuring in the human body[2].

ITP is not a rare disease in the structure of hematological pathology. So, for example, in Uzbekistan ITP is registered among children with a frequency of 1.5 - 2.0 cases per 100 000people[2,3].

The pathogenetic treatment of ITP is the use of glucocorticoid (GCS) hormones, however, taking per os hormones often gives gastrointestinal complications[4].

Given the pronounced side effects with prolonged use of corticosteroids, especially when taken per os[5], other method of corticosteroid administration are being sought to reduce or prevent complications of corticosteroids[6]. In this regard, the inhalation method of administering GCS hormones to patients with ITP is noteworthy[7], although in the available literature we could not find works devoted to the study of the use of GCS hormones in the form of inhalations in patients with ITP[8].

When performing splenectomy (SE), various method of mobilizing the spleen and processing the elements of its gates areused[9]. Bleeding during SE and after surgery is from 300 ml to 1 litre, postoperative pancreatitis occurs up to 6% and has no tendency to decrease[10]. Complications associated with the technique of surgery adversely affect the results of treatment[11].

Therefore, the improvement of both conservative and surgical treatment of ITP is undoubtedly of great scientific and practical interest for modern hematology and surgery[12].

Materials and Method

Patients Data: This case-control study retrospectively recruited 224 consecutive patients with a diagnosis of «ITP» in the surgical and pediatric wards of the clinic Scientific-research institute ofHematology and blood transfusion, Ministry of Health, Republic of Uzbekistan Among patients with ITP with a chronic form was 187, with an acute form was 37. Men were 88 and women were 136. Only 95 patients (42.4%) received the hormonal treatment: - including traditional

treatment - 48 patients (men –18 (37.5%), women –30 (62.5%), inhaled hormonal treatment of 47 patients, 22 (46.8%) of them were men, and 25 women (53.2%). SE was performed in 129 (57.6%) of patients with chronic ITP (of these, 40(31.1%) of men and 89 (68.9%) of women). The traditional method of SE was performed in 65 (50.4%) patients; we proposed this method in 64 (49, 6%).

To verify ITP, the following criteria were used below (except for complaints, medical history and objective examination):

1. Thrombocytopenia (platelets $<150x10^9$/L) in the absence of other abnormalities in the calculation of blood cells.
2. The absence of clinical and laboratory signs of the disease in blood relatives.
3. Normal - or increased number of megakaryocytes in the bone marrow.
4. The absence of clinical manifestations of other diseases or factors that can cause thrombocytopenia in patients.
5. The effect of corticosteroid therapy.

During SE, the amount of blood loss was determined by weighing the operating dressings - balls, before and after the operation, and blood loss after the operation from the drainage tube entering the dishes with a mark. In addition, patients with ITP underwent ultrasound for examination of internal organs, electrocardiography, and, according to indications, an endoscopic examination of the gastrointestinal tract.

Patients complained of hemorrhagic syndrome: petechiae and ecchymoses on the skin, nasal, uterine bleeding, bleeding from the gums and the gastrointestinal tract, which often appeared with platelet counts <20.5 - 30.0 x 109/L. The duration of the disease at the time of the first visit to the hospital ranged from 3 days to 5 months in acute ITP. In the anamnesis, the duration of the disease ranged from 6 months to 20 years with a chronic form of ITP and during this time patients received hormones in tablets from 2 to 10 times.

GCS was prescribed in the traditional treatment of 2.0-2.5 mg/kg in the acute form, 1.0-1.5 mg/kg in the chronic form of ITP per os and parenterally. Inhalation (solution of prednisolone and dexamethasone) was carried out on a nebulizer inhalation device “Boreal” (manufactured in Italy) at a dose of 1.0-2.0 mg/kg. In addition, patients received fibrinolysis inhibitors, vascular wall protectors, biological membrane stabilizers and topical treatment for nasal and gingival bleeding. Red blood cell mass was transfused for patients with severe anemia.

In 50 (52.6%) patients with ITP, gastrointestinal complications were revealed; gastroduodenitis in 21, gastric ulcer in 6, duodenal ulcer in 5, colitis in 2, gastrointestinal discomfort in 11, stomach pain in 5.

SE was performed in 129 patients with ITP. For 64 patients of the experimental group, splenectomy was performed by the method we proposed - during revision of the spleen, its mobility and connection with the circumference were assessed, its posterior surface was separated from the parenteral peritoneum by hemostasis in the direction of the pedicle and posterior surface of the stomach.

Then the spleen was easily dislocated into the wound, starting from the lower pole, it was freed from the ligaments and previously bandaged; two clamps were applied over the ligature, then dissected between the clamps and the stump was stitched. Next, a window of 0.5 x 0.5 cm in size was opened in the anterior sheet of the peritoneum from the upper pole of the spleen and the gastro-splenic ligament was ligated in the aforementioned manner.

If the width of the leg is large, more tissue is taken when the poles are highlighted. The front sheet of the peritoneum in the leg area does not open, this preserves the integrity of the tissue and hemostasis. The next stage of the operation is the preliminary ligation of the spleen leg with catgut over the capsule of the pancreas, under the control of the back surface, so as not to damage the tail of the pancreas. At the same time, all the elements of the spleen leg are assembled into a single stem with a straightened axis, which greatly improves subsequent clamping over the ligature.

This, in turn, is the prevention of bleeding. Subsequently, 2-3 clamps are applied over the ligature, and the spleen is removed. The stump is bandaged and stitched. Performing SE in this way prevents damage to the tail of the pancreas, creates reliable hemostasis, maintains the integrity of adjacent tissues

Results

Inhalation was carried out at a dose of 1.0 to 2.0 mg/kg per day. Of 18 patients with ICU, a clinical and hematological effect (CGE) was obtained in 13 (72.2%) patients, an average of 6.5 days, a clinical effect (CE) in 2 (11.1%) patients, on average for 5.5 days. Clinical and hematological effect (K and KGE) were obtained in 15 (83.3%) patients, on average for 6 bed days. In 3 (16.7%) patients, the effect was not obtained. In patients with CITPwho received inhaled therapy of corticosteroid hormones, the hemorrhagic syndrome began to disappear by days 3 and 4, the platelet count began to rise from days 5 and 6 of treatment. 19 patients (adults - 9, children - 10) with ICU, starting from the first or second day of admission, received hormones (prednisone and dexamethasone) in tablets and injections at a dose of 1.5 - 2.0 mg/kg with other HA drugs per day. The results of traditional hormone therapy in adults and children with ICU have shown that CGE was obtained in 13 (68.4%) patients, on average for 9.8 bed days. CE was obtained in 2 (10.5%) patients, an average of 16.5 hospital days. K and CGE was obtained in 15 (78.9%) patients, on average, for approximately 11 bed days. In 4 (21.1%) patients, the effect of hormone therapy was not obtained even after carrying out hormonal treatment for more than 3-4 weeks they were ineffective.

The results of inhalation therapy of sick children and adults with a chronic form of ITP (CITP),inhalation was performed at a dose of up to 2 mg/kg per day. Of the 29 patients who received inhalation therapy, CGE - in 13 (44.8%) patients, an average of 6 bed days, CE in 13 (44.8%) patients received an average of 7 days, 3 (10.4%) - without effect. Twenty-six (89.7%) patients received K and KGE, on average for 7 bed days. Starting from days 2 and 4, in all patients whose hemorrhagic syndrome has subsided.

29 patients with CITP(children - 9, adults - 20) received traditional treatment, including hormones at a dose of 1.0 - 1.5 mg/kg per day as a pathogenetic therapy of HK. From the traditional treatment of HK with hormones, sick children and adults with HITP received CGE of 6 (20.7%) patients, on average, for 9 bed days. Clinical remission (CR) in 15 (51.7%) patients, an average of 11 bed days. K and RAG were obtained in 21 (72.4%) patients, an average of 11 bed days, 8 (27.6%) patients were without effect with the preservation of hemorrhagic syndrome. Hemorrhagic syndromes began to disappear from 3-5 days in patients with remission.

Thus 47 patients withAITP and HITP received dosed cold inhalation of GCS hormones, while in patients with AITP K and RAG were obtained in 83.3% of cases on average in 6 days, on the contrary to traditional treatment 78.9% and 11 days. In patients with HITP K and RAG received in 89.7% of patients, in 6.5 days, on the contrary 72.4% and 10.7 days Of the 47 patients who received inhalation therapy 26 (55.3%) patients with average of 6 bed days admission received a CGE, in 15 (31.9%) with average of 7.0 bed days received a CR and in 41 (87.2%) patients with average of 6 bed days received K and CGE. In 6 (12.8%) patients, the effect was not obtained and they still had skin hemorrhagic diseases, in the form of ecchymoses[14].

ITP splenectomy results for years 2000-2002 in the generally accepted manner, 65 (50.4%) patients with ITP were operated among them: children - 37 (56.9%), adults - 28 (43.1%). Moreover, the total blood loss amounted to between 122.8 - 7980 ml per patient. During the operation, a total of 5590 ml of FFP and 9715 ml of erythrocyte mass were transfused. In total, 235.5-15305 ml were transferred per patient[15].

A complication such as damage to the pancreas during surgery was observed in 12 (18.5%) patients. Days 1 and 2 after surgery, 4 (6.2%) patients had an increase in temperature to 38^0C and 3 (4.6%) patients had complaints on the 2nd day after surgery for pain in the left hypochondrium and lumbar region. From the drainage tube, hemorrhagic discharge amounted to 100.0 ml or more on the 1st and 2nd day. In 50% of patients, the drainage tube was removed on the 1st day after surgery[16].

Relaparotomy for internal bleeding after SE was performed in 2 (3.1%) patients. The immediate postoperative results in patients with ITP with a chronic course of K and RAG amounted to 91.6% of patients. We proposed and performed SE on 64 patients with ITP with a chronic course. Moreover, the total blood loss is estimated to be between 76.8 - 4915 ml per patient. During the operation in 3 (4.7%) patients, the tail of the pancreas on the catgut ligature was damaged, but in the postoperative period, a pancreatitis clinic was not observed[17].

After surgery, hemorrhagic discharge from the drainage tube was up to 30 ml. The immediate postoperative results in patients with ITP with a chronic course of K and RAG were in 96.9% of patients. In 90%

of cases, drainage tubes were removed on the 1st day after surgery. There were no complications during and after the operation[18].

Discussion

Thus, the inhaled method of administering GCS hormones in dosed cold form on the Boreal nebulizer apparatus to patients with acute and chronic ITP is not inferior compared with traditional treatment with oral and parenteral administration of HA and has such positive aspects as;lack of complications from inhalation, good tolerance of the procedure, especially by children; prevention of neurosis, hysteria, pain associated with the manipulation of corticosteroids with hormones in children; lack of withdrawal syndrome; prevention of parenteral infection;economic efficiency by reducing the amount of hormones, blood components, and other drugs introduced by HA; and reducing the number of days. In a comparative aspect, with traditional treatment in acute ITP, 4.4, in chronic ITP 4.2 days earlier, remission was received.

The method we proposed allows us to preserve the integrity of adjacent tissues, prevents damage to the tail of the pancreas, and prevents bleeding during and after surgery. At the same time, the duration of the operation decreased by 10-15 minutes, bleeding during the operation decreased by 45.7 ml in one patient, and after the operation by 2-3 times. Postoperative pancreatitis, relaparotomy, and death were not observed. Erythrocyte mass, blood components and other drugs are saved.

Conclusion

In summary, the inhalation administration of GCS hormones in dosed cold form on the Boreal nebulizer apparatus to patients with acute and chronic forms of ITP is an alternative to the existing traditional method of conservative treatment. From inhalation administration of HA, in a comparative aspect, with traditional treatment for acute ITP, 4.4, in chronic ITP 4.2 days earlier, a remission was received. It prevents a number of complications of corticosteroids therapy and the transmission of parenteral blood-borne infection. Inhalation administration of corticosteroids hormones in patients with ITP disease is indicated, especially in childhood and in patients with diseases of the gastrointestinal tract. Contraindicated in patients with severe chronic condition against the background of the underlying disease and intolerance to inhaled corticosteroids.The use of an advanced method of splenectomy - this operation is less traumatic, has a milder course of the postoperative period, less blood loss and a minimal number of complications.

The use of an advanced method of splenectomy reduces blood flow during splenectomy by 41.4 ml, furthermore, it reduces the need for blood transfusions by 2-3 times. The proposed method reduces risk of damage to the pancreas by 4 times and the development of postoperative pancreatitis. It also reduces the duration of the operation by 10-15 minutes. A good result in the immediate postoperative period is achieved after splenectomy in the proposed.

Study of Hematological Changes in Local Goats (Capran Aegagrus) at Al-Najaf Province, Iraq

Mujeeb Towfik Shamsa

Associated Professor, Department: Heeath Science, Middle Euphrates Technical University, Technical Institute Najaf, Najaf- Iraq

Abstract

Goat is among widespread small ruminants in the Iraq and important animal provides nutrient resources for as well as economical source. The blood values and hematologicalparameters can be greatly affected by environmental factors such as stress, low grassland pasture, parturition and climate. Thus, it can be reflected by blood analysis and reliable medium for health and illness status of individual animals.

200 of normal and healthy goats (90 males and 110 Females) were selected depending on clinical examination in Al-Najaf slaughterhouse (Al-Najaf, Iraq). The study was conducted during the summer season. The gouts were divided into subgroups according to sex and age. Then, Blood samples were collected from the jugular vein for the determination of hemoglobin, packed cell volume, red blood cells count, and white blood cells count and sub determination of white blood cell was included neutrophils, small and large lymphocytes, monocyte, eosinophil, basophil and band-cell. Result showed there are nonsignificant different between male and female hematological parameters in all age period except small lymphocytes in gout larger than 1 year old and Neutrophils for less than 6-month age. In Conclusion: This study includes values that are considered to be the first to be published for the difference in local goats' breeds (Capran Aegagrus) At Al-Najaf Province, Iraq. Such data is considered as preliminary data which can be used as a reference for further studies.

Aim of Study: The aim of the study was to measure hematological parameters in order to monitor the health status of goat breeding with different age in males and female goat.

Keywords: *Hematological, hematological parameters, Capran Aegagrus.*

Introduction

Goat is among widespread small ruminants in the middle east, as well as is considered one of the domestic animals which an important animal provides nutrient resources for humans (Addass *et al.* 2010)[1]. Additionally, is an important economic source in several countries such as Iraq, Jourdan, Oman and other contraries (Kozuh, 2010; Al-Bulushi *et al.* 2017)[2]. Goat meat is well known to be unique meat. In addition, goat meat is not interchangeable with meat from other species that have the same –approximately- maturity and fatness levels (Ivanović *et al.* 2016)[3], as well as goats can be reared under traditional husbandry system in the open atmosphere and breeding under modern husbandry (Gebreyowhens *et al.* 2018)[4]; which are believed as perfect animals to be reared, firstly because they are able to survive severe conditions and secondly because they are able to produce high-quality and milk and milk derivatives (Darcan *et al.* 2018)[5]. The blood values and hematological parameters can greatly be affected by factors like low nutritional grassland pasture, parturition, climatic factors and stress (Mohammed *et al.* 2016; Mahmoud *et al.* 2016)[6]. Besides being one of the useful and reliable parameters to use in order to assess health and illness status of individual animals (Al-Bulushi *et al.* 2017)[7], blood is a guide for several metabolic processes and represents the healthy state of the organ functions and productions of the animal and a realistic measure to evaluate the management practices, nutrition progress and diagnosis in farms (Farooq *et al.* 2011; Momenah, 2014; Panadi *et al.* 2018)[8].

Thus, the aim of the study was to investigate and monitor the health status of goat breeding through the measurement hematological parameters of different age in males and female goat and knowledge different between male and female blood parameter value.

Material and Method

Animals: Two hundred (90 males and 110 Female) of goats which were selected normally healthygoat depending on clinical examination in Al-Najaf slaughterhouse (Al-Najaf, Iraq). The gouts were divided into subgroups according to sex and age. However, four age group of two sex goats were study, its included 0 - 6 months, 6 - 12 months, 1–2 years, and above the 2 year, as showed in table-1.

Table 1: The numbers and ages of goat according to sex

Sex	Number	Age
Males (90)	15	0 – 6 months
	25	6 – 12 months
	19	1 – 2 year
	30	Above 2 year
Female (110)	14	0 – 6 months
	31	6 – 12 months
	35	1 – 2 year
	31	Above 2 year

Blood Sampling: Blood collection was performed from the jugular vein followed by placing blood into a tube containing ethylenediaminetetraacetic acid, placed on ice and transferred immediately to the laboratory to be used for the assessment of blood hematological parameters.

Hematology Analyzer: It is an automated hematology analyzer that is used for analyzing feline blood including the determination of hemoglobin (Hb), packed cell volume (PCV), red blood cells count (RBC), and white blood cells count (WBC) within 2 hours after sample collection. Sub determination of white blood cell was included neutrophils (N), small and large lymphocytes (L), monocyte (M), eosinophil (E), basophil (B) and band-cell (BC).

Statistical Analysis: All data were presented as mean ± standard error of mean (SEM). Graph Pad PRISM8 software was used to analyze data. Shapiro–Wilk normality test was used to test whether our data are normally distributed followed by 2-way ANOVA to determine any significant difference. Those data with p value($p<0.05$) was considered significantly different.

Result

The result in table-2 showed compared between blood hematology in goat in age 0-6 months, however showed no significant different between parameters except in neutrophils since female neutrophils higher than male neutrophil significantly at (P=0.0003).While in table-3 result showed no significant different between hematological parameters of 55 goats (24 males and 31 female)at age 6-12 months**.**

Additionally, result in table-4 explained compare between hematological parameters of 54 goats (19 males and 35 female) at age between 1-2 years which fond no significant different between male and female except in term of large lymphocyte which higher significantly at (P= 0.0046)in female.

Result showed comparehematological parameters between male and female at age above 2 year in table-5 showed only significant different at (P=0.0025) in smalllymphocyte which higher in males' goat than females, while no significant different in others parameters.

In general, from tables-6 observed in compared hematological parameters between all age of 200 goat (90 males and 110 females) showed no significant different in parameters except in small lymphocyte parameter which was higher significantly at (P= 0.0161) in males' goats than females as showed in table-6.

Table 2: 0–6 months

Parameters	Male	Female	P Value
Age	3.8±0.5	2.76±0.45	0.9960

Discussion

This study reported a wide range of hematological values such as RBC, PCV, Hb, WBC in addition to white blood differential count in Local Goats (*Capran Aegagrus*) at Al-Najaf Province, Iraq. Findings reported in this study are generally consistent with previous studies which discussed healthy goats. As shown in tables (2, 3, 4, 5), the levels of hemoglobin were within the normal range for male and female and at different age which results are agreed with (Al-Rukibat and Ismail, 2019) which detection of hematologic variables in Shami goats and (Khan *et al.* 2016) since analyzed the blood sample of Maraz male and female goats. On other hand, Polatet al.(2018)[9] found changes in levels of Hb during month and seasons, which result is contrary to that of Polat et al.(2018)[10] them found significant increase in Hb levels of male than female in all age of Angoragout.

Comparison of the findings with those of other studies table (2, 3, 4, 5) confirms theno significant different in the levels of RBC are generally found higher in males than female in the all age but not significantly as reported that values of hematological parameters in most animal species (Yaqub et al. 2013)[11], while Polatet al.(2018)[20] found significant higher in values RBC of male than female[12].

The levels of white blood cells count for the examined does were within the normal range as showing in tables (2, 3, 4, 5,6) for goats in all age as reported in varied studies values of WBCin different sex goat and age (Fadare et al. 2012; Pehlivan et al. 2017)[13] but not agreed the Polatet al.(2018)[14] which found WBC higher in values of female goats than males. In addition, similar values of WBC were reported in this study to those reported in other studies (Jarić et al. 2015, Nayak and Acharya, 2020)[15] which there are no significant different between gander in WBC value. In organisms[16], WBC are cells of the immune system that represent the integrity of bone morrow to produce cells important for peripheral circulation and storage in different organs or pools (Yaqub et al. 2013)[17]. In this result showed small lymph are higher significantly in male than female as showed in result of (Mohammed etal. 2016)[18].

In general, the tables showed there are not significant different in PCV levels between genders in all age period as showed in other studies (Jarić et al. 2015, Nayak and Acharya, 2020)[19].

Conclusion

Findings obtained in this study are the first to be published regarding the difference in local goats' breeds (Capran Aegagrus) At Al-Najaf Province, Iraq. In addition, it can be concluded that such data is considered as preliminary values that can be used as a reference for further. Furthermore, it can help veterinarians in terms interpretation of laboratory data, selection of an appropriate treatment and diagnosis in capra aegagrus in zoological studies.

Game Method of Rehabilitation of Children with Infantile Cerebral Paralysis

Malika T. Egamova[1], Nasiba K. Murtazaeva[1], Salomat A. Halimova[1], Adiba A. Usmankhodzhaeva[2], R.Zh. Matmurodov[3]

[1]PhD (Doctoral Student) of the Department of Traditional Medicine, Rehabilitation and Physical Education, Tashkent Medical Academy, [2]Head of the Department, Associate Professor, Ph.D. Traditional Medicine, Rehabilitation and Physical Education, Tashkent Medical Academy, [3]Associate Professor, Doctor of Medical Sc., Traditional Medicine, Rehabilitation and Physical Education, Tashkent Medical Academy

Abstract

Nowadays, the problem of the vital functions of patients with infantile cerebral paralysisis in the combination of various aspects of rehabilitation: rehabilitation and recreation, physical and psychological, social, emotional and educational. In a comprehensive rehabilitation system, more attention has been paid recently to new organizational forms, such as the game method.

The aim of research: To develop a new rehabilitation system for children with infantile cerebral paralysis.

Materials and Method: We examined 52 children aged 2 to 12 years with various forms of infantile cerebral paralysis. The control group, we were engaged in physical therapy in a game form along with mothers.

Results: Children who played in a game way with their mothers improved movement in the limbs, improved mood, enjoyed doing exercises and had a positive result more than the previous group.

Keywords: *Game method, disability, speech disorders, rehabilitation.*

Introduction

Relevance: Disability of children with cerebral pathology takes the first place in the structure of childhood disability according to the neurological profile and its severity is due to both motor, mental and speech disorders. The rehabilitation success depends not only on the severity of the damage to the central nervous system (CNS) of the child, but also on timely diagnosis, correct organization of the treatment process, starting from the first years of the child's life[4]

The Aim of Research: To develop a new form and system of outdoor games in the rehabilitation of children with the consequences of infantile cerebral paralysis, by unconventional means.

Tasks of Research:

1. To develop new game method for children - with the consequences of infantile cerebral paralysis in order to correct motor abilities.
2. To substantiate the effectiveness of the game technique developed by us on the physical condition of children with the consequences of infantile cerebral paralysis.

The Object of Research: Examined children aged 2 to 12 years with the consequences of infantile cerebral paralysis.

Table 1: Forms of infantile cerebral paralysis in the studied patients.

Clinical forms of infantile cerebral paralysis	Number of patients with infantile cerebral paralysis	Boys	Girls	Age (Average)
Spastic diplegia	4-7.69%	1-1.9%	3-5.8%	2.8
Hemiplegic form	21-40.38%	9-17.3%	12-23%	5.4
Double hemiplegia	7-13.46%	4-7.7%	3-5.8%	3.7

Mixed form	4-7.7%	1-1.9%	3-5.8%	2.9

All children are divided into 2 groups (30 main and 22 control). All children after 10 days of treatment in the hospital were discharged home. All parents had lessons so that they could independently deal with the child with infantile cerebral paralysis at home. The main group all these activities should be performed in a game way, without forcing a child. Particular attention was paid to the fact that the child himself wanted to be engaged.

All used integrated systems in a game way together with mothers should be affected by the ability to feel the child's self-confidence. Since the rehabilitation of children with infantile cerebral paralysis is complex, it includes psychological, social, medical, pedagogical and other aspects. At the same time, physical education is the most important part of the process[6]. Classes were held 6 times a week mainly in the morning. The lesson duration was 20-30 minutes depending on the condition and mood of the child. All children in dispensary settings received heat therapy for 1 month. Thermal procedures were applied in the form of paraffin-ozocerite applications with a temperature of 45-50°C on the hypertonic and hypotonic muscles of the limbs. A general massage was applied for 15 minutes daily. Massage is used with stroking, rubbing, kneading and vibration techniques depending on the age, severity and degree of the disease for 10 minutes №10. Dispensary conditions in the gym of physiotherapy exercises were performed physiotherapy

4-5 times a week for 15-20 minutes for a course of 30 procedures. To assess the psycho-speech development of the child, the clinical psychological assessment Gnome was used. The results of the study were transferred into points. The maximum score was 10 points.

With the functional classification of infantile cerebral paralysis - GMFCS (Gross Motor Function Classification System) proposed by R. Palisano et al. (1997), the degree of motor skills development and movement restrictions in everyday life was taken into account for 5 age groups of patients with infantile cerebral paralysis.

Table 4: Studied Population Level according to GMFCS

	Level 1	Level 2	Level 3	Level 4	Level 5
Main group	2	4	8	4	2
Control group	2	6	6	5	1

The motor characteristics were investigated on a 100-point scale, which after the study was again measured and compared with the previous result. Since the performance of physical exercises ensures the participation of higher mental functions in the process of mastering motor skills and has a great influence on the nervous system development, we contributed to the mental development of the child with conscious movements[1]. They explained to their mothers that rehabilitation is timeliness, interconnectedness, continuity[5]. The treatment of this disease has long been unpromising [5]. Of great importance for the further rehabilitation of children with infantile cerebral paralysis is the early diagnosis of the disease. The sooner specialists begin to work with the child, the greater the chance to prevent, and not subsequently correct, the delayed reaction of parents, deviations in speech and psyche.[3] Another important criterion for successful rehabilitation work with children with disabilities with infantile cerebral paralysis is to participate in a rehabilitation event for the mothers of a sick child. In this regard, the application. For the restorative effect on the body of a child with infantile cerebral paralysis, exercise therapy with the game method e is a very urgent problem. The technique is a game way and even more so with mothers as a means of physical rehabilitation of children with infantile cerebral paralysis has a very good result[1]. Movement disorders that limit or impede normal physical activity adversely affect all aspects of personality development [6]. The nature of the rehabilitative effects on the child's body with the consequences of infantile cerebral paralysis was complex, supported the motivation of disabled children to permanent classes, conducted classes in a mode corresponding to the child's capabilities, created a favorable psychological background. [1] The comprehensive system of rehabilitation impacts that we used in our work consisted of:

- Special physical exercises that do not bother the child.
- Physical exercises with light gymnastics.
- Game classes with mothers.
- Sports and lightweight outdoor games[4].

The fundamental direction of our thesis is the game method without fail along with mothers.

Results

Physical rehabilitation expressing the improvement of motor abilities by the game method together with the mothers of children with disabilities showed high efficiency. Under the influence of prolonged physical exercises in the muscles of a child with infantile cerebral paralysis, adequate motor sensations arose. The postures and positions of the limbs in the process of medical gymnastics returned to normal, muscle tone and involuntary movements decreased. The child began to properly feel the postures and movements, which is the most important powerful incentive in the process of medical gymnastics [7]. As a result of an integrated rehabilitation system introduction, the game method with mothers and children suffering from the consequences of infantile cerebral paralysis gave a very positive effect.

Table 5: Comparative evaluation of psychocognitive parameters in children with infantile cerebral paralysis before and after the study

Field of study	Field parameters	Main group		Control group	
		Before treatment	After treatment	Before treatment	After treatment
Emotional Functions	Total emotions	3.0±0,2	4.2±0.3	3.1±0.1	3.4±0.1
	Activity	4.0±0.1	5.5±0.6	3. ±0.1	3.4±0.6
	Activity in response	3.0±0.3	4.0±0.3	2.8±0.5	2.9±0.8
Cognitive functions	Attention	4.8±0.6	5.5±0.8	3.8±0.3	4.2±0.5
	Thinking	2.4±0.2	3.4±0.5	2.5±0.1	2.6±0.3
	Game features	5.5±0.1	7.5±0.3	5.2±0.8	5.5±0.8
Child behavior	Food	5.4±0.3	6.5±0.6	5.0±0.8	5.2±0.8
	Life skills	5.2±0.8	6.6±0.3	5.0±0.1	5.4±0.2
Touch functions	Vision	6.5±0.6	7.2±0.8	5.8±0.8	6.2±0.3
	Hearing	6.4±0.8	6.8±0.1	5.8±0.6	6.0±0.2
	Tactile sense	4.5±0.1	5.2±0.3	4.4±0.3	4.4±0.6
Motor skills	Facial expression	3.5±0.3	4.2±0.6	3.6±0.1	3.8±0.3
	Statics Kinetics	3.6±0.3	4.0±0.1	3.2±0.3	3.4±0.6

Table 6: After the study, the obtained results of large motor functions

	Level 1	Level 2	Level 3	Level 4	Level 5
Main group	2	1	9	2	1
Control group	2	7	6	4	1

After the study, the level of large motor function moved in a positive direction.

Table 7: Motor characteristics before and after the study

Parameters	Main group		Control group	
	Before study	After study	Before study	After study
Support development	34.2±23.2	42.3±12.4	24.5±11.2	25.5±10.3
Head holding	42.3±14.5	54.4±14.4	36.6±15.4	37.6±38.2
Hand balance	51.2±13.4	57.6±15.6	48.7±5.6	51.3±12.3
Torso control	54.3±12.3	59.5±14.5	51.3±11.2	51.7±12.4
Walking Verticalization	44.3±15.4	49.4±12.4	38.4±12.4	41.3±42.3
Item Hold	7.5±3.4	8.4±2.2	6.7±1.5	6.8±1.4
Hold posture	42.2±11.3	48.4±14.5	44.5±11.3	43.7±14
Walking speed	18±3.4	22±1.5	15±2.2	15.5±1.4

After completing all the tasks, the child's position was evaluated using a 100-point value. The results above 80 points meant the children without infantile cerebral paralysis without significant motor impairment. 74-80 points - borderline motor disturbance, 64-73 - average degree and below 60 - severe degree.

All these activities, classes with mothers, especially game method, had a beneficial effect on both the physical and mental state of children with the consequences of infantile cerebral paralysis.

Wellness activities using long-term rehabilitation

with a set of exercises for the movement amplitude development, led to positive dynamics in the main groups, regardless of the pathology severity. The proposed rehabilitation program allowed children with infantile cerebral paralysis to increase the range of motion in the joints and muscles.

Thus, a comprehensive system of rehabilitation measures in the game method along with mothers has shown its effectiveness. It gives an improvement in the functional state of the musculoskeletal system, a change in the independence of the child and a positive result when used in practical work with people with disabilities suffering from the consequences of infantile cerebral paralysis.

Abstract

The results of assessing the psychophysiological state of modern teachers of Uzbekistan leading universities as the basis for the preventive measures development to maintain their health are presented. It is shown that the teachers' cardiovascular system (CVS) functional state during the working day basically does not go beyond physiological fluctuations, and the functional state of the central nervous system is characterized by a decrease in the quality of the work performed. Revealed a high frequency of emotional burnout (EB) signs in teaching staff in comparison with the administrative and technical employees of universities; the average statistical indicators of the signs of the teaching staff of different universities do not have statistically significant differences. The average level frequency of emotional exhaustion among the teaching staff members is 52-60%, a high level of personal achievement reduction - 44-50%; the average level of depersonalization is 22-40%. For the EB signs frequency, the work experience at the university matters; at the beginning of the academic year, emotional burnout indicators are less pronounced than at the end.

Keywords: *University teachers, psychophysiological state.*

Introduction

In modern conditions of widespread information technology development, a change in the requirements for higher professional education and, consequently, increasing the effectiveness of university teachers as leading subjects of higher education is inevitable[1]. Moreover, the quality of training depends not only on the degree of teacher's professionalism, but also on his internal state - physical and mental health, which, in turn, largely depends on the teacher's working conditions[4].

The main factors of the teacher's work are: a busy schedule with an increased psychoemotional state, significant voice load, prolonged static load with a slight general muscle load, a large amount of visual work[4]. The busy schedule of the teacher, even with favorable hygienic factors of the working environment, can have an adverse effect on the body and, above all, on the central nervous system[1]. It should be borne in mind that a high neuropsychic stress for a teacher is a factor affecting his body every day throughout the entire academic year and throughout his work at a university[3].

The aim of the present research was to assess the psychophysiological state of modern teachers of universities in Uzbekistan as the basis for the development of preventive measures to preserve the health of the universities' teaching staff (faculty).

Research Object and Method

The research object is the teaching staff of three leading universities of the Republic of Uzbekistan: National State University of Uzbekistan (UzNU), Tashkent State Polytechnic University (TSTU), Tashkent Medical Academy (TMA). As comparison groups, we used the results of the psychophysiological state research of the universities' administrative and technical personnel[5].

The research was performed in two stages. At the first stage, the functional state of the cardiovascular (CVS) and central nervous systems (CNS) was studied during the working day[6]. At the second stage, the frequency and nature of the emotional state symptoms of the teachers' body was studied, taking into account gender, age and work experience[7].

We assessed the CVS and central nervous system functional status in the spring (May 2018) in two universities with a significant difference in the areas of study - humanitarian (TMA) and technical (TSTU). In each of these universities from 30 to 60 people of each gender were studied at the beginning and at the end of the academic day. The CVS condition was assessed by the pulse rate and blood pressure, the central nervous system condition - by Anfimov's correction test (Komarova I.A., Melnikov I.Yu., 2014)[8]. In accordance with the recommendations of these authors, in assessing the functional state of the central nervous system, two indicators were considered - the accuracy factor of task performance (A) and the mental productivity coefficient (P).

The emotional burnout (EB) state was revealed by setting up a test for emotional burnout (Boyko V.V., 2002), which contains 22 statements about the feelings and emotions associated with the teaching staff work.

Testing contains the selection of various answers to 22 questions characterizing three indicators of EB: emotional exhaustion, depersonalization and personal achievement reduction.

Emotional exhaustion (EE) is characterized by a decrease in mood and emotional background, fatigue, depression, apathy, a feeling of frustration, and indifference.

Depersonalization is characterized by a violation of relationships with colleagues at work, indifference to team members, and a lack of positive aspects vision in their activities.

The personal achievement reduction implies self-doubt, the possibility of further development and new achievements.

Results and Discussion

Evaluation of some indicators of the functional state of the body of teachers during the working day. Features of the teaching staff of universities are of the greatest importance for the functional state of the cardiovascular and central nervous system, which was taken into account when organizing functional studies.

Functional state assessment of the teaching staff body showed that during the working day in the teacher's body, functional changes are formed, the nature of which depend on specific functions, as well as on gender and work experience.

The functional state of the tested teachers' CVS system is characterized by the data of Table 1. It is revealed that, on average, the indicators studied are within the physiological norm, both before and after work. At the end of the working day, TMA teachers showed a slight increase in systolic and diastolic pressure and heart rate, while TSTU teachers showed only an increase in heart rate. At the same time, a large scatter of individual indicators was noted, as a result of which the average statistical values did not have significant differences either during the working day or when comparing the faculty indicators of two universities.

Table 1. Functional state indicators of the teachers' body at the beginning and at the end of the working day*

University	Time of research	Number of tested	Indicators			
			Arterial pressure		Heart rate	Breathing rate
			Systolic	Diastolic		
Women						
TMA	Before work	30	113 ±5	73± 2	76± 2	20± 1
	After work	30	122± 4	79± 4	79± 3	20± 2
TSTU	Before work	31	116± 8	74± 3	73± 4	23 ± 2
	After work	60	116±7	74± 2	75± 4	23± 2

University	Time of research	Number of tested	Indicators			
			Arterial pressure		Heart rate	Breathing rate
			Systolic	Diastolic		
Men						
TMA	Before work	29	119± 3	74± 2	76± 2	19± 1
	After work	29	124±4	79± 3	80± 4	20 ± 1
TSTU	Before work	61	124±4	82± 4	74 ± 5	22± 2
	After work	60	123±6	81±4	76± 3	22± 2

In all cases, for indicators before and after work, P> 0.05.

At the same time, it was revealed that for such an indicator as systolic pressure, work experience is important (Fig. 1, 2). Moreover, the differences in the indicator before and after work with work experience of 21 years or more were statistically significant in both women and men.

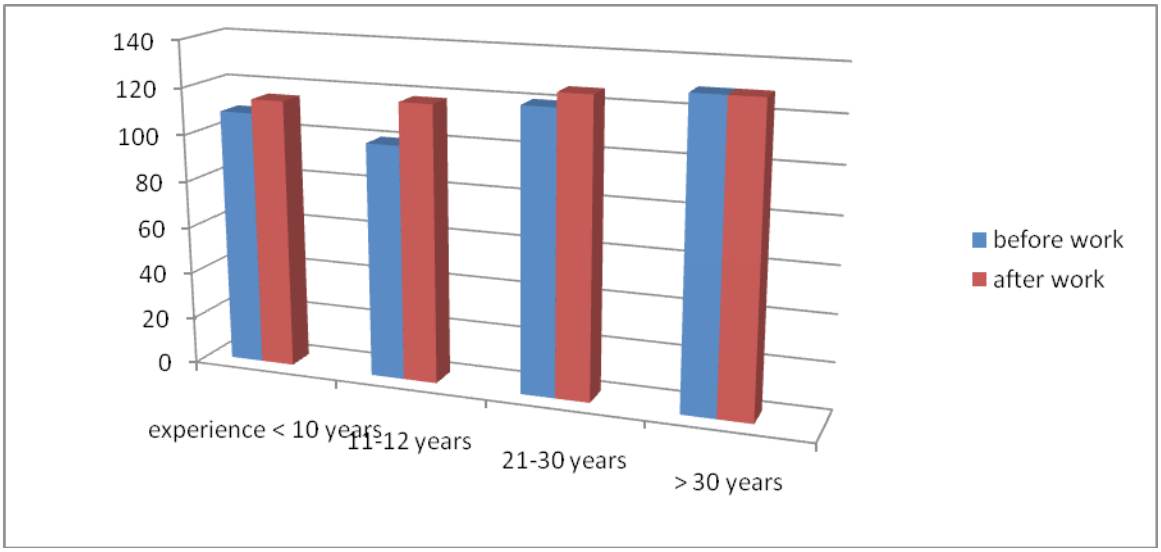

Fig. 1. Change in systolic pressure of TMA female teachers depending on the work experience, mmHg

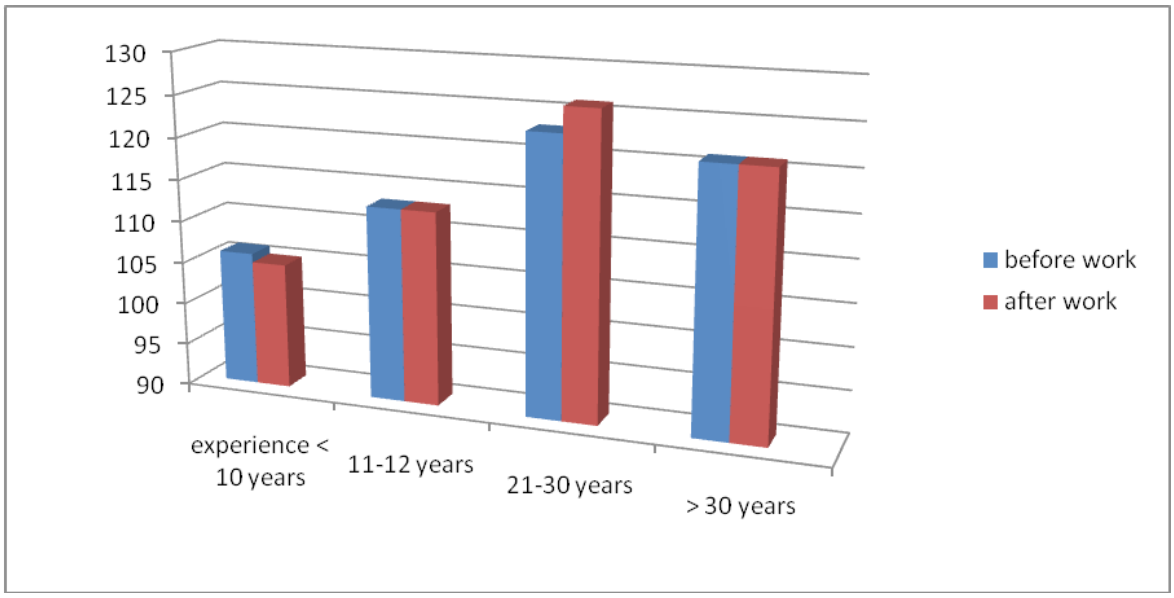

Fig. 2. Change in systolic pressure ofTSTU female teachers depending on the work experience, mmHg

More significant changes were characteristic of the central nervous system's functional state. The amount of work performed by teachers characterizes the mental productivity coefficient, the value of which, for men and women of different universities with rare exceptions, did not have significant differences according to the data of Table 2. At the same time, a number of features are revealed that are characteristic all universities' teaching staff under research. Thus, in all universities the productivity coefficient at the end of work is significantly lower than at the beginning, and the decrease in this indicator in all universities is more noticeable in women: in men, the coefficient decreases by 8.8-12.2%, and in women - by 11.6-24.6%.

Table 2. Comparative characteristics of changes in the productivity coefficient of universities' teaching staff under research at the beginning and end of the day, M±m

University	Men			Women		
	Before work	After work	P	Before work	After work	P
TGTU	659±6	594±4	<0,01	679±8	512±4	<0,01
NUUz	589±8	517±6	<0,01	659±7	558±3	<0,01
TMA	637±5	581±3	<0,01	593±10	524±9	<0,01

The same regularities were revealed with regard to the accuracy of the work performed: the accuracy coefficient of all teachers by the end of the day significantly decreased in all the universities studied (Table 3), and for women this decrease was more pronounced than for men - by 9-17% and 11-19%, respectively.

Table 3. Comparative characteristics of changes in the accuracy coefficient of the task performed by teachers of the studied universities at the beginning and at the end of the day, M±m

University	Men			Women		
	Before work	After work	P	Before work	After work	P
TGTU	0,85±0,04	0,77±0,03	<0,05	0,78±0,04	0,63±0,03	<0,05
NUUz	0,78±0,04	0,67±0,04	=0,05	0,79±0,03	0,67±0,04	<0,05
TMA	0,82±0,05	0,68 ±0,05	=0,05	0,80±0,05	0,71±0,03	<0,05

It was also noted that in all universities the degree of change depends not only on the gender of teachers, but also on their age and work experience. As an example, Table 4 shows the characteristics of TSTU indicators dynamics considering age, gender and work experience.

Table 4. The mental productivity coefficient (P) depending on the age and work experience of TSTU teaching staff

Age or work experience	Men n = 52		Women n = 48	
	Before work	After work	Before work	After work
With regard to age				
Up to 30 years	660±39	611±34 P>0,05	668±38	464±40 P<0,05
31-40 years old	662±28	654±27 P>0,05	840±16	590±95 P<0,05
41-50 years old	752±60	569±41 P<0,05	590±57	464±51 P>0,05
51 years or more	562±40	542±52 P>0,05	619±47 P	533±35 P>0,05

Age or work experience	Men n = 52		Women n = 48	
	Before work	After work	Before work	After work
With regard to work experience				
Up to 10 years	681±31	638±25 P>0,05	680±36	470±38 p<0,05
11-20 years	665±27	616±32 P>0,05	643±57	507±48 P<0,05
21-30 years	655±50	590±53 P>0,05	593±64	515±56 P>0,05
31 years or more	532±50	502±66 P>0,05	633±55	508±50 p>0,05

It was revealed that the central nervous system of men is more resistant to the effects of neuropsychic stress, both considering age and work experience: only for teachers aged 41-50 years, at the end of the working day, a significant decrease in the number of performed mental work. In women, the central nervous system is more labile at a young age - a significant decrease in work productivity was found only in women under the age of 40 years and in people with work experience of up to 20 years (apparently younger than people with more work experience), and the younger women, the changes are all the more pronounced: for people under 30 years of age and with work experience of up to 10 years, productivity by the end of the day decreases by 30.9-38.9%, and at the age of 31-40 years and with work experience of 10-20 years - 21.1-29.8%.

A more accurate indicator turned out to be the accuracy factor of the task, which characterizes the quality of the work performed: a significant deterioration in the indicator was noted in most of the studied age and senior groups of teaching staff in both men and women (table 3); only in the age groups of 31-40 years (for men - and at the age of 51 years or more) the deterioration in the quality of work performed by the end of the day was unreliable. In the experience groups,there was no deterioration in the quality of work only for men with an experience of more than 31 years; in other observations, it was found that the less work experience, the more the quality of its work decreases by the end of the day.

In TMA and NUUz, the dynamics of the functional state indicators of the central nervous system, considering the age and work experience, was similar (Table 5).

Table 5. The accuracy factor of the task, depending on the age and work experience of the TSTU teaching staff

Age or work experience	Men n = 52		Women n = 48	
	Before work	After work	Before work	After work
With regards to age				
Up to 30 years	0,84±0,03	0,80±0,04 P>0,05	0,80±0,03	0,58±0,05 P<0,05
31-40 years old	0,92±0,02	0,88±0,02 P>0,05	0,80±0,07	0,70±0,03 P>0,05
41-50 years old	0,94±0,03	0,70±007 P<0,05	0,76±0,04	0,60±0,04 P<0,05
51 years or more	0,70±0,05	0,70±0,03 P>0,05	0,75 ±0,03	0,66±0,44 P>0,05

Age or work experience	Men n = 52		Women n = 48	
	Before work	After work	Before work	After work
With regards to work experience				
Up to 10 years	0,87±0,02	0,78±0,03 P<0,05	0,80±0,03	0,58±0,04 p<0,01
11-20 years	0,90±0,02	0,76±0,04 P<0,05	0,80±0,04	0,69±0,001 P<0,05
21-30 years	0,88 ±0,02	0,70±0,05 P<0,05	0,80±0,05	0,68±0,04 P=0,05
31 years or more	0,65±0,06	0,70±0,08 P>0,05	0,76±0,04	0,64±0,05 P=0,05

Identified similar shifts in the central nervous system's functional state in all tested individuals, in our opinion, are caused by constant neuro-emotional stress, which is the main harmful factor in the activities of the universities' teaching staff and which, ultimately, lead to the emotional burnout development.

The identification and assessment results of the psychoemotional burnout state in the studied population. Emotional burnout indicators in accordance with the methodology used (emotional exhaustion, depersonalization, personal achievement reduction) can be detected in a variety of people, but their nature and severity depend on many factors, including on the characteristics of work.

It can be assumed that one or another EB level is characteristic of all people, in connection with which we tested a group of university employees (50 persons) not belonging to the teaching staff - laboratory assistants, technical workers, accounting workers; this group of researchers served as a control in relation to the teaching staff of universities. It was revealed that emotional burnout signs do occur in this group of patients, but their level is very variable. Thus, low level emotional exhaustion is typical for most people in this group (64.0 ± 6.8%), while a high level of this indicator is noted only in 2 out of 50 cases (4.0 ± 2.8%). A more characteristic EB sign in this group is depersonalization, the average level of which is observed in 52.0 ± 7.1% of the examined, and the personal achievement reduction is characteristic of most of these individuals - its high level was detected in 84% of cases. It is obvious that the claims of this group of people were quite high, but they were practically not realized, which nevertheless did not oppress them, without causing despondency, without depriving the feeling of joy in life.

The data obtained also allow us to conclude that EB indicators can be detected in any person; therefore, the significance of control in such studies is less than considering the level and nature of changes in emotional burnout indicators recommended by the testing methodology.

The emotional burnout possibility and degree assessment of the universities' teaching staff in Uzbekistan, conducted by us in the three universities under research, allowed us to establish a number of important patterns.

General characteristics of emotional burnout among teachers of the studied universities are presented in Table 6.

Table 6. The level of emotional burnout signs at the studied universities' teaching staff, %, M±m

Pcomparing to the control: * p<0,05, ** p<0,01, ***p<0,001

It is necessary to note a fairly wide individual scatter of indicators, however, the data presented in the table indicate that we practically did not reveal any reliable differences in the average statistics in different universities, with the exception of 3 of 27 indicators. This suggests that the dynamics and level of emotional burnout indicators in all universities are approximately the same, although the percentage distribution of indicators among universities is slightly different (in 88.9% of cases, p> 0.05).

In all 3 universities, the most typical is the average level of change in the EB indicators (from 28.0% to 56.0% of the tested); less often, a low level of changes (from 16.0% to 42.0%) is noted and even less often, a high level (from 14.0% to 52.0%). Of the 3 EB indicators, the highest indicators of emotional exhaustion are characteristic of the average level (39.0-56.2%), for depersonalization - also the average level (24-44.0%), and for the personal achievement reduction - the high level (44-52.0%).

When comparing the EB indicators of the teaching staff with the control group, it was found that the teaching staff is characterized by significantly higher indicators of high and medium levels of emotional

exhaustion and depersonalization, while the personal achievement reduction of medium and high level is more characteristic of individuals in the control group. This allows to conclude that if dissatisfaction with the achieved is typical for 75-80% of the teaching staff, then in the control group, claims of 94% of the tested people were not implemented, which confirms the relative importance of control in this research.

At the same time, comparison with control shows that the teaching staff is characterized by a significantly higher frequency of unfavorable EBindicators. This makes it necessary to identify factors contributing to the formation of the EB of the faculty. It is completely obvious that typical hygienic working conditions (microclimate, lighting, ventilation, etc.), which are not particularly rigid, cannot be the EB cause, although a prolonged deviation of these conditions from hygiene requirements can play the role of contributing factors in the EB development.

We hypothesized that risk factors for EB can be gender, age, and work experience at the university. To assess the significance of sex for EB, the test results were distributed in each university by the frequency and EB indicators level depending on gender. The data presented indicate that both men and women in all universities have unfavorable EB indicators (medium + high level), amounting to 52-85%.

Despite the fact that the natural values of indicators in men and women have some differences, a statistical analysis of the data showed that in no case have we revealed any significant differences in the indicators in these groups. At the same time, the comparative characteristics of the men and women indicators are almost the same in all universities (Table 6). This is also clearly seen in Fig. 3, where the frequency of various levels of EB indicators in men and women at TSTU is presented.

Of all the EB indicators in both men and women, the highest frequency - at the level of average indicators (52-60%) - is emotional exhaustion characteristic. A high frequency of a high level indicator (44-50%) is characteristic for the personal achievement reduction. Given that in the control this indicator is also the highest, it can be assumed that dissatisfaction with the achieved is characteristic of any person and should be considered as a factor in stimulating human activity in the event that this indicator is not predominant in relation to other EB indicatorsю

EEDPAR

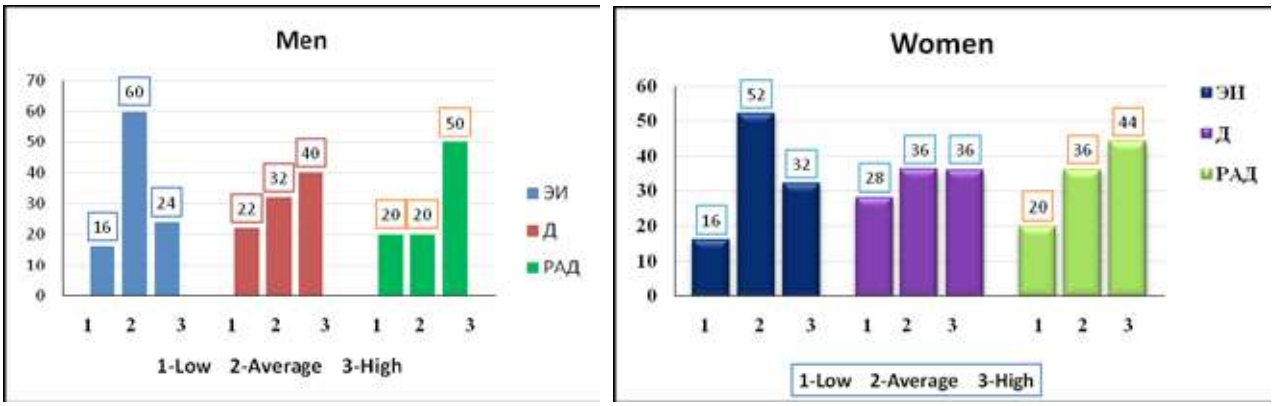

Fig. 3. The frequency of TSTU teaching staff's emotional burnout indicators depending on gender,%

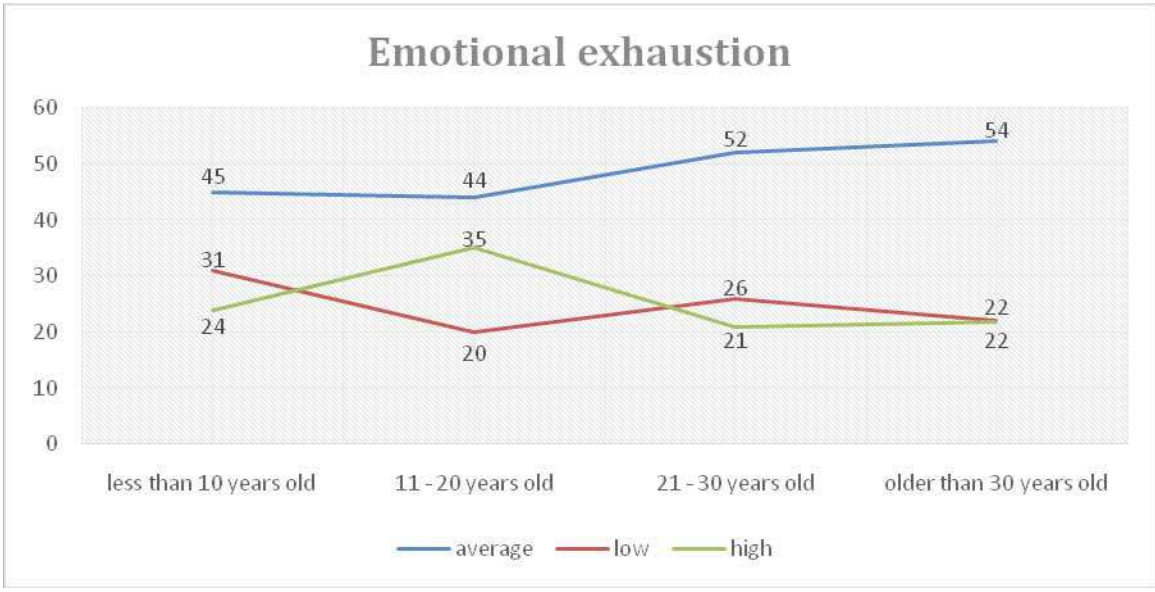
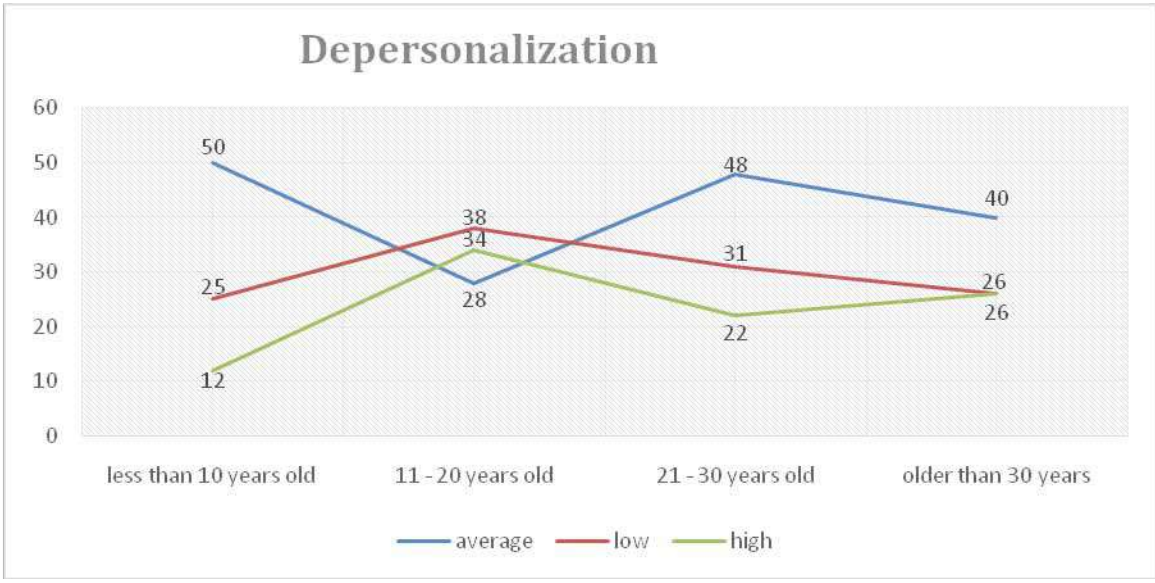
When assessing the significance of the age for EB, we tested all persons under research into age groups: up to 30 years, 31-40 years, 41-50 years and older than 50 years. Given the absence of significant differences between men and women, when assessing the significance of age, the division of subjects in age groups by gender was not carried out.



First of all, a comparative analysis of the frequency of the most significant indicator, emotional exhaustion, was carried out in the age-gender groups. The results of this analysis are presented in Tables 7 and 8, from which it can be seen that the distribution of the frequency and level of this indicator in all 3 universities studied is similar, i.e. differences in indicators between universities are not significant.



In general, the following patterns can be traced: less often in all age groups there is a low level of emotional exhaustion (3.6-8.1%), somewhat more often (7.8-10.7%) - a high level, most often (7, 2-18.2%) - the average level of EI. At the age of 31-40 years, the frequency of unfavorable types of EE (medium + high) significantly increases (2-3 times in comparison with people under 30), and in 41-50 years - 2.5-7 times compared with the group under the age of 30 years.

After 50 years, the frequency of unfavorable EE levels decreases, but still remains significantly higher in relation to the first age group. Consequently, the most vulnerable group in relation to emotional exhaustion are people aged 41-50 years, i.e. the time of the most active teachers.

The dynamics of depersonalization and personal achievement reduction frequency is similar to the dynamics of emotional exhaustion frequency, but the indicators values are significantly lower than EE; in addition, a significant change in indicators in older age groups compared with the age of up to 30 years was revealed in the group of 41-50 year old teachers and in isolated cases at the age of 31-40 years (high level of "D" and "PAR") and 50 years or more (increase in the number of people with low levels of PAR).

An important factor for the formation of negative trends of emotional burnout turned out to be seniority at the university. Its influence on the level of the studied indicators was mixed. This is evidenced by the data of and graphically shown on Fig. 4.

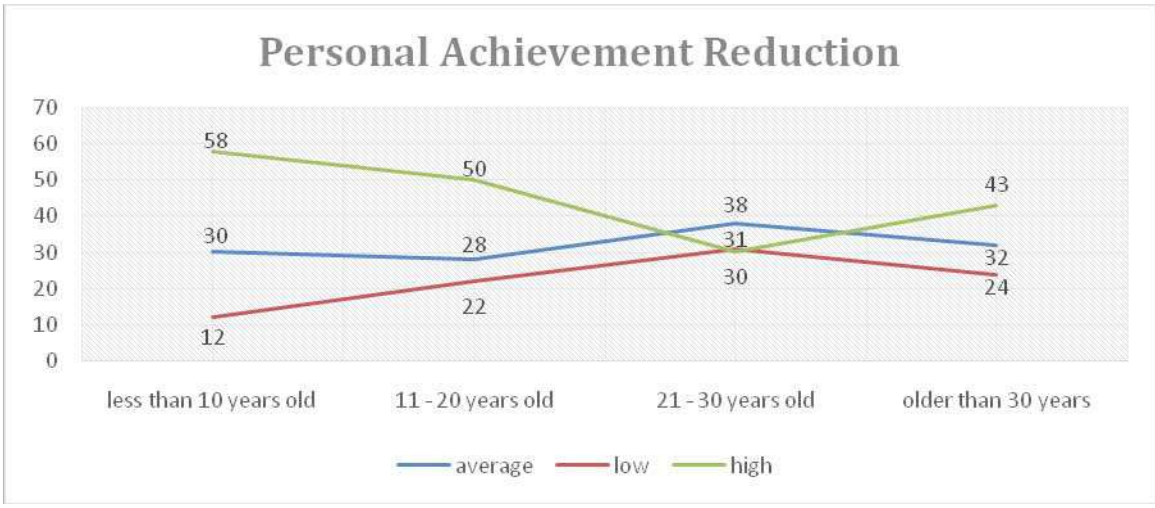


Fig. 4. Dynamics of the emotional burnout indicators level depending on the work experience, %

The indicator of a low EE level changes insignificantly with an increase in the work experience, being detected in 20-30% of the examined persons. Almost at the same level is a high level of changes in EE. The average EE level naturally grows with an increase in the work experience: in individuals with an experience of 21-30 years, the average EE level is recorded 7% more often, and with the experience of more than 30 years - 11% more than with the experience of up to 10 years.

Low and high level of depersonalization occurs in the range of 22-34% and is little dependent on experience. The average level of depersonalization is more characteristic for people with a short work experience (up to 50%), then it decreases almost 2 times (up to 28%), and for people with a work experience of more than 20 years it increases 1.5-1.7 times.

The dynamics of a high PAR level is interesting. Persons with an experience of up to 10 years have a high level of doubt in their own abilities in 58% of cases, then the level of self-esteem increases - with the experience of 21-30 years, only 30% of the tested do not believe in their own strength, but with the experience of more than 30 years, self-confidence is again decreases - 43% of the respondents showed a high level of doubt in their capabilities.

We also studied the psychoemotional state of a TMA teachers group (50 people) at the beginning and at the end of the academic year. The results of these studies showed that by the end of the academic year the number of unfavorable indicators of the psychoemotional state increases significantly. So, by the end of the academic year, the number of teachers with a high level of emotional exhaustion increases 2.5 times, depersonalization - 4 times, with a personal achievement reduction - 2.4 times. This suggests the great importance of a properly organized summer vacation to restore the psychoemotional state of the teacher.

The study of the work content, the functional and psychoemotional state of the universities' teaching staff allows us to draw the following conclusions:

1. Assessment of the functional state of the teachers' CVS throughout the working day indicates that the average statistical indicators of the CVS functional state throughout the working day do not go beyond physiological fluctuations, although the systolic pressure level, especially in people with a long history of work, increases significantly.
2. When assessing the functional state of the central nervous system, a decrease in the quality of the work performed was revealed: a significant deterioration in the indicator was noted in most studied age and senior groups of faculty members in both men and women; it was revealed that the less work experience, the more its quality decreases by the end of the day.
3. Signs of emotional burnout are detected in people who are not involved in pedagogical activities, but the main indicator level of emotional exhaustion in such individuals is low; these individuals are most characterized by a high level of personal

achievement reduction. The revealed facts indicate the relative importance of control in such studies; more informative is the account of the level and nature of the signs of EB.

4. The studied group of teachers is characterized by a wide individual scatter of EB indicators, but the average statistical indicators of EУ, D, and PAR in different universities do not have statistically significant differences:

– The studied group of teachers is not characterized by a low level of changes in the EB indicators, while the prevalence of adverse parameters of changes is noted, i.e. medium and high level changes.

– For EE and D, the most characteristic is the average level of changes, significantly higher than in the control group: for PAR, a high level of changes was detected less often than in the control group, which once again confirms the relative importance of control.

– The average level of emotional depletion of the teaching staff environment is 52-60%, a high level of PAR - 44-50%; average level of D - 22-40%; therefore, the main sign of EB is emotional exhaustion.

5. There were no statistically significant differences in the EB indicators depending on gender - the indicators are almost the same for both men and women in all universities. Adverse parameters of changes in EB (medium + high level) were identified in 52-85% of teachers

6. The most vulnerable age group with a high and medium level of EE are people aged 41-50 years, ie age of the most active teachers.

7. Work experience in a university does not practically change the low and high level of EE and D indicators, while the average level of change in these indicators increases with a work experience growth; a high level of PAR, characterizing the self-assessment of the teaching staff members, was noted among those with the longest work experience, the highest frequency of positive self-esteem was revealed with work experience of 21-30 years, and a sharp decrease in self-esteem of their capabilities was revealed in those with experience of more than 30 years; at the beginning of the academic year, emotional burnout indicators are less pronounced than at the end; this indicates the great importance of rational relaxation for the teachers' psychoemotional state.

Abstract

We have operated on 42 patients ages 22 to62 suffering different forms of obesity and obesity-related metabolic disorders. Body mass indexes have ranged from 28 to 62 kg/m^2. All patients have had symptoms of metabolic disorders of different intensity. Our goal has been exerting maximal influence on carbohydrate metabolism processes rather than mere body weight reduction. The patients have undergone sleeve gastrectomy, laparoscopic mini-gastric bypass, Roux en Y gastric bypass, as well as modified gastric bypass with Rouxen Y gastrectomy with a 180-cm bypass and 70-cm alimentary loop as an independent way of surgical treatment of diabetes type 2 associated with obesity. Sleeve gastrectomy in terms of weight control has demonstrated a 73% efficacy, and gastric bypass –a 89% efficacy. The efficacy of surgeries in patients with carbohydrate metabolism disorders through Roux en Y gastric bypass has totaled 96%,classic Roux en Y gastric bypass - 92%, sleeve gastrectomy – 60%. Roux en Y gastric bypass andmini-gastric bypass are more effective in the treatment of obesity and associated metabolic disorders compared to sleeve gastrectomy. Gastric bypass has proved effective even in diabetes patients with body mass indexes up to 30 kg/m^2.

Keywords: *Obesity, metabolic syndrome, diabetes type 2, bariatric and metabolic surgery, gastric bypasss, mini-gastric bypass.*

Abstract

Today, the incidence of obesity has grown to proportions of an epidemic, especially in the civilized world. In 2016, more than 1.9 billion mature people above 18 were deemed overweight[1]. More than 650 million of those were diagnosed with obesity[2]. According to the World health organization (WHO), as of 2016, 39% of adults (men - 39%, women – 40%) were overweight[3]. In 2016, about 13% of mature population of the planet (men – 11%, women – 15%) were diagnosed with obesity[4]. Within a period from 1975 through 2016, the number of obese people tripled[5]. In Europe, the incidence of obesity ranges from 5% to 23% in men and from 7% to 36% in women[6]. In Uzbekistan, the percentage of overweight or obese people is 24.9%. According to WHO, obesity is a non-infectious epidemic of the 21st century[7].

In 2000, WHO came up with a proposal to lower the overweight threshold for the mongoloid race from 25kg/m^2 down to 23.5kg/m^2, and the obesity threshold – from 30kg/m^{2}down to 27.5kg/m^2[8]. The initiative was put forth because epidemiological research data had shown that mongoloids began to deal with overweight-related issues at a lower body mass index [4][8].

In cases when the body mass index reaches 40 kg/m^2 or higher, even when no complications are observed[9], morbid (pathological) obesity is diagnosed[10]. With complications, such as diabetes type 2, arterial hypertension, dyslipidemia, and lower limb joint pathologies, obesity is classified as morbid at a body mass index of 35 kg/m^2 or higher[11].

The body mass index is subject to criticism for not reflecting the fat/muscle ratio and distribution of fat around the body[12]. For example, it can classify an elderly person with low muscle mass as one with ideal weight, while a heavy-muscled athlete can be termed as overweight or obese. However, so far, body mass index is the only internationally recognized body weight evaluation criterion[13].

Over the past decades, scientists and clinicians have

switched to a complex approach to studying different metabolic disorders and obesity-related conditions[14]. They have concluded that these pathologies share symptoms and generalized them as "metabolic syndrome"[15].

Metabolic syndrome (X syndrome) is a kind of price we pay for urbanization, as it entails physical inactivity, improper nutrition, and sedentary life mode, which can cause serious health problems in future[16]. There is even a symbolic pattern of these consequences: metabolic syndrome – 10 to 20 years old - atherosclerosis – 10 to 20 years old – myocardial infarction, stroke[17].

A person can be diagnosed with metabolic syndrome if he or she has at least three of the following symptoms:

- Overweight;
- Arterial hypertension;
- High blood sugar;
- Dyslipidemia (abnormal lipid profile);
- Early atherosclerosis;
- Ischemic cardiac disease;
- Gout;
- Increased male hormone levels in women.

Today, the most effective and reliable method of morbid obesity treatment is bariatric surgery[18]. Operations that limit food intake and food absorption result in pronounced and continuous weight loss and mitigate the majority of associated conditions[19]. The effect lasts for lifetime, frees patients from having to follow strict diets[20], significantly improves and prolongs life[8,26,46]. Anti-obesity surgeries have been in practice since the 1950s, when the first jejunoileal bypass surgery was conducted in the USA[21]. Over the past 25 years or so, other types of bariatric surgeries have been developed and are now broadly applied (intragastric balloon placement, biliopancreatic bypass, lap band surgery, sleeve gastrectomy)[22].

Today, the number of anti-obesity surgeries per year in the world exceeds 340 000 (as of 2018) [18]. There are lots of factsproving the positive effect of bariatric operations, which lasts for long periods[23].

First of all, the effect of an operation depends on its type. Patients lose 45% to 95% of unhealthy weight, and the effect continues for 1 to 1.5 years[24]. If there are serious underlying conditions, simple bariatric surgeries may be ineffective, so more complex operations – gastric or biliopancreatic bypass – may be required[25].

The initial goal of bariatric surgeries is body weight control[26]. Later they proved effective against diabetes type 2, as it was observed in most patients, who had lost weight after an operation[27]. With different underlying signs of metabolic syndrome, most effects appear during the first month after the surgery[28]. In other words, diabetes, hypocholesterolemia and other symptoms go away before the patient loses weight[29]. This has produced the term "metabolic surgery", which means selective surgical correction of metabolic disorders [54].

In 2009, the American Diabetes Association included these operations in the standards that are applied in the treatment of diabetes type 2 and underlying obesity, and in the USA these operations are covered by insurance companies[30]. In some European (Italy, France, Great Britain) and other countries (Israel), surgeries required for treatment of morbid obesity are covered by medical insurance too[31].

Although there are tons of research and scientific publications concerning bariatric and metabolic surgery, there are lots of issues that still need to be resolved[32]. So far, there are no unified or universal standards that would regulate the use of bariatric surgeries based on indications and surgeon's choice[33]. Given the high spread and incidence of morbid obesity and related metabolic disorders in Uzbekistan[34], we actively use bariatric and metabolic surgery to treat this category of patients while relying on our own observations and studies[35]. Based on these studies, we have presented some results and conclusions concerning the choice of effective surgical tactics in the treatment of patients suffering carbohydrate metabolism disorders with underlying obesity and dyslipidemia[36].

Materials and Method

We operated on 42 patients at Clinic 1 of the Tashkent City Clinical Hospital over the period from 2015 through 2019, ages 22 to 62, dealing with various types of obesity and related metabolic disorders[37]. The body mass index ranged from 28 to 62 kg/m^2. All patients had symptoms of metabolic disorders of different intensity[38]. It should be noted that 20 subjects had applied for a surgery for lack or short duration of effects of conservative treatment (diet, physical exercise, use of dietary supplements)[39]; 22 patients had applied

for treatment due to diabetes type 2 (disease duration – 3 to 15 years)[40]; therefore (see a description below) our goal was to exert maximal influence on carbohydrate metabolism rather than mere reduction of body mass index[41], as we realized the inseparability of bariatric and metabolic procedures[42].

Prior to a surgery, the patients had undergone the following tests:

- Complete blood count;
- Biochemical blood count (ALAT, AST, uric acid, creatinine);
- Coagulogram;
- Blood clotting time;
- Carbohydrate metabolism indexes (blood sugar level; HbA1Cglycosolated hemoglobin; fasting and after-food insulin, if necessary; C-reactive protein);
- Lipid spectrum;
- Imaging: ECG, ultrasound, EGD;
- Other consultations (endocrinologist, diabetologist, hepatologist, cardiologist, therapist, emergency physician and anesthesiologist)[43].

A group of 8 patients underwent sleeve gastrectomy, 23–gastric bypass with Rous en Y (7 patients were subject to gastric bypass with Rous en Y as independent treatment of diabetes type 2 associated with obesity)[44], 11 patients were subject to mini-gastric bypass (MGB/OAGB) with the use of bypass and alimentary loops of different length (Table 1)[45]. Also, a group of 11 patients underwent laparoscopic mini-gastric bypass devised by R. Rutledge with the formation of a small stomach with a volume of 150 ml to 200 ml, and a 4cm to 5cm thick gastroenteroanastamosis was fixed over a length of 150cm to 200cm from the ligament of Treitz[46].

Table 1. Types of surgeries required to treat obesity and obesity-related diabetes type 2

Type of surgery	Sleeve gastrectomy	Roux en Y gastric bypassmodification	Roux en Y gastric bypass	Mini-gastric bypass
Obesity	8	-	7	5
Obesity combined with diabetes	-	7	9	6

Results and Discussion

During the early postoperative period, disease management required special care (control and correction of blood sugar and other indicators) during the first several days; later, all patients were managed on the Fast Track Recovery basis. All patients were discharged after 5 to 7 days with their state defined as satisfactory. Later, all patients were subject to regular monitoring for all related parameters (blood sugar, fasting and after-food insulin, weight loss dynamics, etc.)

Patients, who had sleeve gastrectomy, lost 25 kg of weight on average; it should be noted that after a year weight loss would slow down dramatically or stop completely (Fig. 1)

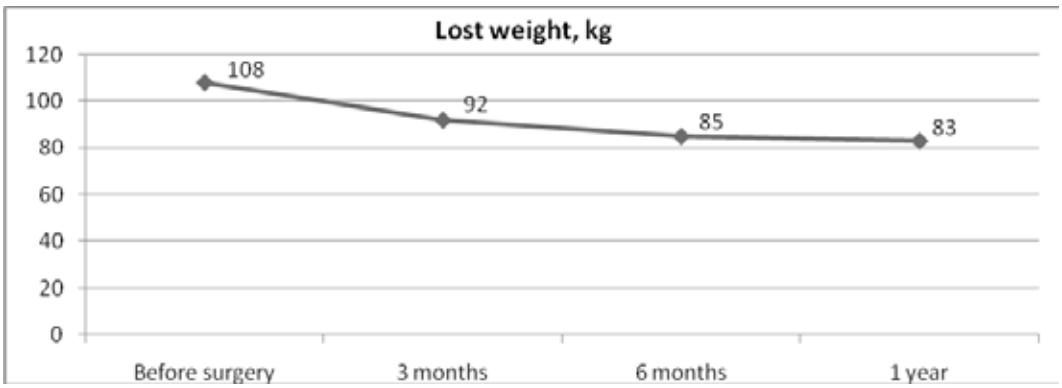

Figure 1.

On the average, patients lost 54 kg during the year following a gastric bypass surgery (Fig. 2).

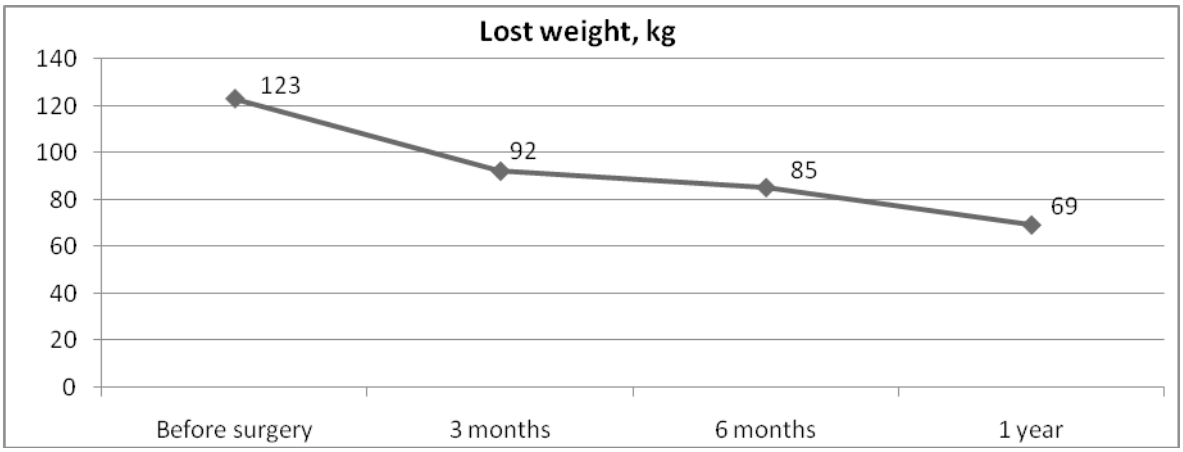

Figure 2.

The percentage of lost weight has been calculated according to the formula:

$$\text{EWL\%} = \frac{\text{Excess weight (kg) in the end}}{\text{Lost weight (kg)}} \times 100\%$$

and totaled 70%on average for sleeve gastrectomy cases and 85% for gastric bypass cases.

As mentioned above, 22 patients had diabetes type 2; therefore, the type of surgery was chosen with special consideration to the duration of the disease, clinical symptoms and their intensity, fasting and post-meal blood sugar and other metabolic syndrome indicators; however, special attention was paid to fasting and after-meal C-peptide, insulin and C-reactive protein blood levels, HOMA-IP, atherogenic and abdominal obesity indexes, which has enabled us to achieve an up to 98% accuracy in prediction of the efficacy of surgical diabetes treatment (Fig. 3). Also, a differential approach was applied to each patient with reference to carbohydrate and lipid metabolism indicators when choosing an optimal length of bypass and alimentary loops and stomach size. This has helped us achieve full and complete remission of diabetes in patients with a body mass indexof up to 30 without losing much of excess weight.

Test results of patients with carbohydrate metabolism disorders and their dynamics during the postoperative year demonstrating a complete remission of both clinical and laboratory diabetes indicators (Fig. 3 and 4)

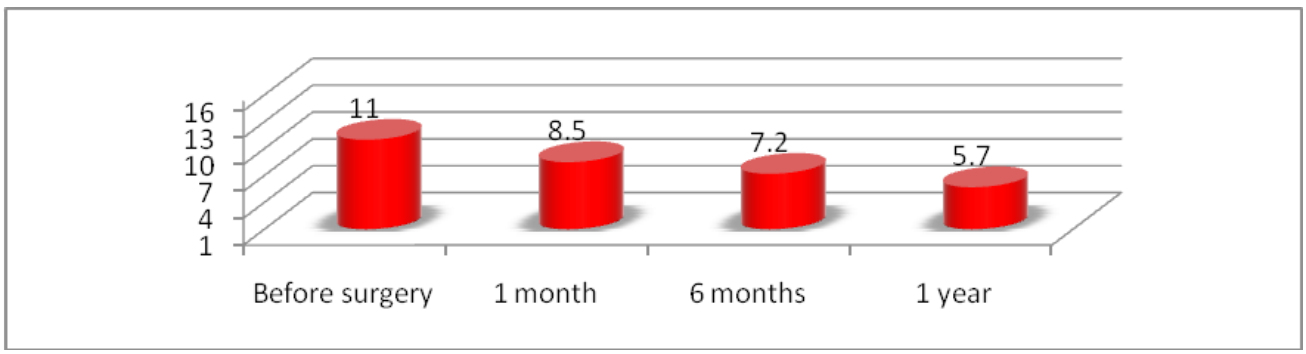

Fig 3. Average blood sugar level**

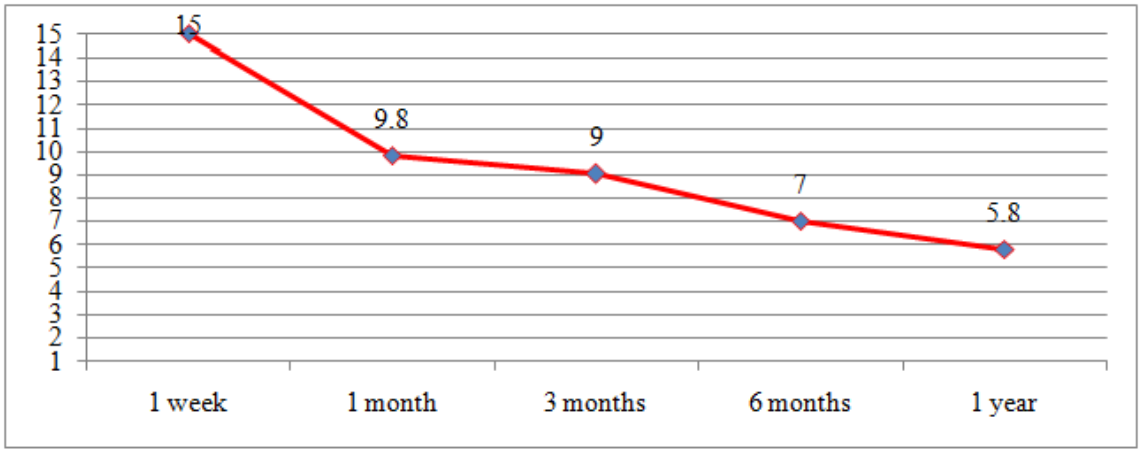

Figure 4. Blood sugar dynamics**

We detected normalization of insulin secretion in response to eating, which indicates a decrease in or disappearance of insulin resistance (Fig. 5).

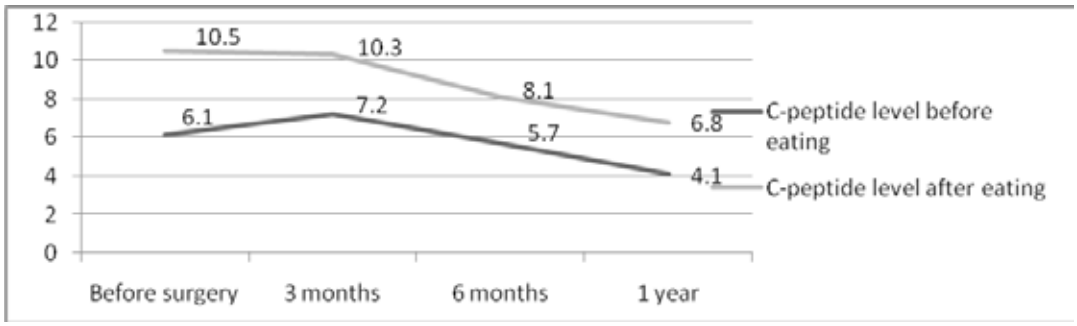

Figure 5. Postoperative C-peptide level

Also, it should be noted that six patients had been receiving 32 units of insulin on average before a surgery with blood sugar exceeding 10 mmol/l. Three patients canceled insulin injections within a month following a surgery due to a complete remission of diabetes; two patients cut down on insulin within three months following a surgery. Only one patient had to reduce insulin injections to a minimum of 10 units of simple (Actrapid) insulin per day.

All obesity patients demonstrated an increased C-reactive protein, which is a sign of metabolic syndrome; after an operation, C-protein levels would decrease as shown in Figure 6.

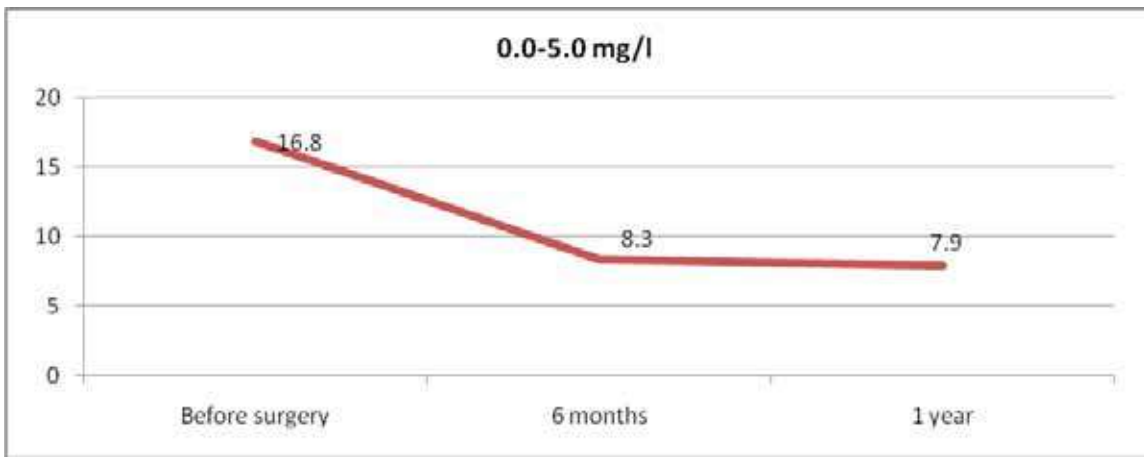

Figure 6. C-reactive protein level dynamics

Table 2. Pre-* and postoperative metabolic syndrome indicators**

	Before surgery*	After surgery (1 year)**	Norm
Blood sugar	9.81	5.8	4-7 mmol\l
Blood sugar after eating	12.9	6.7	4-7 mmol\l
Glycosylated hemoglobin	8.10	6.6	4-7%
Fasting insulin	20.4	0.2	0.7-9.0 mU/l
Insulin level after eating	32.1	6.6	0.7-9.0mU/l
Blood pressure	150/90	130/80	
Atherogenic index	5.0	4.8	Optimal up to 4

* All preoperative tests were made as the patients were taking medications and following strict diets (sugar-lowering, antihypertensive,etc.)

** All postoperative tests were made without the patients' aking of any medicines or following diets(sugar-lowering, antihypertensive, etc.)

Evaluation of the efficacy of bypass surgeries in the treatment of metabolic syndrome revealed a more pronounced weight and metabolic symptom reduction compared to restrictive surgeries (Table 3).

Table 3. Efficacy of bypass and restrictive surgeries

	Weight loss	Diabetes	Arterial hypertension	Dyslipidemia
Modified Roux en Y gastric bypass	98%	95%	92%	98%
Roux en Y gastric bypass	90%	90%	95%	90%
Mini-gastric bypass	85%	92%	85%	85%
Sleeve gastrectomy	73%	No data available	50%	40%

Table 4. Postoperative metabolic improvement in 42 (100%) patients

	Average BMI	Diabetes type 2	AH	Dyslipidemia	Other diseases (apnea, joint and spinal diseases)
Before surgery	38	52%	87%	98%	60%
After 3 months	35	4,6%	36%	40%	42%
After 6 months	32	2,3%	17%	21%	33%
After a year	29	2,3%	8%	9%	18%

We specified general and specific postoperative complications. One of the patients, who had undergone a modified Roux en Y bypass surgery, developed Potassium, Magnesium and Calcium microelement deficiency resulting in dysmetabolic polyneuropathy manifesting itself in different forms of paresthesia. General postoperative complications were observed in three patients; two of them had postoperative hernias, and one developed postoperative wound festering(Table 5); there were complications after the use of the traditional median approach only. No complications occurred after laparoscopic surgeries.

Table 5. Postoperative complications

	Lethal	Specific		General	
		Micro- and microelement deficiency	Dysmetabolic polyneuropathy	Hernia	Wound festering
Modified Roux en Y gastric bypass	0	1(2.3%)	1(2.3%)	1(2.3%)	1(2.3%)
Roux en Y gastric bypass	0	0	0	1(2.3%)	0
Mini-gastric bypass	0	0	0	0	0
Sleeve gastrectomy	0	0	0	0	0

Thus, the conclusion is that the most effective method of treatment of morbid obesity and associated diseases is gastric bypass surgery[47].

However, this type of surgery is technically challenging and may cause unfavorable postoperative reactions[48]; gastric bypass remains effective with the use of an individual approach to each patient and when determining the length of intestinal loops[49].

Sleeve gastrectomy is purely restrictive and therefore not very effective in the treatment of metabolic syndrome[50], and it has a high obesity recurrence rate, as patients may regain weight over several years following the surgery[51]. Gastric bypass is a kind of gold standard of surgical treatment of obesity and related disorders[52]. Non-invasive gastric bypass surgeries significantly reduce the occurrence of general surgical and specific complications[53].

Abstract

At present, there are many drugs and method of anesthesia, each has its advantages and disadvantages. The aim of anesthesia is not only to eliminate suffering and create psychological comfort, but also to improve the quality of life, accelerate postoperative functional rehabilitation, reduce the incidence of complications. The problem of postoperative pain treatment is relevant both in our country and abroad. According to literary sources, 30–75% of patients suffer from severe pain in the postoperative period. Today there is a great number of research, recommendations and guidelines for postoperative anesthesia. *(*Volchkov V.A., Kovalev S.V., Kubynin A.N. Modern aspects of postoperative anesthesia (literature review)//Bulletin of St. Petersburg University. Medicine. 2018. V. 13. Issue 3. p. 245-270).

Keywords: *Analgesia, pain, postoperative, analgesic.*

Introduction

The study results of postoperative pain level after various surgical procedures are of special interest. (Ovechkin A. M. Postoperative pain: state of the problem and current trends in postoperative pain management// Regional anesthesia and treatment of acute pain. 2015. V. IX, No. 2. p. 29-39.)[1] In particular, after orthopedic interventions. An effective method of postoperative analgesia is preemptive analgesia (PEA) combined with use of local anesthetics and various adjuvants. The main drugs for PEA are represented by solutions of local long-acting anesthetics in low concentration, providing analgesia without motor blockade. Narcotic analgesics and adrenergic drugs are most often used as adjuvants. (Yousef A. A., Atef A. M., Awais W. M. Comparison of fentanyl versus meperidine as supplements to epidural clonidine-bupivacaine in patients with lower limb orthopedic surgery under combined spinal epidural anesthesia//BMC Anesthesiol. 2015. Oct. 14. No. 15. p. 146-155.) (Bell R. F., Dahl J., Moore R. et al. Perioperative ketamine for acute postoperative pain// Cochrane Database Syst Rev. 2015. Jul. 2(7). p. 344–348.)[2]

High-tech analgesia method include regional analgesia/anesthesia and patient-controlled analgesia. Patient-controlled analgesia (PCA) or on-demand analgesia is an alternative to the traditionally used analgesic “for cause”or planned analgesic[2].

According to this procedure, the patient himself, by pre-prescribed doses, administers the analgesic using a programmable syringe perfusor[3]. Anesthesia is achieved as a result of repeated injections of small analgesic doses[4]. When in pain, the patient titrates analgesic administration, evaluates its effect and determines the most acceptable level of pain[5]. The working principle of PCA is easily understood by patients. As the pain increases, the patient, by pressing the control unit button, titrates a bolus dose of analgesic until the desired effect is achieved[6].

PCA has several advantages over traditional administration of analgesics. It ensures effective analgesia according to patient's individual needs; quick desired effect; reduction of time of the patient without analgesia; stable analgesic concentration in blood plasma . Besides, when PCA is applied, it is possible to save medical personnel time, decrease the incidence of side effects and shorten their treatment in hospital.[2]

Therefore, the purpose of our study was to evaluate PCA efficiency after orthopedic surgery for prosthetics of lower limb joints.

Material and Research Method

The study was performed in 34 patients aged from 65 to 90 years (average age was 78 ± 8 years) with a physical status of ASA 3 or higher. Patients were hospitalized in the traumatology department of TMA clinic with a diagnosis of: Coxarthrosis; Gonarthrosis. All patients had a concomitant pathology: coronary heart disease - 25, hypertension - 27, atherosclerosis - 28, chronic bronchitis - 19, peptic ulcer - 10. Patients underwent orthopedic surgery: 20 patients - hip replacement, 14 patients - knee replacement.

All examined patients were divided into 2 groups. In the 1st group (n = 15), postoperative analgesia was performed traditionally by administration of opioid analgesics (morphine or promedol) by the patient's request. In the 2nd group of patients (n = 19), postoperative analgesia was performed using "Accumate -1100. Electronic PCEA. Electronic PCA" Device. 0.25% solution of longocain, 5 ml, was fractionally injected into the epidural catheter by a patient every 4 hours. During 24 hours after surgery. The study and control groups of patients were comparable in age, volume and surgery duration.

P.R. Bromage scale was used to evaluate the motor blockade. Postoperative analgesia was evaluated using a visual analogue scale (VAS), hemodynamic parameters (heart rate, SBP, BR,) SatO2, stress hormone cortisol and glucose in blood plasma. Hemodynamic parameters were measured at the following stages: 1 - initially, before analgesia, 2 - in 20 minutes after analgesic administration, 3 - in 24 hours after surgery.

The obtained results were processed using parametric statistics method using Statistica 6 program. Data were presented as mean (M) with standard deviation and evaluated using Student's t-test. Differences were considered significant at $p < 0.05$.

Results and Discussion

Before analgesia in patients of both groups, respiratory and hemodynamic parameters were almost identical. As can be seen in the following table 1, all patients experienced severe pain (more than 7 points according to VAS) before analgesia, which was clinically accompanied by tachycardia, moderate hypertension and rapid breathing.

In the 1st group, introduction of standard analgesia decreased in pain severity. Parenteral administration of narcotic analgesics has often proved to be insufficiently effective for pain relief, although pain intensity was higher than 4 points according to VAS, which is an indication for administration of opiates. However, use of drugs in this group was associated with quite a large number of complications and side effects (hypotension - 2, decreased saturation - 3, bradypnea - 1), which are more often observed in elderly patients (over 80 years old). At the same time, postoperative nausea and vomiting were more often recorded in the group (n = 6). Nearly 30% of patients in the group suffered from adverse reactions.

In the 2nd group, where PCA was used, not a single case of severe pain was recorded, the lowest levels of pain syndrome were observed. Mild motor blockade (1-2 Bromage points) was observed in 3 patients of the group and (p = 0.5). Motor blockade occurred in the first 12 hours after surgery and resolved after the patient increased intervals of using the patient's control unit. Epidural anesthesia, in terms of risk/benefit ratio is not less efficient. The main disadvantages of neuraxial analgesia are represented by arterial hypotension (n = 2), acute urinary retention (n = 1), post lumbar puncture syndrome (n = 2). No other adverse events, typical of neuraxial blockade, including infectious ones, were recorded.

As a result of the postoperative analgesia study with use of PCEA, no statistically significant changes in hemodynamic system indicators and a decrease in systolic and diastolic pressure were observed (see Table 1). Also, in contrast to the control group, in the study group of patients, cardiac depression with a decrease was not recorded. It may be due to the patient's selection of the optimal analgesic dose, when, upon reaching the comfort state in the first hours after the surgery, patients maintained this state at an individual level.

In our studies, all patients did not suffer from severe pain. In study groups, there was not a single case of complications associated with side effects of drugs or anaesthesia during the hospitalization period.

Table 1: Indicators of hemodynamics, respiration and pain syndrome severity

Indicators	Group 1			Group 2		
	Stage 1	Stage 2	Stage 3	Stage 1	Stage 2	Stage 3
	128.5±5.7	119.5±5.4	120.5±5.2	126.7±5.2	123.5±5.7	121.5±5.3
ABP mm Hg	85.6±5.3	81.6±5.1	81.4±5.3	84.5±5.1	84.1±5.3	83.1±5.1
Heart rate, bpm	86.8±7.4	78.8±7.4	73.8±3.4	85.8±8.0	74.8±7.4	71.8±4.4
BR/min	18.6±2.4	14.6±2.4	14.6±2.4	18.5±2.6	16.6±2.5	15.6±2.5
Sat O_2, %	98.3±1.5	96.3±1.5	97.3±1.5	98.1±1.7	98.3±1.8	99.3±0.6
VAS, points	7.4±1.3	3.6±1.8	3.5±1.5	7.2±1.9	1.5±0.5	1.2±0.2
Cortisol, n/mol/l	186.1±51.1	184.5±49.1	178.1±43.1	186.2±52.1	149 ± 43.1	145.3±32.1
Glucose, mmol/l	6.1±1.3	4.26±0.4	4.3±0.3	6.2±1.5	4.09±0.3	4.04±0.1

Analysis of the analgesic effect study results showed, that in the postoperative period, using patient-controlled epidural analgesia (PCEA), a clear tendency to a decrease in cortisol and glycemia levels was observed, which was not the case with the control group. The decrease in cortisol is due to nociception interruption in the lesion, because there is no activation of hypothalamo-pituitary-adrenal axis (HPAA). The humoral pathway is a direct entry of inflammatory mediators into the blood and HPAA activation. The blood glucose level is almost the same, with a slight fluctuation, indicating HPAA deactivation.

The results of studies, performed to evaluate PCA efficiency, showed that analgesia shall be started as early as possible. In patients, who started PCA for mild pain (at rest), good results were observed more often by 30 %, than in patients with severe pain. Inadequate analgesia is observed in 15% of patients, when PCA was used for severe or unbearable pain. At the same time, if PCA started with absent or slight pain at rest, inefficient analgesia was observed in only 3% (p is less than 0.05) of patients. Analgesic action starts 20-30 minutes earlier, as no time is spent for a doctor's permission and a nurse's injection.

The patient-controlled analgesia is a method that makes it possible, depending on the analgesic to be administered, in 82-95% of patients to select an efficient individual dose and control pain.

Thus, PCA method provides adequate analgesia according to the patient's individual needs.

Conclusions

1. PCEA is a reliable way to provide analgesia in the postoperative period with total arthroplasty of lower limb joints.
2. The use of prolonged analgesia in low-concentrated solutions of local anesthetics provides sufficient hemodynamic stability and preservation of motor activity of lower limbs. Advantages of the method are as follows: rapid analgesia, bypasses gastrointestinal tract is not involved, patient-controlled, programmable.
3. Epidural analgesia with extended infusion provides reliable nociceptive protection, use of low concentrations of local anesthetics prevents motor disorders. As a result, early activation of patients is possible even with use of epidural analgesia.

Our Experience of Vitiligo Therapy Through Transplantation of Skin Autografts

Vaisov A.Sh.[1], Fuzailov D.N.[2], Munir Akhmad[3], Umarov Zh.M.[4]

[1]*Associate Professor, Tashkent Medical Academy*

Abstract

Vitiligo is a common disease with a characteristic depigmentation of the skin and not fully understood pathogenesis. Epidermocytes obtained from donor sites of their own skin have been transplanted into depigmented skin sites in 28 patients with 48 foci at the age of 19–35 years with disease duration from 4 to 15 years; the duration of patient monitoring is 12 months. Dermabrasion of the focus has been performed by a dermabrider. Epidermal grafts for transplantation have been obtained by cutting off the covers of the blisters extracted at a negative pressure of 200-300 mm Hg. All patients have tolerated the collection of skin fragments and transplantation of epidermocytes well. After 10-12 PUVA sessions applied to 19 patients, complete repigmentation of 19 foci was observed; repigmentation in 75–80% of the area — in 15 foci; on 50% of the area - in 10 outbreaks, less than 50% - in 4 outbreaks. The greatest effect has been noted in patients with localization of foci of depigmentation on the trunk and proximal limbs, and with skin phototype III. The achieved result was maintained throughout the observation period (12 months).

Keywords: *Vitiligo, transplantation, PUVA.*

Introduction

Vitiligo is one of the most common types of hypomelanosis, and it holds a unique position among various types of juvenile dyschromia [2]. Today, experts admit vitiligo's multifactorial nature and discuss the role of endocrine, nervous, autoimmune and genetic factors, as well as malignancies and other diseases in the condition's pathogenesis[3].

Followers of the oxidation-reduction homeostasis theory suggest that the death of pigmentation cells is caused by intensive free-radical oxidation [4]. The diversity of hypotheses makes it difficult to develop[1] a uniform approach and relevant treatment guidelines. Therefore, treatment of vitiligo has always posed serious problems, and it is still not effective enough[2].

There are two diametrical method of treatment, which are aimed at creation of one-type pigmentation. The first method lies in depigmentation of skin that surrounds the affected area; the second one – in stimulating the pigmentation of a discolored focus until it takes on the normal skin color.

The second method is more common. The most feasible solution is using various cosmetics that mask discolored areas.

However, not all cosmetics can satisfy patients due to their short life, high incidence of allergies and high price.

Another opportunity consists in normalization of the functioning of pigment cells within depigmentation foci. Interestingly, researchers have tried to employ almost every newly discovered scientific fact of a chemical's influence on chromogenesis to boost the pigmentation process in vitiligo patients. Therefore, an abundance of medicineshave been tested in vitiligo therapy, including copper-based drugs, hormonal drugs and vitamins, methyldopa, flurouracil, dinitrochlorobenzene, sampren, chingaminum, oxyferriscirbone[7].

Today, exciplex laser is an increasingly practiced technique. However, every case is followed by reports about complications and side effects, such as persistent erythema and hyperpigmentation at the edge of a depigmentation focus[6].

Over the past few years, autograph transplantation of both skin and melanocytes has been resumed [9]. These works are regarded with particular interest thanks to a rapid growth of cell technologies, which have paved the way for melanocyte culture from donor sites and implantation of these into depigmentation foci[5]. In vitiligo therapy, transplantology has passed the following stages:

1. Skin grafting;
2. Skin autografting;
3. Non-cultured epidermal cell suspension melanocyte transfer;
4. Cultured epidermal graft transplantation;
5. Cultured autologous melanocyte transplantation;
6. Non-cultured extracted hair follicle outer root sheathe transplantation.

An advantage of cell transplantation is an opportunity to extract a population of melanocytes from a tiny fragment of skin, which can be quite enough to repigment a large area.

The method' weak points are the complexity of procedures, having to purchase specific equipment and set up a laboratory, a time-taking and challenging cell extraction process (15 to 30 days), high cost of treatment, a risk of mutagenic and carcinogenic effects of some growth factors and nutritional mediums applied during cell culture.

As of now, there are no fully standardized cell transplantation method, and long-term results of their use are not clear.

Objective: clinical assessment of the effectiveness of epidermocyte culture and their transplantation onto depigmented areas.

Materials and Method

We have monitored 28 patients aged 19 to 35 years old with 48 vitiligo foci and disease duration of 4 to 15 years; the length of monitoring is 12 months (19 female and 9 male subjects) with different vitiligo forms. The following vitiligo triggers have been observed: acute emotional suffering, hepatobiliary and gastrointestinal diseases, family history of vitiligo (3 subjects have relatives with vitiligo).

Distribution of subjects by Fitzptrick skin phototype: 22 subjects have had skin phototype III; 6 subjects have had skin phototype II.

We have transplanted non-culture epidermal cells into 48 foci in 28 vitiligo patients.

Stage 1: Dermabrasion of depigmented area

(Dermabrader SAESHIN, KOREA)

Figure 1: Cutting off blister covers

Stage 2: Epidermal grafts, which were to be transplanted into abraded vitiligo-affected areas, have been obtained by cutting off blister covers.

Obtaining epidermal grafts with the help of a blister (at a negative pressure of 200 to 300 mm Hg during 2 to 3 hours).

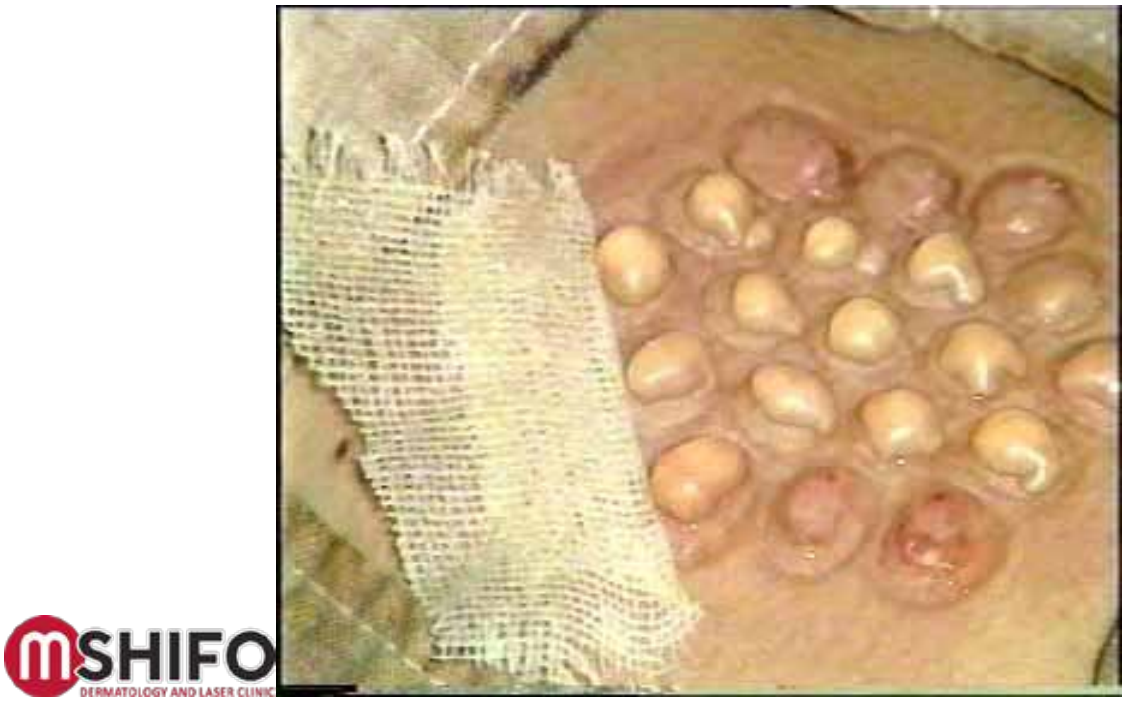

Figure 2: Pan Dulce

Stage 3. The operation ended in the fixation of the grafts and prevention of secondary contamination of the donor site and transplantation site.

Results of vitiligo treatment through epidermal cell transplantation: All subjects previously received various types of traditional and non-traditional treatment without reaching any visible effect. Three patients have had foci with cicatrical changes resulting from folk healers' burning manipulations.

All patients have undergone autologous epidermal cell transplantation. Skin samples have been obtained with the use of aseptic techniques, anesthesia with a 1% lidocaine solution and disinfection with a 70% ethanol solution. All the patients have tolerated extraction of skin fragments and epidermal cells transplantation well.

The skin fragments – 5 to 8 mm blister covers – have been extracted from a symmetrical part of the body or from the buttocks. The samples have been placed into dermabraded depigmented foci. Hemostatic compression bandages have been applied to donor and transplantation sites. We would remove them after 10 to 14 days, ensure that the graft was healing, then we would apply long-wave ultraviolet radiation (with the use of a PUVA device) starting with a 10 to 15 seconds long sessions and gradually increasing the length.

The efficacy of the therapy has been evaluated based on the speed of epithelialization and pigmentation, and the size of repigmentation areas. The follow-up monitoring has lasted 12 months.

After 10 to 12 PUVA sessions, 19 patients showed a full and complete repigmentation in 19 foci, a 75% to 80% repigmentation in 15 foci, a 50% repigmentation in 10 foci, and a smaller than 50% repigmentation in 4 foci. Patients with depigmentation foci on the trunk and proximal limbs and Fitzpatrick skin phototype III showed a more pronounced effect. The effect has lasted throughout the follow-up period (12 months).

Female patient Sh.; diagnosis: vitiligo; 20 days following an epidermal cell transplantation (pre-treatment and post-treatment)

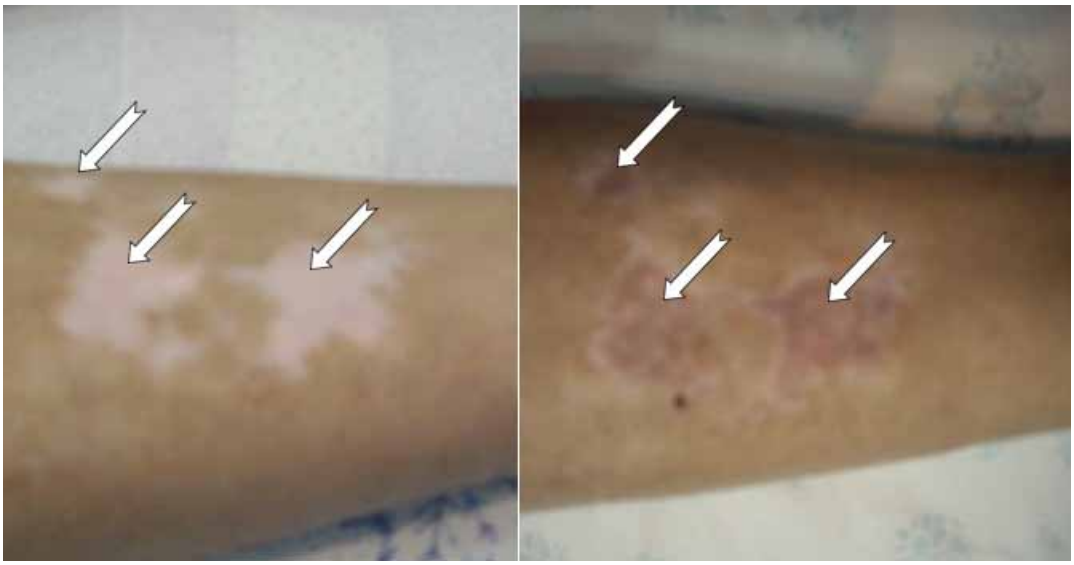

Figure 3: Vegetable

Figure 3: Female patient K. Diagnosis: vitiligo; three months following epidermal grafting

Figure 4: Scar

Results and Discussion

Lately, given the development of regenerative medicine, researchers demonstrate an increasing interest in cell auto grafting method, which consist in transplanting skin grafts into depigmented areas; the grafts contain mature and precursor melanocytes. Today, both culture and non-culture cell transplants are used. However, no comparative analysis of any of these method' effectiveness or long-term results has been carried out so far. Transplantation of blister covers is more preferred because the procedure is simple, inexpensive, quick, and it does not cause serious complications.

The choice of a transplantation method depends on the size of affected areas and localization. Treatment of vitiligo-affected areas like back wrist and foot, knee and elbow, has turned out to be ineffective.

Conclusions

Autologous epidermal cell transplantation in the treatment of different types of vitiligo is a feasible and very promising method, which ensures a pronounced and lasting effect without complications.

Perintis Kemerdekaan KM. 10, Tamalanrea Indah, Kota Makassar, Sulawesi Selatan 90245, Indonesia

Abstract

Objective: This study aimed to determinelevels of expression ET-1 in serum and renal tissue associated with changes in kidney structure.

Method: The rats were divided into two groups. The Obese group was given a high-fat-induced diet chow and a standard diet chow for the control group. ET-1 protein expression and localization in the glomerulus of the kidney were examined. The serum of blood checked for ET-Iusing ELISA method and assessed the ET-1 expression of the glomeruliby Immunohistochemistry (IHC). Mesangial expansion is an indicator to evaluate the degree of glomerular damage by Periodic Acid–Schiff(PAS staining). Associations between the immunoreactivity for ET-1 in glomeruli and the degree of kidney injury were examined.

Results: Lee Index was significantly higher in the obese group than in the control group ($p<0.05$). ET-1 immunoreactivity was considerably higher in the obese group than the control rat. It was a strong correlation with enhancingmesangial expansion glomeruli using PAS staining of the renal tissue ($rs=0.765$; $p= 0.001$). Contrast to ET-1 levels in the serum revealed no significant in obese rat groups ($p>0.05$).

Conclusion: These data confirm the role of ET-1 will provide changes in the levels of glomeruli impairment, but serum levels may well fail to reflect the local expression at the tissue level.

Keywords: *Endothelin-1; Obesity; Glomerular impairment; Chronic kidney disease.*

Introduction

Obesity is a complex multifactorial disease involving an excessive amount of body fat. Kelly et all projects that the prevalence of overweight and obesity will increase to 58% of the adult population by 2030.[1–3] Obesity is not just a cosmetic concern;it is responsible for the growing prevalence of chronic diseases. A meta-analysis was conducted to investigate the association of obesity with more mild kidney disease, including proteinuria (CKD stages 1–2) and low kidney function estimated glomerular filtration rate (eGFR) <60 ml/mnt / 1.73 m2). This study supports the concept that obesity is a direct cause of CKD.[4] This effecthas also been thought to have a strong relationship with the role of ET-1 as a vasoconstrictor agent in obese rats effects on kidney functions.[5,6] Another study,Ferri C et al., revealed a significant increase in plasma ET-1 levels in obese patients.[7] Long term incubation fat tissue increased effect of ET-1 could be a mechanism that contributes to increased basal lipolysis in human obesity.[8] It is suggested that ET-1 plays a vital role in regulating kidney function.

Endothelins (ET) are a family of peptides that act as potent vasoconstrictors and pro-fibrotic growth factors. ET-1 is integral to renal and cardiovascular pathophysiology and exerts effects via autocrine, paracrine, and endocrine signaling pathways tied to the regulation of aldosterone, catecholamines, and angiotensin. In the kidney, ET-1 is critical to maintaining renal perfusion and controls glomerular arteriole tone and hemodynamics. It is assumed that ET-1 influences the progression of chronic kidney disease (CKD).[9] A correlationbetween ET-1 systemic levels and increased endothelin receptors in the kidney have been reported. Local expression of ET-1, especially in the obese kidney itself, is still unclear, so this is what underlies to see the relationship between levels and distribution ET-1 in kidneys in Wistar obese rats compared with Control Wistar rats.[6] The aims of this study provide differences in the expression/levels of ET-1 in the kidneys. It can be used as a reference to see the involvement of ET-1 in kidney pathophysiology in obese patients to develop new strategies in the prevention or treatment of obese patients suffering from kidney disease to reduce patient mortality and improve quality of life.

Material and Method

This study is an experimental study with observing high fat-induced rats reach a Lee Index> 300 for the obese group and maintained obesity status 3-4 month and non-obese rats as Control were then terminated and measured the planned variables. We hoped that the design of this time could show the effect of abnormalities on kidneys due to obesity.

Animal Experiment: This study used sixteen male Wistar rats (Rattus norvegicus), aged 12-16 weeks with an average weight of 185 g (Laboratory of Pharmacy, Faculty of Pharmacy, Hasanuddin University). Rats were housed in cages at 23-25 °C temperature and under a 12-hour day-night cycle. All of the rats were adapted for seven days.On day8th, rats were randomly divided into two groups. The Control Groups (n = 8) was fed a standard laboratory diet containing 4.7% crude fat (CE-2; CLEA, Japan), and the other (Obese groups; n = 8) was fed a High-Fat induced diet containing 14.13% crude fat (Quick Fat; CLEA, Japan),and were allowed to eat and drink water at any time (ad libitum). All of the rats were adapted for seven days in a cage made from plastic material 25 x 35 cm in size. Each cage contained a rat and was reposed by chaff and given cover by woven wire. The protocol of this study was approved by the Medical and Health Research Ethics Committee, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia (number: 1141/UN4.6.4.5.31/PP36/2019). Nutritional details of the two diets are provided in Table 1. Bodyweight and food intake were measured every three days throughout the experimental period.

Table 1. The nutritional content of two experimental diets

Ingredients	CE-2	Quick Fat
Moisture (%)	8.65	6.47
Crude protein (%)	25.1	24.7
Crude fat (%)	4.51	14.13
Crude fiber (%)	5.05	3.33
Crude ash (%)	6.97	5.6
NFE (%)	49.72	45.77
Energy (kcal)*	339.9	409.1
Hardness (kg/cm^2)	27.6	12.4
Fat energy (%)	11.94	31.46

*Calculated by multiplying crude protein (4), crude fat (9), and NFE (4)

Lee index was measured the naso-anal lengths, the body weight, and calculated the Lee index between the study groups. This index was calculated by dividing the cube root of body weight (g) by naso-anal length (cm) and multiplying the result by 1000. Lee Index>300 indicated obese status. Obesity groups and the control groups were maintained for 3-4 months (175 days). Both groups of mice were terminated and measured the planned variables. For termination, rats were anesthetized with intraperitoneal injection using a ketamine cocktail. Xylazine and acepromazine at a dose of 0.1 mL / 10g BW, then we obtained the right kidney to 10% formalin buffer for IHC ET-1 analysis of paraffin block tissue.

ET-1 Serum Analysis: The blood has drawn from the tail, and retro-orbital vessel, then centrifuged at 3000rpm to extract serum. A commercial Rat Endothelin 1 ELISA Kit PicoKine ™ (Boster Biological Technology, Pleasanton CA, USA, Catalog # EK0952) was used to assess for circulatory ET-1 level, which followed the manufacturer's manual. Data wereanalyzed by SPSS with all data presented by the mean and standard deviation.

Immunohistochemical Staining Procedures: We used 4 μm paraffin sections of the right kidney sample on the warming block in a 60ºC oven for 30 minutes.

The next step to deparaffinization and rehydration procedure begins with successive submersion in Xylene: twice each for 5 minutes 100%, 90%, 80%, and 70% ethanol concentration for 5 minutes. The rehydration antigen is given for 10 minutes using citrate buffer at 103°C, then incubatedto block endogenous peroxidase activity with 3% H2O2 for 10 minutes at room temperature, rinsed for three times each time for three minutes with Tris-buffered saline (TBS), and then incubatedfor 30 minutesin 10% bovine serum albumin (BSA) at room temperature in a humidified room. The tissue area that has been circledby the PAP penon glass objectsand dripped with primary antibodies, monoclonal anti-ET-1 (GeneTexCat No. GTX22786) that has been diluted using a 1:250 dilution and incubated at room temperature for 2 hours. The sections wererinse three times for three minutes each with PBS and incubated for 30 minutes with anHRP conjugated secondary antibody at room temperature. Then, they are rinsed and dropped with diaminobenzidine (DAB) substrate, and then balanced with hematoxylin. The final step is dehydrated and mounted with Entellan medium.

Right kidney samples prepared with ET-1 immunostaining that were analyzed and mounted, then assessed. ET-1 expression was reported in glomeruli.In each specimen, the staining intensity of ET-1 recorded by two independent observers in 10 adjacent high power fields (±100 glomeruli) and graded as 0 (staining not detectable), 1 (minimal immunostaining in some cells), 2 (weak immunostaining intensity in all cells) and 3 (strong staining in all cells). The mean grade was calculated by an averaging grade assigned by the two authors and approximating the arithmetical mean to the nearest unity.[10]

Glomerular Impairment: The glomerular injury was scored based on PAS staining. Scoring was done by grading mesangial expansion by looking at the pink color of the mesangial matrix and glomerular basal membrane. The lesions were graded on a scale from 0 to 4: 0: normal; 1: the injury involves less than 25% of the glomerulus; 2: the injury involve 25 to 50% of the glomerulus; 3: the injury involves 50 to 75% of the glomerulus; and 4: the extensive damage affecting more than 75% of the glomerulus.[11]

Statistical Analysis: Data were analyzed using SPSS version 18. Quantitative variables were expressed in means ± SDs. Shapiro–Wilk test was used to analyze the normality of distributions. The comparison of quantitative data was compared using a t-test to analyze variables with normal distribution and equal variances. Mann–Whitney U test was used to analyze the differences when data did not correspond to a normal distribution andthe graphics using Prism 6; GraphPad Software.A p-value of < 0.05 was considered statistically significant. Correlation analysis was measured by *spearmen's* rho.

Results and Discussion

Obesity Status: Table 2 shows that the obesity status of each group. It offers significant differences (p= 0.000) between the obese and the control groups after being fed for 63 days and maintenance until the day before terminated (175 days) (p=0.002). There was a significant increase in the Lee index of the obese group compared to the control group.

Excess weight gain and obesity may cause renal dysfunction, including glomerular hyperfiltration, sodium retention, enlargement of Bowman's space, increased glomerular cell proliferation, mesangial matrix expansion, inflammatory cell infiltration, and tubulointerstitial lesions. These early renal alterations can progress to more intense and diffuse lesions in the kidneys, such as focal segmental glomerulosclerosis, proteinuria, and tubulointerstitial lesions, observed in prolonged obesity.[12]

Table 2. Comparison Lee index between control and obese rats group.

	63 day		175 days	
Variable	**Control (Mean±std dev)**	**Obese (Mean±std dev)**	**Control (Mean±std dev)**	**Obese (Mean±std dev)**
Weight (gr)	283.25±44.98	325.50±27.33	341.50±50.07	417.125±37.68
Length (cm)	21.94±0.73	22.00±0.65	23.00±0.65	23.56±0.68

Calculated with an independent sample t-test. *p<0.05; ** p<0.001

Systemic level of ET-1: Table 3 shows that the level of serum ET-1 is not increased significantly (p>0.05). This is relevant to earlier studie[13], has been demonstrated that circulatory levels of ET-1 might not directly reflect the full physiological. Normally circumstances, ET-1 produced by endothelial cells is released abluminal and, therefore, the circulating level of ET-1 is thought to be the result of spillover,the half-life of ET-1 plasma is less than 2 min, owing to its efficient harvesting in the pulmonary or renal vascular beds.[14] ET-1 appears to be foremost a locally acting paracrine substance, rather than a circulating endocrine hormone. Besides, it is vital to bear in mind that ET-1 plasma concentration is dependent not only on generation but also on renal and receptor-mediated clearance and enzyme-mediated metabolism of the peptide.[13] Nevertheless, ET-1 plasma concentration could be useful as an index of ET-1 synthetic activity and venous plasma. ET-1 concentrations have been used as markers for the endothelial synthesis of the peptide.[7,13]

Table 3. Level of serum ET-1 (pg/ml)

Group	n	Mean±std dev	Median (Range)	*p*-value*
Control	8	9.5±1.60	9 (8-12)	
Obese	8	11.37±1.85	10.5 (10-15)*	0.062

*Calculated with a Mann Whitney U test *p*>0,05

Interpretation of ET-1 immunohistochemistry: The glomerulus is the functional filtration unit of the kidney. Glomerular injury is frequently associated with progressive CKD. ET-1 expression is positive staining of the glomeruli by Immunohistochemistry (IHC) shows a significant difference between the obese group and the Control group, *p* value=0.03 (*p*<0.05)(Figure 1). William et al. investigated the immunolocalization of ET-1 in the vasculature and glomerulus of the normal kidney. It is abundantly expressed in the endothelium of glomeruli, arteries, veins, and capillaries. Although ET-1 was rarely detected in the mesangium of the normal kidney[15], By contrast, in stress-induced condition shows mesangial localization of ET-1 peptide consistent in cultured human mesangial cells.[15,16] ET-1 activation can escalate the progression of chronic kidney disease (CKD) via ET-1 and ETA mediated pro-fibrotic pathways, playing a role in conditions such as diabetic nephropathy (DN), hypertensive nephropathy and focal segmental glomerular sclerosis (FSGS).[12]

The local effect expression of ET-1 in the kidney, especially in the glomerulus, was significantly different between the obese group and the control group (p> 0.05). Glomerular injury and scarring is the hallmark of CKD progression regardless of the underlying disease. Increased production of ET-1 has been found in multiple conditions associated with CKD, including diabetes and insulin resistance, obesity, and dyslipidemia. ET-1 binding of ETA stimulates renal fibroblasts, driving increased extracellular matrix synthesis, inducing collagen production, and mesangial cell proliferation with the secretion of fibronectin and type IV collagen furthering scar formation.[12]

Figure 1 Light microscopy of kidney sections immunostained for endothelin-1 (ET-1, 400x). Immunostaining scores were graded as follows; (1a) score 0 =No staining, (1b).score 1= minimal immunostaining in some cells; (1c). Score 2 = weak immunostaining intensity in all cells; (1d). Score 3= strong staining in all cells. 1e. Semiquantitative analyses of kidney sections stained for ET-1 scores are reported as means±SE. The significance level for the obese group compared to the control group **Mann Whitney u test *p*=0,003 (p<0.05)

Glomerular Impairment: The effect of increasing ET-1 expression in the glomerulus correlates with the increase in mesangial expansion in the glomerulus can be seen in figure 2. Grossly, endothelial cells comprise 45%, mesangial cells 25%, and epithelial cells 30% of all cellular elements of the glomerulus. The mesangial cell is PAS-positive (pink color). An increase in extracellular matrix implies an increase in mesangial matrix or basement membrane material. In the former instance, this may be in a uniform and diffuse pattern in all lobules or cause a nodular appearance to the mesangial healed proliferative lesions are PAS-positive. It leads to the obliteration of capillaries and solidification of all or

part of the tufts. Sclerosis may be associated with the destruction of the urinary space by collagen and an increased extracellular matrix in the capillary tufts. An older and less precise term is glomerular hyalinization. Complete sclerosis is known when the entire glomerulus is involved. When the entire glomerulus is involved, this is known as complete sclerosis[17], but no data reaches score 4 (diffuse sclerosis) in this study. Figure 2B revealed discrete and focal morphological changes in glomeruli indicate early glomerular impairment in the obesity group than in the control group ($p<0.05$).

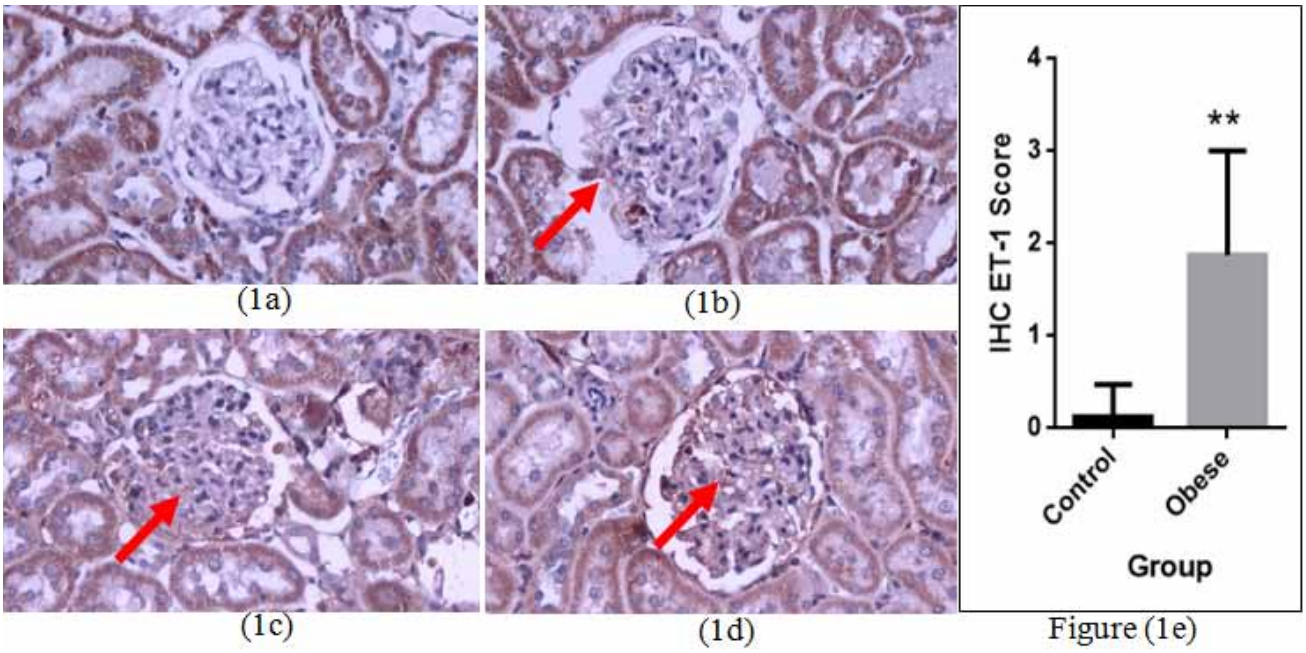

Figure 2A. Light microscopy of PAS staining of the glomerulus from Control dan Obese (400x). The mesangial expansion score of glomeruli was graded as follows: 0 represents no lesion (2a), 1 represents the mesangial expansion of 25–50%=2; (2b), >50–75%=3 (2c), (2e). Semiquantitative analyses of kidney sections stained for the PAS staining score are reported as means±SE. The significance level for the obese group compared to the control group. *Mann Whitney u test *p*=0,03 (p<0.05).

The Correlation Glomerular ET-1 glomerular expression and glomerular impairment: A significant correlation between ET-1 expression and glomerular impairment is based on PAS staining. The spearman's rho correlation value is 0.765, indicates that the direction of correlation is positive with strong correlation strength at the p= 0.001. The mesangial matrix is a contractile function important in changing the filtration coefficient. Accumulation extracellular matrix to be responsible for progressive CKD involves glomerular sclerosis and interstitial fibrosis.Although glomerular endothelial cells are probably the principal source of ET-1 in normal conditions, glomerular ET-1 can increase in the presence of proteinuric renal disease. ET-1, probably secreted abluminal from glomerular endothelial cell modulates podocyte and mesangial cell structure and function. The mesangial cell itselfmakes it possible to produce a significant amount of ET-1.[17] We conclude that the effects of ET-1 can cause changes in glomerular filtration area and intraglomerular hemodynamics.

Conclusion

In summary, our results revealed the local effect expression of ET-1 in the kidney, especially in the glomerulus, leads to glomerular injury as a hallmark of CKD progression regardless of the underlying disease.However, systemic or circulating ET-1 level is detected from serum might not directly reflect the local expression at kidney injury in obesity. Further studyis needed to assess the relationship between GFR, metabolic disturbances in the blood to determine the degree of kidney function, and what about the receptors (ETA and ETB receptor).

The Study of Antiallergic Activity of the Phytocollection of "Phytoallergoderm"

Bakhtiyor Imamaliev[1], Ziyoda Fayzieva[1]

[1]*Associate Professor, Tashkent Pharmaceutical Institute, Tashkent, Uzbekistan*

Abstract

The antiallergic activity of "Phytoallergoderm" phytocollection was studied, which was recommended for topical treatment of a topic dermatitis, on the model of allergic contact dermatitis, caused by skin application of turpentine. The following drugs were used as comparison: antihistamine "Psilo-Balsam" gel, manufacturer: OJSC "Nizhpharm" Russia; glucocorticoid (topical steroid) "Dermoveit" cream 0.05%, manufacturer: "Glaxo Smith Kline Pharmaceuticals SA" Poland; zinc product "Zinc" ointment, manufacturer: NPP "Radiks" Uzbekistan.

During the experiment, it was found that the test drug has a reliable anti-allergic activity, which is clearly caused of decrease in total allergic reactions, in the reduction of recovery time and in a decrease in the dynamics of the severity of allergic reactions. Also, the study of antiallergic activity showed that the test drug has a comparable antiallergic activity with the etalon synthetic drug.

The foregoing indicates the presence of a reliable anti-allergic activity of the phytocollection "Phytoallergoderm", which is comparable to reference synthetic preparations.

Keywords: *Atopic dermatitis, experimental allergic contact dermatitis, turpentine, phytocollection.*

Introduction

Atopic dermatitis (ATD) is a chronic allergic skin disease with a genetic predisposition and complex development mechanisms that lead to impaired immune response, the development of allergic inflammation and the appearance of a specific symptom complex, which is characterized by age-related features of the localization and morphology of the inflammation hearth, as well as excruciating skin itching[1]. ATD is a socially significant problem due to its wide prevalence, as well as a significant impact on the quality of life, limitation of working capacity up to disability (Elisyutina, 2014).[2]

Today, glucocorticosteroids are widely used in the external treatment of atopic dermatitis, which, despite their effectiveness, have a number of side effects and often cause complications in the form of pyoderma (Elisyutina, 2014 and Skripkin, 2000).[3] However, the treatment of skin diseases with medicinal plants remains a promising direction, since medicinal plants act in a complex manner, and being non-toxic rarely cause adverse reactions (Skripkin, 2000 and Imamaliev, 2015)[4].

Based on the foregoing, we have developed a phytocomplex (phytocollection) "Phytoallergoderm", recommended for external treatment of a topic dermatitis, and having the following composition: tricolor violet grass; hop cones; licorice roots and; flowers of chamomile pharmacy, the leaves of nettles; flowers of marigolds medicinal; the grass of horsetail (Kochueva, 2014)[5].

The aim of the study was to investigate the antiallergic activity of phytocollection "Phytoallergoderm", recommended for the local treatment of atopic dermatitis[6].

Materials and Method

The study was carried out in accordance with the requirements of the current GLP regional standard- "good laboratory practice", as well as in compliance with all the rules and regulations of the "European

Convention for the Protection of Vertebrate Animals used for experimental and scientific purposes". In the study, were used healthy animals, that have passed their quarantine for at least 10-14 days.

A study of the anti-allergic activity of the drug was carried out on a model of allergic contact dermatitis caused by skin application of turpentine (turpentine oil) (Kochueva, 2014). Turpentine is known to be an industrial allergen, and external exposure to turpentine causes a strong allergic reaction, including dermatitis. It is known that when an allergen is exposed, histamine and a number of other inflammatory mediators are released, which contribute to the formation of an allergic reaction.

As comparison drugs (control drugs) were used:

– Antihistamine "Psilo-Balsam" gel for external use 1% in 20 g (tube), manufacturer: OJSC Nizhpharm, Russia, active ingredient: Diphenhydramine 1%;

– Glucocorticoid product (topical steroid) "Dermoveit" cream 0.05%, 25 g each (tubes), manufacturer: "Glaxo Smith Kline Pharmaceuticals SA" Poland, active ingredient: Clobetasol 0.05%;

– Zinc product "Zinc" ointment, manufacturer: "Radiks" Company, Uzbekistan, active ingredient: Zinc oxide 10%.

To study the antiallergic activity, the tincture was prepared the collection by GF-XI, in the ratios of 1:5, 1:10, 1:15 (the water was added taking into account the water absorption coefficient CV = 2.5 ml/g). The solids content of the infusion made up 2.97% (1: 5), 1.96% (1:10) and 1.47% (1:15) respectively.

The experiments were carried out on 60 white mice (both sexes) with a body weight of 18-22 g, which were divided into groups of 6 animals in each. In the experiment were used only healthy animals that have passed quarantine for at least 10-14 days.

To do this, turpentine was applied to the animals daily and once for six days on pre-depilated skin of the right femoral part (hair was cut out a day before the experiment), the depilation area was 2.25 cm^2 (1.5 x 1.5 cm). Turpentine was applied in the form of a moistened cotton swab, while the exposure diameter was in the form of a circle, with a diameter of about 1 cm and an area about 0.785 cm^2. As a result, pronounced morphological changes in the skin were observed in the animals, accompanied by skin itching, anxiety, lichenization, and hyperkeratosis.

Then, on the next day after the last application of turpentine, the animals of the test groups and comparison groups were injected once and daily with drugs until complete recovery:

1. Control group (control) - animals without treatment;
2. Test group No. 1 – the affected skin of the animals was smeared with 2.97% infusion of phytocollection (through a cotton swab), at a dose of 445.5 mg/kg (0.3 ml/20 g);
3. Test group No. 2 – the affected skin of the animals was smeared with 1.96% infusion of phytocollection (through a cotton swab), at a dose of 94 mg/kg (0.3 ml/20 g);
4. Test group No. 3 - the affected skin of the animals was smeared with 1.47% infusion of phytocollection (through a cotton swab), at a dose of 220.5 mg/kg (0.3 ml/20 g);
5. Comparison group (reference group) No. 1 - 1% Psilo-Balm gel was applied to the affected skin at a dose of 35 mg/kg (0.07 g / 20 g);
6. Comparison group (reference group) No. 2 - on the affected skin was smeared with 0.5% Psilo-Balm gel, at a dose of 18 mg/kg (0.07 g/20 g);
7. Comparison group (reference group) No. 3 - 0.05% Dermoveit cream was applied to the affected skin at a dose of 1.75 mg/kg (0.07 g/20 g);
8. Comparison group (reference group) No. 4 - 0.025% Dermoveit cream was applied to the affected skin at a dose of 0,88 mg/kg (0.07 g/20 g);
9. Comparison group (reference group) No. 5 - 10% Zinc ointment was applied to the affected skin at a dose of 350 mg/kg (0.07 g/20 g);
10. Comparison group (reference group) No. 6 - 5% Zinc ointment was applied to the affected skin at a dose of 175 mg/kg (0.07 g/20 g);

During the experiment, a skin condition was assessed daily, according to the severity of inflammation and skin reaction. The severity of signs of inflammation (hyperemia, edema, pain) was evaluated in arbitrary units:

0 – absence of visible reactions;

1 – pale pink erythema throughout the site or along its periphery;

2 – bright pink erythema throughout the site or along its periphery;

3 – red erythema throughout the site;

4 – skin infiltration and edema (thickening of the skin fold) in the presence or absence of erythema;

5 – erythema, severe infiltration, about local ulceration (necrosis), hemorrhages, about the formation of crusts are possible.

The criterion for assessing pharmacological activity was:

– Reduction in the amount of an allergic reaction (inflammation), compared with the control;

– Reduction in the recovery time of animals, compared with control;

– A decrease in the dynamics of an allergic reaction (inflammation), as compared with control.

To assess the amount of an allergic reaction, after the experiment was completed, the skin reaction scores for each animal were summarized, observed throughout the entire period of the experiment (during the treatment period), and the antiallergic activity of the drug was judged by the amount received.

When conducting the experiment, the room temperature is in the range of 18-25^0 C and the relative humidity in the range of 40-70%.

The results were processed by the method of variation statistics according to the Student criterion at p= 0.05 (Khabrieva, 2005 and Mirobov, 2012). The tables show the arithmetic mean values (M), the corresponding standard error of the mean value (m), student criterion (t), the number of samples (n), and confidence limits (lower confidence limit/upper confidence limit).

Results

When assessing the changes in total allergic reaction, it was found (Table 1) that the test drug in doses of 445.5 mg/kg (54.1%), 294 mg/kg (62.8%) and 220.5 mg/kg (56, 4%) had a reliable antiallergic effect. In this case, the highest antiallergic effect in the test drug was observed at a dose of 294 mg/kg.

In the case of preparation “Psilo Balm” at doses of 35 mg/kg (47, 6 %) and 18 mg/kg (51.2%) also observed a significant anti-allergic effect. At the same time, the highest anti-allergic effect of the drug “Psilo-Balm” was observed at a dose of 18 mg/kg.

In the case of the drug “Dermoveit” at a dose of 1.75 mg/kg (50.0%), a significant anti-allergic effect is observed. However, at a dose of 0.88 mg/kg (12.6 %), although an antiallergic effect was observed, it was not significant. Moreover, the highest antiallergic effect of the drug “Dermoveit” was observed at a dose of 1.75 mg/kg.

Table 1: Results study of antiallergic activity (according to the total allergic reaction) (M±tm; p = 0.05; n = 6)

Group	Result	% effect
The control	41.00 (34.07÷ 47.93)	-
“Fitosbor” (at a dose of 445.5 mg/kg)	19.17 (14.84÷ 23.49)	54.1 %
“Fitosbor” (at a dose of 294 mg/kg)	18.67 (15.24÷ 22.09)	62.8%
“Fitosbor” (at a dose of 220.5 mg/kg)	21.33 (13.21÷ 29.45)	56.4 %
“Psilo-Balm” (at a dose of 35 mg/kg)	21.50 (16.63÷ 26.37)	47, 6 %
Psilo-Balm (at a dose of 18 mg/kg)	20.00 (14.29÷ 25.71)	51.2 %
Dermoveit (at a dose of 1.75 mg/kg)	20.50 (14.88÷ 26.12)	5 0, 0 %
Dermoveit (at a dose of 0, 88 mg/kg)	35, 83 (27.69÷ 4 3, 97)	12.6 %
“Zinc ointment “ (at a dose of 35 0 mg/kg)	17.17 (14.02÷ 20.31)	58.1%
“Zinc ointment “ (at a dose of 175 mg/kg)	17.17 (13.11÷ 21.23)	58.1%

In the case of "Zinc Ointment" at doses of 350 mg/kg (58.1%) and 175 mg/kg (58.1%) also observed a significant anti-allergic effect. Meanwhile, the highest anti-allergic effect of the drug "Zinc Ointment" was observed in both doses of 350 mg/kg and 175 mg/kg.

When the experimental data on the decrease in the total allergic reaction of the most effective doses of the test drug compared with the most effective doses of the comparison drugs, it turned out that the difference between them was not statistically significant.

When assessing the change in the timing of recovery, it was found (Table 2) that the test drug in doses of 445.5 mg/kg (40.6%), 294 mg/kg (48.7%) and 220.5 mg/kg (45.9 %) significantly reduces the recovery time. In this case, the greatest decrease in the recovery time for the test drug was observed at a dose of 294 mg/kg.

In the case of the Psilo-Balsam at doses of 35 mg/kg (48.6 %) and 18 mg/kg (44.3 %), a significant decrease in the recovery time is also observed. In this case, the greatest decrease in the recovery time for the drug «Psilo-Balm» was observed at a dose of 35 mg/kg.

In the case of the drug "Dermoveit" at a dose of 1.75 mg/kg (44.3 %), a significant decrease in the recovery time was observed. However, at a dose of 0.88 mg/kg (5.7 %), although a decrease in recovery time was observed, it was not significant. At the same time, the largest reduction in the recovery time for the Dermoveit drug was observed at a dose of 1.75 mg/kg.

In the case of preparation «Zinc Ointment « at doses of 350 mg/kg (51.4 %) and 175 mg/kg (51.4 %) also observed a significant decrease in recovery terms. The greatest reduction in drug recovery terms «Zinc Ointment « is observed in both dosages of 350 mg/kg and 175 mg/kg.

If we compare the experimental breakdown by the reduction of the time of recovery the most effective doses of comparator drugs, the difference between them was not statistically reliable.

Table 2: The results of the study of antiallergic activity (by the timing of recovery) (M±tm; p = 0.05; n = 6)

Group	Result	% effect
The control	11.67 (9.95÷ 13.38)	-
"Fitosbor" (at a dose of 445.5 mg/kg)	6.50 (5.62÷ 7.38)	40.6 %
"Fitosbor" (at a dose of 294 mg/kg)	6.33 (5.25÷ 7.42)	48.7%
"Fitosbor" (at a dose of 220.5 mg/kg)	6.67 (4.71÷ 8.62)	45.9 %
"Psilo-Balm" (at a dose of 35 mg/kg)	6.00 (5.06÷ 6.94)	48.6 %
Psilo-Balm (at a dose of 18 mg/kg)	6.50 (5.40÷ 7.60)	44.3 %
Dermoveit (at a dose of 1.75 mg/kg)	6.50 (5.21÷ 7.79)	4 4.3 %
Dermoveit (at a dose of 0, 88 mg/kg)	11.00 (7.75÷ 14.25)	5.7 %
"Zinc ointment " (at a dose of 35 0 mg/kg)	5.67 (5.12÷ 6.21)	51.4%
"Zinc ointment " (at a dose of 175 mg/kg)	5.67 (5.12÷ 6.21)	51.4%

When assessing changes in the dynamics of an allergic reaction (inflammation), it was found (Table 3) that the test drug at doses of 445.5 mg/kg and 294 mg/kg already on the 3rd day of treatment, and at a dose of 220.5 mg/kg by 4 the day of treatment there was a significant decrease in the severity of the allergic reaction, which was traced to the end of treatment. In that case, the most pronounced decrease in the severity of the allergic reaction in the test drug was observed at a dose of 294 mg/kg.

In the case of the Psilo-Balsam preparation at doses of 35 mg/kg and 18 mg/kg, a significant decrease in the severity of the allergic reaction was observed already on the 4th and 3rd day of treatment, which can be traced to the end of treatment. Meanwhile, its most pronounced decrease in the severity of the allergic reaction in the Psilo-Balsam, which was observed at a dose of 18 mg/kg.

In the case of the drug « Dermoveit « at a dose of 1.75 mg/kg already on the 3rd day of treatment, there

was a significant decrease in the severity of the allergic reaction, which can be traced to the end of treatment. However, at a dose of 0.88 mg/kg, a significant decrease in the severity of an allergic reaction was observed only on the fifth day. In that case most of its marked reduction in severity of an allergic reaction in preparation « Dermoveyt « was observed at a dose of 1.75 mg/kg.

In the case of the drug "Zinc ointment" in doses of 350 mg/kg and 175 mg/kg already on the 4th and 3rd day of treatment, there was a significant decrease in the severity of the allergic reaction, which can be traced to the end of treatment. At the same time, its most pronounced decrease in the severity of the allergic reaction in the drug « Zinc Ointment « was observed at a dose of 175 mg/kg.

If we compare the experimental data by the decrease of the dynamics of an allergic reaction (inflammation) of the most effective dose of the drugs under experiment and the most effective doses of comparator drugs, it reveals that the experimental data of the test drug and «Psili Balm» and « Dermoveyt « are comparable, and in the case the «Zinc ointment», there was no significant difference.

Table 3: The results of a study of changes in the dynamics of an allergic reaction (inflammation) (M±tm; p = 0.05; n = 6)

Days Treatment	The control	"Fitosbor" (at a dose of 445.5 mg/kg)	"Fitosbor" (at a dose of 294 mg/kg)	"Fitosbor" (at a dose of 220.5 mg/kg)

Discussion

There are some data in the literature analyzing the effectiveness of antiallergic drugs. One interesting study analyzed the results of the treatment in forty-one patients[7]. Authors observed a significant difference between the acute radiation dermatitis scores on the test and the control arms[8]. Mometasone furoate cream reduced the stages of acute radiation dermatitis when the radiotherapy used over 6000 cGY[9]. Compared to the control arm, local application of mometasone furoate significantly reduced the singes of dermatitis like itching and pain regardless of the radiotherapy dose (Liao, 2019)[10].

Bao et al conducted a trial treating one hundred and sixty-four cases of allergic rhinitis with the Chinese medicine Biminkang mixture. That mixture was mainly included the Kazak folk herb Artemisia rupestis. They compared the results of 52 cases of allergic rhinitis were treated with the patent medicine Biyankang. The results showed that Biminkang mixture was an effective drug in treating allergic rhinitis (Bao et al, 1997)[11].

However, another study concluded investigating the overall effects of herbal therapy against allergic pathologies concluded that there is an existence of a number of clinically important interactions, although cause and effect relationships have not always been established. Herbs and drugs may interact either pharmacokinetically or pharmacodynamically. Yet, for many of the interactions discussed here, the understanding of the mechanisms involved is incomplete. Taking herbal agents may represent a potential risk to patients under conventional pharmacotherapy (Izzo, 2005)[3].

Based on the data obtained, we can conclude that the test drug has a reliable antiallergic activity, which is reliably manifested in the decrease of total allergic reaction, in a reduction in the recovery time and in a decrease of the dynamics of the severity of allergic reactions[4]. Also, the study of antiallergic activity showed that the tested drug has a comparable antiallergic activity with the reference and synthetic drugs, since the experimental pharmacological activity of the most effective doses of the drug, which we tested and the reference synthetic drugs have no statistically significant difference[9].

Conclusion

The antiallergic activity of the phytocollection for the treatment of eczema in comparison with the reference drug was studied. According to the results of the study of antiallergic activity, the testing drug has a reliable antiallergic activity, which is comparable to reference synthetic drugs.

Abstract

Objective: This research aims to explore the effect of social support on the health of pregnant women in the Minangkabau matrilineal community, Indonesia, from the perspective of the husbands, community leaders, health cadres and workers.

Method: This study employs qualitative research, while purposive sampling techniques were used to select 51 informants comprising 18 husbands, 14 community leaders, eight medical workers, and 11 health cadres. In addition, the data collection method involved focus group discussions and in-depth interviews and was analyzed using content analysis.

Results: The findings showed the social support of the Minangkabau matrilineal community towards pregnant women was non-optimal and was in the form of emotional, informative, and instrumental assistance.

Conclusion: The improvement in the health status of pregnant women is achievable with an intervention to increase social support, particularly in the Minangkabau matrilineal community, West Sumatra.

Keywords: *Matrilineal; Pregnant Women; Social support.*

Introduction

According to the 2015 Inter-Census Population Survey (SUPAS), Maternal Motherly Rate (MMR) in Indonesia is 305 per 100,000 live births.[1] Furthermore, interventions to reduce this are majorly focused on increasing access to trained health workers, and obstetric emergencies management.[1] The factors causing non-access comprise subordinate societal status, culture, and religion[2], and results in the inability of women to refer to pregnancy-related complaints, difficulty in taking initiatives, and medical treatment delays.[3] Therefore, to enhance women activities in health services, empowerment is a necessary component of the healthcare system.[4]

Several myths, stereotypes, and labels about women's roles are inseparable from the prevailing social

construction because the origin is the socialization process in the family, education system, and other communal environments. In addition, the kinship system is a significant aspect of social structure and, in Indonesia, comprises patrilineal and matrilineal. While patrilineal refers to a community custom where the descent line originates from the father's side, matrilineal relates to the mother's side.

The Minangkabau are the only Indonesian ethnic practicing the matrilineal system and the largest adherents globally. Moreover, the women there hold a more important position because of the presence of a child signifies the next generation.

However, the maternal health and antenatal care overview in this region shows an appalling condition. Hence, K4 coverage in West Sumatra province is at 73% while the lowest is Tanah Datar District, with a 3-year decline comprising 72.4% (2015); 70.6% (2016) and 64.06% (2017).[5]

There is little research focuses on the social support of pregnant women in matrilineal societies. Therefore, this study contributes information about the subject matter, particularly in the Minangkabau ethnic group, from the perspective of the husbands, community leaders, health cadres, and workers.

Research Method

Research Design: A qualitative design was employed to determine the social support of the Minangkabau matrilineal community for the health of pregnant women, and the study showed emotional, informative, and instrumental assistance.

Research Informant: Fifty-one native Minangkabau informants were selected by purposive sampling techniques and comprised husbands, community leaders, health cadres, and medical workers. Furthermore, this was done in collaboration with the head of Subdistrict, the head of the Public health center, *Wali Nagari, Wali Jorong*, public figures, and other community groups, including the PKK.

Research Sites: The study was conducted in Sungayang and Pariangan Subdistrict, Tanah Datar District, and West Sumatra Province in Indonesia.

Data Collection Technique: The data collection method involved detailed informant interviews and focus group discussions.

Data Analysis Technique: The data were analyzed using content analysis and information triangulation techniques.

Research Result

Emotional Support: The focus group discussions and in-depth interviews of the husbands, community leaders, and health workers showed emotional assistance from the community as a form of social support towards pregnant women's health. However, this was insufficient because the attitude was not widespread. Also, emotional support entails attention, empathy, and concern.

" .....In our area, there are still a small number of people who provide support to pregnant women"(Sytoma03)

Local health workers affirmed the absence of special support for pregnant women in the region.

" …special support for pregnant women "(Sytnks 01)

Furthermore, certain husbands expressed emotional support by giving attention and encouragement to their wives.

*"……*giving attention to the wives)*....(*sysm02; sysm04; sysm06)

"……cheering the wives*(*sysm02; sysm04; sysm06)

The cadres confirmed provision of emotional support by husbands in the form of attention giving.

"……*was given attention by the husband*…. (sykdr01, sykdr02, sykdr04, sykdr05)

Also, the cadre disclosed good emotional support from the local community.

"…*several social support given to pregnant women by the* community…."*(Kpr01)*

According to certain community leaders, communal emotional support involves inquiry on the condition of pregnant women.

"...the community asks about the condition of pregnant women…."(tomapr01, tomapr02, tomapr03, tomapr04, tomapr05, tomapr06, tomapr07)

The health workers reinforced an additional communal effort of communication and sharing of

pregnancy experiences with the women during available periods.

"…the community talks to pregnant women about prenatal experiences…"(Prnks02)

Also, health professionals revealed a custom of the local community culture, particularly for first-time pregnant women, called the 7-month tradition.

"…the community carries out a festive seven-month-of-birth ceremony, involving preparation of a pumpkin meal, particularly for the first child " (prnks03)

Therefore, there is a consensus by cadres, health workers, and community leaders on observable daily communal empathy for pregnant women through inquiry on the pre-natal stage and problems faced.

Informative Support: Informative support entails the provision of advice, direction, or feedback, to positively influence the recipient. Furthermore, the interviews with health workers revealed this form of assistance through the supply of information, advice, and suggestions to conduct pregnancy checks with health workers.

"the community reminds pregnant women to check with midwives or at the health centers …."(Prnks02 dan Prnks04).

The cadre understands the duties and functions of providing wellbeing information to pregnant women. Hence, women call on health workers.

"….*the cadres provide information to pregnant women….." (kpr02).*

The husbands, community leaders, health workers, and cadres affirm the participation of the community through encouragement to check with health workers rather than traditional healers. Also, pregnant women are actively reminded of the examination schedule.

"people inquire about the condition of pregnant women, share food restrictions and give reminders to check up "(*Tomapr 01-07)"*

Similarly, certain husbands provide informative support by constantly prompting the wives about the nutritional needs, check-up schedule, and consumption of Fe tablets.

"…..*there are husbands who do not care about the pregnancy* …"(sykdr02)

"….a small number of husbands remind their wives to attend pregnancy checkup.." (prkdr05)

The health workers claim the information offered to pregnant women by the public is usually based on related personal experiences or habits. This information is conveyed informally at spare times.

"…the community socializes with pregnant women to share antenatal experiences….. "(Prnks02)

"….occasionally, the community reminds pregnant women to check with the midwife or at the public health center.…" (Prnks03).

Instrumental Support: The interviews with health cadres showed instrumental support by the Minangkabau matrilineal community through the availability of privately owned public transportation to serve as an ambulance to transport pregnant women to more adequate facilities.

"…the cars of people in the village are borrowed during an emergency " (sykdr01).

"….*several residents believe providing personal cars to transport pregnant women to the hospital brings fortune, and hence, give permission*…."(sytoma05)

Discussion

Pregnant women require adjustments to both physical and psychological changes. Furthermore, emotional support is needed due to the inability of some to properly acclimatize. These women share the comfort and discomfort felt, pregnancy development and birth concerns to trusted persons.[6]

Edmons et al. (2011) posit four support types usually obtained by pregnant women, comprised of practical assistance with routine activities, information or advice, emotional support and guarantees, and resource or material provision. Furthermore, the most frequent support includes good mothers, mother-in-law, sister-in-law, and husband.[6]

Socio-cultural influences affect pregnant women and families during the welcoming period. In addition, several ceremonies are carried out during the3rd and seventh month, birth and postpartum periods based on the customs of each region.[7]

Pregnancy is a crisis phase in the life cycle of a woman, and people in various cultures pay attention to this. Also, the several rituals required indicates the community views pregnancy as an extraordinary event. Therefore, public attention towards pregnant women is a form of social support.[8] The traditional philosophy of "badunsanak" (a strong solidarity culture with fellow kin group members) identified among the Minangkabau people. Furthermore, this relationship is apparent in the social support practiced by family members. Informative social support is easier to provide due to efficiency, effectiveness, ability to share through any media, without the requirement of personal information.[7]

Bagalkot et al. (2018) found informal peer-to-peer female networks to play a major role in Indian pregnant women care, through the sharing of stories, experiences and general knowledge.[9]

Therefore, a mindset of women support is necessary to foster the ability to solve related and family problems, including facility choice, means of transport, alternative house and children care, costs, fulfillment, among others. Moreover, the habit of living in "a gadang house" (large house) consisting of several families in the matrilineal Minangkabau community enables the provision of this assistance. However, this living together habit has begun to fade, but the principles of cooperation and collaboration remain strongly maintained in their daily lives.

Therefore, the basic instrumental support encompasses direct assistance, comprising finances, facilities, personnel, and other related assistance. This is aimed at facilitating pregnancy care and monitoring. Furthermore, concern and encouragement from the family makes pregnant women feel cared for and motivated to be careful.[6,10]

Also, a feature of the Minangkabau community is the deliberation among the tribes where there are problems faced.

Conclusion

The research shows the social support of the Minangkabau community towards the health of pregnant women is not optimal, although a unique culture and potential exists. The assistance provided is limited to emotional, informative, and instrumental support. Therefore, further studies on the factors influencing social support are needed for use as a basis for making health promotion interventions models to the community based on local culture. Through this, improving the health status of pregnant women in Minangkabau Indonesia is achieved.

Understanding Patient Compliance During Orthodontic Treatment

Snigdha Pattanaik

Associate Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The practice of orthodontics has sometimes been described as involving two distinct but related processes, the physiological-mechanical and the psychological-educational. Proper application of appliances to the physiological-mechanical is essential to successful treatment, but no amount of attention by the orthodontist to sophisticated techniques is likely to have much effect, if those efforts are met with resistance or indifference on the part of the patient. But how does one counter that indifference or overcome that resistance? How does one even understand it? This is a most serious and baffling problem, because it is very difficult for those in the health professions to distinguish which patients will be compliant and which will not, and to know what to do about it.

Keywords: *Patient Compliance, Orthodontic Treatment, Behavioral Pattern.*

Introduction

For centuries, medical practitioners have been concerned with unsuccessful outcomes of treatment. Physicians have sometimes rationalized their failures as resulting from an incurable illness, ineffective medication, or divine interference. Some research conducted in the past twenty years suggests that unsuccessful outcomes are not so much a function of patient biology, drug potency, or heavenly interference as they are a matter of noncompliance. The medication may not have been taken in the prescribed way, or may not have been taken at all[1].

Some orthodontists believe that their specialty and its attendant problems are so unique, that what applies to physicians does not apply to them. No doubt, some aspects of the practice of orthodontics are unique. However, orthodontists have their share of noncompliant patients, who affect both the quality of care and cost-effectiveness. A noncompliant patient is less likely to achieve quality results, and more likely to become a "special case", requiring more time, effort, and staff attention than more compliant patients. This time and energy loss might indeed be charged for, but this usually penalizes the parent, not the uncompliant patient. There is very little reason to believe that charging additional fees brings about a cooperative attitude in an adolescent patient, who does not pay them. Moreover, charging additional fees shifts the emphasis to the payer of the penalty and away from the noncompliant patient.

Compliant/Noncompliant Research: It makes sense for the orthodontic specialty to pay attention to what general medicine has learned about noncompliance, by reviewing the relevant literature. Most of the research has consisted of comparisons of compliant and noncompliant patient groups drawn from communication studies and general medicine. However, the psychological principles involved apply generally throughout health care delivery. From such research factors that are not believed to influence compliance are:

1. The severity of the illness.
2. Patients' demographic characteristics, although there may be some sex differences.
3. Patients' knowledge about the illness and an understanding of how to follow the regimen, which are necessary for compliance, but not sufficient by themselves to guarantee it[2].

Factors which are believed to influence compliance are:

1. Some psychological characteristics of the patient (although these tend to be complicated and confounding).
2. Beliefs that patients have about their illness and treatment.
3. Some features of the interaction process between doctor and patient.[1,2]
4. Some features of the treatment regimen.

A summary of the research on compliance, based on hundreds of investigations, is provided on the accompanying chart.

Psychological Characteristics: Compliance is not a simple matter of "kinds of people"— those who will comply and those who will not. Compliance is behavior, just as noncompliance is. Since behavior is observable, one can know eventually who the compilers and noncompliers are; but, other than in behavior, how do compliers and noncompliers differ from one another? Do they have traits or characteristics or personalities, which would distinguish them from one another? Even though the behavior may appear to be a simple matter of cooperating or resisting, the human motives behind the behaviors may be highly complex and confusing. Nevertheless, there are a few guidelines for understanding the person behind the behavior. These have been called general response tendencies.

Yeasaying/Naysaying: The first of the general response tendencies has been termed "overall agreement" or the "yeasaying-naysaying tendency"[3] It describes people who have a typically favorable or typically unfavorable response to whatever they encounter. Some people, as a matter of personality, would be agreeable to a treatment regimen and accept it, while others are predisposed to be negative and resist it. In either case, the response has nothing to do with what the doctor says or does. These people are prone to respond to most situations that way.

The yeasayer's general attitude is described as stimulus acceptance. He is ready to respond affirmatively, impulsively, and quickly. He is attracted by enthusiastic presentations, while naysayers are repelled by the same thing. Naysayers are extremely careful and critical, trusting objective data, rather than feelings or impulses. Alert clinicians may be able to distinguish between yeasayers and naysayers, and treat them differently.

Persuasibility: The second guideline for understanding the person behind the behavior is called "general persuasibility" Women were found to be more susceptible to persuasion than men. During childhood, girls tend to be more obedient to commands and directions from adults, but this diminishes with maturity. As children, they are more easily influenced by young boys than by young girls, but they are not as easily influenced by adults, once they reach puberty. Young boys are especially concerned with maintaining their status in their peer group, and are probably more vulnerable to peer group pressure than girls.

It is important to remember that, although there are average numbers, there are no average people. Even though women may be generally more persuasible than men, it is difficult to predict just which women they will be; whereas men do tend to respond more consistently to persuasive messages. Janis6 has hypothesized the following characteristics associated with persuasibility, but applying more to men than to women:

1. Individuals who are hostile toward the people they encounter in daily life are predisposed to remain uninfluenced by any form of persuasion[4].
2. People who are socially withdrawn are relatively uninfluenced by any form of persuasion.
3. People with rich fantasy lives — with strong responses to rich imagery and words and pictures — tend to be more persuasible than those whose fantasy responses are more constricted.
4. People with low self-esteem— as manifested in feelings of personal inadequacy, social inhibition, and depressive affect— are predisposed to be more readily influenced than people with high self-esteem.
5. People with an "other-directed" orientation are predisposed to be more persuasible than those with an "inner-directed" orientation. It seems reasonable that a person who relies more on his own opinions

than those of others would be less influenced by the opinion of others. While those with basic feelings of insecurity and those who rely on external authority may be more easily influenced by persuasive messages and more willing to comply, this is not the case with dogmatic individuals. For them, the messages which oppose their beliefs are more likely to be rejected. Dogmatic persons dismiss evidence and logic with which they disagree. They may be influenced in their peripheral or inconsequential beliefs, but will resist information which they cannot incorporate into their existing central beliefs. There is some evidence that levels of dogmatism can be changed[5].

There are some psychological characteristics which help to determine compliance-noncompliance. Among these are agreeing tendencies, general persuasibility, the sex of the patient, dogmatism and centrality of the belief in question. Even though they have been insufficiently researched, these appear to be potentially crucial concepts for understanding what is involved when a patient cooperates or does not cooperate with a treatment regimen[6].

Patient Beliefs: While the seriousness of the illness has very little to do with patient compliance, what a person understands and believes about the illness and the treatment might. For example, a person who believes that the treatment extends over "too long" a period, or a person who believes that the treatment is "too complicated' will typically not comply with treatment. The combination of the "too long" and "too complicated" beliefs almost ensures noncompliance. "Too long" and "too complicated" are subjective and relative. Too long or too complicated compared to what? They are a "judgment call" based on belief, rather than something as factual as the severity of the illness or the difficulty of the procedures involved in treatment.

Patient beliefs about the illness and treatment and doctor-patient interaction seem to be tied together, although not completely. Some of the beliefs may come from the doctor, but a good many may not. Some may be no more than myths or "old wives' tales" Recent studies on the "Health Belief Model" conclude by recommending that the health worker systematically explore the patient's beliefs related to illness and treatment. Examples related to orthodontics might include:

"Is there anything that worries you about getting orthodontic treatment?"

"Can you think of any problems you might have in wearing headgear?"

"Have you known anyone else who has had orthodontic treatment?"

"Did they have any problems with it?"

"How did things turn out for that person?"

The "Health Belief Model" suggests that patients' beliefs can change from visit to visit, and that these types of questions should be asked at each visit to monitor those changes. However, in terms of cost and efficiency, this is a very expensive approach to improving patient compliance. There is good reason to believe that the "beliefs factor" is closely related to the "doctor-patient interaction factor", and that it is not the Health Beliefs Questionnaire which facilitates compliance, although it fosters a better understanding. It is rather the fact that the health worker must spend a considerable amount of time with each patient, asking questions and demonstrating a sincere interest in the patient, which increases his compliance[7].

Doctor/Patient Interaction: In an attempt to create a questionnaire to predict which orthodontic patients would comply and which would not, the authors put together a variety of items related to self-concept, attitudes toward dental hygiene, attitudes toward authority, and the interaction between the doctor and the patient. Using what is known as the method of "known groups", the questionnaires were given to hundreds of patients who were identifiable as extremely compliant or noncompliant in orthodontic offices in Texas, Kansas, and Colorado. Since the groups were selected as the extremes of compliance, it was felt that they might answer some of the questions differently, and that those items might be the best predictors of compliant-noncompliant behavior. The only items that produced opposite responses between the two groups were:

"My orthodontist praises me when I do well."

"My orthodontist cares about my feelings."

"My orthodontist is fair in judging my progress."

These items are not so much about the patient or even about the orthodontist as they are about the relationship between the patient and the orthodontist. Interaction influences that relationship, which in turn influences compliance. Several factors have been found

to interfere with doctor/patient interaction and, thus, reduce compliance. These factors include:

1. The doctor seeking information from the patient without providing the reasons why the information is being gathered, as if the information were only important for the doctor.
2. Tension emerging during the interaction, which is not addressed or resolved.
3. Patients feeling that their expectations are not being met, or feeling that the doctor is treating them impersonally.

It would appear that, if a health worker intentionally set about establishing such a relationship with patients, compliance would significantly increase. Carolyn Hudak-Murphy tried that at the University of Denver with arthritic patients and found it didn't work. Perhaps it was because the patients suspected that they were being manipulated and that the relationship was not as genuine as it was presented to be. Another explanation is that compliance may flourish in an authoritarian environment. It suggests that one person knows what is best for another, and that the other person should accept that. There is the possibility that equality in a relationship interferes with that authoritarian format and interferes with compliance. It suggests that, while the doctor can encourage compliance by being personal and authentic, he may very well defeat his compliance aim by being too friendly and making the patient a peer[8].

Rachelle Kaye, at the University of Denver, was interested in finding out what mode of communication was most successful in securing compliance from a doctor who was not living up to the hospital standards of quality of care. What Kaye discovered was that it was not oral versus written communication or individual versus group communication that made the difference in achieving change. It was pointing out to the physician that there was a discrepancy between the standard previously agreed upon and his failure to maintain that standard[9].

If these findings might apply to noncompliant orthodontic patients, an orthodontist would avoid a personal attack on the patient, and concentrate instead on calling attention to the fact that the patient had earlier agreed to a certain treatment regimen, but was now falling short of what he had agreed to. Some health practitioners have found it useful to tape-record the interviews at which the regimen was agreed to, and play them back to the patient. They are like an oral contract that can be reviewed, when necessary. They place the responsibility exactly where it should be— on the shoulders of the person who is not living up to the agreement.

The question of compliance/noncompliance is involved in virtually every case a doctor treats. At the same time, it is a baffling problem, not easy to understand because the causes are complex, and not easy to deal with because what works with one patient may not work with another. In some instances, the noncompliance may be a feature of the psychological makeup of the patient, and the beliefs that the patient has about the condition and treatment, and can in a way be "blamed" on the patient. Although the doctor may not have much effect on the psychological characteristics of the patient, he might take those into account in attempting to influence the beliefs of the patient to secure compliance[10].

It is also important for the doctor to know that the actual treatment regimen influences compliance and that a doctor who reduces negative aspects and optimizes positive aspects of the treatment regimen will increase his or her chances of treating cooperative patients. Some features of the treatment regimen, such as length of treatment, maybe "givens" and, as such, are unavoidable conditions of the treatment. Others can be altered in a positive way.

Enhancing patient compliance: It is not uncommon that there needs to be any learning of psychology in the field of orthodontics, yet, in the approach to the patient there will always exist an element of psychology that will enhance the progression of treatment.

Usually, patients do not co-operate in treatment in one/more of the following ways:

- Frequent absence from scheduled appointments
- Frequent damage to orthodontic appliances
- Unpleasant or negative office behavior
- Failure to attend to proper hygiene
- Failure to wear headgear and/or elastics
- Failure to wear retaining devices

The question to ask here is **Why do they exhibit such a behavioral pattern?** To this there may be several reasons.

Firstly, if we were to analyze the age at which most

kids approach for treatment they would fall in pre-pubescence or early adolescence. Classically these are the ages when repressed expressions exist between the parent and child. The struggle is between the child's ownership of his/her body and the parents' demands that the child does as he is told. Taken in this perspective, the parent might be saying "we will fix your body the way we like it." The child in turn may be revolting in a passive-aggressive way by saying "it is my body and I shall resist any efforts you might make to change it.

Secondly, every human being reacts in different ways to pain. The mouth per se is an organ for the ingestion of food, a means for the expression of thoughts and feelings and an orifice of erogenous significance. For kids intrusion by means of placing foreign objects may not produce dramatic pain but they tend to place things in a figure of overestimation thereby introducing psychological factor[6].

Thirdly, appliances in the mouth in addition to improving smile and appearance do invite ridicule by others in one way or the other. Whether the response is positive or negative is to be perceived by the individual who is undergoing the treatment. For instance, individuals with braces may be greeted with remarks such as 'tinsel teeth', 'metal mouth', 'tracky smile' and so on. These remarks may end up in a response that ranges from complete withdrawal to a blow in the mouth. However, there is the other section of individuals who perceive wearing braces as a badge of pride. These individuals look upon themselves as being different from others and flashing their braces earns them the reputation of being a subculture of an 'elite' background[11].

But still there does exist that small group for who before any orthodontic appliance had been applied were considered as unacceptable or unwilling among their peers. When they decide to finally go ahead with the treatment the appearance of the braces draws remarks of jeer. They thus become fearful of it and withdraw from any situation that singles them out. So they tend to miss appointments and not co-operate in the hope that the inattentiveness will ward away[12, 13]

Conclusion

Fourthly, there is a belief that by orthodontic treatment the result should be more esthetically pleasing. It is intended to make one more attractive, pleasant and socially more pleasing. This is generally the idea with which most people opt for treatment. Yet there are many whose self-image is essentially negative. They could not be made attractive because they do not feel so from the very start. It is better for such people that they do not invest in orthodontic treatment. They do not want to be more attractive because they feel themselves unattractive. What these youngsters are saying is that any external cosmetic appearance will not make me look better and is an unwelcome assault on my self-assumption which is not only negative but over the years have become so.

The way out with such patients would be to:

1. Conceptualize, describe and define the various attitudes towards orthodontics in young patients.
2. Develop instruments, which will help to assess the attitude of the patient.
3. Once the patient has been identified, the next plan is to develop plans and processes to modify or counteract the results of a negative attitude pattern.

It would appear that the Orthodontist is placed in direct conflict with the unrestrained and/or indifferent adolescent. It would seem advantageous to develop programs like the **O**rthodontic **A**ttitudinal **T**est **S**urvey (**OATS**) which is a questionnaire designed to tap patient attitudes about appearance, authority and invasion, comprehend the attitude of the individual and address the patient's needs and deal specifically with hidden feelings that can often become a hindrance in patient compliance. Booklets, programs and personal relationships based on this approach actually serve to control the battles that are likely to exist between the orthodontist and the patient.

Plasma Cell Gingivitis Due to an Antitartar Toothpaste: An Unusual Case Report

Manoj Kumar[1], Lora Mishra[2], Rinkee Mohanty[3], Rashmita Nayak[4], Saurav Panda[1]

[1]Associate Professor, Department of Periodontics & Oral Implantology, [2]Professor, Department of Conservative Dentistry & Endodontics, [3]Professor and Head, Department of Periodontics & Oral Implantology, [4]Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha "O" Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

Plasma cell gingivitis is a rareform of atypical gingival inflammation which is characterized by erythematous marginal gingival hypertrophy which may involve the adjacent attached gingiva. Plasma cell gingivitis (PCG) is an atypical form of gingivitis and is characterized by massive infiltration of plasma cells into the subepithelial connective tissue. It is a rare condition; the cause of which is still not fully understood. It is often attributed to an allergic reaction to the components of chewing gums, dentifrices or various diet components. A case of PCG is presented here in a 52 -year old male who switched to an anti-tartar toothpaste on the advice of a dentist which manifested in a generalized form. This report is the first, as far as we know, that relates PCG to the use of Glister toothpaste manufactured by Amway. The histological examination revealed the infiltration of polyclonal plasma cells. The PCG disappeared within two weeks of stopping the use of the dentifrice.

Keywords: *Plasma cell gingivitis; Anti-tartar toothpaste; Glister toothpaste.*

Introduction

The increase in the size of gingiva is a common feature of gingival inflammation. Several causes for gingival hyperplasia have been incorporated in the dental literature like an inflammatory, drug-induced, neoplastic enlargements, systemic diseases like leukemia[1,2] chronic kidney disease patients on immunosuppressants,[3] to name a few. Among them, few are uncommon and come under the category of conditioned enlargement. Plasma Cell Gingivitis (PCG), also known as plasma cell gingivostomatitis is an abnormal type of gingival inflammation which involves marginal as well as attached gingiva. The exact cause of its appearance is not known, but it is believed to be an allergic or exaggerated response to the ingredients of chewing gum, toothpaste/ or maybe to some dietary elements.

In the early 1940s and 1950s, many reports of mucosal hypersensitivity to edible gum had come out. The cinnamon compounds in them, as well as, toothpaste were identified as the etiological agents in causing PCG. The histopathology revealed a dense penetration of plasma cells separated by collagenous stroma seen predominantly in the keratinized gingiva. These findings can mimic some fatal diseases like multiple myeloma and solitary plasmacytoma, and hence a thorough case history to rule out these conditions is warranted.

Similarly, desquamative gingivitis has also been reported with the use of anti-tartar dentifrices. Pyrophosphates and flavouring agents have been identified as the offending agents. Oral reactions to cinnamon compounds (cinnamon oil, cinnamic acid, cinnamic aldehyde)[4-6] used to mask the taste of

e-mail: manojkumar@soa.ac.in

pyrophosphate produce intense erythema of the gingiva characteristic of PCG as seen in this particular case.

Case Report: A 52-year-old man reported to the outpatient department of Periodontics and Oral Implantology with the chief complaint of bleeding and swollen gums for one month. The medical and dental history was non-contributory. There was a particular emphasis on diabetic status as diabetes significantly increases the chances of periodontal disease as compared to non-diabetic patients.[7] The patient did not report of any deleterious habits like smoking, alcohol intake or any form of tobacco usage. He was well built and nourished and was cooperative. He had undergone scaling six months back. Extraoral examination showed no gross facial asymmetry with a straight profile and competent lips. Upon further asking, he told that he had started using Glister toothpaste around two months back and had developed swollen gums 2-3 weeks after that. Intraoral examination revealed strawberry red coloured enlargement of gingiva present throughout with rolled out marginal gingiva and blunt interdental papilla. Gingiva appeared friable, granular and bled easily, and desquamative gingivitis was also present (Figure 1).He was advised to change the toothpaste in his daily regimen for two weeks. There were minimum plaque and calculus, which was not consistent with the inflammation seen in the oral cavity. No cutaneous lesions were present elsewhere. Complete hemogram and blood sugar levels revealed no abnormalities and were well within normal limits.

A provisional diagnosis of Severe chronic generalized gingivitis was made. A conservative approach was planned initially with patient education, motivation followed by phase one therapy. The patient was also instructed to rinse with 0.2% chlorhexidine twice daily. Since the patient was using anti-tartar toothpaste, we raised our suspicion towards PCG and hence a biopsy was taken from the representative site. On the persistence of the symptoms after two weeks of phase one therapy, the patient was scheduled for a biopsy of the lesion. The procedure was carried out under strict asepsis, and all the protocols were followed. The patient was administered local anesthesia, and after subjective symptoms were positive, we used a Bard parker handle and a No 15 BP blade, gingival tissue was removed from the attached gingiva of the maxillary anterior region and was subsequently sent for histopathological examination. (Figure 2) The patient was advised routine post-operative instructions and necessary medications were prescribed. While the histopathological reports were awaited scaling and root planing was continued. In the subsequent visits, the patient reported improvement in the condition. Histopathology revealed an abundant congregation of plasma cells in the connective tissue without the presence of any atypical cells, and hence a final diagnosis of Plasma Cell Gingivitis was made. (Figure 3) Within one month of the stoppage of the anti-tartar toothpaste, the lesion completely subsided without any treatment. (Figure 4).

Discussion

Plasma cell gingivitis is an uncommon and rare condition that manifests clinically as a diffuse erythematous gingival lesion which may or may not extend to the mucogingival junction.[8] The number and infiltration of plasma cells vary in variouscases and are said to result from an allergic hypersensitivity reaction to various flavouring agents used in chewing gums and dentifrices. Lamey et al. 1990[6] and Miller RL 2002[9] reported that Cinnamonaldehyde, which is usually added to dentifrices to mask the unpleasant taste of pyrophosphate, has been associated with the development of PCG. The etiology is primarily unknown but is believed to be associated with the cinnamon compounds used to mask the taste of pyrophosphates in anti-tartar toothpaste. Macleod and Ellis in 1989 reported a case related to the use of herbal toothpaste. Cinnamon, when used as a flavoring agent in toothpaste, was found to be anetiological factor in gingivitis.[8] Miller et al. had reported 14 cases of cinnamon induced stomatitis.[9] The present case also had desquamative gingivitis which further stresses the role of cinnamon compounds for the same as the patient was using anti-tartar toothpaste. The differential diagnosis of the condition is critical because of its similarity with other mucosal lesions. Most cutaneous disorders were eliminated for consideration by the absence of skin lesions, a negative Nikolsky sign and no abnormalities in the hemogram in this case. Differential diagnosis needs to be done to exclude it from other aggressive lesions such as pemphigus, and once the diagnosis of PCG is confirmed, we should scout for the antigenic substance. In this particular case, the patient had switched to anti-tartar toothpaste (Glister from Amway), and that was the only contributing history.

Conclusion

This case again stresses the role of history taking in arriving at a correct diagnosis. Irrational use of herbal or anti-tartar toothpaste should be avoided, and as the use of herbal products are on the rise. Early diagnosis of plasma cell gingivitis is essential because it mimics other aggressive diseases like leukaemia and multiple myeloma.

Rethink Retraining: A Review

Susant Mohanty[1], Kalimireddy L. Priyanka[2]

[1]Professor & Head, [2]Senior Lecturer, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

As we advance with time, there is a change in the attitude of the kids and their parents which in turn demands a change in the pediatric dentist's approach to them. When we treat young children, there is an added responsibility to gain their co-operation for rendering the best treatment. Sometimes, the added challenge will be to gain the confidence and co-operation of the child as well as the parents with a previous unpleasant dental experience. Hence, there is a need to re-evaluate the retraining of a patient by considering advanced and innovative behavioral guidance and management techniques.

Keywords: *Retraining, Reframing, Dental Anxiety, Behavioral management.*

Introduction

Establishing a connection with the child, the child's family and the dental team is an energetic process. This can be in the form of an exchange of pleasantries, voice tone, body language, facial expressions and other ways of non-verbal communication. The dentist needs to have at their dispersal a variety of behavior management and communication techniques to deal with children of different mindsets.[1,2]

The complexity of growing up involves a lot of things that can be pleasant as well as frightening to the children and they learn to deal with new experiences as they develop their cognitive skills. In this regard a very important but, often overlooked is the consideration of the cognitive stage of child patients before we approach them. So, when the patient with a previous unpleasant dental experience ends up on your dental chair, it is better to start retraining the patient by first assessing the cognitive stage of child development she/he is in.Retraining involves usage of a combined approach of different behavior management and modification techniques to assist the child to show favorable behavior.

Retraining Techniques in Sequence:

1. **Pre-requirements of a dental set up:** Before even thinking of treatment for any patient it is important to have a clean dental operatory set up. Dental clinics should not have a cluttered environment as it leads to a cluttered mind. The dental set up should attract and instigate some sort of inquisitiveness in a child patient.
2. **Attire of the dentist:** When dealing with children with 'White coat anxiety' it is better to avoid wearing the usual doctors coat or replace it with a less threatening attire.
3. **Appointment timings and duration:** Morning appointments with brief waiting time and short treatment time of not more than 30 minutes is appropriate to avoid appointments in their nap or playtime which might make them more restless and irritable.
4. **Team Effort:** Pleasant and warm welcome to the child and the parents by the receptionist and other staff members will put them at ease and calm them.[3]
5. **Positive pre-visit imagery:** Before taking the child to the operatory chamber, showing them images that are agreeable and compliant to the child puts them in the path of acceptable behavior. This can be used in any patient. The objectives of positive pre-visit imagery are to:
   - Provide children and parents with visual information on what to expect during the dental visit.
   - Provide children with a context to be able to ask providers relevant questions before dental procedures are initiated.[4]

6. **Functional questionnaire:** Set of questions can be asked to gather information regarding the child's temperament and their previous dental visit such as:
   - How did the child behave during the past dental/ medical visits?
   - Age of the child in the last dental visit?
   - What is the anxiety level of the parent? (anxiety in parents is reflected in the child's behavior)
   - How does the parent think the child would behave in the operatory?[2]
   - What caused the unpleasant dental experience in the past? (Any particular treatment/incident)
   - Visual scaling of the patient's perception regarding dental treatment if the patient is old enough to interpret it.[5]
7. **Recognizing dental anxiety:** Feeling of restlessness about the dental treatment that is not essentially connected to a particular external stimulus is defined as Dental Anxiety. In the opinion of Chadwick and Hosey (2003), children are familiar with anxiety and the symptoms depend on the age of the child. Crying is a common expression of anxiousness in children. Phase of development plays an important role in the way a child deals with anxiety. Sometimes, children cannot be supported as they may be very young or have special health care needs with whom cooperation may not be accomplished. Anxiety of a child can also have their roots in parent anxiety levels or previous dental experience Recognition of this paves the way for a different path to be taken for a child with unpleasant dental experience.[6]
8. **Communication:** Communication has a twofold purpose as a preventive measure in behavior management (setting the tone of the environment into which the child enters) and a part of the behavior management strategy later.

Verbal communication: The choice of words is extremely important to establish the environment. Words of affirmation and expectations of behavior can be communicated to the patient by the doctor, assistant, or receptionist. Multiple targets may also be used to convey information. For example, affirmation can be given to the child for good behavior by telling the assistant or the parents how well the child is doing. Similarly, explanations about potential behavior management strategies can be given to the parent in case of an uncooperative child. When a child and his or her family do not speak a language known to the practitioner then an interpreter may be necessary. Employing auxiliaries or staff with the language skills represented by the surrounding community is favorable. Training the auxiliaries to communicate in a way consistent with the dentist's is important in such cases. In any event, nonverbal communication becomes more significant.

Non-verbal communication: It involves communicating with a child through physical contact, posture, facial expression and eye movements.[7] Either way, communication must be appropriate to the developmental age of the patient and the cultural context of the family.[4]

Reframing: Reframing is defined as, "taking a situation outside the frame that up to that moment contained the individual in different conditions and visualize (reframe) it in a way acceptable to the person involved and with this reframing, both the original threat and the threatened"solution" can be safely abandoned." It is a part of neuro-linguistic programming that helps to strengthen the relationship between the dentist and the child. The content is perceived depending on how it is framed. So, to change the behavior of the patient we need to change the content in the frame by changing the meaning or sense of the situation or by changing the context. [8,9]

Direct observation: Patients are shown a video or are permitted to directly observe a young cooperative patient undergoing dental treatment to familiarize the patient with the dental setting and dental procedure. This also allows the patient and parent to enquire about the dental procedure in a safe environment. It is based on the "Observational learning theory" by Bandura given in 1969. It aids in removing the fear of dental treatment and it can also be used to make the child aware of the expected co-operative behavior like the model(live or video) while undergoing treatment.[10, 11]

Ask tell ask: This method involves enquiring the child about their current emotions and anxiety level (ask) and then offer reassurance by explaining the procedures through demonstrations and non-threatening language appropriate to the cognitive level of the patient (tell). After comforting the child is again enquired how they are feeling (ask).[2] If the concerns continue, we need to address them and assess the situation, and modify the procedures or behaviorguidance techniques

if necessary. This will assess the anxiety that may lead to non-compliance during treatment and also teach how the procedures are going to be accomplished.[12]

Teach Back: A similar strategy called teach-back is similar to the dentist or dental assistant asking the patient to **teach back** what they have learned. It may be useful for patients with low literacy who cannot rely on written reminders. It is important to inculcate this process as a part of the routine. The patient is asked to tell/demonstrate what they have understood and if they express it incorrectly or doubtfully, we need to reteach/ demonstrate them.[4]

Successive approximation/Tell show do: "Tell show do" technique was given by Addleson in 1959. This is one of the most effective techniques of behavior modification. The child is told about the procedure in a language and manner understandable to the child after which the child is shown the equipment and the performing method(approximation). When the child becomes assured and relaxed, the treatment can begin.[3] This is most beneficial for a child who is progressing beyond the pre-cooperative stage. This also effective in an uncooperative child with 'fear' as a core issue. This is used to even demonstrate patience and concern in compensatory and overprotective parents and to retrain their vocabulary in front of kids. Successive approximation can be used to gradually expose the child to invasive procedures.[7]

Being tolerant and truthful: It is important, to tell the truth to children as that is what lets us gain their confidence. In case if they are about to receive an injection, they need to be told the same and shown how little pain would be caused like that of a prick or a mosquito bite. This way they would be prepared to receive what is told to them. Lying that there won't be any pain and then inflicting pain will only shatter their confidence. At the same time, it is of utmost importance for the dentist to be patient and maintain their tolerance levels even in case of an uncooperative child.[5]

Systemic desensitization: Introduced by Joseph Wolpe in 1952, this method introduces dental treatment to children progressively from a competing response such as relaxation to progressively increasing the threatening stimuli.[6] The first sitting involves only examination and diagnostic x-ray procedures if required followed by less invasive procedures like scaling, restorations, sealants,etc and then invasive procedures like extractions or endodontic treatments in the consecutive visits. This will tune the child to the dental setting and treatment procedures.[5]

Memory restructuring: It is a behavioral approach in which memories associated with a negative or difficult dental event are restructured into positive memories using information suggested after the event has taken place. Restructuring involves four components: visual reminders; positive reinforcement through verbalization; concrete examples to encode sensory details; and a sense of accomplishment. A visual reminder could be a photograph of the child smiling at the initial visit (i.e., before the difficult experience). Positive reinforcement through verbalization could be asking if the child had told her parent what a good job she/he had done at the last appointment. Concrete examples to encode sensory details include praising the child for specific positive behavior. The child then is asked to demonstrate these behaviors, which leads to a sense of accomplishment. The aim is to restructure difficult or negative past dental experiences and improve patient behaviors at subsequent dental visits.[13, 14]

Flexibility: In the current times, it is not uncommon to come across patients who show uncooperative behavior despite trying the common behavior management and retraining techniques. In such cases treatment shouldn't be done by force or immediately resort to protective stabilization. It is better to give time to the child and schedule another appointment for treatment after gaining their trust in the initial visit.[5]

The Current Needs of Parents from a Dentist: The parents of today seem to be moving toward a more laissez-faire attitude in parenting by providing the child with lavish freedom and choices leading to them having no self-control and discipline in some cases. Perhaps this is the reason we have newer categorization of children.[15] Children of today often present with a variety of behavioral problems such as attention- deficit hyperactivity disorder, conduct disorder, oppositional defiant disorders, and other disruptive behavior disorders. This calls for a change in the professional guidelines for behavioral guidance as well as retraining procedures.[16] Verbal reprimands and voice control are far less favored when compared to time outs. Interestingly, in a 2002 survey of 577 diplomates of the American Board of Pediatric Dentistry88 percent of respondents felt that parenting styles had changed in their practice lifetime, with 92 percent believing that these changes were

"probably or bad." Most respondents (85 percent) also believed that these changes resulted in "somewhat or much worse" patient behavior. In concert with changing parental attitudes, the diplomates reported less use of assertive behavior management techniques.[17] Younger practitioners, who may have grown up with modern values of parenting bear the influence of the modernist generation.[7]

Using classic behavior management techniques with assertive method is not favorable in the current times. Usage of physical restraints is not acceptable to most parents and Hand over-mouth exercise has fallen out of favor even with dental practitioners, possibly as a result of the implications of abuse. Voice control is questionable to overindulgent parents who consider it against the self-esteem of the child.

Conclusion

So, right now it is important to understand every child's parenting method of disciplining their children and incorporate it in our approach to the child along with behavior management science and it should be custom made for every child as they are all different from one another in one way or the other. Our goal should be to maximize their comfort levels on our dental chair especially in cases requiring retraining.

Abstract

One-fourth of the population globally is infected utilizing a bacterial infection-tuberculosis (TB). TB remains the most contagious killer disease globally having 10 million people falling ill with TB. The transmission route of TB is through the air and when symptoms occur, Therefore, as a dentist we need to be aware of oral tuberculosis such that proper protocol can be followed in our daily practice. This article highlights the important oral manifestation of tuberculosis and its confirmed diagnostic criteria so that a dentist can follow all the guidelines for proper management of a tuberculosis-infected dental patient.

Keywords: *Dental protocols, Oral manifestations, Tuberculosis.*

Introduction

Tuberculosis (TB) kills five thousand people every day. About 25% of the population is infected with tuberculosis globally whereas, in India, the TB incidence is 199 recent cases per 100000 population per year, with the global average being around 130. However, TB remains the most contagious killer disease worldwide having 10 million persons falling ill with TB as per report till 2018.[1] Maximum counts of current TB cases have been found in Southeast Asia, Western Pacific regions and Africa. Recently 8 countries were reported which were meant for 2/3rd of the new Tuberculosis cases globally.[2]

The bacteria usually attack the lungs, but they can also damage other parts of the body. Oral cavity provides a variety of surfaces for bacterial colonization, and each environment supports a characteristic bacterial population. The composition and quantity of the bacterial population on mucosal and tooth surfaces are influenced by many factors, such as the integrity of the soft-tissues, oral hygiene, saliva, diet, and the host's immune and inflammatory responses. Transmission of TB occurs very frequently in the dental clinics either from doctor to patient or from patient to dental staff. Therefore, as a dentist we need to be aware of oral tuberculosis such that proper protocol can be followed in our daily practice.

Microorganisms responsible for this disease is Mycobacterium Tuberculosis and the transmission route of TB is through the air and when symptoms occur, they generally consist of cough (sometimes blood-tinged), weight loss, night sweats, and fever. The majority of people infected with the bacteria results in tuberculosis don't have symptoms and, in such cases, it is known as latent tuberculosis.[3] Secondary tuberculous lesions of the mouth are more commonly found. An oral manifestation is observed as a painless ulcerated lesion in the palate, lips, or tongue, along with persistent

cervical lymphadenopathy. Although most cases of oral TB manifests with a chronic ulcerative mucosal lesion, it may also present as a granuloma, osteomyelitis, or salivary gland disease.[3]

The social and economic impacts are devastating, including poverty, stigma and discrimination. The world has committed to end the TB epidemic by 2030[4] so we need a dynamic, global and multisectoral approach to reach this goal. Hence, this review article focuses on the oral manifestations of tuberculosis and guidelines for management by the dentist.

Oral Manifestations of Tuberculosis:

Tuberculous ulcer presents as single or multiple, superficial, or deep, painful or painless ulcers with an irregular border which tends to increase slowly in size. Usually develop as a small tubercle which then softens to form a shallow, ovoid ulcer with undermined margins and is lined with pale granulation tissue.[5] Tiny single or multiple nodules called "sentinel tubercles" may be seen surrounding the ulcer. Tongue is most commonly affected. However, lesions also occur on the floor of the mouth, gingiva, palate, and lips.[6] Provisional analysis of an ulcer in the mouth because of tuberculosis can be traumatic ulcers, syphilitic ulcers, aphthous ulcers as well as various carcinomas like squamous cell carcinoma, lymphoma etc.[7]

Tuberculous gingivitis may appear as nodular or it can be seen as the papillary proliferation of gingival tissues which is diffuse along with hyperaemic.[8] There may be an absence of any clinical attachment loss, alveolar bone loss or significant cervical lymphadenopathy. Sometimes tuberculous gingivitis can be seen simultaneously with marginal periodontitis and enlarged cervical lymph nodes or may present as periodontal loss of tooth shore up leading to loose teeth and gingival overgrowth.[4] A biopsy of the lesion is mandatory for arriving at the diagnosis of TB.

Tuberculous dental periapical granuloma: Three routes can be perceived to be entry portals for the tubercle bacillus. Incursion into the dental pulp throughout a very deep carious lesion by the acid-fast bacilli in the saliva is one route. The second route is hematogenous and the third is a deep periodontal pocket. The lesions are usually painless and sometimes involve a considerable amount of bone by relatively rapid extension.[9]

Tuberculous involvement of extraction sockets of teeth: Healing of the tooth extraction sockets is delayed and the socket gets filled with "tuberculous granulation tissue" consisting of many pink to red elevations.[10]

Tuberculous osteomyelitis of maxilla and mandible: Rate of occurrence of tuberculous osteomyelitis is less than 2% of skeletal TB.[11] The mandibular association is more frequent than maxilla and alveolar and angle regions have maximum affinity.[12] Tuberculous osteomyelitis commonly affects the adults; however, in some cases children are also affected. The spread of infection may be by direct transmission from infected sputum, throughout a tooth socket because of extraction or mucosal opening coupled with a completely erupted tooth or by regional extensions of soft tissue lesions and also it can be through hematogenous spread. Diagnosis of tuberculous osteomyelitis is a significant challenge as the smears for acid-fast bacilli usually do not yield positive results.[11-13]

Tuberculosis of maxillary sinus – It is usually a disease of adults and remains an underdiagnosed entity. It is usually secondary to pulmonary or extrapulmonary TB resulting from the bloodstream or by direct extension.[14] It is found as nasal discharge, stuffed nose and formation of crust along with epistaxis. It resembles as fluctuant swelling, i.e. Pott's puffy tumor as well as a malignant lesion. 3 varieties of sinonasal TB : (i) There can be involvement of mucous which can result in the formation of poly using minimal pus discharge, this type is more common; (ii) There can be involvement of bone with the occurrence of fistula and rich discharge of acid-fast bacilli (AFB); this type can lead to midfacial defect; (iii) the third type is hyperplastic that has presence of granuloma and mimics a malignancy.[15] The confirmation of Tuberculosis sinusitis is generally decided on the nonexistence of reaction to regular common antibiotics as well as by bacteriological culture or polymerase chain reaction assay. Sinus surgery may be required for sinus drainage and specimen collection. CT or magnetic resonance imaging can be helpful to figure out the extent of disease. Appearance of calcification in sinuses on CT scans can be indicative of sinonasal TB, and imaging findings are mostly nonspecific.[16]

Tuberculosis of temporomandibular joint: Tuberculosis of the TMJ is very rare in occurrence; therefore, only a few cases have been reported.[16,17] The clinical manifestation of TB infection of TMJ is unspecific and can resemble osteomyelitis, arthritis, cancer or any kind of chronic joint disease. Therefore,

TMJ TB should be taken as a confirmed diagnosis when patients present with pain and stiffness of the joint or with chronic joint diseases.[10,11] The presence of signs and symptoms is menacing like Nocturnal type of muscular spasm can lead to soft and elastic joint tumefaction, typically without erythema and with edema that will be resulting in early to severe and localized periarticular muscle atrophy.[12] Treatment of TMJ TB consists of conventional drug therapy.

Tubercular sialadenitis: TB of the salivary gland is a rare condition even in countries like India, where the disease is rampant.[18] The most common salivary glands involved in primary TB are parotid glands, whereas in systemic TB submandibular glands are most commonly involved.[19] There are two clinical forms of tuberculous parotitis. First is the localized form which is common and involves intraglandular/periglandular lymph nodes. It may be secondary to nodal infection. It presents as slow-growing, non-tender localized swelling in front and below the ear.[15] Diagnosis of tubercular parotitis is very difficult because of the absence of symptoms and may often be misdiagnosed as a benign parotid tumor.[16] A detailed history, examination and FNAC have been advocated for diagnosis of tubercular parotitis.[14]

Tuberculous lymphadenitis: Tuberculous lymphadenitis in the cervical region, also known as scrofula, is considered as the common site of extrapulmonary TB which accounts for up to 5% of the cervical lymphadenopathy. It often affects children and young adults in the age range of 30–40 years and shows female predilection.[20] It can be manifested as multiple neck mass which can affect deep lymph nodes and may relate with supraclavicular and axillary node involvement. Patients present with slowly enlarging asymptomatic lymph nodes in the persistent neck. Fine - needle aspiration cytology (FNAC) and direct microscopic screening for acid-fast bacilli (AFB) are recommended intended for the usual daily diagnosis of tuberculous lymphadenopathy along with the culture that remains the gold standard for diagnosis.[21] Diagnosis often requires biopsy. Therapy includes various types of anti-TB chemotherapy, surgical excision, or a combination of surgery and chemotherapy.[21]

Lupus vulgaris: It is the most common form of cutaneous TB found in individuals with moderate immunity and a high degree of tuberculin sensitivity that spreads through a hematogenous or lymphatic route.[22] Eighty percent of the lesions are on the head and neck and most often on the face around the nose, eyelids, lips, cheeks, ears. Females are affected two to three times more often than males.[22] Lupus vulgaris skin lesions are of five types – (a) plaque, (b) ulcerative or mutilating, (c) vegetating, (d) tumor-like and (e) papulonodular. Commonly found LV form is the plaque form that accounts for 32% of cases, whereas the destructive and deforming of all lesions is the ulcerative form.[20] The distinctive lesion is a reddish-brown plaque, containing nodules which show an "apple-jelly" color when pressed with the help of a glass spatula (diascopy).[23]

Apart from the above-mentioned oral manifestations, droplets from the contaminated sputum may result in tuberculous tracheitis and laryngitis resulting in hoarseness, coughing, and pain along with tuberculous ulcers on the tonsils resulting in dysphagia.[11]

Diagnosis Confirmation:

1. Recording detailed medical history including general and local signs and symptoms of the patient.
2. Symptoms that might help to distinguish oral tuberculosis from other varieties are fever along with lymph nodes enlargement and gastrointestinal disorders. Also, chronic cough and excessive fatigue can be seen.
3. Incisional biopsy is required to be done for each oral ulcer that lasts for more than 3 weeks .[11,17,18,22]
4. The existence of granulomatous seditious access with Langhans giant cells along with lymphocytes can be found along with foci of caseous necrosis of the tissue during histopathological assessment.
5. For confirmed diagnosis microbiological culture of sputum should be done[7,11,12,21] and also Ziehl-Nielsen stain of sputum swab to be done for acid-fast bacilli which can be positive.[11-13,22]
6. Its mandatory for are all individuals suspected of TB to do posterior-anterior (PA) and lateral view chest radiograph. The positive findings suggestive of TB are disseminated infiltrations, nodules, fibrotic scars and cavities in the lungs and also pleural effusion.[12,19]
7. One of the common Tuberculosis diagnostic tests is the Mantoux tuberculin skin test however its positive result cannot always mean active TB. There might be an indication of previous contamination or intake of the BCG vaccine.[3,5]

8. Currently interferon-g release assays (IGRAs) are now in use as a substitute of the Mantoux test because of its higher sensitivity and specificity.[9] But in suspicious patients, molecular tests (PCR) may be helpful.[1,7,13]

Protocols for management of tuberculosis patients in dental settings: A detailed medical history and physical examination of patients, specifically high-risk people should permit the dentist to make out Tuberculosis patients who can then refer for medical conduct. Sputum culture should be done for the patients who are already on anti-tuberculous treatment (ATT) to make certain that disease is not in active state.[11]

Budding routes of transmission of contamination include:

- Contact transmission through blood, oral fluids or other body fluids.
- Contaminated objects like instruments or equipment or any environmental surfaces by indirect transmission.
- Transmission route through eyes, nose, mouth and/or mucous membranes with droplets/splatter containing microorganisms.
- Breathing of microorganisms present in the air which can float for a longer period.

Recommended protocols for tuberculosis patients:

1. Limiting the utilization of ultrasonic scalers as well as very good speed handpieces in actively infected patients. Aerosolized M. tuberculosis can also survive more than nine hours. High volume suction should be mandatory for carrying out any procedure to minimize aerosol generation.
2. Rubber dam isolation should be used to have high vacuum suction but to be avoided in case the patient has a productive cough.
3. Proper hand hygiene should be maintained and individual protective things like eye shields, facemasks, head caps, gloves as well as surgical gowns needs to be followed.
4. Properly constructed, soft pleated, high filtration face masks have to be used and face masks should have at least 95% Bacterial Filtration Efficiency (BPE) for particles more than 3µm diameter.
5. Dilution of contaminated operating air/aerosols should be done for dental operatories. TB rooms should have effective air evacuation with either exhausted or HEPA-filtered if recirculation is necessary.
6. Standard fumigation of dental operatories should be done along with cleaning and disinfecting significant and contact surfaces like Dental chair and accessories. Anti-bacterial sprays can be utilized.
7. Barrier method and high valued filters otherwise UV light in the exhaust air ducts.
8. All hospitals and clinics definitely should conduct an annual report on risk assessment for Tuberculosis infection.

Conclusions

Tuberculosis is highly contagious and infectious transmitted disease which have created a rank in the list of deadliest disease globally. Since the route of transmission and all its causative factors are common especially in the hospital and dental settings, therefore detailed information and its oral manifestation need to be aware of among the health care professionals for its prevention. As per the motto of this review, the dental health professionals should follow all the protocols for the management of any tuberculosis patient. Diagnosing the disease at the early period will increase the morbidity and mortality of tuberculosis-infected patients. Hence, it becomes the responsibility of the dentist to consider tuberculosis in the provisional diagnosis of suspicious oral lesions to avoid unwanted delay in the treatment of this disease.

Tunnel Technique for Anterior Interdental Papillary Reconstruction with Amniotic Membrane and PRF Membrane: A Case Report

Anurag Satpathy[1], Bhagyashree Lenka[2], Rinkee Mohanty[3]

[1]Professor, [2]Post Graduate Student, [3]Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Aesthetics play a crucial role in enhancing the outlook and self-assurance of a person.Loss of interdental papilla which occurs in the anterior maxillary region, usually known as the "black triangle" is one of the demanding missions to take in hand as it requires precise and meticulous handling of tissues in the interdental area thereby posing a great challenge inperiodontal plastic surgical procedures. Various non-surgical and surgical techniques have been recommended with varied success rates for its management. The present case report presents a tunnel technique for interdental papillary reconstruction procedure using platelet-rich fibrin and amniotic membrane.

Keywords: *Papillary recession, black triangle, amniotic membrane, PRF.*

Introduction

The space between two adjacent teeth is occupied by interdental papilla which protects the underlying periodontal tissue thereby acting as a physical barrier against microbial invasion and plaque accumulation as well as improving the aesthetics and self-maintenance by the patient. Improper tooth brushing habits, abnormal position of the tooth,extension of inflammation from gingiva to periodontal tissues, parafunctional habit, faulty orthodontic and restorative procedures are factors leading to interdental papillary loss. The interdental papillary loss have been classified by Nordland and Tarnow classification in 1982[1], taking interdental contact point,facial and interproximal cemento-enamel junction into consideration.

Papillary reconstruction has been one of the most difficult periodontal plastic surgical procedures to master and has a very low success rate. Forced eruption, use of gingival and porcelain veneers are some of the non-surgical techniques which have been used with a successful outcome. However, managing the lost interdental papilla surgically is critical as the only source of blood supply in the narrow space at the base of the papilla. Various surgical techniques such as Beagle's technique[2], Modified Beagle's technique[3], Robert Azzi technique[4], Han and Takei technique[5] and surgical reconstruction using connective tissue graft and also regenerative materials have been carried out so far.

In recent years, platelet-rich fibrin (PRF) has gained a lot of popularity as a predictable regenerative material in the treatment of osseous and gingival recession defect because of the abundance of growth factors which are slowly released from the fibrin matrix and hasten wound healing process[6,7]. Few studies have also been reported the use of Amniotic Membrane (AM)in the reconstruction of anterior papillary recession. However, the adaptation of such membranes is quite difficult during surgery. Therefore, the present case report presents a novel tunnel technique for anterior interdental papillary reconstruction.

Case Report: A 25-year-old healthy female patient reported to the Department of Periodontology and Oral Implantology, Institute of Dental Sciences, Bhubaneswar with the chief complaint of receding gums between the upper anterior teeth. She was concerned about her look since the increased space was visible during smiling. She reported that the unaesthetic gap persisted since last one year and had slightly increased recently. Clinical examination revealed class I papillary loss between maxillary central incisors (Figure 1). There was no evidence of periodontal pocket and no bone loss was revealed radiographically. A plan for surgical reconstruction of the lost papilla was made and explained to the patient. A written patient consent was taken for the same. Routine blood investigations did not reveal any deviation from normal health.

Surgical Procedure: After performing intraoral asepsis with 0.2% chlorhexidine digluconate rinse for 30 seconds,local anesthesia (2% lignocaine) was administered in the region of #11 and #21. The distance from the contact point to the bone crest was evaluated by transgingival probing, using the UNC15 periodontal probe which was found to be 5 mm. A small horizontal slit incision was made apical to the mucogingival junction in the interdental region of #11 and #21. This was followed by a crevicular incision with the central incisors without splitting the interdental papilla.A pouch in the interdental area was created with the help of the tunneling instrument to relievethe gingivopapillary from its periosteal attachment (Figure 2a). A similar slit incision was made on the palatal aspect and using an Orban's knife the entire papillary complex was relieved from its base(Figure 2b).

Platelet-rich fibrin[8] membrane was prepared by following the standard procedure of withdrawing 10 ml of patient whole blood intravenously and centrifuging for 10 min at 3000 rpm. The amniotic membrane was procured from the tissue bank of Tata Memorial Hospital, Mumbai. Amniotic membrane was then inserted from the facial slit incision (Figure 3a) and pushed horizontally so that a portion could be pulled from the palatal aspect and manipulated to remove any folds (Figure 3b). The prepared PRF membrane was then inserted underneath the Amniotic membrane so that it lay interdentally pushing the entire papillary complex coronally. The amniotic membrane was then tucked internally, adapted and sutured on the facial (Figure 3c) and palatal side (Figure 3d). The coronally advanced papillary complex was stabilized with 4-0 vicryl sutures, secured on the labial surface of the tooth followed by placement of periodontal dressing (Barricaid)at surgical site. Suitable post-operative medications were prescribed and instructions were explained. Suture removal was done after 10 days and followed till 6 months (Figure 4). Fig 5 (a-d) shows the schematic diagram of the proposed technique.

Discussion

The enhancement of lost interdental papillae is however one of the most difficult periodontal plastic surgical procedures as the interdental papilla is an end-organ that is deprived of its blood supply. Many techniques have been employed for its reconstruction but no predictable absolute surgical procedures advocated for its reconstruction are present currently. The shape of the interdental papillae depends on a variety of factors such as contact point between two adjacent teeth, presence or absence of degree of recession, and width of proximal tooth surfaces.

The tunneling approach used by us is a step further which has been used earlier where the approach was restricted to the facial side only, in that there was an addition of palatal window. This technique is particularly

beneficial in cases where a barrier membrane is used. The palatal window makes the manipulation of the membrane very easy especially when an additional regenerative component such as PRF is used in conjunction with the membrane.

As suggested by Tarnow et al[9],if the distance from the contact point to the bone crest is 5 mm, there will be complete fill of the interproximal embrasures of the various techniques put forth for the amplification of the lost interdental papillae, placement of connective tissue graft under the flap showed statistically significant results inthe improvement of both papilla presence index score and papillary height when observed for a period of 12 months[10]. Due to the small, restricted space interdentally, any form of free grafting cannot be utilized since the surface area for blood supply to the donor tissue is minimal. Patient morbidity,post-operative discomfort and involvement of the second surgical site are the demerits associated with soft tissue grafting[11]. To overcome this, Arunachalam et al [12], used PRF in the reconstruction of papillae and stated that papilla regenerated was structurally stable in its new positionwhen reviewed at 6 months postoperatively.

Amnion tissue is a potent source of stem cells that helps in the stimulation of growth of the fibroblast,formation of granulation tissue and neovascularization. In addition, the stem cells found within tissue enhance clinical outcomes[13]. It also possessesan ability to form an early physiologic "seal" with the host tissue precluding bacterial contamination[14] and various studies also support its potential to reduce the host immunologic response [15].Sharma et al in 2015[16] in a study reported that amniotic membrane provides an effective alternative to autograft tissue as the self-adherent nature of the amniotic membrane significantly reduced surgical time and it is also easier to perform thus making it membrane of choice. Shetty etal[17] studied bilateral multiple recession coverage with platelet-rich fibrin (PRF) in comparison with amniotic membrane and found that the clinical outcome of the surgical procedure accounted for 100% root coverage, an enhanced gingival biotype, with both the membranes.

However, in this study we obtained a partial coverage of the papillary recession which could be attributed to various factors such as lack of following a standardized protocol, use of microsurgical instruments and evaluation of biologic width.

Conclusion

Thus, at the end,it could be concluded that the surgical technique evaluated for reconstruction of interdental papilla using PRF and AM was fairly successful. Although many refined approaches showing good clinical results, have been proposed to restore interdental papilla, use of PRF and amniotic membrane may be the solution for interdental papilla augmentation. To confirm the use of amniotic membrane as a good alternative for the treatment of papillary recession, more longitudinal studies are required in this field of periodontal plastic surgery.

Ameloglyphics: A Biometric Analysis

Pradyumna Ku Sahoo[1], Smita R. Priyadarshini[2]

[1]Associate Professor, Department of Prosthodontics, [2]Associate Professor, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Forensic Odontology is a budding science that utilizes dental knowledge in the court of law. It has now proved itself as an important science in medico-legal issues and personal or individual identification, gender & age determination. Ameloglyphics stands for imprints of the tooth and the enamel rod end patterns on the surfaces of the tooth. Teeth are resistant to environmental alterations like fire, desiccation, or decomposition. Enamel rod patterns are unique and are different for every individual. This review covers the basics of using enamel rod end patterns that are employed in personal identification in natural calamities.

Keywords: *Forensic odontology; Ameloglyphics; Tooth prints.*

Introduction

Forensic odontology is a branch of dentistry that involves the application & identification of individuals comparing the ante- and post-mortem records. Like fingerprints, ameloglyphics are analogue to identification and is unique with a record that remains for lifetime.[1] There should be working establishments & centers with facilities at the dental laboratories. Even it should be mandatory to maintain records for all dental clinic & hospitals either government or private. [2]

Amelo stands for enamel whereas glyphic suggests that carving thus Ameloglyphics stands for enamel rod patterns and tooth prints. Enamel could be a spin-off of germ layer cells. [3] Enamel rod is the structural unit which is synthesized by specialized cells the ameloblasts. Ameloblasts form enamel rods in associate undulating and inter-twining with the enamel rods.[1] Enamel descends from the ectoderm. It is a complex organized procedure derived from specialized cells the ameloblasts. They are laid in an undulating and inter-twining path that provides a high tensile strength that traverse in different directions.[4]

Biometrics-play a vital role in determining the tooth prints. They have constraints when decomposed, burned, fragments of calcified tissues are the remnants. As enamel is highly mineralized that forms enamel prism or rods (Hunter Schreger bands)so it withstands the degradation procedures during post mortem.[5] Biometric analysis of enamel conceals each intra- and inter-individual variation that is distinctive and specific to either gender. The formation of the enamel prisms may be categorized into 3 main patterns with Prisms being circular, aligned in parallel rows and keyhole look types.[6]

Orientation of enamel rods: The orientation of enamel rods is perpendicular to the dentin surfaces they are slightly different in deciduous and the permanent dentition. In deciduous dentition, enamel rods lie in a horizontal plane in the cervical and middle third that becomes oblique in the incisal and occlusal third with vertical in the incisal edge or the cusp tips.[3]

In permanent dentition arrangement is similar to deciduous teeth in the occlusal and middle thirds but

Corresponding Author:
Dr. Smita R. Priyadarshini

e-mail: smitapriyadarshini@soa.ac.in

show a rootward inclination or outward orientation in cervical third. The enamel rods also known as enamel prisms are described as circular, parallel or key whole appearance type patterns. In another classification they classified these enamel rods into Wavy branched & un-branched, Linear branched & un-branched, Whorl open, closed and Loop varieties[7.]

Recording Enamel rod end patterns: There are several techniques for recording the patterns of enamel rods that are useful in mass disasters. In Ameloglyphics, recording of enamel rod is done by using acid etchant, acetate peel technique, and automated biometrics for producing accurate enamel rod end patterns.[4] Macroscopically pattern of enamel rods appears incrementally on the tooth surface as perikymata but microscopically, they have a unique direction, which is different from adjoining group of enamel rods unique to ever person.[8,9]

1. **Acid Etching:** It removes the surface mineral element within the rod and rod sheath. But as the rods and rod sheaths have different mineral density, the etching leads to uneven dissolution of the surface enamel with the removal of the smear layer.

   Procedure: Initially the tooth is scaled and polished acid etched using 37% orthophosphoric acid for 30 s the preferred site being the buccal/lingual surface of tooth. Thereafter the surfaces are rinsed with water, dried & conditioned using a drop of acetone and covered using cellulose acetate film and left undisturbed for 20 minutes which is pulled gently and transferred to a clean glass slide for microscopy. Slides are visualized under a light microscope under different magnifications along with a digital camera that is sent for biometric conversion using fingerprint analysis software.[10]

   Uses: It can be used as an accurate personal identification tool. Ameloglyphics is an easy, cheap and fast procedure. It can be readily used as an adjunct antemortem dental record of firefighters, soldiers, jet pilots, etc.

2. **Peel technique:** It enables the study of the tooth structures in a 3-dimensional form that is completely mineralized as enamel. This process doesn't require the routine decalcification, sawing, and mounting.[11]

   Procedure: It is a modification of the cellulose acetate peel technique Here the enamel rod end patterns are duplicated on cellulose ester paper, rubber base impression materials, plastic wrap tape. It completely reproduces the distinctive patterns, sub-patterns of surface enamel rod end. Verifinger software readily matches the enamel rod end patterns with specific identification.[6]

   Advantages: This process is simple & inexpensive with a rapid method in making replicas of dental hard tissue surfaces.[12]

3. **Automated Biometric analysis:** Biometric-based identification is primarily used for fingerprint recognition, facial recognition, and iris scanning using automated systems and software tools. Similarly, amyleglyphics have certain desirable prerequisite characteristics, like uniqueness, easy transmit ability, to acquire as uninvasive as and distinguishable to humans. Software applications like M2SYS fingerprint SDK software system, Sig ID biometric fingerprint software system, Verifinger standard SDK etc.[7,13]

Minutiae points are the broken lines that appear as endings of lines, dots, small lines, ponds, bifurcations. Multiple bifurcations are collectively termed minutiae. The minutiae sets can be coordinated using manytechniques. In the case of fingerprints, matching a print poses a big computational problem due to the following three factors: Poor quality, very large fingerprint database, structural alteration of the fingerprint images.[14] These become irrelevant in tooth prints because being a hard surface enamel rod ending produces a good quality digital image and does not show distortion as in the fingerprints.[8] Thus forensic investigation, the team should compulsorily have dental personnel who specializes in forensic odontology. [15]

Need for Further Research: Dental caries being a complex process involving microbiologic action resulting in destruction as well as loss of tooth structure. Ameloglyphics can be utilized in determining tooth surfaces affected by caries than on relatively unaffected surfaces. Until now it doesn't illustrate any predisposing structural variations in dental caries or any variation in the shape or orientation of the rods.[9,16]. Even as we are aging, changes occur in the enamel structure due to continuous micro and macro wearing like attrition, abrasion & erosion of the tooth surfaces. Thus inducing a possible change in the structure of the rods. So the pattern is to be recorded and checked for any specific pattern. Thus requiring a need for further research.[17]

Conclusion

Enamel is the hardest structure in the body, it is exposed to continuous wear & tear. Processes like routine tooth brushing, abrasion, erosion, exposure to acidic occupational hazards, wear the enamel to expose the underneath layer. Since teeth can withstand extreme temperatures, dental findings should be a technique of choice for disasters. Thus, the biometrics reveals that the enamel rod-end patterns are unique for individuals. The reproducibility and reliability of the pattern suggests its utility as a reliable tool for identification in mass disasters.

Prognosis of Periodontal Disease-A Dilemma

Saurav Panda[1], Rashmita Nayak[1], Abhaya Chandra Das[1], Manoj Kumar[1], Gatha Mohanty[1], Rajat Panigrahi[2]

[1]Department of Periodontics and Oral Implantology, [2]Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan, (Deemed to be University), Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Prognosis is a statistical measure of the likely outcome for an individual who undergoes periodontal treatment. Determining prognosis at an early stage before treatment planning would help the clinician to render the periodontal treatment in confidence. The prognosis is determined by assessing the factors which could make the outcome of rendered treatment favorable as well as the factors which can negatively affect the outcome. Therefore, it is crucial for the clinician to judge the prognosis with his knowledge, expertise and patient's compliance. This review outlines all the factors which could possibly affect the prognosis and the clinical application of the same.

Keywords: *Periodontal Disease; Prognosis; Periodontal Treatment; Risk factors.*

Introduction

Periodontics is one of the areas of dentistry that is especially directed to the total-mouth concept, which means that, success or failure is not measured on a tooth-by-tooth basis, such as is the case in operative dentistry. The prime objective of therapy is to maintain the mouth in health throughout the life of the individual. Prognosis is defined as a prediction of the probable course, duration and outcome of a disease based on a general knowledge of the pathogenesis of the disease and the presence of risk factors for the disease.(1) It is a statistical measure of the likely outcome for an individual who undergoes treatment. Prognosis is determined before the treatment plan after the diagnosis of the condition is made. The determinants of prognosis include the nature of disease/ condition, severity of the disease, the type of treatment it requires (influenced by clinician's expertise and itPrognosis can be classified in to: Overall prognosis (dentition as a whole) and Individual tooth prognosis (more specific, and determined after the overall prognosis and is affected by it.(2)

Factors Affecting Overall Prognosis: The factors affecting overall prognosis include Type of periodontitis, Age, Systemic background, Malocclusion, Assessment of periodontal status and prosthetic possibilities, Plaque control, Smoking, Cooperation of the patient, Individual tooth prognosis, Genetic factors and Stress

1. **Type of Periodontitis:**
   - i. **Slowly progressing periodontitis:** Onset is in the 3rd and 4th decade and progresses slowly. It responds to conventional treatment if not severe. Prognosis is directly related to severity of inflammation and height of remaining bone.
   - ii. **Rapidly progressing periodontitis:** It occurs in second decade and exhibit rapid bone loss. Either slight inflammation not suggestive of underlying osseous defect or extensive inflammatory reaction may be present. They have a hopeless prognosis, however some cases respond to conventional therapy and antibiotics.
   - iii. **Refractory periodontitis:** Patients are resistant to treatment due to impaired defense

mechanism, resistant bacteria, untreatable morphologic problems or combination of these factors.

iv. **Prepubertal periodontitis:** This type of periodontitis is associated with systemic disease in children, most cases prognosis is poor.

v. **Juvenile periodontitis:** It starts at puberty, limited initially to 1st molars and incisors. It is associated with specific flora; patient may have leukocyte defect. Prognosis is poor, but administration of systemic tetracycline in conjugation with surgical pocket therapy has good results.(3)

2. **Patient's age:** Prognosis is better in older patients with comparable levels of remaining bone. Prognosis is not good in younger patients because of rapid periodontal destruction in a short period of time and they may suffer from aggressive periodontitis.

3. **Systemic background:** Prevalence and severity of periodontitis is higher in patient with systemic disorders like diabetes, hyper parathyroidism, and nutritional deficiency. Incapacitating conditions like Parkinson's disease adversely affects the prognosis. Newer automated oral hygiene devices are useful for these patients to improve prognosis.

4. **Malocclusion:** Irregularly aligned teeth, malformation of jaws, abnormal occlusal relationships interfere with plaque control. Orthodontic or Prosthetic correction is essential for success of periodontal treatment. Overall prognosis is poor for the patients with occlusal deformities that cannot be corrected.

5. **Smoking:** Smoking plays an important element and considered to be one of the environmental risk factor in pathogenesis of periodontal disease. Smokers do not respond well to conventional method of treatment. Patients (smokers) with slight to moderate periodontitis have fair to poor prognosis. Patients (smokers) with severe periodontitis have poor to hopeless prognosis.(4)

6. **Patient cooperation and compliance:** Prognosis critically depends on patient's behaviour, perception, desire to retain his natural teeth, attitude and oral hygiene maintenance. The patient's cooperation in following the prescribed treatment protocols and post treatment instructions also affect the prognosis.

7. **Plaque control:** Bacterial plaque plays an important role in initiation and progression of periodontal disease and is considered as the primary etiologic factor. Effective removal of plaque either during treatment procedure or patient's approach to follow plaque control on a daily basis is critical for successful periodontal therapy and for prognosis.(5)

8. **Genetic factors:** IL-1 gene polymorphisms leads to production of increased IL-1β which is believed to associated with pathogenesis of chronic periodontitis.(6) Prior knowledge and diagnosis of patient's IL-1 genotype and smoking status would help the clinician to judge the prognosis and comment on the survival rate.

9. **Stress:** Physical, mental, emotional and environmental stress may affect the patient's response rate to the periodontal therapy. Proper identification of these factors on the patient's behalf would give a clear picture about the overall prognosis of the patient.

Factors Affecting Individual Tooth Prognosis: Factors affecting individual tooth prognosis include percentage of bone loss, probing pocket depth, Bone loss patterns and its location, presence of furcation involvement, tooth mobility, tooth morphology, crown to root ratio, root concavities and its forms, caries, non vital teeth, occlusal relationship, developmental grooves, enamel projections, teeth adjacent to edentulous area, relation to adjacent teeth.

1. **Percentage of bone loss:** Greater the bone loss, poorer the prognosis. As bone loss exceeds 50% the prognosis worsens rapidly. More irregular the bone loss, the poorer is the prognosis.

2. **Distribution and type of bone loss:** Horizontal bone loss, pocket elimination is easier. When vertical/trough like bone defects are present, the feasibility of osteoplastic, new attachment attempts or bone grafting must be considered. (7)Vertical bone loss with 1 or 2 walled infrabony defects or interproximal bony craters have worse prognosis than horizontal type. However, considering vertical defects, three walled infrabony defects and two walled defects have better prognosis than One walled defects for bone regeneration.(8)

3. **Periodontal pocket:** Pocket depths, clinical attachment, degree of bone loss, and nature of pocket are important in determining prognosis.(9) The extent, location, depth and complexity should

be taken into consideration.

4. **Mobility:** Teeth with 4–5mm remaining bone or grade 3 mobility has doubtful prognosis. Teeth that can be rotated or depressed is much more seriously involved than a tooth with horizontal mobility. Mobility due to occlusal trauma has favorable prognosis.

5. **Furcation involvement:** The problems associated with furcation involvement are, difficulty of access to surgical area, inaccessibility of the area to plaque removal by the patient.[10] The divergence of the root, the accessibility to the clinician for better instrumentation, the trunk of the tooth are to be considered when determining prognosis.

6. **Relation to adjacent teeth:** In dealing with teeth of questionable prognosis, the chances of successful treatment should be weighed against any benefits that would serve to adjacent teeth if the tooth under consideration was extracted. Heroic attempts to retain a hopelessly involved tooth may jeopardize the adjacent teeth.

7. **Caries, Non-vital teeth, Tooth resorption:** In teeth with extensive caries, feasibility of adequate endodontic therapy should be considered before undertaking periodontal therapy. The resorption of root (internal or external) leads to mobility of the tooth and this can affect the treatment outcomes therefore jeopardizing the instrumentation, maintenance of oral hygiene and success of any periodontal therapy rendered to the tooth n question. Vitality of the tooth also plays an important role in deciding the prognosis of the periodontal therapy. The non-vital tooth behaves differently than vital ones. It is believed that new attachment can occur in cementum of both non-vital and vital teeth, however the nature of attachment is not even close to regeneration.

10. **Tooth morphology:** Root form and morphology, Crown root ratio**,** Root concavities**,** Developmental grooves**,** Enamel projection are to be considered. Prognosis poor for teeth with short, tapered roots and relatively large crowns. Developmental grooves which sometimes appear in the maxillary lateral incisor (palate-gingival groove) or in the lower incisors, create an accessibility problem. (5.6% maxillary lateral incisors and 3.4% maxillary central incisor). Cervical enamel projections on the root surface interfere with the attachment apparatus and may prevent regenerative procedures from achieving their maximum potential. Therefore, there presence may have a negative effect on the prognosis for an individual tooth.

Clinical Applications: Careful analysis of the factors determining individual and overall prognosis, will allow the clinician to assess the type of prognosis.[1] The below mentioned criteria are used to determine the type of prognosis in a patient suffering from periodontal disease:

1. **Excellent prognosis:** The prognosis is considered excellent when the patient presents with no evident bone loss**,** however, the gingival condition is maintained at an excellent condition. The patient is cooperative and complaint with no history of systemic or any environmental risk factors.

2. **Good prognosis:** The prognosis is considered to be good when there is adequate amount of remaining bone support along with the periodontium, and the patient as well as the clinician has adequate possibilities to control etiologic factors and establish a maintainable dentition. The patient is cooperative with no history systemic or any environmental risk factors. And systemic factors if present, it should be well to moderately controlled.

3. **Fair prognosis:** The prognosis is considered fair in case of patient presents with less than adequate remaining bone support along with weak periodontal support and tooth mobility. There may be presence of Grade I furcation involvements. The patient cooperation may be acceptable and can take adequate maintenance and plaque control measures. There also may be presence of limited systemic or any environmental risk factors.

4. **Poor prognosis:** The prognosis is considered fair in case of patient presents with moderate-to-advanced bone loss, weakened periodontal support, tooth mobility along with Grade I and II furcation involvements. There may be presence of difficult-to-maintain areas. The patient's cooperation and compliance may be doubtful and there is always presence of systemic or any environmental risk factors.

5. **Questionable prognosis:** The prognosis is considered fair in case of patient presents with advanced bone loss, weakened periodontal support, tooth mobility along with Grade II and III furcation

involvements. There may be presence of inaccessible areas. The patient's cooperation and compliance may be doubtful and there is always presence of systemic or any environmental risk factors.

6. **Hopeless prognosis:** The prognosis is considered fair in case of patient presents with advanced bone loss, weakened periodontal support, Grade III tooth mobility. There may be presence of non maintainable areas. The patient's cooperation and compliance may be doubtful and there is always presence of uncontrolled systemic or any environmental risk factors. Extraction is indicated in such a scenario.

Excellent, good and hopeless prognoses are the only prognoses that can be interpreted with a reasonable degree of accuracy. Fair, poor and even questionable prognosis depends on a large number of factors that can interact in an unpredictable number of ways. In many of these cases, it may be advisable to establish a provisional prognosis until phase I therapy is completed and evaluated.

Prognostic Judgement and Treatment Planning: Treatment can alter prognosis. The severity and distribution of the lesions, the ADA classification type and complicating factors of the diseases must be assessed to determine the effect of the therapy. Severity distribution of inflammatory and traumatic factors, severity depends on pocket depth, degree of bone loss, tooth mobility, crown root ratio. Distribution of disease may be generalized or localized. Inflammatory and traumatic factors must be considered and may produce variation in prognosis of individual teeth.

Conclusion

Periodontal prognosis, a fascinating aspect of periodontal therapy, requires experience and judgment as well as a keen attention to meticulous detail. The fate of the dentition sometimes rests on the decision of the therapist. Patients almost always ask for reassurance on the chances of retaining natural teeth and usually express their questions in the form of an expressed doubt on the advisability of proceeding with therapy. Hence, the determination of prognosis is a vital and essential step in periodontal treatment planning.

Chronic Inflammatory Gingival Enlargement Managed by Scaling and Root Planing with Curettage: A Case Report

Abhaya Chandra Das[1], Sourav Panda[1], Manoj Kumar[1], Rinkee Mohanty[2], Rashmita Nayak[2]

[1]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Gingival enlargement (GE) is defined as an increase in the size of the gingiva. It is also known as gingival overgrowth. A wide variety of etiological factors play an important role in the development of GE. GE may be acute or chronic. However chronic inflammatory GE is most commonly found. Prolonged exposure of dental plaque is the most common etiological factor of chronic GE. A 23-year-old girl came to the Department of Periodontics, with a chief complaint of swelling of gums in lower front teeth regions. On clinical examination, there was grade II GE in 33 to 43 regions along with the presence of calculus in the lingual side, and poor oral hygiene too. It was planned for phase I therapy followed by phase II therapy. So scaling and root planing was performed and after 4 weeks curettage was done under infiltration local anesthesia. The subject was instructed to maintain oral hygiene. After 2 months, it was found complete resolution of GE. She was very satisfied with the result.

Keywords: *Curettage, gingival enlargement, root planing,scaling.*

Introduction

Gingival enlargement (GE) is the most common characteristic of gingival disease.[1] Increase in size of gingiva is known as GE.[2] These GE may represent as mild enlargement of the isolated interdental papilla to segmental. It may sometimes be uniform and marked enlargements affecting one or both jaws. These GE may be due to various etiopathogenesis. It may be due to multifactorial origins such as from interaction between host and environment, or to various stimuli.[3] But it generally develops from plaque-induced or any associated with systemic hormonal disturbances. It is also associated with the manifestation of leukemia, thrombocytopenia.[4] These GE may sometimes lead to functional disturbances such as altered speech, difficulty in mastication, and esthetic and psychological problems.[2]

Inflammatory GE may be divided into acute or chronic. But chronic GE is much more common. This chronic inflammatory GE is due to prolonged exposure to plaque accumulation.[1,4] This plaque-induced inflammatory GE is easily treated with debridement of plaque and calculus and encouragement of oral hygiene.[5] Sometimes it is subsided without curettage. But in case of fibrotic GE gingivectomy is needed.[6] This case report is presenting chronic inflammatory GE and its treatment.

Case report: A 23-year-old girl came to our Department of Periodontics, with a chief complaint of agum swelling in front lower region, gum bleeding and bad breath. The patent had marked the swelling and told that the swelling gingiva had increased in size since then. Onclinical examination, it was found that there

Corresponding Author:
Dr. Abhaya Chandra Das
Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: drabhaya2011@gmail.com

was grade 2 GE which involved marginal and papillary gingiva, slight erythematous color, loss of stippling, obliterated contour, bleeding on probing in the complaint area (figure 1).[7] The gingiva appeared as soft and friable with a shiny and smooth surface. There was the presence of false periodontal pockets.[1]

Figure 1: Preoperative view showing enlarged gingiva of mandibular teeth

She was almost systemic healthy. She had no tobacco chewing habits. However there was the presence of sub gingival calculus, especially in the lower anterior region, which was the main culprit of enlarged gingiva. On further investigation, she maintained poor oral hygiene and poor plaque control.

Treatment: Scaling and root planing was done. After 4 weeks, there was some amount resolution of GE with no bleeding on probing as shown in figure 2. So the next plan was decided to curettage. Under local anesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine), curettage was performed in the anterior mandibulararch (33 to 43) with the help of Gracey curettes # 1, 2, 3, 4. The patient was advised to perform proper oral hygiene maintenance and trained the proper brushing technique (Modified Bass Technique).

Figure 2: After 1 month of Scaling and root planing

Figure 3: After 2 month of curettage

Results

The present case was againre called after 2 months of curettage. It was found that there was a complete resolution of GE as shown in figure 3. There was no bleeding on probing, presence of stippling and scalloped gingiva, melanin pigmented pink health gingiva. She was satisfied with the final result.

Discussion

Chronic inflammatory GE is the most common occurrence of GE which is mainly originated as a result of prolonged exposure to dental plaque.[1] So factors that favor the plaque accumulation and retention include poor oral hygiene, maligned teeth, loss of tooth function, any defective restoration, previous history of orthodontics treatment, mouth breathing habits, etc. Treatment of chronic inflammatory GE depend upon the understanding the underlying the causes and pathological changes.[2]

In the present case, there is a case of chronic inflammatory GE. Generally, these type GE is associated with prolonged exposure of dental plaque and later accumulation dental plaque. This type of GE can be managed by regular professional scaling and root planing along with good patient compliances. If the GE is not resolved, then curettageis done after 1 month. If still the GE is not resolved and gingiva becomes fibrotic, then gingivectomy or flap surgery should be performed.[2,3,6]

Conclusion

Chronic inflammatory GE in our case was due to mainly poor hygiene maintenance. There was more inflammatory component in our case. So there was a drastic reduction of GE after scaling and root planing and followed by curettage. To prevent relapse of GE, it is very important to maintain oral hygiene, as well

as it needs oral hygiene education supplemented with positive motivation at the initial stage of the treatment.

Post Orthodontic Cosmetic Detailing

Snigdha Pattanaik

Associate Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Post orthodontic cosmetic detailing is perhaps one of the most deceiving and difficult phases of orthodontic treatment. The cosmetic detailing procedures are considered as a part of the total scheme of treatment to enhance the stability and esthetics of the cases. In recent times, a great deal of emphasis is placed on achieving perfect finishing and detailing of the orthodontic treatment, so that the results are pleasing to the eye. This article aims to provide comprehensive knowledge about post orthodontic cosmetic detailing.

Keywords: *Esthetics, finishing and detailing, cosmetic detailing, orthodontic treatment.*

Introduction

Enhancement of facial beauty is one of the primary elective goals of patients seeking dental care. The goal of orthodontic treatment should be the attainment of the best possible esthetic result. Orthodontists enjoy a high level of patient appreciation, partly because their results are almost always an esthetic improvement. Still, many orthodontists finish treatment short of the finest possible esthetic result[1].

The finishing of orthodontic cases can usually be enhanced through restorative techniques such as cosmetic contouring, bleaching, bonding, porcelain laminating, or crowning. Each patient should be educated in advance about these techniques and told that the orthodontist will evaluate the treatment after the appliance therapy and decide what, if any, additional treatment would be beneficial. This should be a joint consultation with the patient's general dentist to ensure that all choices are considered[2,3].

Corresponding Author:
Dr. Snigdha Pattanaik
Associate Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

The following are certain procedures that are considered under the cosmetic finishing:

1. Gingivectomy
2. Gingivoplasty
3. Bleaching
4. Veneers.
5. Porcelain jackets
6. Selective contouring.
7. Bridges and
8. Cosmetic build-ups

Gingivectomy: It is done to eliminate gingival enlargements – aesthetic considerations particularly in the anterior maxilla either by conventional surgery or by electrosurgery. Pockets on each surface of the tooth are explored and marked with pocket markers. Kirkland knives are used for labial and lingual incisions and Orban's knife for interdental incisions. The incision is given apical to points marking the course of the pockets and directed coronally to a point between the base of the pocket and the crest of the bone. The excised pocket wall is removed along with the granulation tissue and any remaining calculus or necrotic cementum. The area is covered the area with surgical pack[4,5].

Gingivoplasty: It is Similar to the gingivectomy technique. Gingivoplasty is reshaping of the gingiva to create physiological gingival contours, with the sole

purpose of recontouring the gingiva in the absence of pockets[6].

Conservative alteration of tooth contours and contacts:

Reshaping of teeth: Rounding of sharp angles–prophylactic measure to stress and to help prevent chipping and fracture of incisal edges is done to achieve youthful feminine characteristics; Rounding the incisal edges, reducing facial line angles, opening incisal embrasures. Opposite characters are considered masculine.

The patient must understand what is involved and just want to have the alteration made. The patient should be explained about the expected postoperative result. Areas to be reshaped should be marked with a pencil. Diamond instruments, abrasive points are used contouring, finishing and polishing[7].

Many orthodontic results can be improved by a slight reshaping, or cosmetic contouring, of the teeth. This can help achieve an illusion of straightness, especially in cases where patients demand early removal of appliances or where particular teeth are impossible to position ideally.

Contouring is useful in compromise treatment. When the occlusion is good but anterior crowding is present, minor tooth repositioning followed by cosmetic contouring will often improve the appearance[8].

Irregularly fractured incisal surface: In these cases, **the** esthetic result can be achieved by slightly shortening incisal edges and reshaping both teeth to symmetrical form. Similar procedures are done to recontour the tooth[9].

Alteration of embrasures: Anterior teeth may have embrasures that are too open, e.g. when laterals are congenitally missing. Facial surface and cusp angle of some canines reshaped to appear like lateral. But in many instances, mesio incisal embrasure remains too open. Composite restorations can be done to enhance the esthetic contour and correct open embrasure. Evaluation of occlusion before restoration determines if the addition will be compatible with functional movements.

Coarse flame-shaped diamond is used to remove overly convex enamel surfaces and to roughen area to be augmented. Wedge with abrasive strips is used in difficult proximal surfaces. Polyester strip is inserted to protect the adjacent tooth during acid etching. After etching, rinsing, and drying the contoured strip is positioned. Either self-cure or light cure material is inserted and the strip closed for polymerisation[10].

Closure of Diastema: The most frequent site of diastema is between the maxillary central incisors. Prominent labial frenum with nonelastic fibers extending proximally is often the cause. Other factors are congenitally missing tooth, undersized or malformed teeth, Bolton discrepancy, supernumerary and heredity. Diastema should not be closed without first recognizing and treating the underlying cause. Occasionally diastema is too large to esthetically close with comp augmentation alone. In such cases, spaces are best redistributed orthodontically among anterior teeth so that symmetrical and equal composite additions can be made[11].

Discolored teeth:

Discolorations are of two types; Extrinsic and intrinsic: Extrinsic discoloration is due to the remnants of Nasmyth's membrane, poor oral hygiene, existing restorations, eating habits and presence of chromogenic bacteria. Most of the surface stains can be removed by routine prophylactic procedures. Some require micro abrasion or macro abrasion[12,13].

Intrinsic discolorations are generally caused by deeper internal stains or enamel defects and are more difficult to treat than external types. It is due to hereditary disorders, medications, excess fluoride, high fever etc. Tetracyclines create the most distracting, generalized, intrinsic stains. Severity will depend on several factors such as–dosage, duration and the type of tetracycline analog. Yellow-orange to dark blue-gray (more difficult to treat) type of staining is the most difficult to treat[14].

White spots: Poor oral hygiene during orthodontic treatment creates decalcified areas. White spots with intact enamel surface–evidence of remineralization–no invasive procedures. Mild discolorations are best left untreated, bleached or treated conservatively with micro or macro abrasion, because no restorative material is as good as the healthy, natural tooth structure. The patient should be told that the gingival tissue never would be as healthy when adjacent to a restorative material as when next to normal tooth structure.

Bleaching treatments: The lightening of the color of the tooth through the application of a chemical agent to oxidize the organic pigmentation in the tooth

is referred to as bleaching. Most bleaching techniques required some form of hydrogen peroxide in different concentrations.

Mechanism of action–Bleaching agents creates oxidation of organic pigments. Generally has a life span of 1-3 yrs, although the change may be permanent in some cases. With all bleaching techniques there is a transitory decrease in the bond strength of the composite is generally expected. Residual oxygen or peroxide residue in the tooth which inhibits the set of bonding resin. No loss in bond strength is noted if the composite treatment is delayed at least 1 week after cessation of any bleaching[15].

Micro/Macro abrasion: It is called Microabrasion as it involved the surface dissolution of enamel by acid along with the abrasiveness of the pumice. Croll modified the procedure by reducing the concentration of acid to 11% and adding silicon carbide particles –'Prema' for improved and safer means of removal of superficial stains. They represent conservative alternatives for the removal of superficial discolorations. As the term implies, the stained areas or defects are abraded away only when stains or defects do not extend beyond a few tenths of a millimeter (0.2-0.3mm) in depth. If the defect persists a restorative alternative is indicated[16].

When should they be used?: The nature and extent of the defect should be evaluated. Non-hereditary developmental demineralization defects (white or light brown fluoretic enamel and the idiopathic white or light brown spots) versus the incipient carious lesion should be properly differentiated. *Incipient caries* usually near gingival margin where abrasion contraindicated (thin enamel). Smooth surface, opaque or chalky white when dried but invisible when hydrated. It is generally reversible by improved oral hygiene.

Developmental discolored spots (opaque white or light brown) are due to unknown local traumatic events during amelogenesis and are Idiopathic. They occur on Intact, smooth and hard surfaces usually in the incisal half. The patient should be informed that an accurate prognosis for microabrasion cannot be given. It will be tried first and if unsuccessful due to the depth of defect exceeding 0.2-0.3mm, the tooth will be restored with tooth-colored restoration. Surface discolorations due to fluorosis can be removed by microabrasion if the depth is within 0.2-0.3mm[17].

Technique–Rubberdam to isolate and protect the gingiva from acid. Prema paste is applied to a defective area with a special rubber cup with fluted edges. Low-speed handpiece, to avoid excessive removal of tooth structure. Treated areas are polished with fluoride-containing prophy paste to restore surface luster. Immediately after treatment topical fluoride to enhance re-mineralisation[18].

Microabrasion: Simply utilizes 12-fluted composite finishing bur or a micron finishing diamond in high-speed handpiece to remove defects.

Care should be taken to monitor the removal of tooth structure.

Air-water spray is recommended – facilitates assessment of defect removal.

It should be emphasized that these techniques involve the physical removal of tooth structure and does not remove stains or defects through any bleaching phenomena. *Microabrasion have b*etter control over tooth removal

Microabrasion*: It is done using* high-speed instrumentation. It is technique sensitive and can have catastrophic results. The procedure is faster and does not require a rubber dam or special instruments. It is easier to remove the defect with Macroabrasion[19].

Veneers: It is a layer of tooth-colored material that is applied to the tooth for esthetically restoring localized or generalized defects or intrinsic discolorations. It is made of chairside composite, processed comp, porcelain, or cast ceramic materials. Veneers are indicated on the facial surfaces that are malformed, discolored, abraded, and/or eroded. *Partial veneers* are indicated for the restoration of localized defects or areas of intrinsic discoloration. *Full veneers are indicated for the r*estoration of generalized defects or areas of intrinsic discoloration. Discolored mandibular anterior are rarely indicated for veneers, because the facio-incisal portions are thin and usually subject to biting forces and attrition.

Conservative bridges: In selected cases conservative bridges can be made by acid etching and bonding a pontic to the adjacent teeth. According to the type of pontic are of four types; Natural tooth pontic. Denture tooth pontic. PFM or All Metal with metal retainers and All-porcelain pontic. They are used for the conservation of natural tooth structure. Because of

the bonded nature of these bridges retention is never as strong as conventional bridges. Patients should be told of potential risks of dislodgement and must be cautioned not to bite hard food[20].

Periodontal Plastic Surgery and Orthodontics: For many years, periodontal mucogingival surgery was employed only to cover exposed roots with soft-tissue grafting. Today, periodontal plastic surgery is used not only to enhance esthetics in a variety of ways, but also to aid in orthodontic treatment.

Periodontal plastic surgery is the term for a procedure that corrects or eliminates an anatomic, developmental, or traumatic deformity of the gingiva or alveolar mucosa. This would include treatment of excessive gingival display, marginal tissue recession, asymmetrical or unesthetic gingival margins, and localized alveolar-ridge deficiencies, as well as exposure of unerupted teeth for orthodontic movement.

If excessive gingival display, commonly called a "gummy smile," or high lip line is caused by insufficient clinical crown length, this can be corrected with gingival contouring.

Root-coverage techniques can be used to correct inadequate attached gingiva, root sensitivity, or an unesthetic appearance. Although the success of root coverage for treatment of canine marginal tissue recession was once unpredictable, Miller has recently developed a reliable technique using a free gingival graft after citric-acid root conditioning. Langer and Langer have described a subepithelial connective tissue graft that improves the esthetics of root-coverage grafting; this technique is particularly useful in treating the recession of canine marginal tissues[21].

Esthetic finishing of an orthodontic case often involves periodontal plastic surgery. The art of periodontal procedures can be used to improve facial esthetics and complement the results of orthodontic treatment.

Conclusion

Post orthodontic cosmetic detailing is probably the most challenging and difficult stage of treatment. In certain cases, it takes much effort for planning the detailing to provide better esthetics. The time spent by individual clinicians in detailed finishing is an important factor in the variation of treatment duration. Orthodontists must keep them in mind and take care of the beginning of treatment to minimize errors in the different stages so that he has to do the minimum amount of work during the actual stage of finishing and detailing thereby providing efficient treatment to his patient.

Abstract

Disease is an important entity in healthcare. In-depth understanding of disease causation aids in planning prevention and steps to tackle the disease in a population. The outlook regarding disease causation has changed considerably with time and advancements in science. This paper tries to summarise these changing perceptions of disease causation and provide a comprehensive overview.

Keywords: *Disease Causation; Theories; Models.*

Introduction

Disease is usually considered the opposite of health, a deviation from the normal function. Webster defines disease as "a condition in which body health is impaired, a departure from a state of health, and alteration of the human body interrupting the performance of vital functions". However, from an ecological view, disease is defined as "a maladjustment of the human organism to the environment".[1]

The key to finding remedies for the cure of diseases, necessitates an understanding of the cause of the disease. But our perception of disease causation has undergone a vast alteration with the ever changing advancement of science and its contribution to health. Our explanation of disease causation is based on these:

Theories of disease causation:

i. Theories of the pre-modern era
ii. Germ theory of disease
iii. Biomedical model
iv. Epidemiological triad
v. Dever's epidemiological model
vi. Theory of multifactorial causation
vii. Web of Causation
viii. Wheel of disease causation
ix. Other theories
    - Lazaru's theories of stress response
    - Wolf's theory of stress, organ maladaptation and disease
    - Holmes and Rahe's theory of life change and the onset of illness

i. Theories of the pre-modern era: These theories were in play before the existence of microorganisms was established, till the end of the 18th century.

a. The demonic theory: According to this theory, the disease is a result of being possessed by demons, or evil spirits. Hence the sick person

was subjected to sorcery to rid the body of the evil occupant.

b. **The punitive theory:** For a long time,the disease has been thought to be caused as a punishment for any bad deed done, as an outcome of the outrage of Gods. Hence the diseased individual is to appease the deity to rid himself of the disease.

c. **The miasmatic theory:** It is the notion of bad air. Breathing in certain areas was proposed to cause disease, such as air around swamps, marshes and air at night times was thought to cause an array of diseases.

d. **Theory of four humors:** It proposes that the body is constituent of four humor; blood, phlegm, yellow bile and black bile. Any imbalance in these resulted in disease. Blood-letting was considered the most common method of treating disease.[2]

The Ayurveda believes that the imbalance of the three Doshas (tridosha) is the reason behind disease causation. While the Chinese medicine considers a discrepancy between the male (yang) and female (yin) principle resulting in disease.[1]

ii. **Germ theory of disease:** The demonstration of bacterial presence in the air by Louis Pasteur and Anthrax is caused by bacteria by the turn of the 18th century caused a drastic shift in the understanding of disease causation. Thus, focus from empirical causes such as bad air and wrath of God was altered to scientifically plausible causes like the presence of specific microorganisms.

The germ theory implies the causal effect is one to one, i.e. a single microorganism is the culprit behind a specific disease. Eg. Mycobacterium tuberculosis bacteria and the occurrence of tuberculosis. But that seldom is the case, as many diseases cannot be explained by this one to one causal relation but in reality, an interaction of various other contributory factors.[3]

iii. **Biomedical Model:** This envisions the healthy human body as an efficiently functioning machinery, and any resulting aberration as malfunction of the component organs. Eg. Hypothyroidism caused by improper functioning of the thyroid gland.

But the human body seldom functions independently of its surrounding environment. This theory overlooks the complex and summative role of psychological and social attributes.[4]

iv. **Epidemiological triad:** It proposes the disease is an outcome of imbalance of interactions between three essential components, Host, Agent, and Environment. Disease is caused when a susceptible host is exposed to the causative agent, in a compatible environment.

It's a broader concept and overcomes the limitations of germ theory. Intercepting any of the three links provides a means of halting the disease process, thereby highlighting areas for focus preventive efforts.[5,6]

v. **Dever's epidemiological model:** This model highlights the interplay of four factors namely: Human biology, Lifestyle, Environment and Health system. All of which can have a positive or a negative effect.

Human biology includes genetics along with complex physiological systems, factors that are related to maturation and aging. While, lifestyle factors include daily habits, customs, and traditions; environmental factors are all the living and non-living factors that surround us. Health care system is comprised of accessibility and availability of health services.[7]

This model is used to explain those diseases where, rather than a causative organism, harmful living conditions and lifestyle are to be blamed.

vi. **Multifactorial causation:** Pettenkofer proposed that disease is a result of many factors as opposed to germ theory where the idea of a single cause was used. Improvements in public health and medicine brought about a decline in communicable diseases. But other noncommunicable ailments were on a rise which could not be explained based on the germ theory of disease. Hence single cause was deemed to be oversimplifying etiology of a disease where factors such as social, cultural, genetics, and economic factors were overlooked. Also having multiple causes for a disease meant numerous method of preventing that disease. But it was essential to prioritize the sequence of modification of the causal factors to tackle the disease causation.[1,8]

vi. **Web of causation:** Was proposed by MacMahon, Pugh, and Ipsen (1960), who argued that multiple factors causing a disease cannot be explained using a linear causal relation as, there are complex

precursors to each causal component in the chain that have their respective complex interactions that overlap each other. Hence giving the metaphorical appearance of a complicated ***web of interactions*** rather than a linear causal relation.

This web of causation gives each component equal prominence in recognizing determinants and helps in planning interventions. It integrates social factors to biomedical etiological factors.[9]

vi. **Wheel of disease causation:** This was proposed by Mausner and Kramer in 1985. It eliminates the agent as a sole cause of disease, but emphasizes the complex interaction of physical, biological, and social environments. It also introduces genetics into the mix. The outer circumference is divided between environmental factors comprising of social, biological, and physical factors. The core depicts the genetic component.[6,10,11,12] (Figure 1).

Rothman's Component Causes and Causal Pies Model: It proposes that the causation of disease is by a collection of factors, which are represented by a pie.

This model discriminates the causal factors into ***Sufficient and Necessary causal factors.***

Sufficient cause: is a set of minimum conditions, events, or factors that are required to produce a given outcome. These factors that form the ***sufficient cause*** are called **component causes**. A disease can have more than one sufficient cause.[6]

Necessary cause: is a causal factor whose presence is imperative for the emergence of the effect. If the disease cannot occur without the factor being present then the causative is termed as ***"Necessary".***A component that appears in every pie or pathway is a necessary cause.

So, in figure 2, component cause"A" is present in all pies making it a necessary cause.

The disease can be controlled by removing one component from the pies or the removing the factor that is common to all pies.

Eg: Mycobacterium Tuberculosis bacteria is ***necessary*** to cause tuberculosis but cannot cause the disease in isolation, i.e. is not ***sufficient*** to cause the disease. A host of other factors are required such as impaired nutrition or immunity which can be deemed ***sufficient cause***.

Postulates of Disease Causation: Postulates explaining the process of disease causation have been given by Henle and Koch in 1877 and then by Hill and Evans in 1965. Though our perception about disease causation has changed greatly due to advancements in the field of science, these postulates still hold with some modifications.[13]

a. **Henle-Koch's Postulates:** Postulates were formulated by Robert Koch and Friedrich Loeffler. These postulates helped the germ theory of disease gain popularity over other theories in the 1800s. Certain sets of criteria are to be met before a particular infectious disease agent can be accepted as a cause for a disease.

- The microorganism must be found in abundance in the subject suffering from the disease, but should not be found in healthy subjects.
- The causal microorganism should be isolated from the diseased subject and be grown in pure culture.
- The cultured microorganism thus grown should cause disease when introduced into a healthy organism.
- The microorganism must then be re-isolated from the inoculated, diseased experimental host subjects and cultured and identified as the original causative agent.[14]

However, Koch's postulates can't be applied in all scenarios.[15] As in instances of asymptomatic carriers of diseases such as typhoid and cholera or where two or more microorganisms cause disease. Additionally, some symptoms can be brought about by multiple microorganisms.

b. **Hill-Evans Postulates:** Austin Bradford Hill in 1965 proposed criteria for assessing evidence of causation. These supersede Henle-Koch postulates and considered extensions of Mill's Method of inductive inference (mentioned later). Each criterion contributes to the strength of the causal relationship between a factor and disease.[16]

- **Strength:** Stronger the association between the factor and the disease, more likely it is the causative agent.
- **Consistency:** Consistent observations seen in different scenarios and across different populations strengthens the likelihood of the

causal effect.

- **Specificity:** More specific an association between a factor and an effect, greater the probability of the effect.
- **Temporality:** Exposure to the cause should precede the effect.
- **Biological gradient:** Greater exposure should cause a greater incidence of disease. The strength of causality is reinforced when lesser exposure decreases incidence.
- **Plausibility:** A valid scientific explanation of the causal relationship, though limited by current knowledge is essential.
- **Coherence:** The findings should be coherent with the causal argument.
- **Experimental evidence:** When a feasible causal relationship should be demonstrated.
- **Analogy:** Similar effects should be caused by similar factors.[17]

Another method of inferring causal relation is based on Mill's Eliminative Method of Induction. John Stuart Mill put forth five method of experimental reasoning in his paper System of Logic in 1843. If a specific effect (E) is to be investigated to be caused by the presence of certain factors then the following method are used to reason.[18]

1. Method of agreement: looks for factors present in all circumstances where (E) occurs.
2. Method of difference: advises to look out factors that are present when (E) occurs and the factors that are absent when (E) doesn't occur.
3. Joint method: combining the method of agreement and difference, reinforces the causal relationship.
4. Method of residues: if a range of factors are believed to cause a range of effects, with exception of one factor let's say 'C', and there is an effect that cannot be explained by all the other factors, then we could infer that Factor 'C' is the cause for that effect.
5. Method of concomitant variations: If reducing of a factor causes a reduction in the effect and increasing a factor increases the effect, then a causal relationship between the factor and the effect can be established.[19]

Hence, having a clear picture about the causal mechanism of disease, aids in understanding the disease process, its course and treatment planning. Proper knowledge of disease causation also helps in planning epidemiological studies, adjusting for confounding factors, and ensuring a competent method of research.

Dental Negligence During Prosthetic Treatment

Pradyumna Ku Sahoo[1], Smita R. Priyadarshini[2], Kajal Kiran Sahoo[3]

[1]Associate Professor, Department of Prosthodontics, [2]Associate Professor, Department of Oral Medicine & Radiology, [3]Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Dentists treat patients intending to restore the patient's health. However adverse effects may occur despite all their efforts, some of which could have otherwise been prevented, hence amounting to malpractice. Any patient coming to the dental office needs to be diagnosed accurately first to formulate the correct treatment plan. Its the sole responsibility of the clinician to make the patient aware of the treatment needs and difficulties during and post the procedures. A thorough diagnosis with a proper record of the case history & consent should be obtained. As the dental malpractice lawsuits are extremely, expensive and emotionally draining for the clinician.

Keywords: *Dental Negligence, prosthetic treatment, diagnosis.*

Introduction

Dental malpractice is a form of medical malpractice focussing on injuries suffered during dental visits which range from obvious trauma to dental or oral tissues, negligence by the treating dentist, or misconduct like abuse or molestation of sedated patients. Often dental patients have an underlying systemic disease and are on multiple drugs; lack of proper history taking by the dentist or ignorance regarding the drug interactions or medical complications, even administration of correct dental treatment may still lead to medical emergencies and can be designated as dental malpractice. With advancements in oral and dental treatment modalities, many issues regarding the wrong diagnosis, procedural delays in treatment, improper management and failure in follow-ups have cropped up, comprising dental practice.[1,2] Fixed oartial dentures or crown and bridge are responsible for one of the greatest proportions of negligence claims, damages & legal costs against dentists.

Impression Making: All prosthetic procedures start with impression making and judicious selection of the impression material is the key. Depending upon the accuracy of the structures needed to be recorded the impression material is selected. Here an in-depth knowledge regarding the manipulation and setting times of the various impression materials used is essential. Hypersensitivity to impression materials also needs to be noted in the history taking and then substituted. Any mistake in impression making leads to significant problems in the prosthesis thereby amounting to negligence and malpractice which can be easily prevented by using correct techniques and expertise.[3,4,5]

Diagnosis & Treatment Planning: Prosthodontic treatment requires to thoroughly evaluate every detail from initial patient interaction to the various treatment phases to follow-up & post-treatment care. Problems during treatment could be due to errors during history taking and overlooking of the initial examination.[6]

Articulated casts during the planning of fixed prosthodontic treatment are essential as they provide

Corresponding Author:
Dr. Smita R. Priyadarshini

e-mail: smitapriyadarshini@soa.ac.in

static and dynamic relationships of the teeth. Unmounted casts can give information as to the alignment of the individual arches without providing information about the functional relationships. The diagnostic casts, when attached to an articulator,simulates the jaw movement.[7,8]

Diagnostic Cast Modification: One advantage of having accurately articulated diagnostic casts is that proposed treatment procedures can be rehearsed on the stone cast irreversible changes in the diagnostic procedures are essential when attempting to solve complicated problems.[9] Even the most experienced clinician may have difficulty deciding between different treatment plans.

Diagnostic cast modifications include the following:

1. Changing arch relationship, preparatory to orthognathic procedures when surgical correction of skeletal jaw discrepancy is to be performed.
2. Changing the tooth position before orthodontic procedures.
3. Modifying the occlusal scheme before attempting any selective occlusal adjustment.
4. Trial tooth preparation and waxing before fixed restorative procedures.[10]

On many occasions, it will be necessary to combine two or more of these options. Most treatment planning decisions–whether preparation design, choice of abutment teeth, selection of an optimum path of withdrawal of a fixed partial denture, or deciding to treat a patient with a fixed partial denture or a removable partial denture can be simplified by adhering to these diagnostic techniques.[11]

A logical and systematic approach to diagnosis helps the operator avoid mistakes. Often a completely edentulous patient presents with a resorbed residual alveolar ridge incapable of providing retention for complete denture prosthesis and pre-prosthetic surgery is required.[12] A good treatment plan keeps the patient informed about the conditions, extent, time and treatment costs along with the home care and professional follow-up to achieve success.

Correction of existing disease & Prevention of future disease: Determining and reduction of the initiating factors with the improvement of the resistive factors are crucial to arrest the disease process. Like oral hygiene, instruction tends to improve gingival & periodontal health. Treatment should be directed to correct impaired function primary of mastication, speech and esthetics.[13] Treatment should be planned in such a manner that it shouldn't compromise unwise attempts to improve appearance. They should be advised about the possible adverse consequences of treatment.

Selection of Abutment Teeth: Replacement of missing tooth is done by fixed partial dentures with the use of abutment tooth unless bone support is weakened by periodontal disease.[14]

Cantilever fixed partial dentures have the unilateral side of pontic attached to a retainer. Here forces are tolerated when periodontal structures are directed in the long axes of the teeth. Cantilevers induces lateral forces on the supporting structures leading to tipping rotation or drifting of the abutment.

Assessment of abutment teeth is important before the tooth preparation. Radiographs along with thermal and electrical stimulation of tooth should be done to access the pulpal health. Teeth, when pulpal health is compromised, should be treated endodontically before the denture.[12]

Endodontically treated abutments with post and core have better retention and strength. Failures do occur, mostly on teeth which have shorter roots or less coronal tooth structure.[13]

Unrestored abutments: are the one ideal for the abutment. It is to be conservatively made to obtain good retention & aesthetics. The margins can be made which should contain restorations.

Post- insertion problems: The clinical procedures involved in fabrication and insertion can cause irreversible pulpal damage. Correct techniques should be followed for reduction of tooth, temporary fabrication of restorations, with proper cementation of the final restoration along with the post-insertion care.[14]

Table 1. Symptoms dental negligence during prosthetic treatment

Thermal Sensitivity	Pulpal discomfort from temperature change is frequently encountered following cementation of fixed partial dentures (1) The temporary restoration which don't cover all prepared tooth surfaces, (2) A loose temporary restoration that allows seepage, of oral fluids over the prepared surfaces, (3) A temporary restoration that places excessive occlusal forces on the prepared teeth.[15]
Discomfort during Function	Pains during chewing due to premature centric or excessive contact during eccentric mandibular movement
Gingival Inflammation	Occurs post cementation of prosthesis. This can occur as a result of faulty cervical contour, marginal fit, or embrasure form. Even inadequate oral hygiene aids could cause food retention & inflammation.[16]
Retention of Food	This occurs usually around pontics and connectors. This cannot be completely avoided but proper oral hygiene measures help in removing the food.
Trauma to the cheek or Tongue	Cheek and tongue are the common areas of trauma due to poorly polished portions of the prosthesis. Pontics when placed in areas in which the tongue and cheek were previously not restricted or when flanges of dentures are sharp or cusp-to-cusp or ends -lo-end occlusal relationship without normal horizontal overlap is present. [17]
Sensitivity of Sweets	This occurs when the prepared tooth is not completely covered by the final prosthesis. Sweet sensitivity occurs when the luting agent has undergone dissolution or if the abutment retainer is loose.
Tooth Mobility	Occurs due to poor occlusal relationships, overloading of prosthesis affecting the periodontal ligament and supporting bone causing excessive movement. [18]
Neuromuscular Discomfort	Pain in the temporomandibular joint & associated muscles occurs due to improper occlusion created by a prosthesis. The discomfort caused by occlusal contact on the prosthesis, causing the patient to habitually brings other teeth into a different position. The new mandibular position can create neuromuscular pain in such patients as a result of positional changes in the ligaments and muscles associated with the temporomandibular joint. It must be recognized that other factors may cause pain.[19]
Nonspecific Complaints	Like feels different or slightly uncomfortable this is due to an additional force applied to the abutment teeth, a slight occlusal discrepancy, or simply the presence of an artificial tooth.[20] Esthetics of the prosthesis, Not Cost-effective, Candida infection due to denture stomatitis,improper vertical dimensions causing discomfort with clicking noise, or an unaesthetic appearance. Use of a suction cup in the maxillary denture bearing surface leads to unequal pressure on the hard palate leading to ulceration or even perforation of the palate.[21]

Conclusion

No denture can adequately replace the natural teeth in totality. It can serve in restoring some function and aesthetics but prosthesis however good it maybe does not always satisfy the patient. Moreover, a dentist is not always liable to be sued for malpractice as dental prosthesis involves a lot of lab work which is done by dental technicians and the dentist cannot be only held responsible for the result. Thus, adhering to the most conservative procedure that is in the patient's best interest.

The Mysterious Chemo-Preventive Player in Oral Cavity: Retinoids

Gatha Mohanty[1], Rinkee Mohanty[2], Anurag Satpathy[3]

[1]Senior Lecturer, [2]Professor and Head, [3]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, Odisha, India

Abstract

Vitamin A is considered as one of the essential micronutrients which are extensively associated with chemo-preventive and therapeutic modalities. Carcinogenesis is a complex disease where environmental and genetic factors act as a predisposing cause bringing about alterations in the overall cell microstructure. Possible role of Retinoid, which is a form of Vitamin A, has been recognized in suppressing breast cancer, lung carcinoma, cancer of the colon, prostate cancer, blood cancers and to some extent the cancers of the oral cavity. Retinoid is known to act through RAR/RXR receptors to form ligands and thereby affect the transcription process and controls angiogenesis, abnormal proliferation, and metastasis. Some varieties of leukemia have shown better results with Retinoid therapy. However its role in oral premalignant and malignant lesions are not much known. This review discusses the physiologic, epigenetic and molecular role of Retinoids in lesions of the oral cavity.

Keywords: *Retinoids, Oral Carcinoma, Chemopreventives.*

Introduction

Oral carcinoma is a major area of concern that has increased incidence and associated with a 5 years survival rate in 50% of patients.[1] Chemoprevention refers to the term that includes repairing and reversal of the cellular defects thereby preventing the initiation of disease and its further progression into a tumour. The rich source of Vitamin A is vegetables and animal products such as milk, eggs, cod liver oil, spinach, carrot, butter, etc. These are a precursor to retinol that consists of a retinoid molecule family. The extracted forms are retinol, retinal, pro-vitamin A like carotenoids and retinoic acid. Esterification of retinol takes place in the Liver and then it is distributed to the body parts through the bloodstream. Chemopreventive role of Retinoids was first identified by Sporn MB et al 1976.[2]

RXR or rexinoid receptoris a cell membrane receptor and its isoforms are α,β,γ. These isoforms allow swift movement of retinol in the cell as Retinoic Acid (RA). Similarly 9 cis RA, 13 cis RA and all TransRA(ATRA) are derivatives of retinoic acid. RA and Retinoic Acid Receptor (RAR) with α, β, γ isoformsbind together with hormone binding receptors causing gene transcription. Retinoid Acid Receptor β (RAR β) expression has shown alterations in leukemia,squamous cell carcinoma, breast carcinoma, etc.[3]

Immunomodulatory role of Retinoids: Vitamin A levels are maintained at a physiological level to protect the host from daily harmful stimuli thereby providing immunity. In autoimmune diseases the harmony between the T Helper cell (Th cells) and Regulatory T cell (Treg) population is disrupted.

(a) Th17 acts as a mediator for initiating autoimmune responses that help to protect the host from undesirable bacterial and fungal stimuli.

Corresponding Author:

e-mail: gathamohanty@soa.ac.in

(b) Treg, a member of the FOXP3+ family suppresses massive effector T cell activation by producing interleukins.[4,5] The role of RA is to directly influence FOXP3+ Treg cells in regulating the ratio between Treg and Th17 thereby preventing any untoward body's reaction to inflammatory responses. These changes cause improved resistance of the host towards the autoimmune disease.

(c) ATRA reduces anti-DNA antibodies. According to *Kinoshita K and Wasserfall C* et al, ATRA is used to treat autoimmune diseases like SLE and type 1 diabetes.[6,7] ATRA is also known to inhibit virus-induced T cell death in HIV positive patients. It down regulates the fasL production and alters the ratio of CD8+ and CD4+ T cells. [8,9]

(d) According to Gupta and Sansoni, et al. age-related changes can be due to a progressive increase in effector/cytotoxic CD8+ T cell population producing IL-2, IFN-γ and TNF α.[4,5]

However,a study by *Mecocci P*et al has shown that elevated levels of RA provide resistance to antigenic load in elderly patients.[10]

(e) T Lymphocytes that originate from thymus cells generate T Cell Receptors (TCRs) that carry an important signal for the maturation of T cell.[11] The survival of T lymphocyte depends upon antigen expression in acute diseases which increases IL-2 and BCL-XL expression and prevents apoptosis in the cell.[12,13]

Retinoids regulate healthy reserve of T lymphocyte by allowing maturation of normal cells and selective apoptosis of defective cells.

Retinoids act synergistically enhancing glucocorticoid-induced death and decreasing TCR–mediated death of thymocytes and T cell hybridomas.[14,15]

Tumor suppressionrole of Retinoids: Interaction of retinoid and its receptors downstream the proliferating tumor cells. They either undergo apoptosis or allow the abnormally proliferative cells to differentiate.

It has been observed that expression of RAR-β is either lost or masked hence resulting in reduced intracellular binding of RA.[16,17]

Similarly, specific members of cytochrome (CYP 450) maintains the concentration of retinoic acids in the cell, for a specific period.

A link between RA signal and carcinogenesis may be established via the expression of enzymes of the CYP 26 superfamily. The anti-proliferative property of retinoids is diminished by the enhanced expression of CYP 26.Oxidative stress on the cell is prevented by extending the half-life of RA intra-cellularly, this is done by CYP 26 enzymes which help in preventing oncogenesis.[18]

Role of Retinoids in Apoptosis: Angiogenesis and neo-vascularization promote proliferation and metastasis of a tumor. Angiogenesis is a known predisposing factor to support the survival of neoplastic cells. It is present in all types of head and neck cancers with increased expression of VEGF. Anti-apoptotic activity of tumors can be associated with disrupted expression of NF-Kβ in carcinomas. Increased NF-Kβ expression is seen in bacterial or viral stimuli that lead to inflammation. Increase in NF-kβ expression means there is increasing resistance of the tumor to treatment. Retinoids act through the mitochondrial pathway to release cytochrome c into the cytosol which allows the caspase pathway to activate and cause apoptosis. According to Chen Z and Di Donato, et al, expression of NF-Kβ is seen due to phosphorylation of IKB (inhibitor of kappa beta) by IKB Kinase (IKK) which allows polyubiquitination and proteasome-dependent degradation of its inhibitors.[19] Then the entry of NF-Kβ into the nucleus permits various gene transcriptions to prevent apoptosis.

Anti-proliferative role of retinoids

Size, stage, size and type of tumor influences the fate and prognosis of a disease. Similarly Preferentially Expressed Antigen in Melanoma (PRAME),that is present in tumors is also expressed.PRAME can trigger cytotoxic T cell-mediated immune response in melanoma and other solid tumors like HNSCC. Usually PRAME is expressed weekly or negatively but in tumours its presence can be exponential. PRAME act as a co-repressor of the retinoid signaling pathway. Epping MT et al concluded that the direct mechanism of action of PRAME is unknown but it might prevent ligand-receptor activation of retinoids by acting as an antagonist that allows the growth of tumor cells and differentiation of malignant stem cells.[20] It also inhibits the action of retinoic acid thereby explains the failure of RA treatment in malignant and premalignant lesions in the literature.

Role of RA in the treatment of various conditions:

Oral Lichen Planus: Oral lichen planus is an autoimmune disease that affects the oral mucosa, nails, skin, and genital mucosa. There is a tendency for malignant transformation to SCC in about 1-2 % of affected patients.[21] Often characterized by the presence of inflammatory mediators like cytokines that interact between keratinocytes and T lymphocytes.[22] It is postulated that gene dysregulation is caused by aberrant productions of the cytokines and causes autoimmune reactions with basal cell apoptosis. Expression of (MHC) class II antigen, human leukocyte antigen DR and variable degree of epithelial thickness are features of lichen planus.[23] Vitamin A deficiency might favour the reprogramming of Treg cells into IL-17. RA treatment regulates Th 17 synthesis by inhibiting IL that further influences Treg cells to regulate peripheral tolerance.[24] The plasticity and phenotype of Treg cell production are maintained by RA which helps in controlling a disease. Cytokines production can also be influenced by local microenvironmental which may be controlled by introducing Vitamin A at early stages to reverse the pathogenesis.

Squamous cell carcinoma: Initiation, progression and metastasis of a complex multistep disease is influenced by genetics and environmental factors. Proliferation of stratified squamous epithelium is limited to the basal and parabasal layer and the maturation of the cell is the sequential process of terminal differentiation. In neoplastic lesions IL-8 and TGF β maintain angiogenesis. Retinoic acid treatment suppresses angiogenesis by neutralizing the IL 8 concentration in cancer cells.Retinoids inhibit the cell growth and GJIC- connected cells in HNSCC.[25]Retinoids exert their pleiotropic effects by binding to nuclear receptors in cells and causing inhibition of cell proliferation, modulation of cell differentiation and enhancement of apoptosis.[26,27]

Leukoplakia/Epithelial Dysplasia: The proliferation of basal and suprabasal cells of epithelium associated with a malignant transformation due to extrinsic factors such as tobacco products and with a high rate of proliferation as 43% are features of Leukoplakia. Ramaswamy G, et al. studied the association of intrinsic factors with leucoplakia, decreased plasma levels of vitamin A, B12, C, β carotene, and folic acid were found in patients with oral leukoplakia.[28]

Use of antioxidants like vitamin A block the generation of reactive oxygen species which further prevent normal cell to undergo genetic aberration thereby may revert the tissue to normal state.[29] Vitamin A supplementation and habit can control the variable degree of epithelial dysplasia. Meir, et al. observed that loss of RAR β mRNA as a result of hypermethylation in premalignant lesions may be restored by application of 13 cis RA. Vitamin A can exert its effects when initial signs and symptoms are noted, but once the disease process is advanced, no satisfactory results could be obtained solely. At present, further studies are still under research to estimate the effect of Vitamin A at the molecular level following treatment.

The molecular modification of vitamin A, aids a role in the expression of growth factors, differentiation of cells, immunity, reproduction and repair of epithelial tissue. In oral tissue, deficiency of endogenous vitamin A may cause defective tooth formation and hypo/ dyskeratosis of oral mucosa due to dysregulation caused during the development of dental lamina and oral ectoderm respectively.

Future Perspectives & Conclusions: This article attempts to review and present the chemotherapeutic effects of vitamin A and its analog as a preventive measure in oral premalignant lesions and oral cancer. Extensive research is being conducted to evaluate the usefulness of the molecule as a chemotherapeutic drug, though promising results are seen in leukemia and high-risk breast cancerous lesion but its usefulness in treating epithelial premalignant and malignant lesion is still under question. The effective use of chemoprevention may decrease the potential malignant transformation but it is yet to be authenticated by long term studies to analyze the effectiveness of retinoids following treatment. Moreover, we still stand deficient to identify the targeted receptor which maintains inter and intracellular homeostasis. Invent of targeted markers has given a promising scope to understand the molecular bases of Vitamin A therapy. Research should, therefore, focus on retinoid molecules that can delay the metabolism of RA inside the cell like RAMBA (Retinoic Acid Metabolism Blocking Agents). Validation of treatment to therapy must be viewed using the latest biomarkers to overcome undue exposure in resistant cases. More clinical studies are needed in this direction for treating epithelial malignancies using retinoids as a targeted epigenetic approach.

Pemphigus Vulgaris: Oral Pathologist as Sentinal

Alkananda Sahoo[1], Swagatika Panda[2], Santosh Subudhi[3], Neeta Mohanty[4], Debkant Jena[5]

[1]Senior Lecturer, [2] Professor, Department of Oral and Maxillofacial Pathology and Microbiology, [3]Professor, Department of Oral and Maxillofacial Surgery, [4]Professor & Head, Department of Oral and Maxillofacial Pathology and Microbiology, [5]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The word 'Pemphigus' has been derived from a Greek term meaning "blister". Pemphigus vulgaris is a chronic autoimmune vesiculobullous lesion primarily manifesting as intraoral blisters, gradually involving other parts of the mucous membrane and skin. Though the exact etiology is unknown the lesion is characterized by the production of autoantibodies directed against the intercellular substances thus categorizing it as an autoimmune disorder. Early diagnosis and management determine the course of the lesion hence dental practitioners should be well aware of the clinical features of pemphigus vulgaris as early diagnosis is of considerable value since therapy is simplified when the lesion is confined to the mouth. Here we are reporting a case of a 40 year old female presenting with pain and burning sensation in the left retromolar area along with an overview of the disease.

Keywords: *Pemphigus, autoimmune, corticosteroids, immunosuppressants, oral, vesiculobullous, skin.*

Introduction

Pemphigus is a group of potentially life-threatening autoimmune mucocutaneous disorder which is characterized by epithelial blistering affecting the cutaneous and/or mucosal surfaces. Pemphigus vulgaris is an autoimmune disorder with blister formation on the skin and mucous membrane. It has multiple clinical variants. It has a strong immunological and genetic etiology. Generally,the elderly population is affected and in 50% cases oral mucosal lesions are the initial manifestations.[1] 1 to 5 persons per million populations are affected every year. It has a female predilection with female to male ratio being 2:1 and peaks between the 4th to 6th decades of life.[2] Clinically, oral lesions are recognized by the formation of blisters,which ruptures within no time leaving behind painful ulcerations. Predominantly involves the buccal mucosa, lips and soft palate but can also occur in other areas of the oral cavity.[3] Intra-epithelial vesicles, acantholysis and Tzanck cells are the key histopathological features that confirm the diagnosis.[2] We are reporting a case of pemphigus vulgaris diagnosed with oral vesicles as the most initial sign.

Case report: A female patient aged 40 years resident of Nayagarh, Odisha, came to the Department of Oral Pathology and Microbiology with the chief complaint of pain in the lower left back teeth region for the past 20 days. She had pain during swallowing and also burning sensation on taking food and water. There were no other findings neither on the skin nor on any other mucosal sites. The patient's medical and family history was not significant and non-contributory. The patient had poor oral hygiene.

On general examination, all vital parameters of the patient were normal. There were no extra-oral findings and lymph nodes were not palpable. Intra-oral examination revealed ulceration present on the

oral mucosa extending from left retromolar trigone posteriorly till the anterior faucial pillars (Figure 1).

Figure 1. Erythematous ulcerated areas with ragged border in the left retromolar area.

The lesion extended upwards and backward from the distal of the third molar,ill-defined in shape and covered by pseudomembrane with erythematous surroundings. On manipulation, bleeding from the lesion was positive. There was generalized attrition of teeth and gingival inflammation.

Based on the clinical features differential diagnosis were pemphigus vulgaris, bullous lichen planus, mucous membrane pemphigoid, erythema multiforme, pyostomatitis vegetans, recurrent herpes lesions in immunocompromised patients and pemphigus associated with inflammatory bowel disease.

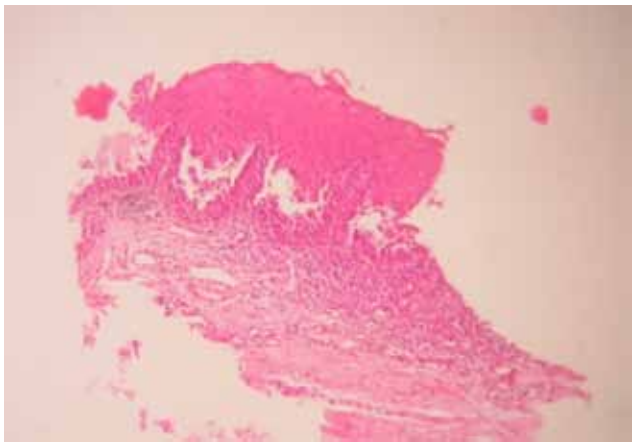

Figure 2. Photomicrograph (4x) shows intraepithelial vesicles and Tzanck cells.

A diagnosis of Pemphigus vulgaris was done after evaluation of the incisional biopsy performed on the perilesional site. The specimens were submitted for direct immunofluorescence study and conventional histopathology. Histopathological examination revealed parakeratinized stratified squamous epithelium beneath which is a moderately collagenous connective tissue stroma. Juxtaepithelial collection of chronic inflammatory cells can be seen in the stroma (Figure 2). Epithelium shows intraepithelial vesicles and clumps of epithelial cells (Tzanck cells) in the vesicular spaces. Tzanck cells exhibit hyperchromatic nuclei (Figure 3).

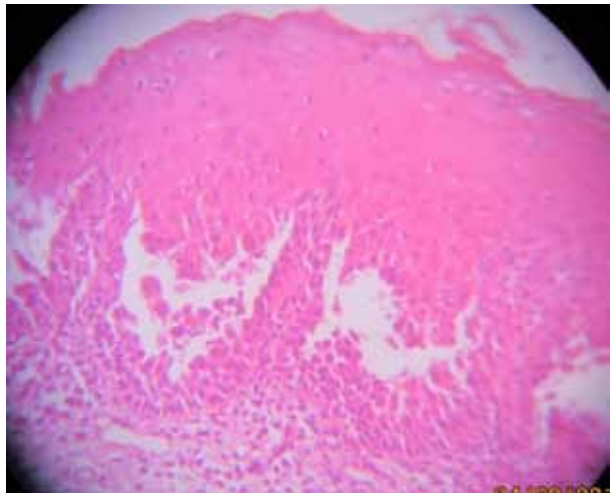

Figure 3: Photomicrograph (10x) shows vesiculation with suprabasilar cleavage and acantholysis and numerous Tzanck cells exhibiting hyperchromatic nuclei.

Direct immunofluorescence (IgG) reveals an immunoglobulin deposit in intercellular areas in a fishnet pattern (Figure 4).

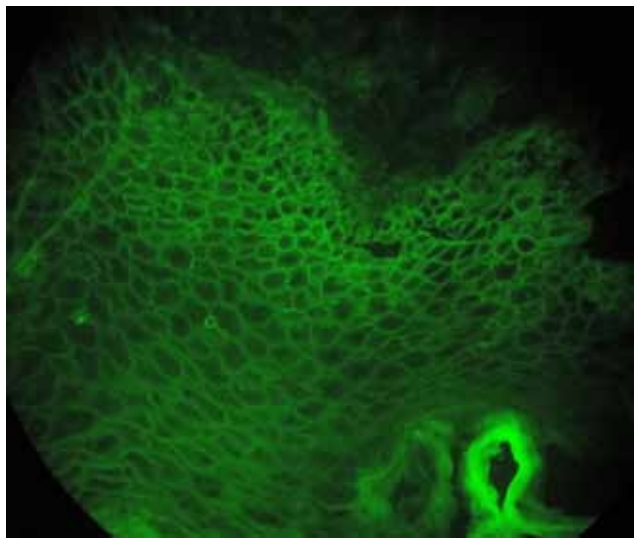

Figure 4. Direct immunofluorescence (IGg): Immunoglobulin deposit in intercellular areas in a fishnet pattern.

Based on histopathological and direct immunofluorescence findings final diagnosis of Pemphigus Vulgaris was given. The patient was immediately put on a combination of immunosuppressive and corticosteroid therapy. Unfortunately the patient was lost for follow up.

Discussion

Pemphigus Vulgaris (Latin: Common) the most common and severest form of pemphigus is a life-threatening vesiculobullous disorder. It is widely recognized that the incidence of pemphigus is higher in Ashkenazi Jews than in any other ethnic group.[4] The estimated incidence is 1 - 5 cases per million people in a year.

The peak age of occurrence is primarily between 4^{th} to 6^{th} decades of life, rarely before puberty. The classical sign is the epithelial blisters/bullae with a very frail wall appearing on cutaneous and/or mucosal surfaces. The bullae rapidly rupture and expand peripherally eventually causing large areas of denuded skin and/or epithelium with ragged edges. The lesions are usually painful. Buccal mucosa is the most common site especially areas of trauma along the occlusal plane. Gingiva and palate are the other common sites of involvement. A characteristic sign of this disorder is this phenomenon called Nikolsky's sign where when lateral pressure is applied to a normal-looking skin, results in the formation of a new lesion.[5,6]

In this case report the patient is a female and is 40 years old presenting with the chief complaint of pain and burning sensation in the left retromolar area. Moreover the patient has the initial intra-oral manifestations first as minute vesicles which rapidly ulcerated. Apart from the left retromolar area there was no involvement of skin or any other parts of the oral cavity. All the above manifestations were in accordance with a provisional diagnosis of pemphigus vulgaris. Histopathological evaluation and by the virtue of direct immunofluorescence the lesion was diagnosed to be pemphigus vulgaris. Because of the vigilance of the oral pathologist and with correct diagnosis immediate therapy was instituted.[7]

The oral lesions are often the first sign (First to Show and the Last to Go) of the disease (in 60 % or more) and they are most difficult to resolve with therapy. Hashimoto and Lever studied the microscopic features of the oral mucosa from patients with pemphigus vulgaris and theorized that initial lesions of pemphigus vulgaris most frequently occur in the oral mucosa because the epithelia demonstrate less intercellular junctions, thus making the area more susceptible to acantholysis.[5,6]

In the pathogenesis of pemphigus vulgaris there is a strong association between genetic and inducing factors. Genetic factors (soil) include HLA class 11 alleles. Predisposing individual factors (seed) that trigger disease initiation include diet, drugs, viruses in association with other diseases and others like smoking, hormone, irradiation and pesticides. The apoptosis theory is a multistep pathogenetic mechanism, first the autoantibodies target keratinocyte membrane acetylcholine receptors leading to activation of apoptosis(cell shrinkage). This is early acantholysis. Anti Dsg Ab targets Dsg 3 and Dsg 1 leading to cell-cell dishesion. This is advanced acantholysis.[4,8]

The ideal site for biopsy is an intact bulla which is rarely encountered and hence biopsies are best taken from the active border of the denuded area. Early changes in this disease consist of intercellular edema and the disappearance of intercellular bridges in the lower part, especially just above the basal cell layer. As the fluid increases the space is increased and a bulla is formed. After the formation of the suprabasal cleft, the intact basal layer remains attached to the lamina propria producing a pattern that resembles a row of tombstones.[9]

The characteristic histopathologic feature is the demonstration of acantholysis, i.e. separation of epithelial cells in the lower stratum spinosum. The separating cells (Tzank cells) present degenerative changes, the cell outlines are round, loss of intercellular bridges and large hyperchromatic nuclei. The underlying connective tissue is densely infiltrated with chronic inflammatory cells. A smear is prepared by unroofing the vesicle and gently scraping the base of the lesion. The smear is dried, fixed and stained with a polychrome stain such as Giemsa. On microscopic examination, a positive smear shows a large number of characteristic acantholytic epithelial cells.[7,8]

Electron microscopy studies indicate that breakdown of the epithelial intercellular substance is the first stage in the development of acantholysis followed by an increase of intercellular space, desmosomal lysis and finally degeneration of the cells. The gradual disintegration of desmosomes and clumping of tonofilaments occurs. As the desmosomal attachment disappears, the cell separates and the cell surface develops numerous microvilli.[6,7]

Direct immunofluorescence technique utilizes the patient's biopsy to demonstrate autoantibodies already fixed to the tissue and in indirect immunofluorescence technique patient's serum is reacted with normal control tissue to demonstrate the presence and concentration of the circulating autoantibodies.[10]

All the vesiculobullous lesions should be considered for differential diagnosis which include bullous pemphigoid, erythema multiforme, bullous lichen planus, dermatitis herpetiformis, aphthous ulcer (when pemphigus vulgaris lesion is small) and herpetic gingivostomatitis. The feature that differentiates pemphigus vulgaris from other lesions in the presence of suprabasillar split whereas pemphigus vulgaris can be differentiated from herpetic gingivostomatitis from the prodromal signs.[11]

Pemphigus Vulgaris was frequently a lethal disease, with most deaths occurring due to electrolyte loss and wound infection. With the advent of immunosuppressive therapy treatment consists primarily of systemic corticosteroids often in combination with immunosuppressive drugs. Pemphigus rarely undergoes complete resolution although remission and exacerbations are common.[1,8]

Conclusion

Some patients with pemphigus vulgaris develop acute fulminating disease, but most cases develop slowly. As oral lesions are first to appear, the oral pathologist should act as a sentinel to keep a check on disease progression before it flares up to give rise to dermatological manifestations.

Osseodensification: A New Era of Implant Osteotomy

Utkalika Das[1], Gatha Mohanty[2], Rinkee Mohanty[3]

[1]Tutor, [2]Senior Lecturer, [3]Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Successful osseointegration is achieved by the primary and secondary stability of dental implants. The primary stability of any successful dental implant is dependent on the quality and quantity of bone. Besides the experience of the surgeon and bone-implant contact (BIC)at the time of implant placement is equally important. Similarly the high insertion torque helps in obtaining primary stability. Several techniques have been introduced to enhance the bone quality and quantity in an attempt to achieve primary implant stability. One commonly used technique is under preparation of the osteotomy site by use of a drill that is one size small than the implant diameter. However undersized osteotomy compromises the healing between the bone and implant and hampers secondary biological fixation. Osteotomes have also been used in an attempt to increase the bone width buccolingually and improve the peri-implant site bone density. However studies have reported that there was only an increase in bone density at the periapical area with no influence on the lateral margins and primary stability of the implant. The associated trabecular fracture with osteotome bone condensation may further damage the osteocytes and cause extension microfracturesand delayed healing. Finally,the success of implant therapy relies largely on the stability and mechanical durability of the prosthesis delivered to the patient. As such several modifications, reinforcements and techniques have been suggested over the years to optimize the same. The latest in line is the non-subtracting osteotomy by specially designed Densah burs. This article aims to review the theory, advantages and disadvantages of this technique as compared to traditional osteotomy.

Keywords: *Osteotomy, Osseodensification, Dental Implant, Implant stability, Densah burs.*

Introduction

With the advent of recent technology and science owing to the increase in patient awareness there is a remarkable rise in expectation of the patient regarding the final aesthetic outcome and longevity of all dental treatment especially in Implant dentistry. The most important mandate in implant placement is the increase in the stability of the implants. That in turn depends on primary and secondary stability. Osseointegration i.e., structural and functional connection between ordered, living bone and the surface of a load-carrying implant,is crucial for the predictability of the implant.[1] Osseointegration provides secondary stability and largely depends on the primary stability. Primary stability is obtained by the mechanical friction between the external implant surface and walls of the implant osteotomysite.[2] The factors playing a leading role in achieving optimum primary stability are implant material, implant surface,and implant design, host factors and implant surgical technique respectively.[3] Ultimately it is dependent upon an increased implant torque value and a decreased micro-motion between the implant surface.[1] The insertion torque is directly proportional to peri-implant cortical bone and high insertion torque ensures an increase in the initial bonetoimplant contact percentage (%BIC).[4] To achieve

this,various surgical techniques have been proposed such as smaller osteotomy sites, tapered preparation and hand instrumentation.

Condensation of the osteotomy site to increase primary stability by increasing the bone density was reported for the first time by Summers in 1994.[5] He advocated condensing the cortical bone of the implant site by using osteotomes. There is however the disadvantage of limited accessibility and instrumentation by osteotomes. In 2013, Huwaiset aladvocated a new technique for densification of the cortical bone using a specialized bur.[6] This article further aims to review the feasibility of the new Osseodensification burs for implant site preparation and its advantages over conventional techniques.

Osseodensification–innovative approach to implant osteotomy: Traditionally implant osteotomy relies upon excavation of bone from the planned site using bone-cutting burs. It is often limited by the inherent density of the bone especially in the sites where extraction socket has not been preserved and by the surrounding anatomical limitation.In 2013**.** proposed a novel surgical protocol that relied on a biomechanical, non-excavation osteotomy preparation by burs specially designedfor densifying the adjacent cortical bone called Densah burs (by Versah LLC- Company).

In Osseodensification the osteotomy site is prepared with more precision and continuous irrigation decreases the heat production protecting the osteogenic potential of the cortical bone. It is a new method of bone preparation biomechanically for the placement of dental implants. Low plastic deformity of bone is created by sliding and rolling contact with the fluted bur that density the bone with minimum heat. Huwais 2013 developed this as a bone non-extraction technique where specially designed Densah ™ bur densify the bone while preparing osteotomes.[6]

Osseodensifying drills design allows preservation of bone by compacting it at the osteotomy site by rotating in a reverse direction at 800 to 1500 rpm.[1] This approach for implant site osteotomy is called non-subtractive drillingwhich increases the bone density in the peri-implant area and implant torque which in turn ensures a decrease in micro-motion and increase in implant mechanical stability.[7] It is also reported that it helps in bone expansion enabling insertion of wider diameter implants into a narrow ridge without creating bone dehiscence or fenestration.[8] Densifying burs thus combines the advantages of bone condensation by osteotomes with the speed and tactile control of the drills.[2]

Table 1. Showing the difference between Traditional osteotomy and Osseodensification

Sl.No	Property	Traditional burs	Densah bur
1	Bone excavation	Bone preservation, Non- excavation method that allows compacting the autograft while inducing minimal trauma	Bone cutting and excavation of the same at the implant site is involved.
2	Bur design	Tapered, greater than 4 lands and flutes with a tip to eliminate potential chatter.	Twist drills with 2-4 lands to guide it through the osteotomy site
3	Osteotomy	The preparation is precise with a diameter, 0.5 mm lesser than the traditional drills.	May not always be a precise circumferential osteotomy, i.e., it may be elongated or elliptical due to chatter on the drills
4	Heat generation	Bur used in bouncing pumping action and along with copious external saline irrigation, ensuring minimal rise in temperature	Greater friction leads to greater heat production
5	Insertion torque	Increased	Decreased
6	BIC%	Increased	Decreased
7	Narrow and short ridges	Facilitates expansion circumferentially	Often leads to fenestration, dehiscence

Bur design and technology: The Densah burs cut the bone in a clockwise manner and densify the same in a non-cutting anticlockwise manner along with copious irrigation during the surgical procedure. The design incorporates helicalflutes separated by lands, each having a burnishing face and an opposing cutting face withina taperedgeometry.[9] This ensures lesser heat productionand a faster feed rate. Bone condensation is obtained by non-cutting action of the lands with a negative rake angle and cutting is obtained by chisel edge. The expansion of the osteotomy site is obtained by a tapered shank (maximum diameter adjacent to the shank and minimum diameter adjacent to the apical end). This feature allows the operator to lift away from contact instantly to allow for irrigation. The bur producesan outward pressure that creates a hydrodynamic compression wave when combined with irrigation at the point of contact. This drives the bone chips and debris into the implant bed rather than removing it.[1]

The principle of working depends upon the plasticity of the tissue and its water content.[2] Hence it is recommended to be activated by an 'in and out' motion at the site of osteotomy to create a rate dependent stress and strain that increases the plasticity of the tissue.It was reported in a study that after osteotomy, when left empty for imaging, the diameter is reduced by 91% of the bur diameter. This is explained by the spring back phenomenonof the compacted bone brought on by the residual strains of viscoelastic deformation.[9] This creates a compressive force against the implant and increases bone-to-implant contact maximizing the primary stability. This in turn promotes osteogenesis by a mechano-biologic healing process.

Bone density and Osseodensification: Secondary stability of bone and dental implant by the process of osseointegration is vital for the success of implant placement. The maxillary posterior region with low bone density affects histomorphometric parameters such as the percentage of bone-implant contact and bone volume, However, the increase of bone density by osseodensification has improved the negative effect thereby having a potentiating effect on secondary stability.[10,11]

Primary stability and Osseodensification: The most critical factor in immediate loading implants is the primary stability that helps to achieve osseointegration. Studies by **Berardini** et al and **Li** et al reported no difference between crystal bone resorption and failure of implants inserted with high or low torque respectively reported that only drills could increase the percentage of BIC And BV in poor density bone compare to convention osteotomy.[12,13]

Figure 1. Densah bur

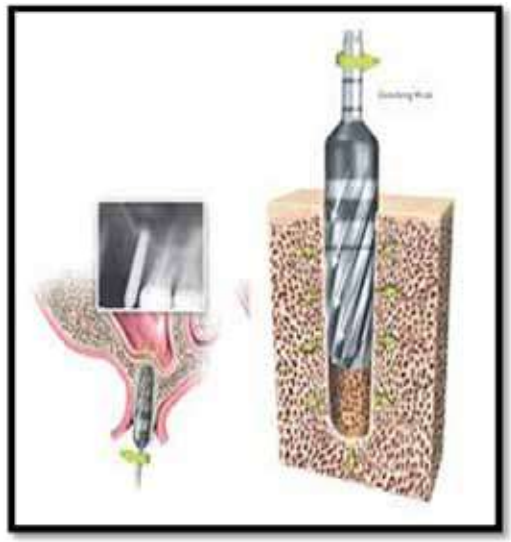

Figure 2. Drilling Mechanism

Figure 3. Drilling kit

Factors leading to decrease in insertion torque in traditional drilling:

- Traditional osteotomy lacks precision due to the chatter of the drills leading to elongated and elliptical osteotomy sites.[10] (10)
- One of the crucial factors influencing the osseointegration is the heat generation during rotary cutting.[11] This rise in temperature is caused by plastic deformation and friction at the machining face. It also affects the viability.

Advantages of Osseodensification:

- It is a bone preservation osteotomy site.It creates a crust of bone mineral density increased by three times around the osteotomy site as compared to traditional drilling.[2]
- The protocol increases the diameter of the residual alveolar ridge without causing any dehiscence or fenestration.[8]
- The non-cutting, condensing action enables the clinician to autograft the maxillary sinus and increasing the height without the necessity of another surgery and enables placement of total implant length.[2]
- Due to a decrease in micro gap and micro-movement healing is faster and more predictable.[1]
- The traditional drills remove and excavate bone during implant site preparation, induce fracture of trabeculae leading to delayed bone growth. (1) Osteotomy sites prepared by Densah burs heal faster and uneventfully.[9]
- The burs provide advantages of both osteotomes where both tactile control and the speed of drills are combined.
- Osteotomy Densah burs preserves and condenses the bone through compaction autografting whereas the standard drills cause factor of trabeculae that requires long remodeling time and cause delaying secondary implant stability.
- Osseodensification preserves the bone bulk increase the density of bone and certain healing period. Whereas the conventional drills to lead the healing period to more than 3 months. The specialized Densah burs with steady external irrigation drills with high speed in anticlockwise direction. This causes a rate depended on stress to produce a rate dependent stress such as a pumping motion causing increased bone plasticity and bone expansion.[13]
- Ridge expansion with osseodensification maintains the integrity of the alveolar ridge and shortens the waiting period of the restorative phase.[14]

Contraindications of Osseodensification: In dentistry use of technology and the use of smart devices makes the life of a dental practitioner easier.[15] However, every technique has its disadvantages. This principle does not work in the non-dynamic cortical bone which lacks plasticity. Further, owing to its inherent difference in the biomechanical properties, the process does not work predictably on xenografts should be avoided because they behave biomechanically different (not viscoelastic) than the bone tissue.[1]

Conclusion

Modern dentistry focuses on techniques that ensure maximum durability and aesthetics as well as preserves as much viable tissue as possible. In this, osseodensification by Densah burs guarantees an advantage over traditional osteotomy in no uncertain terms atleast in theory. But, it is a relatively new concept and the biological implications on a long term basis are yet to be evaluated by longitudinal studies.

Medico-legal Aspects in Dentistry

Smita R. Priyadarshini[1], Pradyumna Ku Sahoo[2]

[1]Associate Professor, Department of Oral Medicine & Radiology, [2]Associate Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Dentists as healthcare professionals have a duty and standard for patient care. Any violation in the duty and practice makes dentists liable to negligence & legal actions. Law protects the dentists as well as ensures ethical practice. With the steady increase in the number of dental graduates and decrease number of job facilities,the dental profession seems to descend of its ethical standards. So a thorough knowledge about the medico-legal aspects is mandatory for smooth execution & delivery of productive services. In this paper we review comprehensively different aspects of avoiding negligence.

Keywords: *Negligence, Medico-Legal, Ethics.*

Introduction

Law regarding health care workers has been accepted in many advanced nations but is still in its early stages amongst a few. With advancement there is an increase in the awareness of the rights of the patients, so it should be mandatory for dentists to know the law and prevent from being a victim of unfair legal proceedings.[1] It is fair on dentist's part to follow ethical practice and obtain patients consent before any dental procedures or any research including human.[2]

But dentistry has degenerated with its ethics as the number of graduates has been increasing with lesser job perspectives and budding dental clinics in India making it more of a business set up. There has been no record keeping, no consent and negligence amongst a lot of practitioners as we are ignorant about the medico-legal concerns.[3]

Corresponding Author:
Dr. Smita R Priyadarshini
Associate Professor, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India
e-mail: smitapriyadarshini@soa.ac.in

Ethics: Ethics technically deals with the professional code of conduct. These rules every dental student should learn before graduating. They affect every resolution made at the dental office that could be the association with the patient, staff or other professionals. It's the fundamental objective to furnish excellent services to the patients. It also prevails around the human values, responsibility, culture, ideology and morality.[4]

The most common ethical issues that have been reported are deficient sterilization and waste disposal in dental clinics, poor knowledge and inadequate orientation of ethics with incompetence for dental procedures, expensive treatment, lack of consent, lack of harmony about procedures among fellow dentists, Conflict in Advertising, clustering of dental clinics in a particular area, the difference of opinion about the treatments among dentist as well as a patient along with improper record keeping all of it stands to unethical practice.[5]

Principles of ethics:

Patient autonomy: Dentists at all times should regard the self-resolution & privacy of the patient. They are righteous to take decisions for their treatment. Therefore to keep the respect of patients decision a informed consent is mandatory. The Dentist should explain the treatment options its pros and cons along with

other treatment facilities available thereby respecting the final decision of the patient. [6]

Non-maleficence: It states to not harm the patient. Dentists should reconsider procedures which solves one issue and begin a new one, in such condition the dentist should evaluate the treatment by keeping in mind the advantages and disadvantage of the procedure. At any point in a procedure if a dentist feels a lack of skill he shouldn't hesitate to call a specialist.[7]

Beneficence: It directs to aid in doing good. It should be inculcated in daily practice to provide benefits to the patient. Like timely adequate functioning of the patient with good esthetic treatment as the patient desires.[8]

Justice: It states equity. It is the moral responsibility to be legitimate in all the dealings with patients, staff & society. There should not be any type of racial, gender, caste, creed discrimination. [9]

Veracity: It is the truthfulness and respect of the self-esteem of the relationship with the patient. This involves trust in maintaining the intellectual, billing, advertising integrity of the patient. [10]

Confidentiality: It is the right of the patient to expect that all communications and case records related are confidential. And the dentist must respect it.[11]

This also includes professional conduct and etiquette which should not include any kind of commercialism. With the difficulties dentists face these days one should succumb to gifts, Continuing Dental Education programs, trips, etc. Even not provide substandard treatment to patients, refer cases to specialists and not fear of loss of patients.[12,13]

Consent: Consent is for safeguarding the rights of the patient as well as the dentists. It helps in better exercise of patient's autonomy. It also demands a mature decision by the provider and safeguarding his interests. Audiovisual aids could be used to teach patients about treatment procedures thus enhancing informed consent. [14] These provide a considerable proof and documentation although its been categorized under the following:

- **Competence:** It states that the patient suffices with the ability to understand the treatment completely also with its limitations though this depends upon several factors like age,educational qualification, intelligence, cognitive function, locus of control and anxiety levels. [15]
- **Voluntariness:** In this the patients agree to the treatment without and compulsion
- **Information and knowledge:** It means that sufficient comprehensible information is disclosed to the patient regarding the nature and consequences of the proposed and alternative treatments.[16,17]

Types of Consent:

1. **Implied Consent:** Refers to when a patient is unassertive about the consent. This doesn't need to be documented but is understood by an excellent communication where the dentist provides the details of procedures.[17]
2. **Verbal Consent**: here verbally the patients agree to certain routine diagnostic procedures following a well-documented record of the procedure. [18]
3. **Written Consent:** This is mandatory for procedures that involve risk to life like sedation, administration of anesthetics, restorative & endodontic procedures along with the surgical procedures & administration of medications. [19]
4. **Implied Consent:** The patient comes to the dentist suggests that he is willing to undergo the procedures.
5. **Expressed** Consent or tacit consent is a strategic consent which is written in the most pleasant languages.
6. **Informed Consent**: It is expressed in the patient's language about the diagnosis, treatment, advantages, limitations, etc.
7. **Proxy Consent:** When consent is given by parent, guardian or close relative
8. **Blanket Consent**: It's a printed consent that involves anything and everything a dentist or the hospital can do to a patient.[18]

Informed consent should be such that should specify the treatment plan, the outcomes along with the benefits and limitations, any possible risk of the materials used, the treatment alternatives along with the cost of the procedures & consequences of treatment. This should be immediately computed with the patients & dentists signature and date. Special care should be taken to have a readable signature and name. [17]

Consent can be not considered in cases of emergencies, compulsory drug screenings, procedures related to mental disorders & when the court of law has directed for any treatment. In the case of minors

the consent is obtained from the parents or if any legal guardian as they are not mature enough to decide their well-being. If the adult accompanying the child is not a legal guardian they are not allowed by the court of law to decide such cases a telephonic consent may be obtained.[18]

Negligence: Negligence is the lack of proper care and attention or guiltyof carelessness. It is in general violation of duty by the exclusion of something that judicious person wouldn't do. The Supreme Court also has put forward the four components of negligence which are as follows:

Duty: Is the trust that is placed in the dentist and patient relationship. The dentist owes a duty for his patient the moment he agrees to treat. This doesn't happen when the dentist doesn't agree to treat in case of any emergencies or so. [14]

Dereliction of duty: Occurs when the dentist is negligent while performing the procedure. It consists of a series of procedure that produces an injury and without which the injury would not have occurred.[15]

Damage: The damage caused due to dereliction and is judicious. In such cases the patient can sue the dentist for remuneration.

Direct Causation: Damage must results directly from the carelessness and not from the other reason.[18]

Types of Negligence:

1. **Doctors negligence:**

   (a) Civil negligence: This happens when the patient demands money as compensatory damage. Here both the dentist for a fee as well as the patient can file a case. These cases are dealt with in the civil court or consumer courts. As per the court directive as punishment the dentists have to pay the compensation without any criminal proceedings. Sometimes even the dental council is involved for temporary or permanent removal of name from practice. But in either case, the patient has to prove negligence against the dentist .[19]

   (b) Criminal negligence: This happens when a case is registered against the dentist for negligence. If guilty dentists is prosecuted under various sections of Law.

Table 1

Section 304A (IPC)-	Negligent homicide. Act that could lead to the death of the patient. Penalty- imprisonment of 2 years, or fine (any amount) or both.
Sec 336 (IPC)-	Jeopardizing the life of the patient even in the absence of injury Ex. an in case of medical histories like heart disorders where the patient is at risk without a prophylactic antibiotic or discontinue use of Asprin. Penalty– imprisonment of 3 month, or Rs 250 fine or both.
Sec 337 (IPC)-	Simple Injury during dental procedure like pain and swelling post-extraction Penalty – imprisonment of 6 month, or Rs 500 fine or both
Sec 338 (IPC)-	Serious Injury during procedure like fracture of jaw during extraction Penalty Prison for 2 yrs or Rs 1000 fine or both

2. **Patient negligence:** Here the patient is negligent. The patient is not responsible enough to give a proper history which in due course of proving fatal. The patient is not taking medications or following instructions properly in such cases dentists have to prove the negligence of the patient.[20]
3. **Contributory negligence:** Here both the dentist and the patient are negligent but the burden is on the dentist. It is usually dealt with in the civil courts and doesn't contribute to any criminal charges.[21]
4. **Composite negligence:** Here the injury is caused by combined negligence of two or more dentists. The claim can be divided by the dentist or if the patient claims from anyone then they are liable to pay. [12]
5. **Corporate negligence:** Here the dentist is not responsible but the concerned corporate or the hospital is responsible eg. Use of outdated instruments or medications at a hospital.[22]

Conclusion

Dentists are unaware of the laws regulating their profession. In this article we briefly see the importance record-keeping as any of the notes, radiographs, photographs or models & casts are the only available proof while we are defending ourselves in a negligent lawsuit. The legal proceedings are strenuous and upsetting tonegotiate so it's always better to prevent. Once a legal lawsuit is filed it not only becomes a financial burden it drains one emotionally and psychologically.

Suction Cup on Denture: A Case Report

Pradyumna Ku Sahoo[1], Smita R. Priyadarshini[2], Kajal Kiran Sahu[3]

[1]Associate Professor, Department of Prosthodontics, [2]Associate Professor, Department of Oral Medicine & Radiology, [3]Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Complete Dentures with perfect retention are complicated to attain and several method have been applied for obtaining the same the same. Ill-fitting dentures are due to residual ridge resorption causing difficulty while eating and even dislodgment during talking causing embarrassment for the patient. Suction cup was widely used for retention & stability of dentures but is said to be associated with complications like palatal perforations and oro-antral communications. Here we present a case report of denture stomatitis & palatal perforation due to the suction cup.

Keywords: *Denture stomatitis, Suction cup, Palatal Perforation.*

Introduction

Denture Stomatitis indicates an inflammatory process in the denture bearing mucosa. It is also seen in individuals who do not follow proper denture hygiene while using a complete or partial removable prosthesis. The most common site is the palatal mucosa and not mandible due to the cleansing properties of saliva. In fabricating a complete denture, retention is very important that depends on several factors - Anatomy like size & quality of denture bearing area, parallel ridge walls, Physical factors like adhesion, cohesion, interfacial surface tension, capillarity, atmospheric pressure & gravitational forces all play important role in stability and retention of the denture.[1,2]

The primary difficulties experienced during denture usage are discomfort, pain, usual noises like clicks and snaps chewing difficulties, change in phonetics and dislodgment of the prosthesis while talking or chewing.[3] To withstand these issues suction cups were used. But continuous use of these suction cups destroys the tissues even leading to perforation of the palate. They create a negative pressure on the mucosa leading to a destructive effect on the palatal tissues. This occurs as it reduces the blood circulation of underlying tissues leading to hypoxia and necrosis of the underlying bone leading to tissue perforation.[4] The pathological changes are severe with the habit of continuous denture usage for 24 hours a day. But suction cups are used when the diameter is < 1mm and has no risk of irritating the tissues/building up bacteria.[5]

Case Report: A 65 years old male patient-reported to the department of Oral Medicine & Radiology with a complaint of missing teeth in the lower jaw for 2 months. He was all right when mobility of teeth started eventually leading to its loss. Some of it were lost on its own & few were extracted. Past dental history suggested the usage of a maxillary denture since 2 and half years with non-contributary medical & family history.

The oral hygiene of the patient was moderate. He cleanses his mouth using his finger and warm saline water. Denture hygiene was bad as he wore the denture overnight and Cleaned it at morning in water. The patient was moderately built with normal gait. Blood pressure and respiratory rates were under normal limits.

e-mail: smitapriyadarshini@soa.ac.in

On Examination: Well defined, circular; punched epithelial indentation measuring 2x3 cms approximately resembling a suction cup. Extending from palatal rugae to 2 cms anterior to the soft palate anterior posteriorly, 2cm medial to the edentulous ridge concerning 15 & 25 mediolaterally i.e. center of the palate. [Figure 1,2]

Figure 1: Palate with suction cup indentation

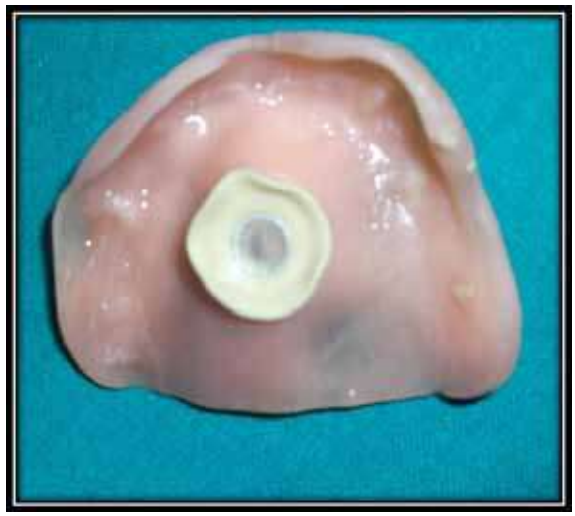

Figure 2: Maxillary denture with the suction cup

Mucosa overlying appears erythematous interspersed granular erythema in the center and posterior half of the hard palate [Figure 1,2]. Mucosal Hyperplasia in 13 & 24 is present measuring approximately 1x1cm at the extension of the denture flanges. [Figure 3,4].

Figure 3. Traumatic Denture Flange

Figure 4. Mucosa Hyperplasia

Provisional diagnosis of Completely Edentulous maxillary and mandibular arches, Denture stomatitis & Epulis fissaratum 13 & 24 was given another line. Orthopantomogram revealed impacted 38 and smear report revealed multiple candida hyphae (Figure 5).

Figure 5. Orthopantomogram reveals impacted 38

The patient was advised to discontinue the use of denture & fabrication of new dentures was done. Application topical anti-fungal agent (Candid 4 times daily for 14 days) & gum paint to be massaged on the palatal mucosa.

Discussion

Denture stomatitis is an inflammatory process of mucosa in patients with complete or partial removable dentures. Its classified into Type I: simple inflammation or pinpoint hyperemia. Type II: diffuse erythema involving a part/entire denture bearing area, Type III: Granular with inflammatory papillary hyperplasia.[6,7] All the patients with dentures are to follow the oral & denture hygiene instructions meticulously & other local factors that promote the growth of yeasts. [8]

The denture hygiene is maintained by brushing it with soapy water, warm saline and soaked at night in an antiseptic or chlorhexidine without any metal components or sodium hypochlorite solution of 0.02% concentration can also be used.[9] Fabrication of new prostheses should be made in cases of ill-fitting or overhanging flanges. An adequately polished and glazed denture reduces the poresin the denture reducing the contamination by oral microorganisms.[4] Inflammatory papillary hyperplasia or the epulis fissaratum is to be excised by scalpel, cryosurgery, electrosurgery or laser beam along with antifungal medications.[10]

Conclusion

The prosthetic construction of patients is essential in restoring the oral health of completely edentulous patients. Fabrication of the suction cup to enhance the retention of maxillary denture is contraindicated because of its potential to cause palatal perforation. Adequate retention should be obtained by the proper record of the posterior palatal seal and close contact of the denture base to the underlying tissues.

Abstract

In dentistry, indications of antibiotics are determined by multiple clinical and bacteriological epidemiological factors. Treating odontogenic and non-odontogenic infections, for local infections, anti-microbial coverage is recommended. These act as an adjunct to dental treatment. The paper reviews the indications, usage, dosage of antibiotics, precautionary measures to be taken while prescribing them.

Keywords: *Antibiotics, Dentistry, Indications, Dosage.*

Introduction

In the year 1929, antibiotics were discovered by the "Scottish bacteriologist Alexander Fleming" while working in a teaching hospital in London on anti-bacterial action of the Penicillium species. In the 20th century, antimicrobialsare considered as theutmost contribution. The word "Antibiotics" is derived from the word "Antibiosis". This term was coined by Louis Pasteur in the year 1889 which suggests that life could be used to eliminate life. These are nowadays considered as a wonder drug in dental practice for numerous issues like periodontal, mucosal infections, etc. These are used both for treatment as well as prevention of the infections. According to studies, "Dentists prescribe between 7% and 11% of all most common antibiotics such as– metronidazole, tetracycline, beta-lactam, macrolides, clindamycin, etc." These are also associated with multiple unfavourable side effects like gastrointestinal issues to anaphylactic shock. Here in this review, we will be discussing the role, dosage, usage, indications associated with antibiotics in the field of dentistry.[1]

Classification[2]:

"According to the mode of action, classified as follows:

1. Antimetabolite action – Sulphonamide, Trimethoprim
2. Cell wall inhibitor – Penicillin, Cephalosporins, Vancomycin
3. DNA gyrase inhibitor – Ciprofloxacin, Ofloxacin, Nalidixic Acid
4. Bacterial protein synthesis inhibitor – Tetracycline, Clindamycin, Aminoglycoside."

An ideal antibiotic should be bactericidal rather than bacteriostatic, should be selectively toxic to the microbes and spare eukaryotic cells. It should be soluble and remain active for a long duration to be effective enough. It should not create host resistance and allergies in the host It should be safe for the gut microflora during a long-term prophylactic usage. There should be minimal drug interactions recorded for an ideal antibiotic.

Particularities of Antibiotics Use in Dentistry: Clinician's antibiotic prescriptions are empirical as the microorganism responsible for the infections such as pus

or exudate is not known. Abroad range of microorganisms are encountered in the oral cavity; a broad-spectrum antibiotic is typically prescribed. Sometimes two or more combinations of antibiotics are prescribed due to the increasing antibiotics resistance among bacteria.[2]

Antibiotics Indications: Antibiotics are considered as an adjunct to numerous dental procedures. They are used in treating immune-compromised patients, systemic infections and rapidly progressing infections.

1. **Antibiotics used for odontogenic infection:** "Penicillin" is the drug of choice as it is susceptible to gram-positive aerobes and anaerobes which are found in periodontal & gingival abscess and pulpal necrosis. Clavulanic acid in combination with penicillin acts miraculously for infections caused by "Streptococcus, Pneumococci and Streptococci." Clindamycin 300 mg is preferred drug for patients with penicillin allergy followed by "Azithromycin" and "Metronidazole", for delayed type of hypersensitivity reactions caused by penicillin, Cephalosporins are advisable. Tetracycline is most effective in cases of acute necrotizing ulcerative gingivitis as these are considered bacteriostatic antibiotics that obstruct the binding of aminoacyl-t- RNA synthetase to ribosome acceptor site. In 3% - 5% of the population, the side effects noted by the use of penicillin are hypersensitivity reactions. Cephalosporin and tetracycline are also considered to have hypersensitivity reactions after penicillin.

   In endodontic infections, azithromycin showed excellent pharmacokinetics. "A loading dose of 500 mg followed by 250 mg once daily for a week should be followed".[6] Ciprofloxacin has also shown positive results in treating endodontic infections. Against anaerobes, metronidazole, a synthetic anti-microbialagent is considered effective. With "a loading dose of 1000 mg followed by 500 mg six hourly for a week is recommended". However, for odontogenic infections, beta-lactam antibiotic is always recommended.[6]

2. **Antibiotics for non-odontogenic infections:** As these infections require prolonged treatment, a newer synthetic antibiotic namely fluoroquinolones are used for management. It is a broad-spectrum antibiotic and restricts bacterial DNA replications. It is indicated for "bone and joint infections, genitourinary infections and respiratory infections". Chronic infections like tuberculosis require long-duration antibiotic prescriptions such as – "Rifampicin, Ethambutol, Isoniazid, etc. Penicillin G Benzathine is effective in the treatment of syphilis.

3. **Antibiotic prophylaxis in preventing infective endocarditis:** Standard regimen for children and adult include high doses of amoxicillin one hour before any dental procedures. An effective dose is considered as 2 g of amoxicillin for adult patients before any dental procedures.[6] First-generation cephalosporinsare recommended for patients having an allergy to penicillin or amoxicillin. Patients having prosthetic heart valve, "Vancomycin & Streptomycin" are prescribed for the prevention of infective endocarditis. Negligence of the antibiotic prophylaxis during the dental procedure may lead to subacute bacterial endocarditis.

4. **Antibiotics in treating local infections:** Surgical procedures such as an impacted third molar, implant placement, orthognathic surgery, benign tumor surgery etc are regularly covered with systemic antimicrobials. Studies reveal postoperative pain after third molar surgery has reduced with antibiotic prophylaxis. Abu-Taa et al reported a marked reduction in the post-operative discomfort as he compared "the benefits of pre and post-operative antibiotics prophylaxis in the third molar surgery."[8]

Danda et al documented clinically significant results when he evaluated "the prophylactic value of single-dose antibiotic prophylaxis to single day antibiotics for postoperative infection in patients undergoing orthognathic surgery".[9] Numerous studies reported a significant reduction in implant failure under appropriate antibiotic prophylaxis. Rizzo et al reported an efficient reduction in post-operative infections after analyzing five hundred twenty-one dental endo osseous implants, those were placed under antibiotic coverage.[10] But on the contrary, "Gynther et al revealed that there was no significant difference noted after dental implant placement without any antibiotic coverage for the patient".[11] On the other hand, Nabeel Ahmad et al conducted a literature review. He reviewed the effects of antibiotics among eleven thousand four hundred and six endo osseous implants and reported fairly no significant advantage from the use of antibiotic prophylaxis during the placement of implants.[12] So, the use of antibiotics in implant surgery remains controversial. But during periodontal surgery, the use of antibioticsis compulsory as the surgical site is often contaminated with microorganisms.

Immune compromised patients are more prone to bacteraemia which further leads to septicaemia.[13] The dental procedures should always be performed under antimicrobials coverage. For patients with uncontrolled diabetes mellitus, antibiotic coverage is mandatory before any invasive dental surgery to avoid any infections. Not all patients with joint replacement surgery are recommended for antibiotic prophylaxis but patients with increased risk of blood bornehaematogenous infections associated with the prosthetic joints are advised to be under antibiotic coverage undergoing dental procedures.[14]

Precaution During Antibiotic Usage: Patients with renal failure should be treated with the utmost precautions as most of the antibiotics are excreted through the kidney. It is advised for a reduction in drug dosage to avoid toxicity due to elevated plasma drug concentrations. Modifications can be made in the drug administration interval without modifying the amount of drugs. For patients having creatinine clearance 10-50 ml/min, amoxicillin and clavulanate is prescribed 500-875 mg/8 hours, and if the patient is having creatinine clearance <10 mg/min, it is prescribed with similar dose in every 12-14 hours. There is no adjustment needed when prescribing Clindamycin (300 mg/8 hours), Doxycycline (100 mg/24 hours), Erythromycin (250-500 mg/6 hours), Azithromycin (500 mg/24 hours). For patients having creatinine clearance 10-50 ml/min, metronidazole is prescribed 250-500 mg/8 hours, and if the patient is having creatinine clearance <10 mg/min, it is prescribed with similar dose in every 8-12 hours. In a study, Gudapati et al documented that the dosage of indomethacin. Naproxen, ibuprofen should be reduced for advanced stages of renal failure. [17]

In patients with liver failure, the use of the antibiotic should be restricted to avoid toxicity as the antimicrobials are metabolized in the liver and are eliminated in the bile. Some antibiotics such as erythromycin, clindamycin, metronidazole are advised to administer to the patients with dosage modifications.[16] In a study conducted by Douglas et al, it is strictly contraindicated to use tetracycline and antitubercular drugs in patients with liver failure.[18]

In pregnancy, due to increased teratogenic effects on the fetus, usage of tetracyclines and aminoglycosides is contraindicated. In a study, "Shrout et al focused on the need for antibiotic prophylaxis for pregnant patients as it eliminates the bacterial loads' od periodontal pathogens".[20] During pregnancy, drugs like "cephalosporin, azithromycin, penicillin with or without beta-lactamase inhibitors" are given with utmost caution. Benzodiazepines possess a risk of oral cleft development during initial months of pregnancy according to Haas et al.[21] Gestational use of "Naproxen, Diclofenac, Ibuprofen" alone or in combination is associated with spontaneous abortion.

Principles For Choosing Appropriate Antibiotics: The following are principles to be followed for prescribing appropriate antibiotics to the patient. Starting from "proper identification of the microorganisms, determining of antibiotic sensitivity, use of narrow-spectrum antibiotics with minimal toxicity after obtaining proper drug history and use of bactericidal antimicrobials over bacteriostatic ones are few cardinal principles to be followed by clinicians.

Conclusion

In dentistry as well as in the medical field, antibiotic therapy is considered mandatory. Penicillin is still the gold standard drug in treating various dental infections. As mentioned above, patients at high risk such as endocarditis, pregnant women, immunocompromised individuals should consult clinicians and specialists before undergoing any dental treatments.

Management of Lose Mandibular Denture: A Case Report

Abhilash Mohapatra[1], Radha Prasanna Dalai[2], Debarchita Sarangi[3], Subhrajeet Narayan Sahoo[4], Upsana Dhar[5]

[1]Professor, Department of Prosthodontics, [2]Senior Lecturer, Department of Public Health Dentistry, [3]Senior Lecturer, Department of Prosthodontics, [4]Senior Lecturer, Department of Orthodontics, [5]Post Graduate Trainee, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A lose mandibular denture is the most common problem reported by complete denture patients. So to improve retention and stability we support the denture by placing two implants. In this case report,a patient with a lose mandibular denture is rehabilitated with two mandibular implants. The final prosthesis was stable well retained and esthetically pleasing.

Keywords: *Overdenture, Implant, O ring attachment.*

Introduction

For a complete denture to be a successful prosthesis is dependent on various factors like denture bearing area, psychological assessment of patient and previous experience with dentist[1,2]. So the challenge for prosthodontists is that it not only replaces teeth but also the soft tissue. The usual problem with complete denture patients is retention of mandibular denture, so treatment option for it is implant-supported overdenture. So in this era of implant dentistry mandibular implant overdenture has become the new standard for the treatment of edentulous mandible. So for practitioners this treatment option is the most reliable definite treatment option. Advantage of implant-supported denture is maintenance of bone volume and increased retention and stability.

The most popular attachment used for overdentures are locators and ball and socket overdenture. In this case report three implants are placed with ball and socket attachment which support a mandibular overdenture.

Case Report: A 68-year-old male patient reported to the department of prosthodontics with a chief complaint of ill-fitting mandibular denture. The patient had no significant medical history and his dental history included extraction of teeth due to periodontitis. The patient was using a conventional denture for the past five years and due to non-retention of mandibular denture the patient wants a new prosthesis. On clinical examination the mandibular ridge exhibited a significant degree of resorption and all other parameters like size shape of maxillary ridge and condition of mucosa were found to be normal & healthy (Figure 1). But on evaluation of denture it was found that extension of denture flange was inadequate, retention & stability was poor. Orthopantomograph was advised to evaluate bone availability and architecture (Figure 2). The inter ridge distance was assessed and it was decided to give stud attachment. So for this patient a treatment plan of conventional complete denture for the maxillary arch and 3 implant-supported overdenture for mandibular arch[5]. This treatment plan was explained to the patient and approved by him.

Figure 1. Mandibular ridge of paitent

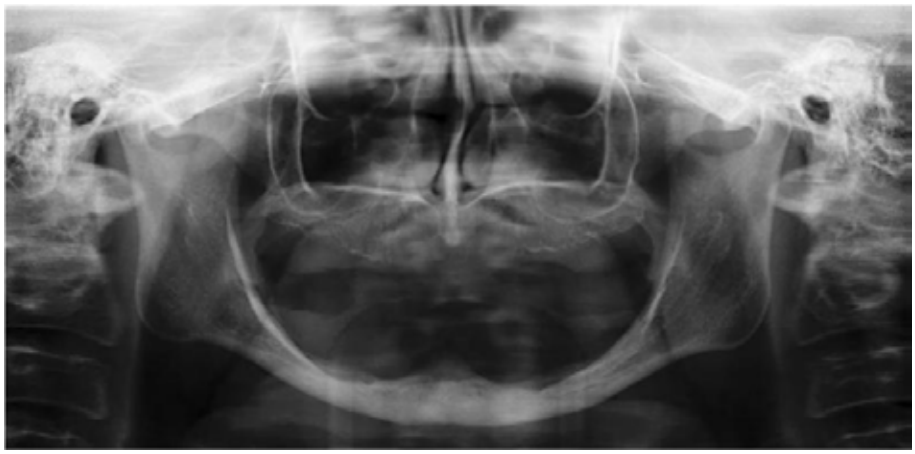

Figure 2. Orthopantomograph

Figure 3. Clear auto polymerizing acrylic resin surgical template

Treatment procedure: Conventional maxillary and mandibular dentures with bilateral balanced occlusal schemes were fabricated for the patient. The mandibular denture was duplicated by using laboratory-grade silicon, using clear auto polymerizing acrylic resin to be used as a surgical template (Figure 3). The vertical space

analysis was done and it was found to be 12 mm which falls in class II category[6] (Ahuja S & Cagna DR). So stud with ball and socket attachment was decided for the patient. Adin (TouregNP) implants of 11.5mm length and 3.75 mm diameter were selected. Implant surgery was carried out in two-stage protocol, first implants were placed with the help of a surgical guide in B, D, E region and loading of the implant was done after three months. Two implant-retained overdenture is a very reliable therapy for patients with edentulous mandible[7]. But in the present case as the ridge is resorbed in the posterior region and space is not adequate for the bar prosthesis, three stud attachments were planned.

Implants should be placed as parallel to each other as possible to increase the prognosis of the prosthesis. For this the surgical stent was used to do the initial drilling and all the osteotomy sites were checked with paralleling pins. After completion of prescribed drilling sequence implants were placed in prepared sites. Surgical cover screw was placed and primary closure of flaps was done. The patient was told not to wear the lower denture for two weeks after surgery and cleanse the mouth with disinfectant mouthwash. After removal of suture the intaglio surface of denture was relieved and tissue conditioners were applied. The conditioner distributed the occlusal forces to the denture bearing area without transmitting it to the surgical sites. Three months later the second stage surgery was done and healing abutments were placed and left for 15 days to help in maturation of gingival tissue. At this procedure the denture is again relined. After completion of 15 days the ball and socket overdenture abutments of 2mm diameter & 2 mm height were placed.(Figure 4) For blockout of the stud attachment a rubber dam was placed and then O rings (RS-2664, yellow) were placed. The second mandibular denture which was prepared previously was loaded with pressure indicating paste and placed on abutments to check the position of implant abutments. The number 6 bur was used to relieve the intaglio surface to accommodate the metal housing of the O ring. The complete passive seating of the denture was verified and then only GC pattern resin is loaded in prepared surface and the patient was asked to bite on the lower denture with the upper denture in centric relation position with a very light occlusal pressure. The pick up once fully cured was removed and trimmed and polished. (Figure 5).

Figure 4. Secondary stage surgery

Figure 5. Polished & trimmed pick up

Figure 6. Postoperative photograph

First the patient was trained on how to place and remove the denture followed by home care instructions. The patient was recalled after 24 hours and then after six month and radiographs were taken. The patients were advised to clean the attachment with the unituft brush. And it was found that the patient was comfortably using the overdenture for the last 3 years.

Discussion

Full mouth rehabilitation of an edentulous patient can be with fixed with 6 to 8 implant for a normal ridge, and all on 4 in compromised ridge condition. And for removable it can be hybrid prosthesis with 4 implants and overdenture with 3 or 2 implants in place. Ideally

for overdenture when adequate interocclusalspace of 15 mm (class I[6]) is present then implants splinted by bar and held by clip is the treatment of choice[8]. As bar has proven to be a longterm successful treatment option for patients who require a high degree of retention and have no undercuts[9]. Recent articles have shown that even if bar attachments allow rotational movement, a higher load is transferred to the implants, as it is difficult to anatomically place the implants in a position to get pure rotational movement[11]. And bar and clip is an expensive restoration with the additional challenge of maintenance of hygiene.

The study on stress distribution between stud attachment and resilient bar and clip attachment has shown no significance difference[9]. And stud type of attachment can be used with existing dentures and also it offers off-axis or angles nylon inserts to accommodate non-ideal implant position[12]. So in this case three free-standing implants were placed in B,D,E position. Two implants supported overdenture was avoided to restrict the PM6 type movement, as the posterior residual ridge was resorbed. And due to financial constrain the patient was not ready for a fixed implant bridge. Overdenture patients have been studied to have a masticatory efficiency in chewing cycles similar to natural teeth[13]. And it already a proven fact that in comparison to conventional overdenture the comfort and satisfaction of patients is quite high[14]. So the success of mandibular overdenture is quite high even after 10 years of function[14].

Conclusion

Treatment option will vary from individual patients but considering the anatomical condition and financial constrain the treatment options has to be devised to give a predictable result. Implant-supported overdenture has become a standard treatment option with edentulous patients. As long term clinical studies have shown that with conventional loading it gives a positive outcome.

Abstract

In India and the South Asian part of the world use of tobacco is seen for a longtime. If we go back decades back tobacco is used as a gift to treat the guests and also it was encouraged to use in past times. Sooner when the malicious side effects of tobacco were noticed people tried to avoid the consumption of tobacco. The psychological mindset of the youth is quite impressionable, seeing the things that the adults do would easily encourage them to do the same. Thus, this article reviews various forms of tobacco used in our Indian society and how the government of India is taking action to curb the tobacco abuse.

Keywords: *Khaini, Mawa, Mishri, Gutka, Snuff.*

Introduction

The use of tobacco by the younger inhabitants of India is reaching a new epidemic levels. The World Health Organisation (WHO) has stated that approximately 82k-99k, youngsters start the habit of smoking each day. Nearly 45000 of them happen to prolong the habit of their adulthood and many of them are expected to perishin advance because of smoking-related diseases. The way the existing developments of smoking cigarettes and other forms of tobacco are continuing it is estimated that near 251 million people will die due to tobacco.

India being the second largest populated country in the globe, and third-largest producer as well as consumer of tobacco in the globe. The use of tobacco is deep-rooted in the history of this incredible nation.

Bearing in mind the gigantic health obstacles accompanying the tobacco usage, it is of paramount relevance to comprehend the causes surge its consumption and to plot stratagems to diminish its consumption. It is exclusively pertinent for emerging nations such as India, everywhere tobacco consumption remains to be a public yet harmful consequence of its practice. This article gives a brief review of the outlines of tobacco usage in India, its occurrence in Indian youngsters, psycho-social aspects in commencement & inhibition & the footsteps reserved by the government to curb its use.

History: Tobacco's use had started as early as 600 A.D[19]. Being familiarised in the European community by Columbus who was acquainted with it from the Caribbean through his world tour. India was familiarised with it by the Portuguese.[20] Previously, tobacco had been smoked by various types of tubes or as panatela or was consumed through the mouth in the form of smokeless tobacco. The mid-nineteenth century saw the introduction of paper cigars and cigarettes. In around 1828 A.D nicotine was sequestered from tobacco leaves. Detrimental properties of tobacco have been renowned over the last 1000 years. Archeologically many kings and emperors have acknowledged the detrimental properties of the tobacco and even strained to prohibit the product form the market.[20,22]

India has a discrete custom of implementations in

contrast to tobacco usage being started by the previous rulers (like Jahangir) and the spiritual frontrunners at dissimilar periods in the past. The prodigious Indian Sikh Guru Gobind Singh forbidden smoking for the followers of the Sikh community. He said, "Wine is bad, Indian hemp (bhang) destroys one generation, but tobacco destroys all generations"[22,23] Tobacco use has been regarded as a spiritual taboo by the Sikhs since then. Still, regardless of old efforts to legitimately prohibit tobacco, its use has sustained to breed in acceptance as a non-productive activity[23]

In contemporary medicine, its detrimental side has been documented in the previous 40 years[19]. Though its usage has weakened in industrialized countries in the current ages, it lingers to be prevalent in emerging countries[3].

Different ways it has been used from centuries: Tobacco can be used as smoke form or smokeless form, examples-beedi and cigarettes or like hookah, hookli, chutta, or chillum.

Beedi- it is an inexpensive smoking stick which can be simply made by rolling the tobacco in a dried piece of temburni leaf and securing it with a strand. The dimension differs from 4-8 cm.

Hooka – It is native to India and is made with the help of wooden and metal pipes. The tobacco smoke travelsfrom side to sidein the water which is in asphere-shaped bowl or instead of tobacco any other flavours can also be used.

Hookli- it is a small clay tube-like device which can be nearly 6.9 cm long

Chhutta- it is an indelicate preparation of tobacco, which puffed with the burning side inside the mouth. It is most prevalent in the Srikakulam area of Andhra Pradesh.

Dhumti- It is a cigar like product which uses leaves of jackfruit trees or dehydrated leaf of musa plant. Men predictably burn dhumti, whereas females use it oppositely.

Chillum- it is a narrowed clay tube of about 9.9 cm in length. The tapered side is kept in the oral cavity, frequently enveloped in a damp garb that acts as a filter. It is sometimes used with ganja in the northern part of India.

Usage of smokeless tobacco: Smokeless form is more common in India among youth.

Betel quid includes betel leaf, areca nut, slaked lime, tobacco, catechu and condiments customized by the consumer.Different regions of India usesa different pattern of preparation for the betel quid.

Khaini- tobacco flakes are roasted and mix with slaked lime. The powder is prepared when the consumer uses his left hand for keeping the mixture and rubs it with a finger. Then it is placed in the labial vestibule.

Mawa – it is a combination of areca nut, tobacco, and slaked lime. Most popular in the Gujarat region,among the 15-19 years age group.

Snuff- it is prepared from tobacco byfrying and liquidation, it is used throughnosesnuffing and is prevalent in the east side ofthe country. It is used as a dentifrice, in some regions it is recognized as Bajar and mishri.

Gutkha- direct preparation from the industry, ingredients are areca nut, tobacco and condiments.

Pan masala- mostly used as an after-meal mouth freshener, it is a betel quid combination which comprises ingredients similar to gutkha, but may or may not have tobacco. The combination is masticated & consumed. The inexpensive smokeless form along with the refreshing taste has led to a colossal upsurge in the usage of different kinds of areca nut plus smokeless tobacco amongst the Indian populations as well as the youth.

Psycho-social issues of initiation of tobacco use:

1. We have to observe the duration that a particular individual spends with people. Also if using tobacco is common in the family of the individual then their more chances of him/her getting addicted. Seeing others who are living close to the individual consuming cigarettes may inspire young people to take up the habit.
2. Peer pressure plays a pivotal role in influencing a person to take up these bad habits. It not only becomes a cool image to carry in front of their friends but acts as an anti-stress medication which is encouraged by friends. It also leads to drug addiction. The individual gets more easily addicted as the tobacco products will be shown as beneficial items to relieve stress or as a most common style adopted by nowadays teenagers.

3. The availability of the products in markets is easier than before. The day by day increase in tobacco manufacturing industries with increasing consumer consumption has led to inexpensive mass products that are available in every street corner. In India it is easier to find a tobacco packet rather than a bandaid.

4. Psychological or emotional stress- a good impression of others on us always works as a endorphins. Poor school results, insults by faculty in front of your friends, demoralization from your professors all these factors play a key role in shifting towards the bad habit. Cause being a good person is difficult in today's work environment so such students tend to find relief in these products and abuse it daily. Mental health is a relevant topic which is ignored by parents these days, the features of depression are quite difficult to identify and thus negligence in communication with children by parent lead to addiction to these bad habits.

5. In a country like India media is everywhere and so are the commercials, on television, radio and on the roadside walls. Tobacco advertisements mostly attract the younger generation which falsely showing the advantage of the product rather than the disadvantages. Even the characters in movies and serials consuming these products in a way contribute to promoting the use of tobacco. Many MNCs have not only sponsored various sports events but also instituted bravery awards. Advertisement and promotions of these vicious products are at a cusp in a developing country like India.

Prevention strategies: Like the old saying "prevention is better than cure" there are certain techniques by which we can prevent the adverse effect of addiction to tobacco.

1. The advantages of educational programs have been well received by school students. Such programs concentrate on harms caused by cigarettes other products like hooka, beedis and gutka. Most Indians are unaware of the harmful effects caused by smokeless tobacco products. There is even an erroneous faith that beedis are less injurious than cigarettes. Countless individuals believe that these products on consumption helps in free bowel movements and they refuse to leave the habit as they believe that it will lead to constipation. Multiple programs have been initiated by the government of India to curb this problem. A training module is generated for Non-profit Government Organisations for offering the intervention to street children according to their needs.

2. A pivotal phase in preliminary anticipation is the rebooting of the current tobacco strategies of the GOI. The GOI has lately made relevant lawful actions nonetheless there are deep-rooted problems in enforcing the tobacco-related laws. Limitations have been instilled in sales and the use of such products in public places. Mainly the price of such products should be hiked and their ease of availability should be reduced. An initiative of this program is stopping the sale of these products in the vicinity of schools. Some developed countries have imposed strict restrictions regarding the sale of these products to children but despite these strict restrictions there are still flaws in implementing them.

3. Due to the failure in proper instillations of school-based interventions it has led the scientists to advocate approaches involving the generation of social environment supporting non-smoking. This is important to Indian society, where monetary difference, joblessness, ignorance and vagrant people are linked to addictive behavior including drug addictions.

Prevention is Better Than Cure!!: In tobacco addiction it is better to curb its use rather than regretting it later in life. The preventive measure can only be carried out if the individual is fully agreeing to quit the habit on his/her own. Not only him but the people surrounding a recovering patient should be supportive in their process. We as responsible citizens of this country should always be helpful to those in need. First and foremost educating the person about the harmful effects of this abuse will certainly help a certain amount of population in the society. While educating an individual he should be enlightened about the detrimental effects of tobacco with a reason as nobody will agree nowadays without any proof so we should introduce them to the people who are suffering from oral cancer caused by the tobacco abuse to tell about the detrimental effects not only the disease patients but also those who have successfully quit the habit should be brought in front of the addicts to build a hope in them that they can quit the habit too.

Conclusion

The use of tobacco dates back to many decades

when it was merely a product for refreshing mouth after a heavy meal. In recent years there is a gradual increase in the consumption of such products. Despite the various strategies adopted by the government it, at last, depends on the individual to understand and acknowledge the harmful repercussions of consuming these products. There is no proper awareness among individuals regarding the harmful effects and the commercials are wrongfully encouraging the use of it. We also lack in collecting the data of consumers in different age groups in different parts of countries. To get rid of this vicious product we need to emphasizeon stricter legal actions to those industries and companies promoting the commercials.

Impact of Pictorial Warnings on Tobacco Packs in India

Ramesh Nagarajappa[1], Debasruti Naik[2], Gayathri Ramesh[3]

[1]Professor and Head, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Associate Professor, Department of Dentistry, Chamarajanagar Institute of Medical Sciences, Chamarajanagar, Karnataka, India

Abstract

Tobacco use is represented as the most important public health predicament as well as the number one reason of preventable death worldwide. India ranks the largest tobacco producer as well as the second biggest exporter of tobacco commodities globally. Numerous people each year are killed because of tobacco consumption as it affects every organ and system of the body. Hence policies need to be directed towards tobacco control globally. This review article highlights the impact of one such policy - pictorial messages on tobacco warnings.

Keywords: *Global, Pictorial, Smoking, Warning.*

Introduction

Tobacco use is still considered as preventable death worldwide.[1] More or less, 6 million people are dying every year because of this tobacco-related causes with a predictable increase in mortality rates getting 8 million cases by the year 2030.[2] Consumption of tobacco is usually in the form of smoking[3] and is associated with many respiratory diseases, cardiovascular diseases, and cancer.[2] According to the World Health Organization (WHO) testimony on the Global Tobacco epidemic 2013, around 500 billion dollars of monetary harm annually results because of tobacco use.[4,5]

Worldwide, several policies have been introduced to address the economic and health burden of tobacco use. The first international treaty on tobacco - WHO Framework Convention on Tobacco Control (WHO FCTC) was held in 2003 where Saudi Arabia was among the 168 states who signed the treaty. In its eleventh article the action of binding and labelling of tobacco commodities started and the FCTC recommends a revolving series of health messages that warns and cover at least 50% (or must cover at least 30%) on average of the front and back of the package. It also proposes the use of graphical health messages instead of textual ones.[5,6] The FCTC policy proved to be one of the very effective policies as act as direct means of communicating the risks associated with smoking.[7] Therefore, the chances of smokers noticing the labels increases up to 50% if the health warning text and image is placed on the front side of the packages.[6]

Also, in November 2008, Article 11 guidelines were adopted at the 3rd conference of the parties which focused on the inclusion of tobacco package health warnings. After this, almost 28 countries globally have started introducing pictorial warnings.[2]

Health communication intervention: This health warning pictorial messages have proved to be the most valuable way for enlightening smokers as well as non smokers regarding their health risk. In most of the countries, smokers alleged that they get to know the risk associated with cigarette from warning messages rather than erstwhile resource except television.[8] In 1950s, it was also established that "fear appeals" were very

Corresponding Author:

Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: smilewithdebshruti@gmail.com

constructive in changing health behaviour (e.g. quitting), especially if they are combined with any knowledge.[4]

Efficacy of pictorial warnings: Facts for better latent effect of pictographic messages have initiated from target groups, questionnaire studies and new coverage research.[3] An investigation of records of the ITC Four Country Survey compares effect of prefacing image-based messages in Australia in 2005 by introduction of lengthy text messages in the United Kingdom in 2003. Pictographic messages are also referred by ex- smokers as an imperative reason in their endeavour to end as well as they should be allied in the utilization of qualitative cessation services like toll-free phone "helpline".[9]

Low literate population: Pictographic warning structures may be predominantly significant in transferring health data to those populations with lower education rates.[1,2] Smokers are reported to be less educated than others. Introductory information suggests that countries having pictorial warning messages exhibit less disparity in health acquaintance throughout all the educational levels.[10] Meticulous care has to assort pictures for using it in uneducated populations like without inserting text messages and putting smoking pictographs could involuntarily imply only approval rather than forewarning of its troubles whereas images might say a 1000 words but it is always difficult to choose from those to utter the thousand correct words.[4]

Lower middle class countries: Data from lower middle class income also ropes the usefulness of bigger pictographical warnings in excess of texting warnings, and also suggests that pictorial messages can be good because of the awareness of health risks of smoking.[11]

Are Current Tobacco Pictorial Warnings in India Effective?: Around 800,000 deaths every year in India is because of this tobacco and out of which 700,000 are correlated to smoking.[12] About 10 million deaths per year are likely to occur globally by 2030. Tobacco use in India is highly complex since consumption rate is much higher in various ways in different parts of the country. Behavioural changes like quitting and reducing the tobacco consumption can be well communicated very effectively by warning labels on tobacco.[1]

India ranks the largest tobacco producer as well as second largest exporter of tobacco products globally.[3] Several people every year are killed because of tobacco consumption as it affects various organs of their body. The load of ailment is because of tobacco smoking which has records for 4 lakh patients of oral cancers and 1.3 million patients of coronary artery disease as well as 7 million patients of chronic pulmonary disease. About 1000 young children now smoke and out of them 500 may die of tobacco induced diseases where 250 of them are in their middle age and the rest of them in their old age approximately.[9,11]

Awareness about tobacco commodities is mandated under The Cigarettes and Other Tobacco Products (COTPA) in the year 2003 in India. [13] Currently, tobacco products are now displaying an image of scorpion on smokeless form of tobacco along with an image of diseased lungs or an image of X- ray of lungs showing cancer due to smoked form of tobacco.[13]

Tobacco Labelling at India: In the year 2006 the health warnings policy of India was drafted. A proposed final set of health warnings after 2 complete rounds of revisions in 2006 and 2007, got released in 2008 and were enforced on each manufactured cigarette packages from 31st May in 2009. Cigarette packages have 2 variety of warnings and on all smokeless tobacco products a totally separate warning was rotated.[14]

The Health and Family Welfare Ministry Department in India in 2011 approved an amendment to the regulations that consists of 4 new variety of image based warnings which should be applied on tobacco and bidi packages as well as 4 new variety of image based warnings for smokeless junks. Tobacco companies were allowed to decide any one photo out of each set of 4 images for smoked and smokeless tobacco products and the rules were implemented on December 1, 2011.[15]

India anticipated a new round of picture warnings on September 27, 2012 and those produced warnings as of April 1, 2013, although execution of these pictures varied. Again, a group of 3 new pictographic messages were made for smoked tobacco products, and as usual a separate group of 3 new variety of message were made for smokeless tobacco products. Health warnings structures had to cover 40% of the frontage of all cigarette packages.[16] After all the above proposals, the government again proposed awareness messages on October 15, 2014 that covers 85% of the front and back of the pack and the deadline was extended awaiting 1st April in 2016.[17]

Pictorial warnings on tobacco products: To make them able to visualise and understand the character of tobacco-related diseases pictorial warnings and images

were made for the users. Awareness were created to inform the serious illness that can be caused due to tobacco usage. Therefore, the messages had to be very effective and should be able to keep away the user.

Because of its multilingual and multicultural communities in a country like India, a warning messages can break all the regional, cultural and language barriers. Likewise, where a maximum percentage of the people are uneducated, and therefore written messaged warnings can be ignored whereas graphic awareness messages can help in understanding. This kind of policy is an effective public health strategy that will overhead the government as well as the people at no cost because the tobacco companies will carry out all the expenses meant for the colourful messages.[18]

Several countries along with India are now assigned as a signatory to WHO's Framework Convention on Tobacco Control at the 56th World Health Assembly in the year 2003 and is expected to pursue the WHO guidelines. Pictographic warnings usage on tobacco commodities which is the WHO's initiative called as six "M POWER" rules were developed and intended to battle tobacco among the countries in 2008.[7,11,12]

M Power rules are as follows:

1. Monitoring tobacco use as well as controlling of activities.
2. Protecting individuals from the hazardous effect of tobacco.
3. Offering help or lend a hand to people who have it in mind to refrain from using tobacco.
4. Warning everybody to know the ill-effects of tobacco.
5. Enforcing rules in opposition to all tobacco linked activities that also includes sponsorships.
6. Raising the worth of tobacco materials to reduce its consumption.[19]

Various western countries like Australia, Singapore, Brazil, Chile, Thailand, Hong Kong, Canada and Chile were successfully working on pictographic messages and images on tobacco merchandise packets. The result of this strategy has come to be very much effective on people with low education and low economic status.[7]

It was realised that only constitutional warnings enforced on all tobacco products in 2005 under COTPA was not sufficient to lead in reduction of the use of tobacco. Therefore, the authentic enforcement of these rules has been postponed repeatedly, apparently because of demands exerted by the tobacco manufacturing companies.[7]

Activities related to enforcement of tobacco pictorial warnings[20,21]:

- July 2006: The government issued an announcement of the definite pictures which could be used by tobacco companies within seven months. They demand for grounding time and therefore the government had to extend time period up to June 2007.
- February-May 2007: The objective of company was to utilize any image of a body which should indicate that smoking tobacco can kill. A Group of Ministers (GoM) was created to make a decision who asked for a further extension till July.
- August 2007: Meanwhile, the parliament amended the bill in support of building the application of the skull and crossbones picture optional and should not be compulsory. The court only marks a deadline of December 1 in the year of 2007 for picture-based messages to be enforced in the public.
- September 2007: The GoM made the withdrawal of the images like skull, crossbones, corpse, citing cultural and religious reasons.
- December 2007: The government now ordered for another extension till 17th of March 2008.
- March 10, 2008: The government of health issues few courses of action as date of enforcement shifted to 24th of June 2008.[19] Messages like "smoking kills" and "tobacco kills" were to be printed on cigarette, beedi and other smokeless tobacco products in English and regional languages.[20]

The fundamental right is to preserve a healthy life and it has to be enabled by the government. Therefore, strong warning messages is required to create awareness about the harmful effects of tobacco to the consumer. Tobacco is the only kind of lethal item for consumption having no safe limit and it is legally marketed to consumers globally.

India's Ranking on pictorial warnings: Around the globe, India stands fifth, jointly with Hong Kong and Thailand sharing with 85 % of the tobacco packets covered as per the Canadian Cancer Society report

and only 58 % of the world's population follow this regulation.[22] In India according to the current regulation of pictorial warnings and in the lead the direction of the High Court as well as the Supreme Court, and the chief executive of Voluntary Health Association of India, said that "India has constantly demonstrating leadership by enforcing the relinquish-line figure on all tobacco packets and everyone have pleaded the government for this.[11]

Conclusions

Graphic image based warnings can considerably enhance the efficacy of warning instructions. The application of lifelike images is a significant way out of replacing those positive relations with that of unenthusiastic associations, which is very much suitable in giving the shattering effect of global health by using tobacco related products. Future investigational research should inspect the impact of pictorial warnings on smoking activities. Such work should build up the worldwide evidence base for pictographic messages in future and should also develop our skill to appreciate the 'active ingredients' that reveal such type of messages as well as making them aware of other various effective tobacco control policies.

Immune Regulation in Periodontal Disease: A Review

Manoj Kumar[1], Lora Mishra[2], Saurav Panda[1], Anurag Satpathy[3], Abhaya Chandra Das[1], Gatha Mohanty[4]

[1]Associate Professor, Department of Periodontics & Oral Implantology, [2]Professor, Department of Conservative Dentistry & Endodontics, [3]Professor, Department of Periodontics & Oral Implantology, [4]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

It is an established fact that dental plaque as a biofilm is responsible for various types of gingival and periodontal diseases. It is a multifactorial disease in which one of the important components is the host defense mechanism. Through many years of research, it has now been established that the bacteria alone are not sufficient to cause the disease, it's only when they evade the host defense, and in the course of protecting the host, its immune system acts against the tissues resulting in native periodontal tissue damage. This review tries to gain insight into the complex immune mechanisms which take place during the pathogenesis of periodontal diseases.

Keywords: *Plaque biofilm, Humoral immunity, Innate immunity, antibody.*

Introduction

It has been very well known over the last thirty years that while plaque is the cause of periodontal disease, it is the inherent vulnerability of the host that decides the end stage of the disease. Innate susceptibility, in turn, is governed by the type of the feedback provided by one's immunity to the specific periopathogenic bacteria residing in the plaque biofilm.[1]

The washing action of saliva, gingival crevicular fluid, phagocytes, non-specific antibodies, complements, epithelium and defensinsseem to prevent the bacterial attachment and subsequent colonization in the gingival sulcus. However, the role of defensins in arresting the growth of bacteria in the plaque biofilm has yet to be ascertained.[2]

Many often low virulent pathogens clear out by scavenger receptor of phagocytes or Innate cells without evoking further adaptive immune responses.[3] However, the highly pathogenic bacteria with strong antigenicity infect the sulcus, TLR mediated cytokines from resident leukocytes, activate Innate cell (PMN, Mo) homing to expedite bacterial Killing. If innate cell is unable to destroy periopathogens, they enter the periodontal tissues because Aggregatibacter actinomycetemcomitans (A.a) and red-complex bacteria are unyielding to phagocytosis.[4]

Role of Host Immune Defense Against Periopathogens: "Virulence factors of these periopathogens induce TLR dependent APC activation results in upregulation of MHC-II and Co-stimulatory molecules as well as cytokine release." With strong innate response against periopathogen, antigen-presenting cells (APC'S) liberate IL-1, IL-12 and NK cell liberates INF-γ. In presence of IL-12 and INF-γ, short term, high-affinity APC-TCR binding between naïve T cells and APC leads to Th-1 response.[5] A continued strong Thl response produces INF-γ (i.e., CD4 cells) that would pool the PMNs, macrophages, Natural killer cells (NK) and CD8 T-cells to the siteof infection, that may contain the disease (i.e., containment of infection in chronic gingivitis) by exerting anti-bacterial activity,

intracellular and/or direct contact killing mechanism. The disease might not be eliminated rather persists due to continuous supply of microorganisms from other niches and plaque biofilm.[5]

Atypical LPS of P. gingivalis induces poor innate response for a protracted course. P.gingivalis LPS inhibits IL-12 release from DC and INF-γ from activated Th0 cells (i.e., increased IL-4, IL-5 secretion). Therefore, Th1 to Th2 shift mainly depended on nature of the antigen, antigen dose, cytokine environment and nature of APC.[5] In presence of IL-4, IL-13 and low level of IL-12, prolonged, low-affinity APC- TCR binding leads to Th-2 response (Figure-5).[5] Exaggerated Th2 response induces B cell proliferation (i.e., Polyclonal B cell activation), class switching of plasma cells and antibody-mediated humoral immune response in periodontal lesion.[5,6]

Increased counts of plasma cells suggest enhanced Th2 action in severe periodontal disease. Increased protective anti-bacterial antibody could removeperiopathogens, but if the secreted antibodies become nondefensive for the host (i.e., Low Ab affinity and avidity) or are unable to kill the periopathogens, periodontal disease may ameliorate to an advanced stage.[5] The presence of both Th 1 and Th2 in periodontitis[7,8]points out the importance of both in the pathogenesis of periodontal disease. Hence, the difference between "protective" and "destructive" antibody synthesis would be the most important determinant in the progression of the disease.[5]Alteration of the Thl/Th2 balance may be a direct outcome of the "super antigenic" actionof the notorious periodontal pathogens.

"Although there was no direct evidence for a role in periodontal disease pathogenesis but IL-10 from Th2 cells would promote T-regulator cell activity with concomitant suppression of cell-mediated immune responses." $CD4^+CD25^+$ cell also play a beneficial part in regulating autoreactive T cells mobilized as a part of the host response to periopathogens.[9]

"High titers of anti-collagen type 1 antibody and specific t-cell clones have been identified in inflamed gingival tissues of periodontitis patients."[10] It has been pointed out that human hsp60-reactive T-cell clones and T cells occupying the periodontitis affected areas had the same receptors and cytokines profile (INF-γ) suggestive of the fact the anaerobic bacteria causing periodontitis may activate the self hsp60-reactive T-cells with similar cytokine form.[11] On the contrary, Petit et al. believed that a higher level of anti HSP antibodies were protective of destructive periodontal diseases.[12] The conflict between the two studies might be due to racial variation, the difference in the extent of the disease and variations in the age of the various study groups.[11]

It was found that expression of Vβ was quite increased in the circulating blood mononuclear cells of individuals with Prevotella intermedia infection in comparison to healthy subjects raising suspicion towards the role of superantigens in periodontitis.[13] But other study results failed to show super antigenic activation of T-cells suggested that role of a superantigen in the periodontal disease was variable and inconsistent.[14] The conflicting reports regarding the role ofsuperantigens in periodontitis is yet to be confirmed.

"Although few if any NK cells are seen in healthy tissues, their numbers increase from health to gingivitis to periodontitis."[15] Besides their cytotoxic nature, NK cells can monitor B-cell movement and propagation, which is the pathognomonic histopathological feature of severe periodontal disease.[16] The cell-killing action of NK cells is potentiated by IFN-γ. "Surface lipopolysaccharides (LPS) from Gram-negative periodontal bacteria appear to provide the major activation signal for NK-cell-mediated cytotoxicity."[9]

"The peripheral and local immune cell profiles in patients with disease differ substantially, which suggests that the immunological response to periodontal pathogens is primarily a local phenomenon with mild to moderate systemic involvement."[17]

RANKL expression by T-cell was not critical for bone resorption rather other mechanisms (i.e., hormones, Calcium ion signaling) also have an effective role in osteoclast differentiation in the absence of RANKL. Several studies suggested that T-cell is only indirectly involved in osteoclastogenesis. Moreover, activated T-cells not only positively regulate osteoclastogenesis by RANKL expression but also negatively affect it by secreting IFN-γ. This counterbalancing action of IFN-γ suppresses boneresorption in normal T-cell response as well as in many chronic periodontitis patients. Thus, the detrimental effects of T-cells onosteoclastogenesis revolve around the compelling balance of RANKL expression and cytokine profile.

There arises the need of added studies to find out the components of alveolar bone loss and pathogenic T-cell phenotype associated with periodontal bone loss.[18]

B-cells secrete high amounts of IL10 and IFN-γ, which are inhibitory cytokines but these seemed to be outrun by stimulatory factors such as macrophage inflammatory protein-alpha (MIP-α), monocyte chemotactic protein-3 (MCP-3), and M-CSF.[19] Although it has been demonstrated both in vitro and in vivo that activated B -cells enhance osteoclastogenesis and bone resorption it is still inconclusive if B- cells are more responsible for bone loss than T-cells.

"Periodontal Antibody (Ab) producing B cells may be inadequate or of insufficient longevity to deal with the continuous assault from biofilm and/or chronicity of the infectious disease. Meanwhile, memory B-cells and Ab-producing plasma cells may eventually become "crippled" or "degenerated" and thus trigger further immune/inflammatory responses by invading pathogens resulted in progressive tissue destruction."[20] Therefore, "Ab-mediated protection is incapable of achieving total or sterile eradication of the invading periodontal pathogens and, hence, is sub-optimal."Contrary to that,"activated" B-cells in the form of antigen-presenting cells totrigger memory T-cells for cellular immunity.[21] This is precisely why antibody-mediated immune response anticipates periodontal pathogens first but fails to curb the advancing form of periodontitis.[22] The B-cells localized in the periodontal tissues also deposit IL-1β that is crucial for alveolar bone loss. It has to be seen in the future as to why the humoral immunity fails to arrest the periodontal disease progression before a definitive attempt to prevent periodontal disease in the form of a vaccine can be thought of.

Conclusion and Future Directions: "Host immune-pathogen interaction is a complex interplay, which is intimately regulated by the innate and acquired immunity to deal with immediate and long-lasting assaults imposed by invading micro-organisms in periodontal pockets." Pathogen-specific $CD4^+$ T cells are both protective, and destructive whereas $CD8^+$ T-lymphocytes are not responsible for periodontal disease. We have sufficient evidence pointing towards the role of $CD4^+$ T cells in the development of the host's antibacterial resistance and maintenance of harmony of the periodontium.

With the basic understanding of the interplay of the immune cells and cytokines in the process of bone resorption, would help to develop novel methodto treat periodontitis and other systemic disease associated with bone loss. Therapeutic approaches such as potassium channel blockers to block the calcium signaling for RANKL expression and gene therapy to reduce IL-1 or TNF-α production are being investigated. In periodontitis host modulation using chemically modified tetracycline (CMT) or low dose doxycycline have shown to reduce the periodontal disease by suppression of matrix metalloproteinases (MMP) activity.

A clear understanding of the immunopathogenesis of periodontal disease is essentially required to develop diagnostic aids for prediction of disease activity reliably, vaccine preparation and to differentiate between a healthy and periodontally affected site.

Currently the relationship between periodontal disease and systemic health is considered as a two-way road. Immunity in most individuals establishes a 'China wall' between the two. Moreover, epidemiological findings suggest that even in the absence of oral hygiene maintenance rapid periodontal breakdown occurs occasionally. Considering the relationship between periodontal disease and systemic health it can be stated that even tooth loss in some individuals as a consequence of chronic infectious periodontal disease represents a protective role of host immune response by essentially exfoliating the infective source (i.e., tooth associated plaque and calculus) that could create a greater danger to systemic health.

Idiopathic Gingival Enlargement and its Management: A Case Report

Manoj Kumar[1], Amit Kumar Srivastava[2], Lora Mishra[3], Rinkee Mohanty[4], Saurav Panda[1]

[1]Associate Professor, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Associate Professor, Dental Surgery Department, BRD Medical College, Gorakhpur, Uttar Pradesh, India, [3]Professor, Department of Conservative Dentistry & Endodontics, [4]Professor and Head, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Idiopathic gingival overgrowth is an unusual condition that leads to a gigantic overgrowth of the gums without any specific etiology. The enlargement leads to multiple issues and makes chewing difficult for the patient along with the unsightly appearance. Here we present a case of idiopathic gingival enlargement without any syndromic association in a 45- year old female patient. It was managed by surgical treatment including gingivectomy followed by gingivoplasty and was monitored regularly due to its high rate of recurrence.

Keywords: *Idiopathic gingival enlargement, gingival overgrowth, Gingivectomy.*

Introduction

It is a well-known fact that the increase in the volume of the gums is one of the most prominent features of gingival inflammation. The enlargement can be restricted to few teeth or may involve more or else the entire dentition in a generalized form. The most common of them is plaque-induced gingival overgrowth or inflammatory gum enlargement. Other causes include drug-related, enlargements associated with systemic diseases, leukemic gingival overgrowth[1,2], subjects with kidney issues and on immunosuppressants[3] to name a few. In the localized form, it was put forth by Cook that all of the enlargements may be known as "Epulis" and is seen mostly in the upper front teeth region.[4] Gingival enlargement can also be caused by few benign and malignant tumors of the oral cavity.[5]

Idiopathic gingival enlargement or fibromatosis as it is known as is an extremely rare condition seen leading to diffuse enlargement of the gums of alarming proportions. The main reason for this type of overgrowth is unknown and sometimes is associated with some syndromes. The enlargement may involve the maxilla or the mandible or sometimes may involve both. It involves both the labial/buccal and lingual/palatal surface. It involves all three parts of the gingiva, that are attached, marginal and interdental papilla which differentiates it from drug-induced gingival enlargement as the attached gingiva is not involved in the latter. The gingiva appears firm and leathery and has a peculiar "pebbled appearance." It can be of two types: One which is nodular and has multiple swellings at the interdental gingiva and the other one in which proportionate enlargements are seen.[6] It can sometimes cover the entire teeth and pose a challenge in mastication and can also lead to distortion of the maxilla and mandible.

Case Report: Here we are going to present a case report of idiopathic gingival enlargement. A 45-year-

e-mail: manojkumar@soa.ac.in

old female, housewife by occupation presented to the Department of Periodontology with a chief complaint of an increase in the size of her gums slowly over a period of 5 years. She also complained of the looseness of teeth and the inability to brush with difficulty in eating. Her medical and dental history was inconclusive. This was the first visit of the patient to a dental setup. She did not give any history of drug intake, fever, weight loss, pregnancy or any other systemic disease. She did not have any deleterious habits. She used to brush with a medium bristle toothbrush and toothpaste with a horizontal scrub technique. She reported that for the past few months, maintaining oral hygiene was difficult due to the gum overgrowth. She had severe halitosis. There was no abnormality was seen in the extraoral examination wherein the profile was convex, no abnormalities detected in the TMJ and lymph nodes and the lips were incompetent. Intraoral examination of the buccal and labial mucosa, palate, tongue revealed no abnormal finding.

Coming to the area of chief complaint, there was diffuse gingival enlargement of both the maxilla and mandible but was severely more pronounced in the lower jaw. The gingiva appeared pale pink, fibrotic with the typical "pebbled appearance" seen in the lower jaw. (Fig. 1) There was generalized mobility of teeth There was a typical erythema seen in the maxillary arch around the marginal gingiva. The enlargement was so much in the mandible that it prevented the contact between the teeth and posterior open bite was seen as a result of it. Since it did not fit any criteria, a provisional diagnosis of "Idiopathic Gingival Enlargement" was made. We advised an OPG and a complete blood hemogram to rule out any other abnormality. OPG revealed generalized alveolar bone loss but the blood investigations revealed all values within normal range, except alkaline phosphatase which was slightly increased. Her diabetic status came out as non- diabetic, it was done to emphasize the fact that diabetic patients are more prone to destructive periodontal disease as compared to non-diabetic subjects.[7,8]

Treatment Plan: After the initial examination, a thorough scaling and root planing was done and the patient was asked to rinse with 0.2% chlorhexidine mouthwash and was again recalled after 3-4 weeks. On her second visit, there was a very slight improvement in her condition. Therefore, we planned to do gingivectomy in all four quadrants in a planned manner. The whole procedure was explained to the patient along with the risks associated with the surgical process. A written informed consent was taken from the patient. Under complete asepsis, after administering local anesthesia, an external bevel gingivectomy was performed on one side and the same procedure was repeated on the other side after healing of the first side. (Fig.2) After the surgical procedure, a periodontal dressing was given at the site of surgery. The patient was prescribed necessary antibiotics and analgesics and was asked to meticulously maintain her oral hygiene. The excised tissue was sent for histopathological test and it revealed inflamed gingival tissues. There was an abundance of connective tissue which was mainly avascular and large congregation of fibroblasts along with heavy infiltration of piles of collagen fiber bundles. The superficial epithelium was broad with prominent thickening of all the layers with extended rete pegs. (Fig. 3) This confirmed our provisional diagnosis and a final diagnosis of Idiopathic gingival enlargement was made. The case was followed up for 6 months and it did not show any recurrence. (Fig. 4).

Discussion

As discussed above, gingival enlargement can be caused by a plethora of reasons. In the present case, as the drug, family, medical and dental history was non-contributory, we gave a diagnosis of idiopathic gingival enlargement. "Idiopathic gingival enlargement is also known as gingivomatosis, elephantiasis, idiopathic fibromatosis, hereditary gingival hyperplasia, and congenital familial fibromatosis.

It has been pointed out about its hereditary origin but has not been proved till now. It has been seen in multiple studies that the mode of inheritance is autosomal recessive in some and autosomal dominant in some. "It occurs either as an isolated disease or combined with some rare syndromes like Zimmerman-Laband syndrome (defects of bone, nail, ear, nose and splenomegaly), Murray-Puretic-Drescher syndrome (multiple dental hyaline tumors), Rutherford syndrome (corneal dystrophy), Cowden syndrome(multiple hamartomas), and Cross syndrome (hypopigmentation with athetosis)."[9]As seen in this case, there is progressive enlargement of attached, marginal as well as interdental papilla which sometimes extends above the teeth making the day to day activities like toothbrushing, eating and chewing quite difficult. The histopathology of this type of enlargement reveals numerous collagen fiber bundles, fibroblasts with an overwhelming connective tissue.

There is acanthosis of the epithelium with prominent rete pegs as seen in the present case.

The management of idiopathic gingival fibromatosis is only surgical as non- surgical therapy seldom helps. The definitive management includes gingivectomy[10] (external or internal) or flap surgery depending upon the case. Since the etiology of this is unknown, the chances of recurrence are quite high. Therefore, we need to follow these patients for a long time and repeat the procedure if deemed necessary.

Figure 1: Pebbled appearance seen in the lower jaw

Figure 2: Performance of gingivectomy

Figure 3: 6 months follow up

Figure 4: Histopathological Examination

Conclusion

This was a case of idiopathic gingival enlargement not associated with any syndrome. The patient was properly diagnosed based on clinical examination and proper correlation with radiological and histopathological examination. The case was followed up for six months without any recurrence, but long term follow up is warranted because of its unknown etiology and high chances of recurrence.

Abstract

In recent years phubbing activities have affected both phubers and phubees'. It has ruined the real-life social relationships. People who are busy in phubbing believes that smartphones are now a daily part of their interpersonal communication. In simple words, instead of giving much consideration to the people, there is a social place, they opt to bolt their eyes on their mobile phones while interacting with people. Phubbing is a threat to the mental health which leads to depression, anxiety and causes a negative impact on relationships. This review article focuses on the effects and signs of phubbing and how to overcome it.

Keywords: *Counselling, Mental health, Phubbing.*

Introduction

Phubbing is a mixture of the words "phone" as well as "snubbing" that describes the action of snubbing a person in a social place by focusing all the attention on one's phone instead of talking to the person openly in one's company. This phubbing terminology was originally coined in a movement by the Macquarie Dictionary to stand for an upcoming problem of smartphone exploitation in a social place.[1] In a public interface, a "phubber" can be considered as a person who keeps on phubbing his or her companion(s), whereas a "phubbee" is an individual who is a receiver of phubbing activity.[1]

Phubbing manners has hampered both phubers and phubees' lives deeply in these years.[2] It can destroy the existent-life community relationships of both phubers and phubees because it is measured as a disrespectful as well as ill-mannered behavior.[3] Several studies[4-6] have reported that when a person is being phubbed, they tend to have very little contentment as they make out the interaction to be deprived of quality, and they also experience less connectedness with their associate. Phubbing behavior may even jeopardize human lives and this shows that there was a case that has taken place at Malaysia where a six-year-old girl unintentionally fell throughout an opening of an escalator and at the same time during that incident, the girl's mother was busy in the phone having an argument with her husband on phone, and for that reason neglected her child. This case depicts how being inattentive while on the smartphone devices can cost lives.[7]

What is phubbing?: Phubbing is a word which was termed in May 2012. An advertising agency at Australia had created this word to describe the budding phenomenon of people who ignore their friends and family who were right in front of them but they kept scrolling over their phones.[8]

While the word might not be in our daily vocabulary, the action likely is. Seventeen percent or more people phubb others at least four times or more a day and out of them only 32 percent of people report being phubbed two to three times a day.[2] While the behavior might

not seem like a big deal, research shows that phubbing can affect your emotional relationships as well as your mental health.[9]

Who does 'Phubbing'?: The word phubbing might be a new term presently but this act of phubbing is around us since the use of smartphones started among the people. They slowly get addicted to this kind of impulse phubbing behavior. Studies reported that phubbing is mostly related with online self-presentation, online impression management and self-fascination.[10]

People who are busy in phubbing believes that smartphones are now a daily part of their interpersonal communication. "So many articles talk about Phubbing in a negative light and it has to be seen as a cultural shift - a generational shift. It could also mean self-love or self-care. Online self-presentation could also mean connecting with more people on a mass level. It's not necessarily a negative."[11]

There are several reasons behind this phubbing action like internet addiction, social media addiction, game addiction, depression, and 'nomophobia'. "Nomophobia" is a term that means the apprehension of being devoid of a smartphone which is also called a smartphone addiction and it is often lightened up by an internet gorge problem or internet addiction disorder. Smartphones are now loaded with various application which go beyond those of early computers. These smartphone applications have a massive effect on addiction. Excess use of these computers has forced the researchers to comprehend and investigate the concept of computer or smartphone addiction or in a short technology addiction.[12,13] Many studies reported that most of those software's had a huge impact on addiction. Some of the examples of such software applications is that it keeps an individual stay online for longer duration such as playing games online, shopping and social apps.[4,14]

How phubbing makes us feel?: According to some studies it was found out that people who were phubbed by the concerned person felt very less satisfied with the quality of interaction with the phubber. Results of few studies also reported that such feelings carry only the negative impact of phubbing on their intellect of belongingness, or the human aspiration to be accepted by others.[9] Now technology and social media are important parts of our smart life, but we shouldn't forget our mental health and well-being.[15]

Gender categorization: Gender categorization has been reported to play an essential role in motivating several smart phone-allied actions such as the preference for online activities,[16] mobile phone dependence,[17,18] internet obsession,[18,19] self-indulgence,[20] and conversation manners.[21] Though very little at present is known about how all these phubbing actions, being phubbed, along with supposed social customs of phubbing differ between males and females, some studies reported that women do more phubbing than men along with frequent text messaging and scrolling all over the pages of social media.[10,22] In the meantime, gender has a moderating consequence on the association that are stuck between social customs and many aspects of human utilization behaviour[23] such as alcohol consumption,[24] internet banking[19] and online purchasing.[14]

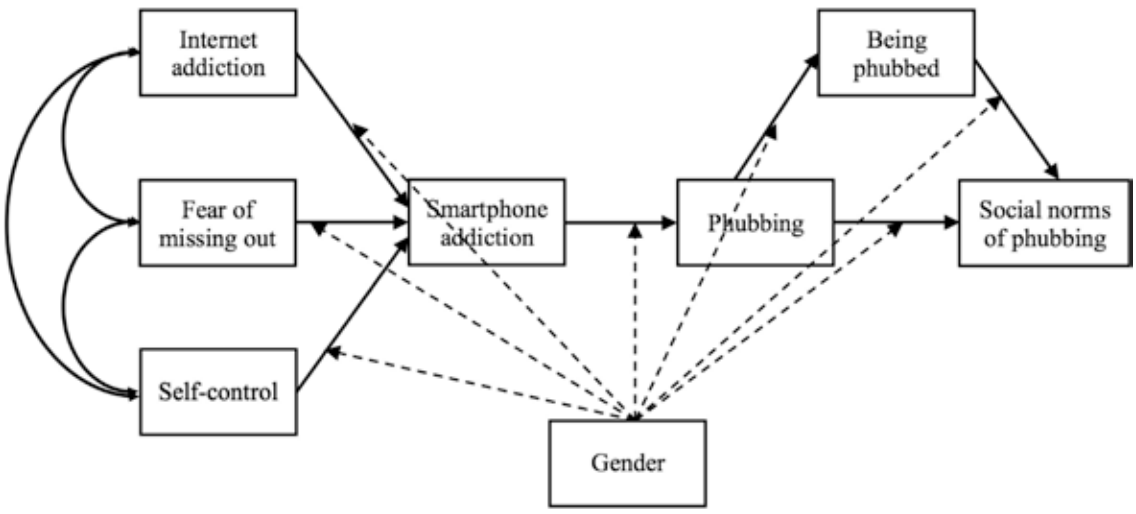

Figure 1. Proposed conceptual phubbing model

Research Model and Hypotheses: A research model to explain the key determinants of phubbing conduct and the apparent social standards of phubbing was developed.[2] The anticipated model is delineated thoughtfully in Fig. 1. It was theorized that Internet addiction and Fear of Missing Out (FoMO) would positively predict smartphone addiction, and that self-control would adversely foresee smartphone addiction. Next, prediction followed that smartphone addiction would positively predict phubbing behavior. Further, it was estimated that phubbing behavior would positively predict the extent to which individuals are phubbed. It was further anticipated that both phubbing and being phubbed would positively predict the degree to which individuals perceive phubbing as normative. Finally, it was predicted that gender would moderate the relationships between every determinant in the proposed model.

How does phubbing affect relationships?: Phubbing stimulates your ability to be present and connect with people around you. Studies reported that texting frequently on phubbing with smartphones during a front-to-front interaction made the experience very less satisfying for each other[24] and these actions can also have a bad impact on marriages. Phubbing behavior decreases marital satisfaction.[10] Conflicts over frequent phone use were the driving cause of marital issues. Studies also reported that spouses who phub each other result in higher rates of anxiety and depression.[13]

How does phubbing affect mental health?: From the mental health perspective, according to World Health Organization (WHO) (2014) someone who is declared mentally healthy is having a whole physical, mental and social condition and not just the absence of illness or weakness. So, when we examine it, someone who is doing phubbing, has experienced an indication of mental illness. This is because one aspect of being mentally healthy based on the definition of WHO is that someone who can establish good social relationships, but not for individuals who tend to do phubbing when interacting.[11,15,23]

What's the driving force behind those feelings?: Phubbing is a threat to four "fundamental needs," the study found.[12] Those core needs are: Belongingness, Self-respect, Meaningful life and Control. If a person phubs you, you might feel rejected, debarred, and nonsignificant that can lead to a negative effect on your mental health. Researchers also reported about a vicious cycle where the people who are phubbed tend to reach their smart phones more frequently and they try to keep on with their social media network to fill that void.[3,8]

According to research published in Computers and Human Behaviour, social media can make feelings of depression shoddier, and the more you use social media, the more you are to feel depression or anxiety.[21] The number one sign that you are guilty of phubbing is in your hand - your phone. If your phone is with you at all times because you're afraid you'll miss a call, a tweet, or a status update, you are likely guilty of phubbing.

Signs you may be a phubber[18]:

1. **Carrying on two conversations at once, on your phone and in person:** You're likely doing neither very successfully, and you're most certainly phubbing.
2. **Immediately bringing your phone out at dinner or other social settings:** Putting your phone beside your plate "just in case" is a warning sign that you'll soon be phubbing. Plus, you don't even have to touch your phone during a conversation for it to negatively impact your relationship. Studies have reported that just the presence of the phone made people feel less connected.[13,18]
3. **Can't get through a meal without checking your phone:** The fear of missing out is real - a real sign you're phubbing.

Three ways to stop phubbing: If the idea of giving up social media makes you nervous and a little sick to your stomach, you're not alone. The urge to check social media is stronger than the urge for sex. That doesn't mean, however, that you can't learn other ways to check in with social media without scrolling endlessly.[16]

1. **Make meals a no-phone zone:** When it's time to eat, no matter where you are, but the phone away. Mobile phones can be made into silent mode or into "do not disturb mode" because a distant buzz of notifications can cause distraction in mind. Engage in sincere conversation with each other and gradually comfort develops with having a face-to-face conversation.
2. **Leave your phone behind:** You might feel as if you've lost a limb, but don't be afraid to simply put your phone in your car, desk drawer, or bag - and leave it there. Whatever alerts or updates happen, they'll be waiting for you later.

3. **Challenge yourself:** Everyone enjoys a little prize now and then. Make ignoring your phone a challenge. Keep track of the meals or hours you go without your phone in hand. When you've completed a goal, treat yourself, and then challenge yourself again.

Three ways to help someone else stop phubbing:

1. **Model a better behavior:** If you want to silently encourage the chronic phubber to stop, be a good example. Put your phone away when you're lounging on the couch. Don't encourage them to show you something on their phone during a date. Focus on the other people at the table. Slowly but surely, they'll get the hint.
2. **Call them out:** There's nothing like hard love. If someone you regularly interact with has a habit of phubbing, tell them. The Stop Phubbing campaign will email your loved one a note about their behavior if a face-to-face conversation is too difficult or uncomfortable for you. Either way, tell them you don't like it, and then help them develop better habits.
3. **Be sympathetic:** Phubbing isn't a real addiction, but it is an impulse problem. It will take some time to break all these impulses as well as learned behavior, so be patient and understanding, but be firm too.

When to seek help for phubbing?: Reading through your phone, again and again, can result in an impulse behavior you can't control. When you go through bad communications with your people, when you realize you are going into depression mode along with irritable behavior with frequent mood swings then if you have difficulty in stopping the habit, you may want to speak with a therapist or psychologist. They can help you learn to redirect your energy. They can also help you find out why you may have developed this impulse in the first place because, for many people, social media begins as an easy getaway, or a way to zone out.[15,20] Therefore it is always better to seek help before it's too late.

Conclusion

Phubbing behavior is nerve-racking for the development of future generations. Therefore, it is required to provide proper guidance as well as counseling services to overcome the overruled behavioral pattern called phubbing that is being experienced by many people. The need for urgency of supervision and counseling services can be implemented in the form of modules that should focus on "use smartphone smartly". We don't have to stop using our phones to prevent phubbing. We just have to be more aware. Being mindful of our actions when we are around other people is a great place to start.

We can also ask friends for accountability. If they feel like we are zoning into our phone, they should feel free to call our attention to it. Phubbing is a learned behavior - after all, it's only recently become a problem - and we can unlearn it. It will take time and some work, but our mental health and our valuable relationships will thank us for it.

Transtheoretical Model of Behavioural Change for Oral Habit, Tobacco and Alcohol Cessation

Anurag Satpathy

Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar–751003 Odisha, India

Abstract

The transtheoretical model of change is one of the most accepted strategies to bring about an intentional change. It addresses the process of change in a structured manner which can be beneficially implemented to bring about positive changes to achieve habit breaking, tobacco and alcohol cessation. In addition, it may help acquire and establish positive habits such as maintenance of oral hygiene.

Keywords: *Transtheoretical Model; Behavioural Change; Oral Health; Tobacco and Alcohol Cessation.*

Introduction

People who intend to change a prevailing behavior, habit or an addiction exist in good numbers. Although several strategies have been put forth to achieve this, a model that makes an approach though health behavioral change such as the transtheoretical model[2] has become quite acceptable over the years. Initially it addressed smoking cessation, however, its success has encouraged its application across a variety of health behaviors including physical exercise, nutrition and diet. It may be further applied to oral care in the area of cessation of tobacco smoking and alcohol, maintenance of oral hygiene[3] and habits such as thumbsucking and oral breathing.

Transtheoretical Model:

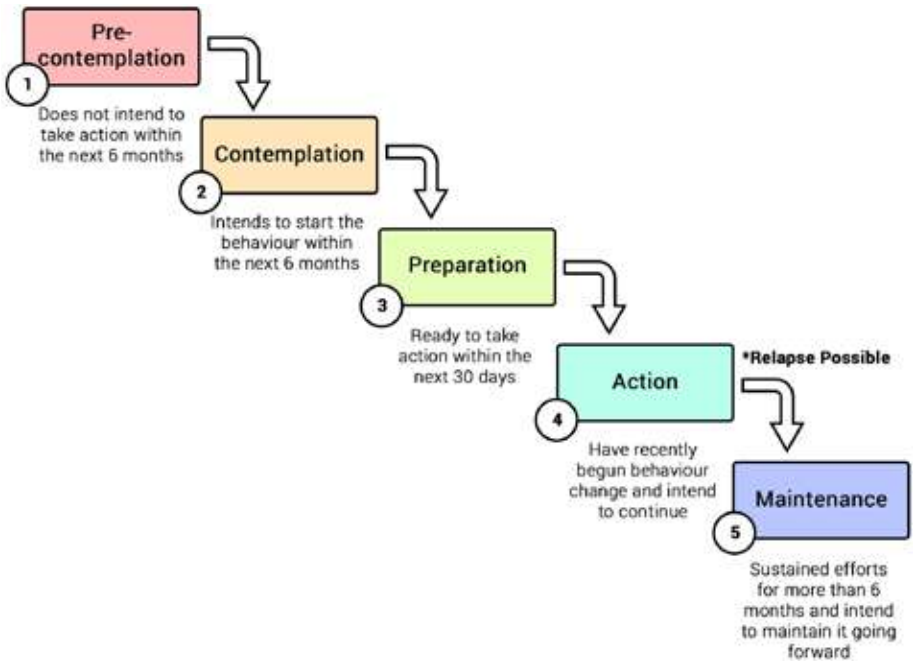

Figure 1. Stages of behavior change within the Transtheoretical Model adapted from Hartin et al.1

Transtheoretical model (TTM) of behavioral change is an integrative theory of therapy thatworks on the premise that change in behavior is a process and not merely a concurrence[4].

Individuals may be at different stages of change and readiness to adapt. The model is an accumulation of several constructs which include various aspect of change such as the stage, process, level, efficacy, and determination.

Pre-Contemplation Stage[5]: In this stage patients are usually not interested and do not indulge in thoughts pertaining to any kind of change in their routine. On the contrary, there is a tendency to defend their current state and do not consider see it as a problem. The defense may even come upfront when they perceive any external pressure. Patients do not lay their attention on the change and avoid any kind of discussion with others.

In this stage, motivational interventions can help raise awareness of the adverse effects of the habit or behavior. In this state, addictsoften outweigh the advantages of their current habit or behaviour and are unwilling to modify them. In this stage,the role of the therapist or a counselor is primarily to guide the patient[6,7].

Contemplation Stage[8]: In the contemplation stage patients have a better awareness about the ill effects of their habit and spendsome of their time thinking about it. Although there is a consideration of the possibility of changing, they display uncertainty in their thoughts and speech. Patients are undecided and are still in a mode of assessing the benefit of modifying their behavior. Although they are aware of the negative and the positive aspects of their habit and also the benefits of choosing to quit or reducing, they may doubt on the fact that the long-term advantages of the change will outweigh the short-term costs. For a patient to be in this stage it may take from a few weeks to an entire lifetime to get through this stage. This is true as some patients plan and plan and keep planning about the change may end up in this stage. On the positive side, patients in this stage are open to suggestions and are more likely to actually self-assess their feelings and thoughts on the change.

Patients are asked to change in the next 6 months, or any date as per the consent of the patient is arrived at. Usually, the vast majority of patients are unaware of what to change and often get caught up in the "chronic contemplation." They replace the idea for acting. Motivational interventions are beneficial for increasing the knowledge about the adverse effects of their present behaviour/habit or addiction. The adverse effects should be clarified[6, 7].

Preparation Stage[9]: In this stage patients have taken a decision to change. And this is revealed in their reciprocation such as: "I've got to do something about this–this is serious. Something has to change. What can I do?"

In other words, this is an experimentation stage and patients are now moving ahead slowly towards the change. They collect information by reading or asking about what they will need to do. Sometimes they may make a call to help centers to figure out what strategies and resources are available. In a good number of times patients tend to omit this stage and jump from the contemplation stage into the action stage. This often leads them to stumble as their knowledge is incomplete.

Preparation of change is underway and a deadline is set within 30 days. At this time a clinical evaluation using the various assessment tools may be made[10].

Action Stage[11]: This is the stage where patients gather acceptance in the fact that they will be able to change are seen actively involved in taking progressive steps and are now open to the use of alternative approaches. This could be the shortest stage, however, the actual amount of time spent by patients in this stage varies. It usually takes as long as six months, but can get over in an hour! In this stage, patients depend chiefly on their strength of will. At the same time where there is an effort to quit or change the behavior there exists a greatthreat for reversion.

Patients assess their self-pledge to themselves and chalk out tactics to counter own and outerdemands that may result in relapse. Intermittently they introduce instant incentives of sustenance of impetus, and evaluate the change achieved so that it enhances their self-assurance. Patients are mostlikely to be open to receiving professional help in this stage.

Beginning is made to stop the prevailing habit or behaviour. Habits can be stopped using drugs appliances, behavior modification, will power, informal exit strategy or some or all of these procedures. This phase of effort lasts 6 months from start to finish. It is the most frequent stage of decline, which may change with treatment approach, lifestyle, mental health and gender. Increased

initial relapse occurs in the first few weeks. Therefore, the first support is very important and interventions that address disruptions,avoidance and satisfying positive actions are most useful. To continue this step, it is important to repeatedly contact the therapist to redirect efforts and celebrate success.

Maintenance Stage[12]: This stage involves the ability toward off any persuasion that may cause the return of the behavior or habit. This stage aims to preserve the acquired status. Patients also tend to be reminiscent about the quantum of progress they have made and devise ways of living so as to counter relapse. They are now able to foresee the possibility and circumstances which might lead to a relapse and formulate strategies to manage it in advance.

Beneficially, they become aware that their goal is individually valuable and consequential. They become increasingly self-tolerant and come to terms with the fact that achieving a stable change takes time and it takes a little while to get accustomed to acquired status until they become like second nature to them. Inspite of temptations coming their way, they are able to keep themselves out the way. Relapses occur frequently, on an average, 3-4 times successful quaternary relapses and cycles occur before the change.

Conclusion

The Transtheoretical model handles the change through a structured and continuous approach. It allows interventions tailoring to meet the needs of the patients. In addition, there can be movement through phases which may be the case for some who succumb to relapses.

Host Modulation Therapy: An Overview

Saurav Panda[1], Rinkee Mohanty[2], Anurag Satpathy[3], Abhaya Chandra Das[1], Manoj Kumar[1], Rajat Panigrahi[4]

[1]Associate Professor, [2] Professor & Head, [3]Professor, Department of Periodontics and Oral Implantology, [4]Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan, (Deemed to be University), Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Host modulation therapy involves a wide array of therapeutic strategies directed towards modulation of host factors in order to prevent the initiation and progression of periodontal disease. Host modulation is one of the non-surgical periodontal therapeutic approaches employed nowadays as better compliance is often seen among the patients. These strategies are basically aiming at reduction of inflammatory mediators or inhibition of destructive enzymes etc. These approaches are much popular in recent times and employ various therapeutics to attain the same. This review enlists the various strategies and approaches in modulating the host for prevention of periodontal disease.

Keywords: *Host modulation therapy; non-surgical periodontal therapeutic approaches; periodontal disease.*

Introduction

It has been clear that bacteria with unique virulence factors contribute to the initiation of periodontal disease. Host derived enzymes and cytokines also play a major role in degradation of extracellular matrix and destruction of alveolar bone in periodontitis.(1) The bacterial insult activates host defense mechanisms, as result of inflammation and its mediators, leads to destruction of supporting structures of tooth.(2) This mechanism of tissue destruction allows the clinician to think of strategy to manipulate such host derived mechanisms for prevention and treatment of periodontal diseases.

Periodontitis is chronic inflammatory, poly-microbial disease affecting the periodontium.(3) Bacteria are considered as the primary causative agent, which subsequently trigger host response. One of the early inflammatory responses by host is diapedesis. If neutrophils able to combat and delineate the infection, the disease limits itself to gingiva, causing gingivitis.

When the pathogens breach the innate defense mechanism of the host and penetrate the host tissues, the disease of periodontitis sets in. This stimulates release of inflammatory mediators like cytokines which play an important role in combating the pathogens, and in turn also leads to degeneration of tissues. The periodontal tissues when destroyed can be clinically evident as pocket formation and alveolar bone loss.(4)

Risk Factors: Patient's risk factors determine the disease susceptibility of host. The rate of disease progression, its severity and treatment response varies with different individuals. The risk factors like heredity factors, hormonal changes, stress, smoking status, systemic diseases, nutritional deficiency, certain medications, increased occlusal load, local factors etc. play a significant role in determining disease susceptibility of an individual.

Host Modulation: Host is defined as the organism from which a parasite obtains its nourishment/in the

transplantation of tissue, the individual who receives the graft. And **Modulation** is defined as the alteration of function or status of something in response to a stimulus.

Host modulation therapy demands the use of pharmacological agents designed specifically to aid in treatment and limit the initiation and progression of periodontal disease.[5]

It includes:

- Antimicrobial therapies that can be used to address changes in the microflora
- Host modulation therapy that can be used to address a host response consisting of excessive levels of enzymes, cytokines, prostanoids & excessive osteoclast function that may be related to risk factors.

The different strategies of Host Modulatory Therapies (HMT) to regulate or block the pathogenesis of periodontal disease include:

A. Regulation of immune and inflammatory responses:

1. immunization method
2. regulating ROS
3. regulating cytokines
4. others – NF kb modulators
   – integrin inhibitors

B. Regulation of arachidonic acid metabolities:

1. steroids
2. antioxidants
3. NSAIDs
4. lipoxins
5. triclosan

C. Regulation of excessive production of matrix metalloproteinases:

1. Tetracyclines
2. Hydroxamic peptides

D. Regulation of bone metabolism

1. Antiinflammatory agents
2. osteoprotegrin
3. anti RANKL
4. SERMs
5. bisphosphonates
6. anti integrins
7. CMTs

A. Regulation of Immune And Inflammatory Mechanisms:

1. **Immunization method:** Bacterial plaque is considered to be the causative factor for initiation and also plays an important role in periodontal disease progression. These antigens are potent mediator for producing antibodies in the host system. Thus, new method are developed like use of protective antibodies via immunization for preventing periodontal disease. [6]

Bacterial whole cells, its outer components and synthetic peptides are used as antigen for initiating immunization. The development of periodontal vaccines has been in boom but not successful due to the multi-factorial etiology of periodontal disease and microbial complexity of bio-films.

Identification of microbial species like *Porphyromonas gingivalis*, *Bacteroides forsythus* for initiating specific disease, is necessary for successful development of vaccines.

3. **Regulating Reactive Oxygen Species:** Reactive Oxygen Species are the molecules with one or more unpaired electrons. These are released in excess amount in the event of inflammation. Tissues get exposed to these free radicals and get destroyed. Hydrogen Peroxide and Hypochlorous acids are the oxygen metabolites released by neutrophils and macrophages, take part in tissue destruction. They cause depolymeraization of collagen, hyaluronan, and proteoglycans. However, these free radicals can be neutralized by providing anti-oxidants or inhibitors in abundance.

Nitric Oxide is considered as a free radical, synthesized by endothelial cells by NO synthases (NOS1/2/3), and is produced at higher concentrations in response to inflammatory stimuli. They cause lipid peroxydation, protein and DNA damage and stimulation of cytokine release.

Inhibitor of iNOS: Merkaptoalkyguanides are inhibitors of iNOS are found to decrease inflammation in animal models. They are found to block iNOS, scavenge

peroxynitrite and inhibit cyclo-oxygenase pathway.

3. **Regulating Cytokines:** Cytokines are defined as the chemical mediators of inflammation which are considered as regulatory proteins which involve in controlling cell proliferation, differentiation and specific function of cells. Their action can be paracrine, autocrine or endocrine in nature.

Microbial biofilm constituents stimulate the host to produce proinflammatory cytokines like IL-1b and TNF-α those contribute in connective tissue and alveolar bone destruction. These cytokines are present in diseased periodontal tissues and Gingival Crevicular Fluid (GCF).

The interplay of pro-inflammatory and anti-inflammatory cytokines decide the initiation and progression of periodontal disease. Cytokines which play a role in suppression of the destructive inflammatory response include IL-4, IL-10, IL-11 and TGF-β. [7]

4. **Others**

   a. NF-kβ inhibitors – pyrrolidine dithiocarbomate
      – proteosome inhibitors

   b. Integrin inhibitors – tepoxalin, sodium cromoglycate

B. Regulation of Arachidonic Acid (AA) CASCADE: The tissue damage leads to availability phospholipids which gets degraded by phospholipase A_2 and thereby results in production of free AA. These are further metabolized by two of the important patheways example, Cyclooxygenease (CO) or Lipoxygenase (LO) pathways.

Prostaglandins, prostacyclin and thromboxane, which are the final products of CO pathway and leukotrienes and other hydroxyl eicosatetraenoic acids of LO pathways play a vital role in inflammation.[8]

PGE2 and AA metabolites in increased levels are found in gingival crevicular fluid and periodontal tissues in patients with periodontal disease. Host modulation therapy can be achieved by modulating the release of these destructive products. NSAIDs is one of the approach by which these metabolites can be regulated.

1. **NSAIDs:** Non-Steroidal Anti-Inflammatory Drugs (NSAIDs) blocks cyclo-oxygenase pathways and reduce PGE2 synthesis leading to inhibition in progression of periodontal disease and further bone resorption.(8) Indomethacin, first proved the host modulatory effect by inhibiting the progression of periodontal disease in a ligature-induced canine periodontitis model.

NSAIDs can delivered both topically and systemically and have been proved efficacious in both forms for treatment of periodontal disease. The systemic delivery of Flurbiprofen has been found to have inhibitory effect on progression of periodontal disease. However, their systemic use counters few adverse effects like gasto-intestinal upset and heamorrhage.

The local application of NSAIDs is also a method to deliver these agents. NSAIDs are lipophilic and readily gets absorbed by the periodontal tissues. Few NSAIDs that are administered topically include ketorolac trimethamine rinse and S-ketoprofen dentrifice.

2. **Lipoxins:** Lipoxins are secreted by neutrophils and most commonly seen in elevated levels in patients suffering from aggressive periodontitis. Lipoxins are believed to be arachidonic acid derivatives formed by Lipooxygenase pathway and are potent inflammatory mediators. Lipoxins are also found to be secreted in increased quantities in gingival crevicular fluid.[9]

The approach in reducing the levels of Lipoxins would be beneficial in inhibiting the progression of periodontal disease by lowering down the inflammatory process or pathway.

4. **Triclosan:** Triclosan is an anti-inflammatory and anti bacterial agent. It is a non-ionic antimicrobial agent. Triclosan is believed to inhibits both cyclo-oxygenase and lipo-oxygenase pathways.

4. **Steroids:** Steroids are found to inhibit Phospolipase A2 enzyme by stimulating the excessive production of annexins/lipocortins. They stabilize the lysosomal membranes and suppress the cellular degranulation. Steroids like dexamethasone cause degradation of preexixting mRNAs for IL1β, TNFα thereby dampening PGE2 release.[10]

5. **Antioxidants:** Antioxidants like Vitamin C and E, Green tea catechins and other herbal products are believed to prevent oxidation of these arachidonic acid metabolites by molecular oxygen and subsequent hydrolysis to form PGE2.

C. Regulation of Matrix Metalloproteinases

(MMPS): MMPs are the enzymes which belong to the family of calcium and zinc dependant endopeptidases. They are secreted by neutrophils and macrophages, along with some resident cells like fibroblast, osteoblast, osteoclast, epithelial cells of periodontium.(11)

MMPs degrade the extracellular matrices like collagen, gelatin, proteoglycan, fibronectin at neutral PH levels. The pathogenesis of periodontal disease is directly proportional to the MMP activity. The bacterial plaque stimulates the resident cells of the periodontium, directly or indirectly, to release theses MMPs and thereby initiating connective tissue remodeling.

Polymorphonuclear leukocyte type collagenase (MMP-8) and gelatinase (MMP-9) are the most potent and are usually seen with increased activity during periodontal tissue destruction. In addition, MMP-13 (collagenase-3) is believed to be a mediator of bone resorption and cartilage destruction and has been identified in GCF from chronic periodontitis patients.

Some of the MMP inhibitors which could help in reducing the disease activity are as follows:

1. **Hydroxamic acid derivatives:** Galardin designed for topical use in non-healing corneal ulcers., Batimostat for breast cancer (parenterally administered) and Marimastat administered for cancer including ovarian, prostatic, pancreatic and gastrointestinal malignances, are the derivatives known to inhibit MMPs.

However, these derivatives may not have sufficient specificity to prevent unwanted toxicity, and includes adverse events including joint pain and stiffness.

2. **Tetracyclines:** Tetracycline belongs to the group of antibiotics which are most extensively investigated MMP inhibitors. Apart from the antimicrobial property, tetracycline appears to inhibit MMP activity drastically. Tetracyclines thereby inhibit extracellular matrix destruction by multiple non-antimicrobial mechanisms (e.g. chelation, inhibition of activation of pro-MMP molecules).(5)

Mechanism of action:

a. mediated by extracellular mechanisms:

- active MMP inhibition

- inhibition of oxidative activation of pro-MMPs

- disrupts activation by promoting excessive proteolysis of pro MMPs into inactive fragments

- inhibition of MMPs protects α1-PI

b. mediated by cellular regulation

- inhibits inflammatory cytokines, iNOS, PLA2, PGE2

- inhibits protein kinase C

C. mediated by pro- anabolic effects

- increases collagen production and bone formation

The reduced dose of doxycycline (20mg bid) is considered as one of the potent HMT agent. This low dosage of doxycycline may not exhibit antimicrobial effects, but can effectively lower MMP levels, hence, referred to as Sub-Antimicrobial Dose Doxycycline (SDD).

Chemically Modified Tetracyclines

CMT 1 – 4 dedimethyl aminotetracycline are also believed to inhibit MMP activities. CMTs 1,3, 6, 7, 8 are effective inhibitors of which CMT 3 is the most potent compound. CMTs 2 and 4 affects MMP8 but not MMP 13. CMT 5 is ineffective.

D. Modulation of Bone Remodelling: Bone is a dynamic tissue under constant remodeling with active formation and resorption. Disruption of balance in this leads to either increased bone formation as in osteopetrosis or increased bone resorption as in osteoporosis, osteopenia, periodontal disease etc.(8)

The effects of osteoporosis and periodontal disease predominantly after the age of 35 and have common risk factors that may interfere with healing (e.g. smoking and influence of disease or medications). Thus, therapeutic strategies used to prevent and manage osteoporosis and osteopenia may also inhibit periodontal bone loss.

1. **Bisphosphonates:** Bisphosphonates are known to manage osteoporosis in an effective way. The beneficial effects of bisphophonates are used nowadays for treatment of periodontal disease.

Bisphosphonates are non-biodegradable analogs of pyrophosphate. They have a high affinity for calcium phosphate crystals and that inhibit osteoclast activity. These compounds also appear to inhibit MMP activity through a mechanism that involves the chelation of cations.

They are classified into three generations of drugs:

First generation drugs with alkyl side chain: Etidronate

Second generation drugs with amino side chain: Alendronate. Pamidronate, zoledronate

Third generation drugs with cyclic side chains: Risedronate

Other drugs that can be used to modulate bone metabolism include,

2. Anti-inflammatory agents
3. Osteoprotegrin
4. Anti RANKL
5. Selective Estrogen Receptor Modulators (SERMs)
6. CMTs
7. Anti- integrins

Conclusion

The variety of known host modulation therapy helps clinicians to modulate the periodontal disease initiation and progression in an effective way. The use of these agents has led to avoid of advanced surgical approaches to treat such periodontal conditions. The prevention of periodontal disease at the host level is a promising strategy.

Applied Aspect of Saliva in Orthodontics

Snigdha Pattanaik

Associate Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Saliva influences oral health both through its non-specific physicochemical properties, as well as through more specific effects. The proline-rich proteins, statherin and the histatins are salivary proteins that influence calcium phosphate chemistry, initial plaque formation and candida infection. Increases or decreases in mastication may affect saliva output. Fixed orthodontic appliances introduce an additional constituent to the oral cavity complex that may enhance the environment in a variety of ways. On the other hand, Orthodontic treatment leads to changes in the oral environmental factors that encourage changes in salivary flow rate, viscosity, pH, bacterial count, increased plaque index, and other more things which all are factors supplement the risk of caries activity and shake the stability of the oral environment. This manuscript highlights the effect of saliva on orthodontic treatment.

Keywords: *Orthodontic Treatment, Saliva, friction, brackets.*

Introduction

The quality and the quantity of saliva play a crucial role in the equilibrium between demineralization and remineralization of enamel in a cariogenic environment. Specific changes, such as increased pH, buffer capacity and flow rate, may contribute to decreased susceptibility to dental caries. All these salivary properties become of utmost importance during orthodontic treatment with fixed appliances, when an increased chance of plaque retention and a greater difficulty in optimal oral hygiene maintenance is thought to predispose to enamel demineralization and white spot formation. There is still no consensus on the way the quality and the quantity of saliva change during orthodontic treatment. So far, investigations have been confined to the first 6 months from the placement of fixed appliances, and no data are yet available in the long term. In this article we have discussed different aspects of saliva and its effect on orthodontic treatment[1].

I. **Friction:** It has been suggested that saliva or saliva substitute services as an excellent lubricant in the sliding of the bracket along the wire. Frictional changes in force values caused by saliva substitution were studied by Baker et al in1987 to determine the magnitude of frictional force changes between several sizes of stainless steel orthodontic archwires i.e. 018, 020, 018 x 025 and edgewise 022 x 028 slot when an artificial saliva medium was introduced. The teeth were bonded with brackets and wire assemblies and subjected to Instron universal testing machine and subjected to tension-type of force[2].

After tabulating results they concluded that Xero lube, saliva substitute as a lubricant provided a 15% to 19% reduction in force value requirement when using 018, 020, 018 x 025 wires. They also concluded that the saliva medium used has a viscosity of 14.0 centipoise at 37°C. They conducted similar research using glycerine which has a viscosity of 325.0 antipose but results obtained did not match to that obtained with xerolube artificial saliva.

To study the Frictional resistance of ceramic and stainless steel orthodontic brackets, Kratten, Popli, Germanine in 1990, conducted a similar type of research and found that saliva substitutes increased static friction for all combination tested. Saliva played an insignificant role in lubricating the surface of the wire or bracket slot. The explanation for the discrepancy may lie in the significance of loading forces used between the archwire and the brackets. At low load levels saliva acts as a lubricant, but at high loads saliva may increase friction if it's forced out from the contacts between the brackets and the arch wire[3].

The effect of artificial saliva on the frictional forces between orthodontic brackets and archwires was studied by Douning, Mc Cabe, Gordon in 1995. Here the effect of artificial saliva on the static and kinetic frictional forces of stainless steel and polycrystalline ceramic brackets in combination with 0.018 inch round end 0.019 x 0.025 inch edgewise archwire sizes and stainless steel, nickel-titanium and β-titanium archwire materials under a constant ligature force were investigated. In all the cases artificial saliva had the effect of increasing the frictional force when compared with the dry state. They concluded that artificial saliva played an insignificant role in lubricating the surface of the archwire in the bracket slot. The explanation they gave for this study was that archwire touches the bracket at only 2 points where the pressure is relatively great. The lubricant could be expelled from the areas of contact allowing no lubrication between the archwire and bracket to exist, hence increasing friction. Use of β titanium archwire produced the smallest percentage increase in frictional forces due to; stick and slip phenomenon[4].

II. Bonding: The Effect of saliva on shear bond strength of orthodontic adhesive used with moisture insensitive and self-etching primers was studied by Zoppieri IL, Chung CH, Maste to investigate the effect of saliva contamination on the shear bond strength of an orthodontic adhesive used with transbond–moisture Insensitive primer (MIP) and transbond plus- self-etching primer (SEP). Hydrophobic transbond XT primer was used as control. It was concluded that Transbond XT adhesive with XT primer and MIP in dry field yields similar bond strength which is greater than all other groups. Saliva contamination significantly lowers the bond strength of transbond MIP. Saliva has no effect on the bond strength of SEP Transbond XT adhesive with transbond MIP and SEP might have clinically acceptable bond strengths in either dry or wet fields.

The active ingredient of transbond SEP is a methacrylate phosphoric acid ester formed when phosphoric acid and a methacrylate group are combined into a molecule that etches and primes simultaneously. The conventional phosphoric acid-etched teeth are washed or rinsed after adequate etching time. Similarly the phosphate group in methacrylate phosphoric acid ester in SEP dissolves the calcium and removes it from the hydroxyapatite. The calcium then forms a complex with phosphate group, rather than being removed by rinsing and is incorporated into the network when the primer polymerizes. The acid group is neutralized by the reaction with calcium. Thus there is no need to rise the tooth because no etchant remains on the enamel[5].

Effect on a New Bonding agent in bond strength to saliva contaminated enamel was studied in 1994 to compare bond strengths of brackets applied to contaminated and uncontaminated enamel following pretreatment of contaminated enamel with Scotch bond MP bonding system. They concluded that bond strength was found to be equal in brackets bonded to saliva contaminated etched enamel treated with Scotch Bond MP primer and bonding agent applied to uncontaminated enamel. Scotch band MP works slightly differently. The primer composed of HEMA and polyalkeonic copolymer behaves similarly to the liquid of glass ionomer in that it forms stronger bonds to a moistened enamel or dentin surface[6].

Greer KS, Lindaver SI, Darling SG in 1996 developed a technique to prevent surface contamination of etched enamel. It has been recommended that a thin layer of primer be applied to the entire etched enamel surface before bonding to seal the enamel, protect it from decay, provide maximal bond strength. If the etched surface becomes contaminated by oral fluids before bonding the bond is likely to fail at resin enamel interface. Contamination can occur during the application of the primer if saliva or sulcular fluid is unintentionally spread by applicator brush. This is most likely to occur when bonding to surgically exposed palatally placed canines or to teeth with short clinical crowns. In such cases it's more effective to apply the primer directly to the adhesive resin on the back of orthodontic attachment. Bond strength in this technique was considered best in cases where there is poor visibility or limited exposure[7].

Isolation: The oral environment needs to be

adequately controlled to prevent from interfering with the execution of any dental procedure. This control is attained through isolation.

Various means of isolation are Fluid absorbents, Saliva ejectors, Rubber dam and Pharmacologic agents.

A. Fluid Absorbents: Here isolation can be achieved by absorption of salivary secretions by cotton rolls with holders, Gauze or throat shields or Absorbent wafers. These can be used for short periods when absolute dryness is not required.

B. Saliva Ejectors: They prevent the pooling of saliva in the floor of the mouth. There are twotypes of saliva ejectors: High volume – they remove metallic debris and Low volume. Based on the material from which they are manufactured; Metallic ones can be autoclaved, but requires delicate use to prevent injury whereas Plastic – disposable and in expensive[8].

Advantages:

- Provides adequate dry field.
- There is no dehydration of oral tissues

Precaution:

- Saliva ejector should be sterilized or disposed to prevent cross-contamination.
- Disposable types are preferred
- Patients should be instructed not to close his mouth with the lip in mouth since the backflow of contaminated solution into the mouth is possible.

C. Rubber Dam: Use of rubber dam provide a clean, visible field and Prevents aspiration of foreign bodies it also reduces the risk of cross-contamination and Improves properties of adhesive materials.

III. Salivary Clearance and Fixed Orthodontic Appliance: Since fixed ortho appliances have numerous recesses, pits, which entraps the food particles, the oral clearance rate is slowed. In 1992 Magnus Forsberg, lively A, Jagerlof F conducted a study to establish the possible influence of orthodontic therapy with fixed appliances on salivary clearance of sugar. The study aimed to evaluate the effect of fixed orthodontic appliances on the residual volume of saliva in the mouth and Salivary clearance of sugar. A total of 15 patients, 2 males and 13 females scheduled for orthodontic treatment with fixed appliances took part in the investigation. Unstimulated salivary flow rate, RESID, and salivary clearance of sugar were determined on two occasions i.e. before the start of treatment and 21 days after a fixed appliance was placed in the mouth. In the results it is seen that the salivary flow rate before the start of orthodontic treatment was 0.46 ml/min, after a wear of appliance for 21 days mean value increased to .57 ml min).

Orthodontic appliance had a similar effect on the residual volume of saliva in the mouth after swallowing. It is a well-known fact that a foreign body put in the mouth will initially increase the flow of saliva. The present study indicates that fixed appliances do not prolong the salivary clearance of sugar during the first month of treatment[9].

Further studies with longer duration claimed to have decreased or normal levels of salivary flow and RESID. Since the appliance consists of many retentive components that provide numerous recesses and minor pits where food particles may be trapped accounting for delayed clearance of sugars on long term treatment schedules.

Because of this factor caries and demineralization will continue to be matters of concern during orthodontic treatment.

The effect of polyol gums on dental plaque in orthodontic patients was studied by Isotupa et al in 1995. They conducted a study on 60 patients wearing fixed orthodontic appliances, who were given chewing gums containing polyol to find out the number of streptococcus mutans present in saliva. They concluded that patients chewing xylitol-containing chewing gums had less amount of *Streptococcus mutans* level and less incidence of caries. A clinical study was carried out IN 1996 to determine the acceptability of a sugar-free, low tack chewing gum by orthodontic patients. It was concluded that low tack sugar-free chewing gums can be used by orthodontic patients to increase saliva flow with the potential to remineralize and help reduce white spot lesion formation. Freedent peppermint gum, from Wrigley company, was the product they used in their study[10].

4. Experimental Salivary Pellicles on the Surface of Orthodontic Materials: Lee SJ etal conducted a study with a purpose to find out whether the composition of salivary pellicles that form on the

surface of orthodontic materials vary qualitatively concerning stainless steel, elastomeric ligature ring, bracket bonding resin. They concluded that the least amount of salivary pellicle which was cariogenic was found on stainless resin, followed by adhesive resin, the highest amount of cariogenic pellicle was found on elastomers[11].

5. **Effect of Salivary Ph on Orthodontic Polyurethane Chain Elastics:** The effect of hydrogen ion concentration on forces degradation rate of orthodontic polyurethane chain elastics was studied by Ferriter and Meyers. The effect of pH on force degradation rates of seven commercial orthodontic polyurethane chain elastics was evaluated in an in vitro study. The pH values of 4.85 to 7.26 were selected for testing because they represent values closes to the reported extremes of plaque and saliva pH. All specimens were equally stretched which delivered equal initial force levels. Force degradation rates were recorded after 4 weeks. They concluded that the force decay rate of polyurethane orthodontic chain elastics is inversely proportional to the pH of the oral environment with a corollary that pH levels above mentioned are more hostile to the polyurethane chain elastics thus increasing their force decay rates[12].

6. **Saliva and Corrosion:** Saliva acts as an electrolyte and hence aids in causing corrosion of metal components of fixed orthodontic appliances. When metal components of orthodontic appliances are in contact with an electrolyte such as saliva, metals corrode by a complex electrochemical process of oxidation and dissolution known as galvanic corrosion. The generation of an electric cell is simple when different metals are involved, but it can also occur within a single metal. Atoms at the grain boundary dissolve faster than those within the grain. Impurities, rough surfaces or irregularities can also alter the corrosion resistance of a metal.Corrosion-resistant metals are known as noble metals or cathodic.

Types of corrosion:

1. **Uniform corrosion:** Metal is attacked evenly and throughout, and its mechanical property diminishes proportionately. This type is rarely seen in orthodontics since all the parts of the appliance are not evenly exposed to corrosion agents.

2. **Localized or pitting corrosion:** The most common form seen in orthodontic attachments. Affects the mechanical property of the metal. This type is seen when several different metals are used.

3. **Galvanic corrosion:** The oral cavity because of saliva, with its salts provides a weak electrolyte. Galvanic corrosion is an important type of electrolyte corrosion which occurs when a combination of dissimilar metals lie in direct physical contact with each other.

4. **Stress corrosion:** If a stressed metal comes in contact with unstressed metals,stressed metal will become the anode of the galvanic cells and will corrode[13].

   Nickel and chromium levels in the saliva and serum of patients with fixed orthodontic appliances were studied by Agaogh, Arun T, Belgin Izgu to evaluate the concentrations of nickel and chromium ions in salivary and serum samples from patients treated with fixed orthodontic appliances. The second aim of the study was to determine any significant changes in these concentrations during any period of the treatment time. Saliva and blood samples were collected from 100 patients ranging in age from 12 to 33 years. The fixed appliances consisted of an average of 4 bands and 20 banded brackets. The results indicate certain differences in the amount of nickel and chromium released from fixed orthodontic appliances during different periods of treatment. In saliva samples, nickel and chromium reached their highest levels in the first month and decreased to their initial level in the rest of the groups. It can be concluded that a fixed orthodontic appliance releases a measurable amount of nickel and chromium when placed in the mouth. Most metals used in the oral cavity can be expected to undergo this type of corrosion. Saliva has a dynamic composition that may be affected by many physiologic variables such as diet, salivary pH, health conditions and salivary flow rate[14].

7. **Saliva and Demineralization (Caries):** The pH of saliva acts as a deciding factor, be it demineralization and induction of carries or remineralization. At pH value of 6.8 to 6.0 hydrogen ions react with phosphate ions in saliva and plaque. At pH value of 5.5 to 5.0 demineralization occurs wherein hydroxyapatite dissolves but fluorapatite forms in the presence of fluoride. At a pH of 4.5 to 3.5 (critical pH) both fluorapatite and hydroxyapatite dissolves. On the

contrary if pH rises to 5.5 from the critical pH and if H^+ ion are not exhausted remineralization occurs and fluorapatite forms[15].

Conclusion

With the innumerous number of functions of salivary glands and its secretion namely saliva that we have come across, we can arguably call this secretion namely saliva the champion among the factors that are involved in the homeostasis of our body. Since dentistry is a material science thorough knowledge is important for us to come out with innovations so that products we use render maximal service to the patient.

A Full Mouth Rehabilitation of a Patient with Uneven Occlusal Plane and Severe Attrition: A Clinical Report

Abhilash Mohapatra[1], Sitansu Sekhar Das[1], Gunjan Srivastava[1], Pradyumna Kumar Sahoo[2], Upsana Dhar[3]

[1]Professor, [2]Reader, Department of Prosthodontics, Crown & Bridge, [3]Post Graduate Trainee, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In clinical practice we usually come across cases with severe tooth wear which requires a full mouth rehabilitation. And management of patients with worn-out dentition was always a tough and complex procedure. For a predictable and favourable treatment outcome a systemic multidisciplinary approach was required. This case report describes the interdisciplinary approach in the treatment of a patient with severe attrition and loss of vertical dimension. After performing endodontic treatment for required teeth, a bite raising transitional prosthesis was given for increasing the VD to acquire essential interocclusal space for post and core buildups and full coverage restorations. After that the porcelain fused to metal permanent restoration was fabricated and scrutinized for stable contact in centric and eccentric relation.

Keywords: *Attrited teeth, full-mouth rehabilitation, Occlusal splint, vertical dimension of occlusion.*

Introduction

When we get a patient with mutilated dentition we as dentist are very happy thinking about it financial aspect only. But to manage these patients of mutilated dentition by restorative dentistry is a tough job. And the dentist need to be trained in different aspect and concept of full mouth rehabilitation. So these patients need a full mouth rehabilitation with a systemic multidisciplinary approach[1]. Severe attrition of the teeth leads to loss of anterior guidance, and overall vertical dimension. To restore the same aesthetically is a challenging job for a novice dentist. So for prosthetic rehabilitation of these patients a multidisciplinary treatment planning is required to restore occlusal vertical dimension (VD) and interocclusal rest space.[2] As an adaptive process in the alveolar bone continues to compensate for the loss of tooth structure due to attrition so an increase in vertical dimension should be done systematically after careful assessment by an occlusal splint.[3,4]

Tuner[5] et al gave a classification of severe wear patients into three categories:

- Category 1: Excessive wear with loss of occlusal vertical dimension
- Category 2: Excessive wear without loss of occlusal vertical dimension but with space available.
- Category 3: Excessive wear without loss of occlusal vertical dimension but with limited space

This case report describes in detailed full mouth rehabilitation of a patient with a multidisciplinary approach in which an endodontist, a prosthodontist, a periodontist, worked together for occlusal rehabilitation of mutilated dentition with loss of vertical dimension. The patient was having wear without loss of vertical dimension but with limited interocclusal space(category 3). As these category patients are most difficult to rehabilitate as the adaptive process has maintained the vertical dimension and to accommodate the restorative materials interdisciplinary approach is required.

Increasing the vertical dimension within the permissible limit is very important and systemic procedure has to follow. The procedure is sequential use of occlusal splint and provisional restoration to slowly increase the tolerance of patients to increase in vertical dimension.

Case Report: A 58-year-old male patient reported to the department of prosthodontic Institute of Dental Sciences, SOA Deemed to be University with a chief complaint of difficulty in chewing and speech problems. The patient gave a history of paan chewing for the last 25 years. The medical history of the patients was non-contributory to the contraindication of dental treatment. On intraoral & radiographical examination, it was found that there was severe tooth loss in the anterior and posterior region in the maxillary and mandibular arch. (Figure 1a). The esthetic concern of the patient was short teeth, lack of display of teeth during rest or smile. And darkened appearance of teeth was due to exposed dentine and bad habits. Due to bruxism an uneven occlusal plane was observed. And to the surprise of all there was no sign or symptom of temporomandibular joint pain or dysfunction. On periodontal examination there were no signs of pocket and status was fair.

Diagnostic procedure: Diagnostic cast revealed reduced clinical crown due to severe attrition. On intraoral examination the discrepancy was found between centric occlusion and maximum intercuspal position. Interocclusal vertical dimension was assessed by measuring the distance between the chin and the nose, the vertical dimension at rest was found to be 58 mm and at occlusion was 52 mm (Figure 1b). Features of collapsed vertical dimension was observed on facial examination. Pseudo mandibular prognathism with a reverse smile line was observed. Radiographic examination revealed partial obliteration of pulp chamber in 31,32,33,34,41,42,43,44. No evidence of any periapical pathology was observed in any teeth. A treatment plan was developed for full-mouth rehabilitation. The objective was to restore the masticatory function and esthetical appearance of the patient. This was done by raising vertical dimension, in the first phase by stabilizing occlusal splint, followed by provisional restoration.

Figure 1a, 1b:

Treatment Procedure: The patient was explained about the entire treatment procedure. The photographs and diagnostic casts were prepared for records. In the following visit, the treatment was explained in detail, it started with root canal therapy of all teeth, then an occlusal splint of hard acrylic has to be worn by the patient for one month, followed byperiodontal treatment of crown lengthening of twelve teeth and at the end,prosthetic rehabilitation was to be done with porcelain fused to metal crowns. Before definitive treatment diagnostic cast was obtained and articulated in semi-adjustable articulator in centric relation. The mandible was guided to the centric position by bimanual palpation and the bite registration was done by bite registration material with

the help of acrylic anterior deprogramming device. the curve of Spee, Wilson & orientation occlusal plane was determined by the Broadrick occlusal plane analyzer. On the articulator the incisal pin was raised by 3 mm and diagnostic wax-up was done in the new vertical dimension of occlusion. (Figure 2).

Figure 2

The first phase of treatment root canal therapy was performed on all the remaining teeth and completed in a phased manner. The occlusal deprogrammer splint with a height of 3 mm was given to the patient for one month(Figure 3a). The splint was designed to offer bilateral contact in posterior in centric relation. And the anterior guidance disoccluded the posterior teeth in all eccentric movement.

The adaptation of the patient to a new vertical dimension was evaluated after one month. The patient reported no muscle tenderness or TMJ discomfort. The surgical phase of crown lengthening was performed using electrocautery to expose the tooth margin of all the anterior teeth. Post and core build-up of the fifteen teeth were done with Coltene Paracore core build-up material & tapered fiber post. Tooth preparation of all the maxillary and mandibular teeth are done in a phased manner (Figure 3b). The diagnostic wax-up was used as a stent for the fabrication of autopolymerizing resin provisional crowns. The provisional were fixed with temporary cement and patient adaptation was monitored. (Figure 3c).

Figure 3a, 3b, 3c

For one more month the interim restoration was adjusted and monitored for any discomfort and muscle tenderness. The mandibular movements, speech, and swallowing was evaluated and adjustment were done to achieve comfort for the patients. And this occlusion was used as a guide for definitive oral rehabilitation. The final preparation was done and the final impression was made with polyvinyl siloxane impression material. Bite registration was done in centric relation using the incisal guidance established with provisional prosthesis. (Figure 4a). The definitive anterior guidance was replicated using the customized anterior guide table. Wax patterns were fabricated in the articulator at the predetermined vertical dimension. The metal crowns fabricated were evaluated radiographically and intraorally for fit, retention and stability (figure 4b). The metal-ceramic was fabricated with equal intensity centric contact in posterior teeth and group function in the anterior region to dis-occlude the posteriors in eccentric movements. Final occlusal adjustment was

done intraorally in the bisque trail. The metal-ceramic crowns were cemented with type I glass ionomer cement.(Figure 4c) and hard acrylic resin occlusal splint was fabricated and given to a patient for use during the night time to prevent occlusal wear due to bruxism. Oral hygiene instruction was given to the patient. On periodic evaluation the patient reported the prosthesis to be comfortable in function (Figure 5).

Figure 4a, b, c

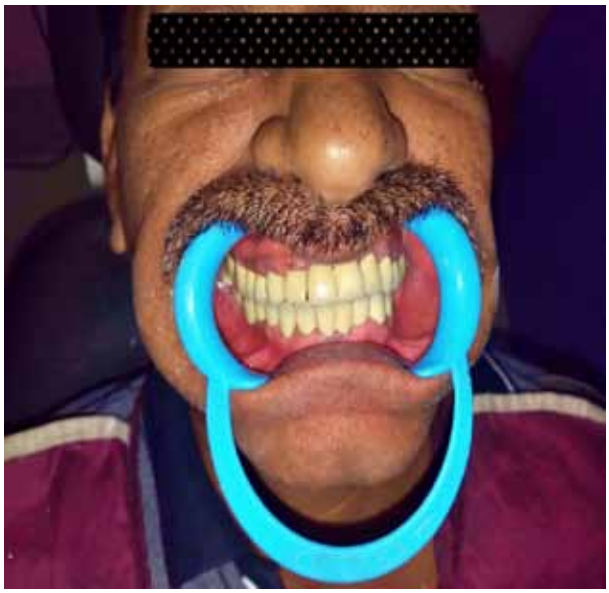

Figure 5.

Discussion

Occlusal rehabilitation of a functionally weakened dentition requires an interdisciplinary treatment approach. We have to restore the esthetic & functional aspect of the patient and our end goal should be a healthy functional masticating apparatus[6]. Tooth wear has many cause[7], and it may be generalized in many patients. Tooth wear distribution was found to be uneven about anterior versus posterior. This was due to posterior occlusal prematurities and bruxism that leads to loss of vertical dimension[8] Clinical controlled trials of restorative and prosthodontic approaches are limited in quantity and quality[9]. So the clinical judgment of the prosthodontist plays an important role in the rehabilitation of the patient. Phonetics, swallowing and patient preference plays a major role. The loss of interocclusal space can be compensated by the following means[10].

- Occlusal adjustment
- Elective endodontics treatment of attrited tooth and core build-up of the same.
- Increasing the vertical dimension by giving occlusal splint, provisional restoration.
- Crown- lengthening procedure; surgical exposure of adequate tooth structure to help in esthetics and retention.
- Orthodontic movement to create interocclusal space.

In the present case,multi-visit endodontics was preferred over a single visit as it has a proven record of

better healing and less post-operative complication.[11] In this present case lack of restorative space was a huge challenge, so the vertical dimension was increased for optimal functional and esthetic[12] The phase of occlusal splint allows time for neuromuscular adjustment to increased vertical dimension and helps to determine patient's compatibility to the new position[13] The minimum recommended period for adaptation to this increased vertical dimension has been determined to be 6–8 weeks.[14] Prefabricated posts were given for anterior teeth as these are simple to use and require less chair side time[15]. Thin tapered treaded posts were used in the present case, as these prevented excessive dentin removal. Threaded post provides the highest resistance to rotational forces and produce uniform stress distribution along the post length. Crown lengthening allowed apical migration of attached gingiva in natural tooth structure so proper core build-up could be done.. So in this case interdisciplinary approach played an important role in enhancing the esthetics, function and to re-establish the lost occlusal function of the patient.

Conclusion

Full-mouth rehabilitation of a bruxer is complex and difficult,and it requires the proper application of interdisciplinary concepts to achieve functional and esthetic success.

Dental Health Care to the Rural Population through Private Dental Institutions

Sourav Chandra Bidyasagar Bal[1], Sukhvinder Singh Oberoi[2], Radha Prasanna Dalai[1]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Professor Genesis Institute of Dental Science and Research, Firojpur, Punjab, India

Abstract

Republic India in the present situation is a fast developing nation whose population is more than one billion today. Looking at the current situation of India there is a minimal increase in the number ratio of various dental specialized surgeons and its population. The burning issue of dentistry in India is not the insufficiency of manpower but uniformity and equitable distribution. The most off-balanced circumstances are 68.89% people of India residing in rural areas and more than eighty-five percent dentist practicing in city areas needs to be properly balanced. One of the issues related to the dental workforce in India is the deficient manpower planning and projection. Due to a shortage of lawful and logical data for gauging of community demands and very less amount of guiding system for monitoring orofacial health care services need to guide planners. This paradoxical situation needs to be looked into immediately. At this time, public stash is scant and competed for strongly. It should not a proper time to schedule large and luxurious programs. State Governments to incorporate various suitable orofacial or oral care planning in its agenda as a matter of prime concern and create the groundwork for dental clinics at general public Hospitals, Primary Health Centers, Sub-centers as well as at referral dental centers in rural areas, to provide oral health care to our rural population.

Keywords: *Dentist-population Ratio, Community Demands, Rural Population, Oral Health Care Service.*

Introduction

Republic India in the present situation is a fast developing nation whose population is more than one billion today. Out of a hundred percent, more than seventy percent of people inrepublic India live in more than 5,50,000 villages, and the remainder around thirty percent are residing in around two hundred well-developed towns and big cities areas.[1] Rural health care groundwork has been developed to protect the rural population through 1,56,231 sub-centers (SCs) till 31st march 2017, 23,109 primary health centers (PHCs), and 4,833 community health centers (CHCs).[2]

In the year 1994 oral health comes into the eye-catching point of WHO and after that WHO chose the theme "Oral Health for Healthy life" for World Health Day.[3] National Oral Health Policy has been composed by the Dental Council of India. The results of two national symposia organized way back in the year 1991 at Delhi and another city of republic India Mysore in the year 1994.[4] Though this policy has never been implemented nor there is oral health care program at national level.[5]

The most off-balanced circumstances are 68.89% people of India residing in rural areas and more than eighty-five percent dentist practicing in city areas needs to be properly balanced[6] in republic India the government fixed a good amount of budget for health purpose from that huge amount only a little amount is

e-mail: generationx.sourav@gmail.com

sanctioned for oral health-related activities. There is no specific separate allocation budget or any specific care for oral health in the Indian budget like general health.[5]

The distribution of BDS and MDS professionals are not proper in republic India. In the private sector more BDS and MDS professionals are working now a day as compared to a public sector that provides subsidized services financial affordability for dental care also becomes a huge barrier in low-income population or under below poverty line population. Form the various studies it is estimated that in republic India above 15 years' people has some form of periodontal disease and its prevalence is around forty-five percentage, near about three percent of the population in between 35 to 50 years has oral cancer, the percentage of dental fluorosis is about 5.5 and a huge amount of people of republic India live below the poverty line.[7]

In recent period all dental professional faces tremendous problems in serving dental services to all citizens. In our republic India Oral healthcare facilities are given through primary health care groundwork is of limited dental care facilities and dental manpower. There are nine specializations in dentistry but till now there is no such dentistry specialization posting or simple BDS posting at PHC level throughout the republic India for the betterment of oral health.[5]

Despite 292 dental colleges in the country, the oral health of our people does not so good enough to the mark, especially to those people who are mainly residing in the rural areas.[6] in republic India there are large skewed distribution of dental colleges, a huge variation in the distribution of different specialization of dentist to total population ratio residing in the rural and as well as in the township areas is seen. The present situation of republic India is 1 dentist for ten thousand people in township areas and approximately two point five lakh persons in rural areas. Most of the time it becomes much more difficult for people who are residing in the rural geographical areas to get emergency oral care facilities or dental facilities. So, we are discussing the problem of difficulty in accessing the oral health care facilities for the rural masses and its remedy through the private dental institutions.

Why focus Oral Health through dental institutions

1.36 billion is a huge mass for these mass providing basic dental care is one of the top challenges facing the oral health care delivery system in India.[8,9] In the rural population, there are negligible dental health services available either through the government or private clinics. As dentistry is expensive, the approach by dental institutions can help 99% of the rural population of India.

Every health service in rural areas are primarily conducted through the primary health centers (PHC), which full fill the health needs of twenty thousand to thirty-thousand people. The PHC holds a key role in the countries health care delivery system; it aims to provide three preventive health care facilities such as primary secondary and tertiary care, promotive care and curative health care services to the people living in a different geographical area. not even out of 100% existing primary health centers less than twenty percent of the existing primary health centers in India have the dental health care available for the population. The oral health services delivered through the primary health centers are deficient in manpower and infrastructure as well.[5]

The focus on the dental institutions to provide dental health care is because of the inadequate Workforce in Rural Areas and skewed Dentist-Population Ratio. The primary goal of dental institutions in rural areas should be to provide qualitative, effective, most basic oral health care facilities to all the people residing in rural areas. Every dental care which is provided to people that includes oral health education, primary, preventive dental care, curative dental-care and rehabilitative oral care.

The prevalence of dental diseases i.e. dental caries, periodontal disease and oral cancer is increasing in the Indian population[6] with a comparatively more increase in the rural areas. To date, 292 Dental colleges are working in India which are permitted by DCI of India, from 292 dental colleges and hospitals only 40 colleges in government colleges, rest are in the private sector.[10] So, there are a vast number of private dental colleges in India which can be potentially utilized for catering oral health services to the masses in the rural areas.

Services provision through Private Dental Institutions

The private dental health institutions can provide services to the rural people such as education and motivation, spreading awareness about different oral diseases, Free dental check-up and treatment camps, outreach treatment camps, service provision through Mobile dental vans, charging a minimal fee for services by having poor people fund, setting up satellite clinics in

the rural areas, school oral health programs, no charges forall dental check-ups for below poverty line families and smart card schemes for BPL families.

Dental institutions can playan important role in educating and motivating the rural population. The educational presentation via charts, models, electronic projectors which explains various etiology of all typesof oral diseases and the importance of 1st stage diagnosis as well as some important diagrams of oral diseases and how they appear in the internal oral environment can be shown to the villagers. Different kinds of oral health care delivery like oral health education (two times brushing daily, taking fresh fruits, avoidance of the use of tobacco etc.) are the easy ways to combat unhealthy practices which leads to such health hazards. The prevention of oral health canthe most affordable, tailoring and desirable measure in the current context of the socio-economic status of our Republic India.[10]

Those people who are residing in rural areas, for them it is the most difficult task for them to visit a dentist for regular dental check-up. Poor groundwork and heavy traveling fair on traveling to and from the clinics, keep lots of rural families away from receiving oral care for a long period. The regular basis dental screening camp, apart from being a perfect tool for the dental surgeons to reach those in need of dental care, is also a perfect setting for dental interns to come in contact with the community people and understand their basic oral health problems.

Free transport facilities can be provided by dental institutions so that the rural population especially the underserved population can easily avail the oral health care. Dental institutions can provide the best treatment at minimal cost providing reduced-fee or uncompensated oral health care to the underserved patient population and Dental institutions can get a sufficient amount of patients for their students, which can fulfill their educational needs.

There should be different programs developed to provide services to individuals with special health problems or patients with special conditions especially the elderly population. Fully equipped Mobile dental van programs can help out the needy patients, especially, those individuals in rural settings with special needs who cannot come to the dental institutions for dental care.[11]

By oral health education rural population should be made aware of the real value of oral health and hygiene and how important is oral health for them, the effectiveness of Indigenous method, teaching about the correct technique of Brushing,teaching about Oral diseases- causes, consequences and prevention. Regular basis oral check-up and treatment camps in rural areas organized by NGOsand various dental colleges cater to the felt needs of the poor rural citizens by providing treatment as well as education about maintaining perfect oral care.

The dental collegesprovide screeningprograms, advice and oral health education to people in faraway villages, which is very effective. For the people residing in the rural area who attends the Camp, this is the only possible pathway for them to receive oral health-related advice, guidance and emergency treatment.A lot of requests for service should be issued by the various community people. These requests may be initiated by the oral health council, the dental health unit, or any concerned NGOs.

All rural people should have taught about the interaction link between the oral and various kinds of systemic diseases. A healthy oral environment can prevent infection throughout the body and protect primary and permanent dentition from dental caries. An unhealthy mouth (intraoral environment), especially one with various types of periodontal disease, may increase the risk of developing communicable heart disease like cardiac arrest, stroke, poorly controlled diabetes mellitus and premature birth. Some systemic conditions such as Acquired Immune Deficiency Syndrome or diabetes mellitus type 1 and 2 sometimes appears first as mouth lesions or other oral related problems. More than ninety percent of all systemic diseases show oral signs and symptoms inside the mouth. So,dental institutions can spread awareness about the different systemic diseases, and their effects on the overall health of the patient.[10]

Activities of peripheral centers which are usually situated in the rural areas or semi-urban areas can emphasize community-based preventive and educative programs as well as basic oral health care. The main goal of the rural dental clinic program is to build a bridge to fill the gap between discipline-based oral educational atmosphere and independent atmosphere for a modern dental practice. All emergency treatment and examinations are performed at satellite clinics and patients are referred to the college for further treatment.

All dental institutions have to make a suitable program for providing regular basis free oral screening

camps on a large scale focusing main concern on good oral habits with the provision of free toothpaste samples and toothbrushes, mouth wash for school children village people who can not afford for these things. This can be done through collaborations with different companies like Colgate, Oral B or NGOs.[10]

Discussion and Conclusion

In recent period all dental professional faces tremendous problems in serving dental services to all citizens. Among various developing countries republic, India is one of them, in which dental care provided by different specialized dentists like the endodontist, periodontist, public health dentist, oral surgeon prosthodontist pedodontist, etc, these dentists are practicing in the township area and treat those people whose financial state varies high. In most of the case,it is very difficult for the poor township citizen and the rural citizen to get the emergency dental care. Community-based dental health programs are rarely found. The topmost missing link creating this unfortunate condition is the absence of provision of dental care through primary health care in republic India.

Expenditure of Indian people over primary preventive health care is very much less as compared to curative health care as a whole. What Indian citizen spending over their healthcare is coming amongst the lowest in the world, whereas its maximum percent of expenditure on the private sector is one of the highest. About one lakh crores are being spent yearly as household expenditure on health-related problems (Source: NRHM).This is probably 3 times the public expenditure on different health aspects. Day by day looking at the urgent need for health care in our country most of the private health institutes are pushing the cost of healthcare up and making it out of reach for the poor rural citizen. Thus the health system in rural India would become untenable. The top challenge of qualitative and quantitative health services in rural areas has to be met with a touch of urgency. Given the opportunity and magnitude of the various problems, it is taken into consideration that primary focus should be given on goal-oriented projects to offset this malady.[11]

As compared to the urban areas there is less competition between the dentists due to fewer dentists in rural areas and the clinical setup costs also less in the rural areas as compared to the township area. Therefore,the government should take immediate steps for the establishment of dental set up in rural areas by providing necessary dental care facilities. They should also focus on strengthening the already existing services in the rural areas and also setting up new facilities in the rural under government regulation. The regular dental visit to a dentist for a dental check-up in the rural areas is very less or in some cases it is nil due to lack of knowledge about maintenance of oral hygiene and low financial condition is also cause for that.

Dental institutions play a major role in providing dental care facilities to under served communities mainly in rural areas. The main mission of all dental institutions should be to succeed, to get in touch with every village and provide basic and emergency oral health facility and it would be possible only when the community is fully aware to take leadership in every health aspect.It is recommended that the government should open the dental colleges in the rural areas. Public health dentists have to take the responsibility of increasing the oral health awareness and its association with the general health (how oral health negligence can lead to various systemic disease) to rural community.[11]

All dental institutes should have their rural satellite clinic in the rural areas and they have adopted maximum villages and schools where they can visit there on a regular basis to provide basic dental care and emergency dental care to the needy and educate village people about maintaining good oral health. A mandatory rural posting of 90 days for the dental interns, which will be very effective for large mass residing in rural areas.

Treatment of Gingival Recession by Lateral Positioned Pedicle Graft: A Case Report

Abhaya Chandra Das[1], Sourav Panda[1], Manoj Kumar[1], Anurag Satpathy[2], Rashmita Nayak[2]

[1]Reader, [2]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Gingival recession (GR) is a condition in which there is an apical shift of gingival margin leading to exposure of root surface. On exposure of root surface, there will be root sensitivity, pain, root caries, poor aesthetic, and ultimately tooth loss. There are various techniques used to treat gingival recession. In this case report, a laterally positioned pedicle graft technique was used to treat gingival recession. A 37-year-old male came to the Department of Periodontics, with a chief complaint of sensitivity in lower left front teeth regions. On clinical examination, there was Miller Class III in 33 with the presence of generalized mild plaque and calculus. It was planned for phase I therapy followed by phase II therapy. So scaling and root planing was performed to reduce inflammation and after 4 weeks, lateral positioned pedicle graft technique was done under infiltration local anesthesia. The subject was instructed to maintain oral hygiene. After 2 months, it was found significant coverage of root with keratinized gingiva. He was very satisfied with the result.

Keywords: *Gingival recession, laterallypositioned pedicle graft, root coverage, root planing, scaling.*

Introduction

Gingival recession (GR) is a condition in which there is an apical shift of gingival margin from cementoenamel junction, leading to exposure of root surface.[1] On exposure of root surface, there will be root sensitivity, pain, root caries, poor aesthetic, and ultimately tooth loss.[2] The severity of GR is found more with age progression, smoking, labially placed tooth, abnormal frenal attachment and sites with supra- and sub-gingival calculus.[3] This GR may be due to various etiopathogenesis.[4] The most common etiology is faulty tooth brushing and labially placed tooth. Many techniques and flap designs are performed to treat GR.[5] Among them, some techniques do not need a donor site as a pedicle graft, while others do as a free autogenous graft. It is very difficult to predict the success rate among various techniques used for the root coverage or the treatment of GR. The success rate of these techniques depends upon several factors such as Miller classification, location of the recession, operator's skill, patient maintenance, patient systemic health and the technique performed.[2] The gingival dimension can be assessed by the height (the distance between the soft tissue margin and the mucogingival junction which is measured in millimeter). This gingival height plays an important role to predict the successful outcome in gingival augmentation procedure (root coverage procedures).[3] Various root coverage techniques are used for the gingival augmentation such as free gingival graft, free connective tissue graft, laterally positioned pedicle graft, subepithelial connective tissue graft, guided tissue regeneration etc.[6–9] The pedicle graft is different from free autogenous soft tissue graft as the base of pedicle graft contains its vascular supply, which ultimately provides nutrition to the graft and reestablish the blood vessel to the recipient region.[2] This pedicle graft can be partial or full-thickness. For these reasons

e-mail: drabhaya2011@gmail.com

pedicle graft has more success rate compared to free soft tissue graft. Lateral positioned pedicle graft can only be performed when there is sufficient keratinized gingiva present lateral to the GR.[5] If there is swallow vestibule, the outcome of the treatment becomes poor. However, there is an ideal color match to the adjacent tissue. But it is often inadequate to treat the multiple GRs.[3] Another important criterion for the success of root coverage is Miller classification. It has been found that the prognosis of Miller Class I and II GR are almost 100% root coverage, whereas there is partial coverage in Miller Class III and almost none for Class IV GR.[1]

This case report is presenting Miller Class III GR in 33 and its treatment with laterally positioned pedicle graft.

Case Report: A 37-year-old male came to the Department of Periodontics, with a chief complaint of sensitivity in lower left front teeth regions. On clinical examination, there was Miller Class III in 33 with the presence of generalized mild plaque and calculus. It was also found that there was slight erythematous color, loss of stippling, accentuated contour, bleeding on probing in the complaint area, and GR with a dimension of height 4mm and width 3mm as shown in **figure 1**. The gingiva in relation to 33 appeared as soft and friable with a shiny and smooth surface.

Figure 1: Preoperative view showing Miller Class III gingival recession in 33

She was almost systemic healthy. She had no tobacco chewing habits. It was noticed the culprit GR tooth was due to labially placed and faulty tooth brushing. There was no abnormal frenal attachment.

Treatment: Phase I therapy (Scaling and root planing)was completed with ultrasonic scaling and Gracey curettes.[6] After 4 weeks, there was some amount of resolution of gingival inflammation with no bleeding on probing. So next plan was decided to root coverage. There was a large and thick strip of keratinized tissue present on the adjacent tooth (i.e. lateral incisor). Hence, lateral pedicle graft (lateral positioned flap) was planned.[7]

The removal of epithelium around the denuded root surface was done under local anesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine). It led to exposure of connective tissue which was present under the epithelium. This exposed connective tissue acted as a recipient site for the laterally positioned pedicle graft. Then exposed root surface was scaled and root planed properly. A vertical incision from the gingival margin to outline a flap adjacent to the recipient site was done with a #15 blade. Then the periosteum was incised and the incision was extended into the oral mucosa to the level of the base of the recipient site. In this waya partial-thickness flap was reflected. A releasing incision, a short oblique incision into the alveolar mucosa at the distal corner of the flap, in the direction of the recipient site, was made to relief from the tension on the flap. Then partial-thickness flap or graft was placed laterally over the denuded clean root surface as shown in **figure 2** and then suture was given to stabilize the flap as shown in **figure 3** and then coe-pack was given with postoperative instruction and followed up to 6 months.

Figure 2: Reflection of partial-thickness flap and displaced laterally

Figure 3: Suturing of Lateral displaced flap

The present case was again recalled after 2 weeks of post-surgery to remove the suture. In this time, it was found there was take up the graft with mild inflammation as shown in **figure 4**. Again the patient was recalled after 1month. It was found that there was a partial resolution of inflammation as shown in **figure 5**.Again the patient was recalled after 6 months, there was partial root coverage with complete resolution of inflammation, no bleeding on probing, presence of stippling and scalloped gingiva, and melanin pigmented pink healthy gingiva in 33 region as shown in **figure 6**. He was highly satisfied with the final result.

Figure 5: After 1 month

Figure 6: After 6 months

Discussion

Nowadays, there is an increase in demand for esthetic and functional treatment, which ultimately led to the need for root coverage for the treatment of GR.[1] The root coverage procedures aim to achieve complete root coverage and restore the aesthetic. There are several method employed for root coverage.[2] However, free gingival or connective graft needs established circulation on the recipient site for its survival and requires second donor sites.[10] But pedicle graft has the advantages of having good vascularity, adequate attached gingiva in the adjacent tooth, better color match and the chance of creeping effect of marginal gingiva after surgical procedure.[11] In the present case report, there was adequate keratinized gingiva adjacent to the involved tooth and favored to select lateral positioned pedicle graft. This technique was first described by Grupe and Warren in 1956.[2] It can be performed to cover the isolated, denuded root surfaces, with having adequate keratinized gingiva. But there must be adequate vestibular depth. Here a partial-thickness flap was preferred over full-thickness flap, because the partial thickness flap provides the following advantages as rapid healing at the donor sites and reducing the risk of loss of facial bone height.[10] This partial-thickness flap is also indicated in the case of thin facial bone or presence of dehiscence or fenestration. However it cannot be performed in case of thin gingiva, as a partial thickness may not be sufficient for the survival of the flap.[5] But in our case, there is adequate thickened gingiva, but there was suspect of presence of dehiscence which was examined by trans gingival probing (bone sounding). A releasing incision was made in our case to relieve tension on the flap, which can damage the blood supply on moving the flap or graft.[11] But there are some limitations such as depending on length and thickness of donor site gingiva, chances of a recession at donor site.[5]

Conclusion

Lateral pedicle graft technique can be used in isolated GR case with adequate keratinized gingiva and shallow recession variety, which ultimately have high predictability outcomes with less donor site morbidity. Although the long term stability remains questionable, still this procedure can be a viable alternative treatment modality for the root coverage in certain cases.

Conflict of Interests: The authors declare they have no conflicts of interest.

Biomedical Engineering in Dentistry

Smita R. Priyadarshini[1], Pradyumna Ku Sahoo[2]

[1]Associate Professor, Department of Oral Medicine & Radiology, [2]Associate Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Biomedical engineering is a developing field that includes engineering principles in the field of biomedicine for diagnosis, treatment as well as preventive procedures. The introductions of new technologies provide new and advanced treatment options than the usual practices. Thus, research in coordination & amalgamation can help biomedical engineers to contribute to dentistry through research, discovery and advancements in dental practice. This article enumerates the utility of biomedical engineering in various dental procedures and the need for research in this field.

Keywords: *Biomedical engineering, Regeneration, Stem cell.*

Introduction

Dentistry is under colossal evolution by the introduction of latest technologies like restorative biomaterials, cell culture, stem cell & gene therapy for regenerative procedures. Regenerative Medicine has tissue engineering that aims in repairing or replacing damaged tissues. These procedures initiate biocompatible scaffolds, cells and growth factors that can in total replace tissues and organs**.** Bioengineered tissues are created using autologous cells from the patient that is cultured in vitro. These processes are dependent on precise identification of cells, scaffold material, fabrication and inductive factors.[1]

Bioprinting of tissue engineering scaffolds: Bioprinting uses additive manufacturing techniques for the production of three-dimensional structures which consist of living cells, biomaterials & active biomolecules that produces a homogeneous distribution of cells. The current techniques used in bioprinting are inkjet, laser-form that create a hydrogel arrangement that is utilized for cellular encase and assistance. [2]

Bioprinting techniques use bio-ink which is the basis of printing called hydrogels. These are three-dimensional molecular networks with high water intake. This ensures cell entrapment and containment without damaging the cells. The bio-ink is reinforced depending on the choice of substance, concentration and chemical properties.[3]

Biomedical materials in Dentistry: The Object of manufacture of biocompatible biomedical materials is to substitute the perished tissues and restore the functioning of the tissues. These improvised materials should enhance the dental treatment and have finer properties. But this requires a thorough understanding of the material with its interaction with the dental structures to obtain an optimum result.[4] These materials are broadly classified under the following materials.

1. **Metallic biomedicals:** such as titanium, dental amalgam, and alloys for metallic restorations Metal are not popular materials and could be either noble (Gold, palladium, iridium, platinum, rhodium, etc) and base metal (silver, titanium, copper, tin, zinc, etc) that are cheaper. These materials have good

e-mail: smitapriyadarshini@soa.ac.in

compatible properties and marginal fit. These metals are usually used for indirect restorations, post & core, crown etc.[5]

2. **Polymeric and hydrogel biomaterials:** In recent days new materials are being produced that simulates the natural biomaterials. These polymers are primarily used for complete dentures, denture liners, resin cements etc.[6]

   Polymethylmethacrylate is the most popular polymer used because of its low price, its lighter, has low water solubility and water resorption., creates great contour enhancing the esthetics. But the drawback of this material is its fragility that breaks on to a slight impact. With the inclusion of copolymer, glass and metal fibers, etc The polymers are used in dental regeneration and tissue engineering. The use of ploy (lactic-glycolic acid) before implants improved in repair of the alveolar socket and enhanced bone formation. They are even used as delivery vehicles by incorporating it with regenerative growth factors.[7,8]

3. **Ceramicbiomaterials** such as hydroxyapatite, bioactive glasses, endodontic filling materials, and zirconia. Ceramics are a blend of metal and non-metallic materials like oxides, nitrides and silicates. It can appear in solid crystalline, amorphous solid & glass. The interatomic ionic & covalent bonding makes it hard, stiff & brittle with good compressive stresses and less shear and tensile stress. Porcelains are biocompatible material made at the laboratory with excellent biocompatibility, natural chemically, esthetic and high strength.[9]

4. **Composite biomaterials** such as resin-based composites, giomer composite, and bone augmentation materials. These materials are commonly used in tooth building because of its color, easy contouring and esthetics. Composites are divided into two types: according to size fine and micro-fine & according to the type of fillers micro-hybrid and microfilmed. The composites are at an edge over other materials for its esthetics, bonding, easy to repair, reducing extensive preparation of the tooth. A limitation of this material is polymerization shrinkage & secondary caries. Commonly used resins are dimethacrylate or urethane dimethacrylate oligomers.[10,11]

3D imaging with oral tissue engineering:

Table 1. The different three-dimensional imaging modalities used in tissue engineering.

Xray/Computed Tomography	These modalities have outstanding penetration depth that is helpful in the diagnosis of bone defects & morphological changes in bone with time. Thus bone ingrowth into scaffolds with mineral accumulation at organic mineral junction is observed. The osteogenic function of mesenchymal stem cells, bone deposition can be visualized by this determining the progression of disease process.[12,13]
Single-photon emission computed tomography (SPECT) and positron emission tomography (PET)	PET/SPECT are established Nuclear medicine imaging techniques with detection of radiations from isotopes used to monitor the stem & progenitor cells function and estimate location within the body also within a scaffold. The polymeric scaffolds release kinetics growth factor that can be evaluated with SPECT.[14]
MRI	MRI is one of the essential modalities for soft tissues. Contrast agents are used to amplifylesions and tracking that primarily is Gadolinium. This is useful in labeling a scaffold and enhances the visibility of the implanted scaffold.[15]
Multimodal Imaging	Multimodal imaging has its advantages as we can remove the limitations of every modality and utilize a single modality to obtain necessary results.[16] Imaging and subsequent analysis provides information about morphological & functional alterations of tissue-engineered scaffolds and regenerating tissue by release of growth factors & cell incorporation within scaffolds and tissue.

Maxillo facial rehabilitation: Tissue engineering prospects replacement of tissues lost post-surgery, concern arises while treating large defects. This is done by the use of autologous bone grafts or tissue free flaps. As an alternative treatment tissue engineering with stem cell and gene therapy evolve forming cells, scaffolds & cell signaling molecules to regenerate normal cells thereby healing of such defects.[18,19]

Periodontal regeneration: Periodontium is an intricate structure with distinctive features making healing complicated. Tissue engineering suggests laboratory constructed periodontal tissues under controlled conditions which is later on implanted onto the surgical site. These periodontal cell sheets cultured when implanted reports to regenerate the periodontal tissues.[20]

Oral mucosal grafting in ophthalmology - The ocular surfaces are complicated with sensitive structures like eyelids, tear film, conjunctiva, and cornea. Minor damage to either of these structures complicates the corneal clarity. Oral mucosa is considered as the best graft material to replace conjunctiva. Oral mucosa is highly vascularized that is effective in rapid healing. They are without any hair follicles & resistant to microbial agents. The oral mucosal grafts are obtained from buccal mucosa, labial mucosa, and lingual mucosa. They are utilized during symblepharon release and fornix reconstruction, cover large conjunctiva defects. It is used for ocular resurfacing and in conjunctivodacryocystorhinostomy & osteo-odonto-keratoprosthesis. [21,22]

Whole tooth bioengineering - should imitate the function, development and functioning of natural tooth. The use of a scaffold when embedded with postnatal dental cells and it was gelatin-chondroitin-hyaluronan tri co polymer which was later implanted into a healed extraction socket of an adult pig produced all the tissues of tooth that resembled the enamel, dentin, cementum & roots. The bioengineered tooth should be vascularized and would be a bio-hybrid of artificial and living cells.[23,24]

Conclusion

Biomedical engineering/regenerative dentistry has been crucial in developing signal pathways for functional replacement of dental tissues. To upgrade the biological presentation of scaffolds it's vital to select relevant material. From the selection of biomaterials, appropriate computing to printing is essential. But there has to remarkable research in the field of biomedical engineering for better comprehension & future evolution.

Artificial Intelligence: The Future in Dentistry

Smita R. Priyadarshini[1], Pradyumna Ku Sahoo[2]

[1]Associate Professor, Department of Oral Medicine & Radiology, [2]Associate Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Artificial intelligence (AI) is an area of computer technologies in influencing our lives. These functions by digital use of algorithms to learn data and form statistical patterns to understand the outcomes thus help in decision making. This article reviews the utility of AI in health care in precise diagnosis and better treatment and patient care. It would provide superior quality and comprehensive patient care in dentistry. These innovations would enable dentists to work with precision in all aspects of diagnosis and treatment planning.

Keywords: *Artificial Intelligence, Comprehensive care, Diagnosis.*

Introduction

The human brain is a complex structure that functions by synchronous activity of the neurons. The longer and faster-acting dendrite along with its faster-acting potential of the neuron during activity determines the intelligent quotient.[1] Newer technologies' are continuously made upgraded that would mimic the activities of the brain. Applications that have a virtual imagination, reasoning abilities with auto-learning methodologies and capability of functioning without being manually operated.[2]

Artificial agency (AI) is defined as the study of intelligent agents, any device that perceives its environment and takes action that maximizes its chance of successfully achieving its goals.[3]

AI is been used in numerous technological applications like gaming, theorem solving & proving, Image and language recognition along with robotics in fields like space, satellites & telecommunications. There has been innovation even in the technologies involved in health care applications and services. The conventional method have been replaced by digitalization. Starting from recording data and maintaining records with capacities in recoding relevant data. [4]They can be widely used for clinical trials and help in treatment planning along with prognosis.

Moreover there are patients who at times doubt the dentists work. So at times this dissatisfaction amongst patients makes them liable to get sued. With the era of computers that work faster with better precision using artificial intelligence, there are chances of better patient satisfaction & care.[5]

Neural Networks: Neural networks are method of information processing which is developed to imitate the brain to concede knowledge and learning. The advantage of artificial neural networks is that this type of system solves issues that are too complicated for standard techniques and people that don't have associate algorithmic solutions or the answer is simply too complicated. Thus are now utilized in diagnostic procedures and health care.[6]

Computer-Aided Detection & Diagnosis: Computer-Aided Detection & Diagnosis software utilizes algorithms in radio diagnosis where computer diagnosis is utilized as an opinion before delivering or confirming the final diagnosis. They provide a differential diagnosis

Corresponding Author:
Dr. Smita R. Priyadarshini
Associate Professor, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

for different abnormalities in radio images in various imaging modalities.[7] Thus digital imaging modalities have enabled the usage of Computer-aided diagnosis in dentistry which is progressing. It was primarily used to determine osteoporosis, arteriosclerosis, and maxillary sinusitis. Though its use even in the detection of dental caries, evaluation of dental and maxillofacial lesions, identification periodontitis and Jaw lesions. Nowadays Computer-aided detection and diagnosis are used in orthopantomography as well as cone beam computed tomographic images. [8]

Augmented reality and virtual reality: Virtual reality utilizes software to create a virtual environment for the evaluation of various anatomical structures for diagnosis and treatment planning. Augmented reality is the process of overlaying an image & creating a three dimensional computed real image that is patient specific to create a virtual working environment. It is found to have an effective role in the dental implantsin ensuring decreased risk and better success rates. .This system can be utilized to effectively plan pre-surgical, surgical with accurate placement of implants with better healingdue to a smaller wound. Even the prediction of the position of the nerve is accurate enabling easy avoiding of the nerve. Similarly, it has application id orthognathic surgeries, dentofacial orthopedics, endodontic and restorative procedures.[9]

Clinical Decision Support Systems: Clinical Decision Support Systems act as a support system for health professionals. As these systems are implanted with various clinical data comprehensions it adjunct's in making clinical decisions by utilizing the patient's data.[7]

Various such applicationsutilize other applications that provide records case histories and radiographs in recommending the treatment plans as well as the recall visits. They are capable of generating caution for any fatal medical condition, drug allergies. Along with it can provide a treatment protocol with prophylactic antibiotics to such patients. Thus it would simulate the human brain and thinking. This entire clinical decision making is by the stored and available data from previous treatment so all this requires a proper recording of data in a specified format.[10]

Merits and Demerits of Artificial Intelligence: Every advancement or technology comes with its good and bad so is this. Though not very evident but artificial intelligence has already starting to take over and is recreating a better future.

Assisting surgeries: Here robots can be used for assisting surgeries along with augmenting nursing faculties

Record Keeping: Maintain a detailed list of the patients along with their histories and treatment administered with subsequent recall and revisits '

Diagnosis: They provide an efficient and accurate diagnosis by carefully correlating and comparing with the radiographic features and comparing it with every possible detailed data.

Treatment: Due to the auxiliary assistance and aids the possible treatment time is reduced.

Time-saving: They don't require breaks as they don't get tired or require breaks from work.[11]

Despite all the advantages, there are certain limitations to the applications:

- Job concerns: as several works is managed it requires less staff so concerns of unemployment
- Initial investment for the application is high because of the expensive software.
- Acceptance by the staff could be difficult along with the lack of efficiency in operating. There are chances of limiting the creativity of the faculties.
- Another important concern is maintaining the privacy and security of the data.[12]

Dental applications of artificial Intelligence:

Oral Medicine & Dentofacial radiology: It can be employed in the diagnosis and treatment of lesions of the oral cavity. Any alteration of the oral mucosa, potentially malignant disorders that are at risk of developing in carcinomas can be easily screened using AI that would be missed otherwise. Assists in evaluating osteoporosis in the panoramic radiographs, also determine the proximity of the mandibular canal, dental biometrics.[13] Effective in interpreting the radiographs for different radiographic lesions, caries detection, assessment of vertical root fractures, evaluating the developing the tooth development phases. Lately the Cone Beam Computed Tomographic images utilize AI in analyzing the slices. Making interpreting and processing of the images fast and easy.[14]

Dentomaxilofacial orthopedics: The initial treatment for analysis done using the photographs

and radiographs can be easily done using an intraoral scanner. They decrease the time and impression making procedures with complete eradication of human errors. The advancement of three-dimensional printers orthodontics casts and models can be made on which aligners can be placed. The Software can suggest the direction of tooth movement along with the pressure points of the tooth. There is a possibility of making digital impressions, thus providing a precise customized treatment planning. They also provide a futuristic outcome of the treatment that the patient can visualize.[15,16]

Prosthodontics: Computer-aided design/Computer-aided manufacturing helps in scanning and designing restoration along with fabrication without the casting steps. They provide perfect occlusion, margins with contacts .[17] Thus providing ease in fabrication. The ideal esthetics of patient can be analyzed using various factors like anthropological calculations, facial measurements, ethnic variations along with the patient fondness can be incorporated.[18]

Oral and Maxillofacial Surgery: Oral surgical procedures can be easily assisted using robotics. This enhances the human skills and prevents any human errors. It helps in treatment planning by decreasing the treatment time and protecting the vital structures simulating a practice surgery thereby increasing the operating accuracy. It even helps in bioprinting of the tissues leading to regeneration of the structures that are damaged.[19]

Forensic Odontology: Age estimation plays a vital role in forensic odontology which is utilized widely in identifying individuals in mass disasters. As it's based on radiographic assessment of eruption of tooth comparing radiographs can be easily done by AI. Though the utility of AI in forensic odontology is sparse.[20]

Conclusion

Artificial Intelligence is the future of dentistry. So it calls for research that understands the algorithms which would enhance the use of it in dentistry. It should act as an adjunct to human skills and we cannot deny the fact that it cannot replace human analyzing skills and knowledge.

An Alternative Technique of Bleaching Vital Tooth: A Case Report

Lora Mishra[1], Pratima Panda[2], Shashirekha Govind[3], Debkant Jena[1], Manoj Kumar[4]

[1]Professor, [2]Post Graduate Trainee, [3]Professor & Head, Department of Conservative Dentistry & Endodontics, [4]Associate Professor, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Fluorosis staining is commonly considered an esthetic problem because of the psychological impact of unesthetic maxillary anterior teeth. Numerous treatment approaches have been proposed, ranging from bleaching to enamel reduction to restorative techniques. The aim of this study was to report the clinical case of a female patient of 18 years with moderate fluorosis with midline diastema, whose smile was reestablished by the application of 5%sodium hypochlorite bleaching agent after cleaning and enamel etching with 37% phosphoric acid followed by direct composite veneering. This technique showed excellent results and the patient was satisfied. This technique is simple,low cost,painless, fast and easy to perform, in addition to preserving the dental structure. Treatment showed immediate and permanent results.

Keywords: *Bleaching, fluorosis, sodium hypochlorite, Veneering.*

Introduction

Tooth discolouration is complex in nature and is broadly classified as extrinsic and intrinsic stains.[1] Extrinsic stains on a tooth surface caused by dietary chromogens can be managed by oral prophylaxis. It is the intrinsic stains that are within the dentine require non-invasive and invasive management depending on the degree of discolouration or stains.[2] One of the most common intrinsic stains seen in Indian population is caused by increased fluoride level in the water. The reason could be that India is in the geographical fluoride belt and in areas where fluoride content is high in rocks or soil, leaching of fluoride occurs, causing excess fluoride level in groundwater.[3] Depending on the extent of exposure to fluoride, the degree of fluorosis can vary from mild to severe and structural deformity of the tooth.[4] Bleaching is a non-invasive and conservative approach to manage mild to moderate fluorosis. The only drawback of bleaching is that hydrogen peroxide causes dentinal sensitivity and gingival irritation. It is contra indicated in the tooth with large pulp horns.[2]

Young patients are usually concerned about their anterior tooth discolouration. Therefore an alternative approach to managing young permanent teeth having large prominent pulp horns is required. A conservative treatment approach for the management of yellow-brown intrinsic staining of dental enamel is described in this case report.[4]

Case Report: A 17-year-old patient complaining of brown stains and spacing of the upper front tooth region reported to the Dental school (Figure 1). After a thorough case history and clinical examination, we arrive at the diagnosis of mild fluorosis. On a radiograph, the Maxillary right and left central incisor (11 and 21) exhibited high pulp horns. Due to mildness of the stains, a conservative treatment plan was presented to the patient that would fulfil his request, which is bleaching with sodium hypochlorite.

e-mail: loramishra@soa.ac.in

The patient was referred to the Department of Periodontics for oral prophylaxis for removal of plaque and extrinsic stains. After two days patient came to our department of Conservative Dentistry and Endodontics. Before the treatment, shade selection of teeth with composite buttons was made under natural light. Anterior segment was isolated with a rubber dam. The teeth was then acid etched with 37% phosphoric acid (Meta Etchant by Meta Biomed) for 60 sec (Figure 2) to enhance the effectiveness of the hypochlorite action on the stained tooth. Etchant was rinsed with three-way syringe. Frosty appearance of enamel completed the etching procedure. This was followed by sodium hypochlorite 5% (Prevest) application on to the entire tooth surface of the anterior segment using a cotton pellet (Figure 3). The bleach is continuously reapplied to the tooth as it evaporates. The teeth were bleached in a single appointment for 25–30 min. Significant improvement in the shade of teeth was observed.

Teeth were thoroughly rinsed with water and again re-etched with 37% phosphoric acid (Meta Etchant by Meta Biomed). A universal bonding agent (3M ESPE) was applied and then gently airdried to have a uniform coat over the teeth. This resin perfuses in the etched and porous enamel, creating resin tags that occlude the porosities and prevent re-staining of the hypo-mineralized lesion. The diastema closure was done using composite (3M ESPE A2 Shade) (Figure 4). The patient was recalled for follow up after 6 months. He did not complain of sensitivity and was very satisfied with the treatment outcome.

Discussion

Bleaching is considered as the gold standard treatment for fluorosis, tetracycline stains and other internal discolourations.[5] It is a non-invasive technique and results in the better shade of teeth in just one to three dental appointment depending on severity. It has high acceptability rate among patients.[5] However, the bleaching procedure poses a threat to young large pulp chambers and pulp horns and therefore contraindicated in a young permanent tooth. The agents like hydrogen peroxide are known irritant and cause a chemical burn of soft tissues surrounding the tooth. They penetrate inside the dentinal tubules and cause dentinal hypersensitivity as well.[6]

Many studies show that the bleaching agent is known to reduce the bond strength of the enamel resin composite. There is a minimum waiting period of 1-week advocate post bleaching and aesthetic rehabilitation of tooth with composite.[7] This technique of acid etching combined with bleaching with sodium hypochlorite is an effective alternative to regular bleaching procedure and can address the above issues effectively.[8] The sodium hypochlorite technique has several advantages over peroxide-based protocols for the specific application of removing stains from localized hypo mineralized lesions in young teeth. It is known to be highly effective at removing organic material by oxidizing it and allowing the smaller degraded molecules to be washed away. Applying sodium hypochlorite to hypo-mineralized enamel lesions, can degrade and remove the chromogenic organic material that is, located in the enamel.[7,8] It has been shown that pretreatment of the enamel with sodium hypochlorite to remove the enamel proteins can enhance the ability of acid to etch the surface, thereby improving the likelihood that resins can bond successfully to the surface.[9]

Figure 1. 11 & 21 with fluorosis stain

Figure 2. Anterior segment etched with 37% phosphoric acid

Figure 3. Anterior segment bleached with sodium hypochlorite

Figure 4. 11 & 21 diastema closure done with composite

Conclusion

The above technique uses readily available materials that show a high level of safety and can be used on young permanent teeth. Permanent incisor teeth that have high pulp horns can be treated from this approach. This technique provides a conservative alternative treatment for yellow-brown hypo-mineralized enamel that shows good clinical success. The application of conservative treatment approaches should be considered before applying techniques that require substantial enamel removal for the treatment of enamel discolourations.

Different Techniques to Establish Occlusal Anatomy of Posterior Teeth with Composite. A Review

Lora Mishra[1], Gathani Dash[2], Shashireka Govind[3], Siba Prasad Jena[4], Satabdi Pattanaik[4], Manoj Kumar[5]

[1]Professor, [2]Post Graduate Trainee, [3]Professor & Head, [4]Senior Lecturer, Department of Conservative Dentistry & Endodontics, [5]Associate Professor, Department of Periodontics, Institute of Dental Sciences Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Composite resin restoration on posterior teeth through the incremental technique is, generally, a time-consuming procedure with the risk of contamination between the layers. Therefore, there is a need to facilitate the work of dental professionals and achieve aesthetic and functional results such as the occlusal stamp technique. "Stamp technique" is a technique used for restoring class I and class II restorations with accurate occlusal topography. It was introduced mainly to restore Class I cavities and erosively damaged teeth. A stamping technique is an easy-to-follow procedure to recreate accurate occlusal topography for a direct composite resin restoration effectively and efficiently with less time needed for finishing and polishing of the restoration. This technique consists of fabricating an occlusal matrix that mimics the natural occlusal anatomy of posterior teeth,before cavity preparation takes place. This matrix is then pressed against the final composite increment before curing takes place and is suitable in cases where caries is evident during the clinical examination or radiographically within tact marginal ridges and ideal occlusal anatomy. For overcoming the main disadvantage of polymerization shrinkage seen in composite restorations, it has [to be done using incremental layer technique. Stamp is used in the final layer to replicate the natural anatomy of the occlusal surface. A precise tooth-like restoration having an accurate functional occlusion is obtained when the stamp technique is performed. This technique also can be utilized for class II cavity restorations where the marginal ridge is intact. This case report describes simple class I composite restoration using stamp technique. The main objective is to replicate occlusal anatomy by making a copy of the original unprepared tooth structure to get a perfect anatomy in a few minutes. This review walks through many techniques utilized for simulating posterior occlusal anatomy.

Keywords: *Composite, Incremental Technique, Occlusal Topography, Polymerization Shrinkage.*

Introduction

Dental caries is a disease of calcified tissues, with demineralization and destruction of their inorganic and organic components. Occlusal surfaces are considered the most susceptible to caries lesions because of their morphology. One of the primary goals of restorative material is to reestablish the original occlusal anatomy of the tooth. Cusp anatomy, contours, and colour all play into the harmony of a smile. Advancement in the direct composite resin and because of the minimally invasive technique, it is considered to be one of the choicest material for restoring posterior teeth. Composite resins are available in many shades and a variety of consistency depending on the clinical need. Probably their versatility in one of the reasons that they are in constant demand by the clinicians. The increase in demand has lead to a lot of research and development with Composites. Besides, they are simpler to deal with and facilitate the

e-mail: loramishra@soa.ac.in

reproduction of occlusal structures. Confronting these upgrades, intercessions with composite restorations have made conceivable the change of explicit and individual subtleties existing in the natural dentition, in a sufficiently tasteful way and undefined to human vision.[1]

Cusps need to be placed appropriately in the inter-arch space. They must be adequately graded in heights and sizes to be in harmony with the movements of the mandible.[2] Optimal occlusion is that which is comfortably adopted by the patient. Therefore, a restoration is designed in a manner that it does not produce any disturbance in the typical condylar path. Its occlusal anatomy influences the magnitude and direction of load borne by the tooth. However, the ability to produce a restoration which conforms with the original anatomy of the posterior teeth must be perceived as one of the complicated and time-consuming technique.

The present review describes different techniques that aid in the reproduction of occlusal anatomy and minimizes the overextension of restorative material, thereby maintaining the health of the stomatognathic system (Figure 1).

Traditional technique: For Grossly decayed tooth or moderate to extensive loss of occlusal anatomy, traditional Increment layering technique is preferred. In this technique, the posterior Composite is placed in small increments, and each increment is individually light cured. The increments can be either placed horizontally, obliquely or vertically. Successive cusp build technique is another modified form of the incremental method. Here, singular cusps are reestablished each in turn up to the level of the occlusal enamel. Little inclining augmentations are applied to each corner of the cavity. This technique allows the handling of material to a minimum and averts voids into the material. [3]

It is indicated in large class I and Class II cavity and in the grossly decayed tooth where occlusal anatomy has been lost. This technique can significantly reduce finishing time by precise attention to the progressive reconstruction of natural morphology. The incremental method showed lower microleakage. One of the significant disadvantages of this case is that it is time-consuming and occlusal anatomy may not correspond to the original anatomy of the tooth. The clinician needs to develop this skill and should have a thorough knowledge of anatomy and characterization of posterior teeth.

Occlusal former technique: Many carious lesions have intact occlusal anatomy. Such caries are occult as they have a macroscopically whole unimpaired occlusal surface however with undermining rot that can be viewed as a territory of somewhat blue/dark discolouration under the enamel surface, or radiographically. There are many techniques that grant registration of intact anatomic details before cavity preparation and for this reason,indicated for small enamel defects and occlusal fissure lesions or Class II preparations with no occlusal involvement. Stamp technique has various advantages.[5] Firstly, it helps in reducing the overall time required for the restoration as instantly desired cusp –fossa relationship is attained. This is suitable in a busy practice scenario as it ensures predictability with accuracy (Table 1).These techniques are broadly classified into prefabricated method, and custom made techniques. Both ways can be used either as a direct or indirect technique.

Table 1. Advantage and disadvantages of occlusal formers.

	Occlusal formers technique
Advantage	1 The anatomy and occlusion with which the patient was comfortable is restored in the new composite restoration 2. The surface of the composite restoration is as smooth as the original surface of the tooth being restored, and therefore minimal, if any polishing is needed 3. There is no air-inhibited layer to be removed, since oxygen is excluded frorn the surface by the matrix during curing 4. The Composite is cured under slight pressure, and is thought to reduce voids in the rcstoration 5. With practice, there is minimal flash to be removed
Diadvantage	1. There is additional time and expense to create the occlusal matrix 2. There is additional time necessary to cure the last layer of Composite

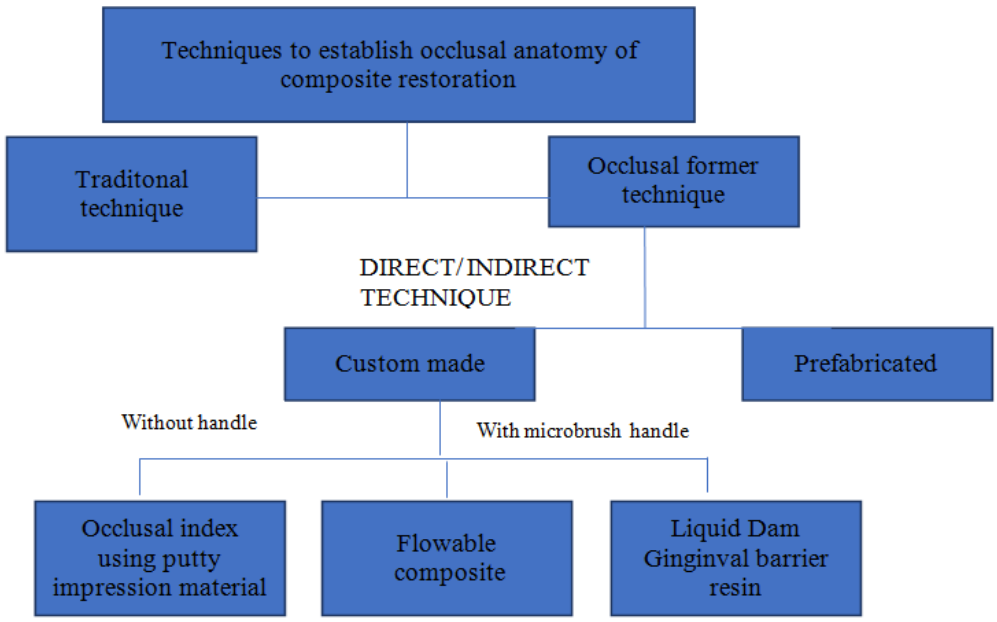

Figure 1. Classification of different techniques to establish occlusal anatomy of posterior tooth.

Direct Technique: In custom made techniques, varied materials can be employed to make the occlusal replica, including light-curable material, chemically activated acrylic resin, polyvinylsiloxane bite registration material, transparent silicone moulds, occlusal matrix technique (Figure 2).[5] In this technique, before penetrating the enamel and before cavity preparation a putty impression material or a flowable material with a micro brush is used to make an impression of tooth occlusal anatomy. After cavity preparation, increment layering of composite is placed, and each increment is light-cured till it reaches the occlusal surface. After the placement of the lastunpolymerized occlusal increment, Teflon tape is placed and on top of that putty occlusal index or stamp is positioned back on the teeth to simulate the previous recorded anatomy. Subsequently, the index is removed and the excess composite istaken out and cured.[4]

Indirect Technique: In the presence of a rather considerable defect, it is challenging to build up cusps precisely enough to occlude with the antagonists. Here, a silicone impression and models of the teeth is made. After which wax is utilized to reconstruct the desired anatomy. On the wax carving, an occlusal stamp is formed which is consequently placed on the last increment of restored natural dentition to mimic the anatomy.[4]

Occlusal matrix material using Biteperf: The Biteperf gadget is made in transparent polycarbonate and comprises of a plastic handle (50 mm long) and clear round head (13 mm in the distance across and 4 mm thick). The base head has a circular shape with one thermoplastic impression material (polyethylene) mounted on it. The occlusal transfer matrix was plasticized by heating for 15–20 seconds or until the surface acquired a shiny appearance. It is then positioned under gentle pressure on the occlusal surface of the tooth. The occlusal matrix is kept immobile for 10 seconds and then cooled with air jets [Figure 3]. A mark is made on the outside of the mould to allow for exact positioning during the restoration.[6] Eventually, the internal detail of the occlusal replica is scrutinized. Post caries removal and cavity preparation light-cure composite resin are added in the cavity using the incremental technique, leaving space for a final increment on which the occlusal matrix device is to be placed.[5] Leaving this final occlusal increment unpolymerized, the occlusal replica was stabilized in the original anatomic position and pressed down firmly. The next step is polymerization of the last resin increment across the occlusal surface, applying light through the matrix while it is held under pressure to ensure perfect positioning. After polymerization, the occlusal matrix device is removed, and the occlusal anatomy is evaluated.[6] Mostly in this technique, occlusal reproduction is accurate, however small adjustment if required, can be done with abrasive silicon carbide instruments or rubber polishers.

Prefabricated Fissure formers for composite filling (Occlu-Print): These prefabricated stamps have an excellent and rapid occlusal modulation of lateral composite fillings. It is manufactured using translucent plastic (Figure 3). It is less time consuming compared to the manual modulation technique of stamp fabrication.[7,8] With Occulu-Print, polymerization is made by placing the curing onto the stamp. Molar and premolar disposable stamps are available 16 different sizes and shapes, separated into upper/lower jaw and right/left jaw with each stamp having a related FDI-reference.

Prefabricated composite occlusal shells for posterior teeth: Edelweiss occlusal composite shells are prefabricated nanocomposite table top restoration which is usually used to increase the vertical dimension of posterior teeth. Depending on the size of the tooth the preformed composite shells are selected. These can be adjusted with stone burs to fit the individual tooth. The tooth and the shells are treated with an etchant and specific bonding agent. The shell is then luted on the tooth with a dual-cure luting agent. Post cementation occlusion is adjusted and minor finishing and polishing procedure is done.[9,10]

Figure 2.Pit and fissure caries with intact occlusal surface

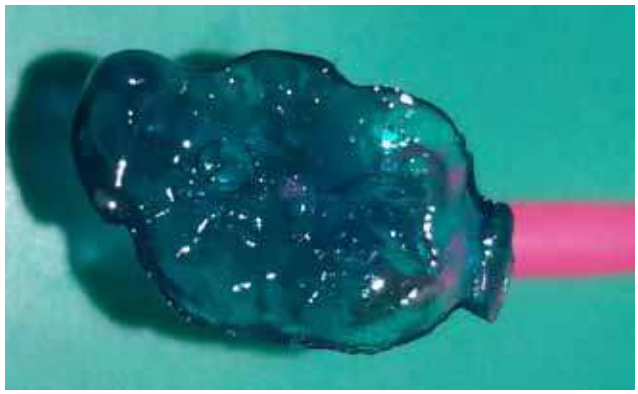

Figure 3. Customized occlusal former with liquid rubber dam

Figure 4. Preformed Occlusal former

Figure 5. Composite restoration with characterization.

Conclusion

Finishing with appropriate anatomy has been difficult and time-consuming in the traditional increment layer technique. An alternative to overfilling and then grinding in the anatomy is proposed. The occlusal replica technique can be carried out with several materials, all of which have their advantages and disadvantages. The anatomy shapes up almost naturally. With only minor adjustments and polishing with a polishing paste, time spent finishing is shortened. Natural-looking, functional, and beautiful occlusal anatomy are now achievable with this uncomplicated technique (Figure 4).

Infection Control in Prosthodontics: A Review

Debarchita Sarangi

Senior Lecturer, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Dentists and dental office personnel are exposed to a wide range of potential pathogens and have high chances of infection transmission not only in the clinic, but also in the laboratory. A proper sterilization and disinfection protocol must be followed. This shall prevent cross-contamination of disease among the dental health care providers. Prosthodontics is a branch in dentistry which includes manipulation of various materials, equipment, their use and instrumentation for rehabilitation of patients. Patients in the geriatric group are of special importance in this branch. A strict protocol for infection control is mandatory to combat any kind of transmission and cross-contamination between the dental office personnel and patient and vice-versa. This article shall discuss the various modalities of sterilization and disinfection followed from a prosthodontist's point of view, in the clinic and the laboratory also.

Keywords: *Dental Clinic; Dental Laboratory; Disinfection; Infection Control; Sterilization.*

Introduction

According to the Centre of Disease Control guidelines, sterilization is a process that destroys or eliminates all forms of microbial life and is carried out in health-care facilities by physical or chemical method. In disinfection refers to the elimination of many or all pathogenic microorganisms, except bacterial spores, or inanimate objects. Cleaning means the removal of any visible organic or inorganic soil from objects or equipment or surfaces, mechanically or manually with water and some detergent or enzymatic agents. Decontamination means removal of pathogenic organisms that would make an object safe to use, handle and discard.[1]

Dental health care providers are exposed to infectious material and potentially infectious materials within the dental office, dental lab and also while handling equipments, materials, etc.[2] Patients in the prosthodontic clinic usually belong to the vulnerable group due to increased age, decreased immunity, compromised health status. Prosthodontists, their staff and also their patients are at a higher risk for possible transmission of micro-organisms and cross-infection due to the use of added equipment and material in the clinic and the laboratory. Thus, infection control is of utmost importance. Even though advances in this field are commendable, the principles of infection control have always been basic. This has to be equally prioritized just as any other procedure to ensure safety, both ways. For a good practice, a sufficient number of materials, instruments and equipment should be available and hence the sterilization has to be managed and routinely done.[3,4,5] Therefore, awareness among clinicians and auxiliaries are a must for overall safety.[6] Dental casts, Impressions, Impression trays, occlusal rims, etc. are commonly used in prosthodontic practice. This article shall review the procedures that should be employed for sterilization and disinfection of these objects in a prosthodontic clinical and laboratory set-up.

General Protocol for Infection Control: Infection control is a comprehensive procedure and there are five steps towards achieving it. They are: Evaluation of patient; Personal Protection; Cleaning and Sterilization of Instrument; Disinfection; Asepsis in the Laboratory.[7] Microorganisms may be transmitted through direct contact with blood; oral fluids; conjunctival, nasal and oral micro-droplets; patient materials, etc. These can be transmitted through indirect contact with contaminated objects and inhalation of long-standing aerosol containing the micro-organisms suspended in

the air.[2] DCNA has classified the level of risks as per the prevention. Diseases like Mumps, Measles, Rubella, Fungal infection, etc. come under Class 1, because their vaccine is available, the risk is minimal. Candidiasis, Staphylococcus aureus, and Streptococcus Group A, etc. are classified under Class 2. Herpes simplex, Cytomegalovirus, EBV and Varicella virus are classified under Class 3. HIV, HBV, HCV, HDV are classified under Class 4 because there are no vaccines except for HBV and all the universal precautions should be taken as the diseases are fatal. Due to the highest risk of airborne transmission, TB is categorized under Class 5. There are no vaccines also for TB. Inpatient evaluation, the above risks have to be identified and proper precautions should be taken.[8,9]

Personal protection employs the barrier mechanism. Not only in the dental office, this is highly recommended in dental laboratory procedures. Use of Personal Protective Equipment like disposable gloves, over-gloves,mask, eye-wear, face-shield, protective coat, and overcoats are essential to prevent contamination through potentially harmful splashes, spray, spatter and aerosols during clinical procedures using rotary instruments and inlaboratory procedures using model trimmers and lathe.[10,11,12,13] Instruments have been classified into 3 types based on their exposure to risks of transmitting infection as described in the **Table I**.[14,15]

Table I. Classification of instruments based on their exposure to risks of transmitting infection

Type of instrument	Type of exposure	Example of instruments	Sterilization method
Critical	Used in invasive procedures which penetrate soft-tissue, bone, enter or contact blood or other sterile tissue	Scalpels, surgical burs, forceps, scalers,bone-chisel	Should be sterilized after every use by pressure, heat, chemical vapor
Semicritical	Do not penetrate soft tissue or bone. Contact mucosa Contact non-intact skin	Mirrors, reusable impression trays, amalgam condensers	Should be sterilized after each use if sterilization is not applicable,disinfection with high-level disinfectant should be done. (high-level disinfectant is labeled as "sterilant/disinfectant" as registered by the US Environment Protection Agency)
Non-critical	Come in contact with intact skin	External components of X-Ray heads, Sphygmomanometer cuffs, Pulse-oximeter	Requires intermittent or low-level disinfection after each use (such a disinfectant is called "hospital disinfectant" as registered by the US Environment Protection Agency. These are not labeled for tuberculocidal activity.)

Most prosthodontic equipment and instruments are semi-critical: Mechanical cleaning of the instruments using disinfectors, washers, ultrasonic cleaners, rust inhibitors should precede the sterilization process. Presoaking instruments should be done with enzymatic solutions and non-enzymatic solutions for removal of blood, proteins anddebris, respectively. Instruments can then packed and sterilized using pressure, dry heat and unsaturated chemical vapor.[16] There are chlorine-based compound and phenolic compounds which are used for surface disinfection and asepsis. These clean and disinfect contaminated surface; prevents surface contamination by use of surface covers or may do both.[17]

Infection Control: Prosthodontics perspective:

Disinfection of Laboratory: The general protocol for disinfection should also be followed in the laboratory. But, the risk status of an object is not always known. In that case, the object should be treated as high-risk. Isolation of the objects should be done and any instrument or device that comes in contact with them should be sterilized. Disinfectant should be carefully chosen such that metallic surfaces are intact and there are no dimensional changes of impressions/prostheses.[18,19] Instruments, attachments, rag wheels,etc. should be disinfected after every case.[20]

The instruments used frequently in the prosthodontic practice have been enlisted in **Table II**; metal framework and denture in **Table III**; Impression materials in **Table IV**; other materials in **Table V**along with their recommended method of sterilization and disinfection.[21]

Table II: Some commonly used instruments, and their sterilization and disinfection procedure

Instrument	Sterilization and disinfection procedure
Mouth mirror and face mirror	Dry heat; Ethylene oxide
Handpieces	Manufacturer's recommendation should be followed; Ethylene oxide; Moist heat
Carbon steel hand instruments	Dry heat; Ethylene dioxide
Stainless steel instruments, Tissue retraction pluggers	Dry and Moist heat;Chemical vapor; Ethylene oxide
Dampen dish	Moist heat;Ethylene oxide
3-way syringe	Dry and Moist heat;Chemical vapor; Ethylene oxide
Saliva ejectors and evacuators	Ethylene oxide
Impression trays, Aluminium trays, Metal trays, Resin trays	Moist heat, Chemical vapor, Ethylene oxide

Ethylene oxide is usually used at a concentration of 450-800mg/l. Moist heat sterilization is achieved by Autoclaving at 121°C for 15 to 20 minutes at 15 lb pressure/square inch.[21,22]

Table III: Sterilization and Disinfection of Metal framework and Denture[21,22]

Vitallium metal framework	**Immersed in Sodium hypochlorite and rinsed with water**
Denture	After rinsing the denture with running water and kept in an ultrasonic cleaner, the denture is immersed glutaraldehyde solution for 12 hours. Then again it is cleaned with running water, scrubbed in chlorhexidine followed by contact with chlorine dioxide for 3 minutes. Then sterilization is done with ethylene oxide.

Table IV: Sterilization and Disinfection of Impression Materials[6,21,22]

Impressions compound	Immersed in 2% Iodophor solution for 20 minutes
Zinc oxide eugenol	Immersed in 2% glutaraldehyde for 10 minutes
Alginate	Sodium hypochlorite spray-rinse-spray; then kept under damp gauze or in a sealed packet for 10 minutes Immersed 2% glutaraldehyde for 10 minutes
Agar	Spray with sodium hypochlorite, rinse, spray again and stand under damp gauze for 10 minutes
Polyether	Immersed in 2% glutaraldehyde at room temperature for 1 hour, then rinsed with sterile water for 45 seconds; Drying for 10 minutes
Polysulfide	Rinsed in normal water for 45 seconds, Immersed in 2% Glutaraldehyde solution for 30 minutes. Or Immersed in 5.25% sodium hypochlorite solution for 15 minutes Rinsed in normal water.
Addition silicon	Immersed in 2% glutaraldehyde for 1 hour, rinsed in sterile water
Condensation silicon	Immersed in 2% glutaraldehyde for 10 minutes, washed with sterile water

Table V: Sterilizationand Disinfection of some other materials

Wax bites, Occlusal rims, Bite registrations	Immersed in a 5.25%sodium hypochlorite solution and kept in a plasticbag for 10 minutes.[17]
Casts	Immersed in a 5.25% sodium hypochlorite solution and kept in a plastic bag for 10 minutes.[17]
Pumice	Antiseptic with Octenidine or Benzoic acid to conventional pumice is added; Pumice once used should be discarded after each use.[22]

Conclusion

For a good clinical practice, good quality instruments, efficient trained auxiliary personnel, skillful clinicians are a must. Infection control within the operatory and laboratory are the only way for a safe practice not only from dental health care personnel's point of view, but also patient's. There are no other substitutes for maintaining the disinfection and sterilization protocol in the dental office before, during and after any procedure and every assistant, technician, the attendant should be trained by the clinician for abiding by the protocol.

Dentine Replacement with Biodentine Under Class II Composite Inlay: A Case Report

Lora Mishra[1], Pratayee Basu[2], Sumit Dash[1], Naomi Ranjan Singh[3], Rini Behera[3]

Professor[1], Post Graduate Trainee[2], Senior Lecturer[3], Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Biodentin is a bioactive cement with dentin-like mechanical properties, which can be used as a dentine substitute for both crown and root. It also helps in the remineralization of dentine along with maintenance of pulp vitality. This advocated to be used in various clinical applications, such as root perforations, apexification, resorptions, retrograde fillings, pulp capping procedures, and dentine replacement. Indirect laboratory-processed composite systems present an esthetic alternative for intracoronal posterior restorations and provide esthetic results that may also reinforce tooth structure. Additional clinical benefits include exact marginal integrity, wear resistance similar to enamel, wear compatibility with opposing natural dentition, optimal esthetics, ideal proximal contacts, and excellent anatomic morphology.

Keywords: *Calcium Silicate Cement, Caries,, Composite Inlays, Remaining Dentinal Thickness.*

Introduction

The caries attack proportion is the highest maxillary and mandibular permanent first molars, followed by second molars. The interproximal surface of molar are highly susceptible to dental caries and often get unnoticed in the usual dental inspection.[1] One suspects Class II caries (Fig 1) only when the patient complains of food lodgement, sensitivity or noticeable frank cavitation seen in the marginal ridge area.[2] There is various material available for the restoration of such defects. The most popular direct restorative material preferred for Class II was Silver Amalgam.[2] Due to its metallic colour and mercury hazards associated with it along with phasing out of this material worldwide, there is a sudden surge in the use of other restorative materials.[3]

Aesthetic restorations for posterior teeth are in current demand by patients worldwide. Composite restoration is among one of the choices preferred by most of the dentist.[4] Nevertheless, one of the drawbacks of composite restoration is that it undergoes polymerization shrinkage, which leads to microleakage and in short span leas to deterioration of the restoration. Indirect composite inlay was introduced to overcome these pitfalls of direct restorations. The composite inlay has an advantage over direct composite restoration since the contraction of the inlay takes place outside the oral cavity.[5] Biodentine is a new generation silicate cement which is bioactive like mineral trioxide but has superior handling properties and strength. It is an adequate dentine replacement and pulp protecting material.[6] This paper presents the clinical cases in which Biodentine was placed to replace the lost dentine during caries and cavity prep, followed by indirect composite inlays

Case Report: A 37-year-old male patient was referred to the Postgraduate Clinic of Conservative Dentistry and Endodontics (Institute of Dental Sciences and Hospital, Bhubaneswar). The patient complained of dislodged restoration and gave a history of restoration done four years back. Patient's had a non-contributory medical history. Intra-oral examination revealed mesio occlusal caries concerning 46. Clinical inspection and radiographic evaluation revealed secondary caries approximating pulp. The pulp sensibility for 46 revealeda positive response to it.

The patient had uncontrolled ropy saliva, and even after the placement of high evacuation suction and isolation device, it was challenging to do the direct restoration. Therefore we settled to restore the tooth with

indirect composite inlay. Subsequently,the patient's consent was taken to restore the tooth with indirect composite resin inlay.

The secondary caries was excavated at a slow speed using round carbide bur and spoon excavator. The weakened and unsupported enamel was removed. Ensuring the principles of tooth preparation to receive inlay, the cavity preparation was done. The cavity walls had divergent walls, rounded internal line angles and cavosurface configuration with butt joint. The walls of the cavity smoothened using finishingbur (Fig 2). As the axial wall was approximating the pulp chamber, a protective dentine replacement was done with Biodentin. After the final tooth preparation, the cavity was cleaned and dried. With the polyvinylsiloxane material (Aquasil/ Dentsply)impression was made using both heavy body putty and light body together.. Subsequently, a direct provisional restoration was placed using temporary light-cured resin-based cement (Cool Temp, Coltene). The positive replica of this impression taken was made using die stone. An appropriate shade of the restoration was selected using the Vitapan shade guide, and the casts and with selected shade image was delivered to the laboratory(Dent Care) for the fabrication of the inlay.

After 1-week patient visited again for a second appointment. The provisional restoration was taken out, and the cavity was disinfected with 2% chlorhexidine The cavity was selectively etched with 37% phosphoric acid, the adhesive (Universal Bond, 3M ESPE)was applied and light-cured (Bluephase, Ivoclar) on the tooth, and the same adhesive was applied on the silanated (Monobond S Ivoclar) internal aspect of composite inlay without being polymerized. Then the cementation was carried out by applying a thin layer of dual-cure Resin Modified Glass Ionomer Cement (Fuji, GC). The resin luting cement was light-cured (Blue Phase Ivoclar) through the restoration from both, palatal and buccal side of restoration. The excess resin luting cement from the interproximal area was removed using a dental floss. The finishing and polishing were done using a composite finishing kit (Ivoclar). Post final finishing and polishing, the occlusion was evaluated. (Figure 3) The patient was informed about the limitation of the technique and was asked to maintain a regular maintenance visit. A radiograph was taken after 6 months during follow up visits to evaluate the restoration (Figure 4).

Figure 1. Class II caries

Figure 2. Class II inlay cavity preparation.

Figure 3. Cemented Composite Inlay

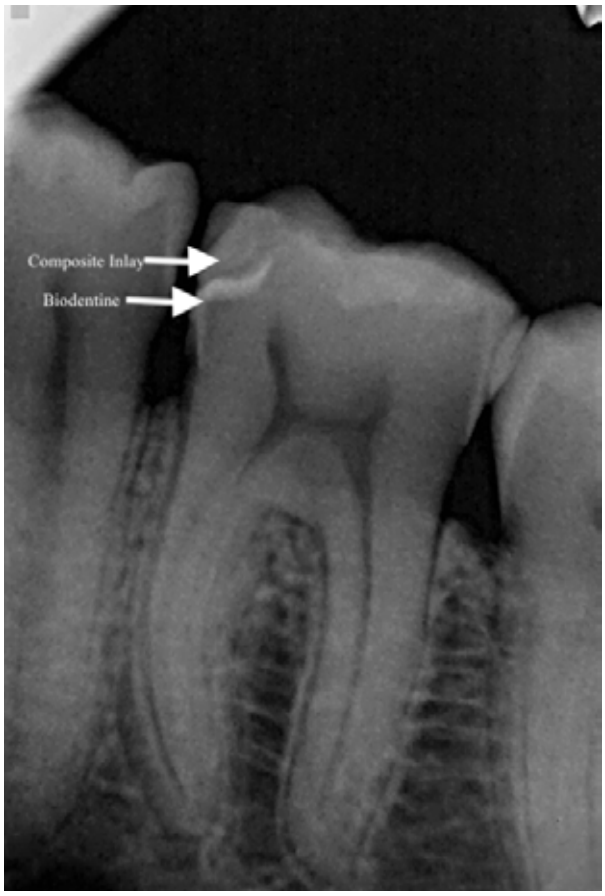

Figure 4. Radiograph of restored 46 during follow up

Discussion

Managing deep dental caries is a challenge. The Remaining dentinal thickness protects pulp from irritation caused by restorative material. It is imperative to replace the lost dentine of the cavity preparation with a biomimetic material which not only protects the pulp but also supports the restorative material like base, Biodentine sets in 45 minutes has high compressive strength and good marginal adaptation. [6]It is recommended to place the overlying direct composite resin after two weeks so that Biodentine material can achieve sufficient maturation and can withstand contraction forces from the resin composite. This drawback is overcome with indirect composite resins which are fabricated in the lab.[7]

Several tooth-colored materials are available like zirconia and ceramic, but they are expensive. In contrast, IRCs ease of handling and exhibits better stress distribution, reparability, lower cost. However, they also have some drawbacks like in the long term the surface exhibits roughness and more prone to colour changes. [8]

Like all indirect restoration, IRC results in less chair-time for the patient and minimizes the finishing and polishing time. Furthermore, it is effortless to make proximal contacts using indirect restorations. An essential advantage of using this indirect restoration method is increased surface hardness, resistance to compression, reduced risk of fractures and cracks in the internal structure of the material.[6]

One of the primary purposes of restoration is to establish and replicate occlusal anatomy and proximal contacts of the tooth. Indirect composite restoration can achieve all that and hence should be considered as restorative material of choice when the tooth can not be isolated, inaccessible areas, limited mouth opening and when the patient cannot sit for a long time during direct restoration.[8]

Disinfection Procedures in Dental Office: An Overview

Nihar Ranjan Sahoo[1], Rashmita Sahoo[2]

[1]Assistant Professor, Department of Dental Surgery, Maharaja Krishna Chandra Gajapati Medical College & Hospital, Berhampur, Odisha, India, [2]Tutor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan, (Deemed to be University), Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Disinfection & Sterilization if done properly, it can prevent transmission of many diseases among the doctors, healthcare personnel and patients. The risk of infection is high in the dental office because the oral cavity is rich in aerobic, anaerobic bacterial flora and many viral pathogens. The method of disinfection and sterilization depends on the use of the medical devices: **Critical** instruments (pierce the tissue) should be sterilized, **Semi critical** instruments (come in contact with the mucosa) should be sterilized & **Least critical** instruments (touch the Surfaces during treatment) & should be disinfected. Cleaning should be done by high-level disinfection and sterilization. Current guidelines of disinfection and sterilization must be strictly followed by doctors, healthcare personnel.

Keywords: *Disinfection, Dental Office, Sterilization.*

Introduction

The risk of infection is high in dental practice as the oral cavity is a host for many commensal and parasitic pathogens. The susceptibility of infection to hazardous diseases like Hep-B & C, HIV & TB, etc through dental treatment procedure is an area to concerned. Orthodontists are more susceptible to contracting hepatitis.[1] At least we should try to reduce the number of infectious organisms to a certain extent so that our immune system can protect from infection and eliminate cross-contamination.

Lister (1867), introduced antiseptic techniques in surgery, also known as Father of Modern Antiseptics. The arrival of autoclave drastically changed the method of sterilization in modern times. So many chemicals with germicidal effects were discovered in the recent times.[2]

Disinfection: Disease transmission doesn't have any specific route. It can pass through direct or indirect contact or even without contact also. All healthcare personnel who always engage with various patients are particularly at a higher risk of contracting disease. Patients particularly with transmissible diseases either viral or bacterial make a constant source of contamination.

Pathway of transmission

According to the Council of Dental Therapeutics the goals of infection control programs are:

- minimizing the number of infectious pathogens to a certain extent where the body immune system will be to resist the infection.
- Disrupting the pathway of infection & terminate cross-contamination.
- considering each patient/instrument as a potential carrier of disease.
- protecting patients, practitioners & other health workers from infections.[3]

Sterilization is making a substance-free from all pathogens both in the *vegetative or spore state*.

Disinfection is making a substance-free from all pathogens except bacterial endospores. **Antiseptics** are mild disinfectants applied to living subjects. **Antisepsis** is preventing infection by the inhibition of growth of bacteria, viruses, fungi on living surfaces such as skin & mucous membranes. For sterilization & disinfection different chemical agents are used. Disinfection indicates cleaning and application of a disinfectant on a surface or object.[4]

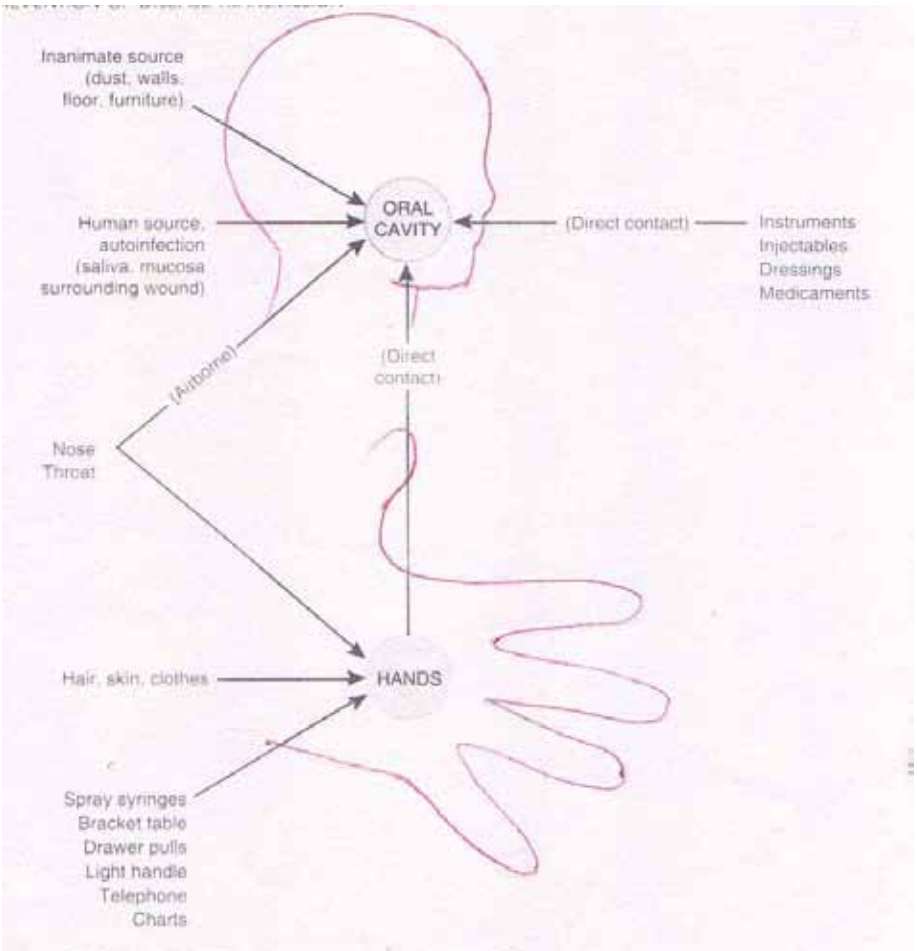

Figure 1. Pathway of transmission

Ideally, a disinfectant should:

- Have stability, high penetrating power and a wide spectrum of activity.
- Be compatible with other disinfectants and noncorrosive.
- Be effective with organic matter & both in alkaline & acidic medium.
- Be nonirritating, safe & easy to use.

Disinfectants used in dentistry are as follows:

- Aldehydes
- Chlorine products
- Alcohols
- Synthetic phenols
- Iodine products

Aldehydes:

- **Formaldehyde**: 10% formalin with 0.5% sodium tetraborate is used as a disinfectant. Its gas is used for the disinfection of instruments that are sensitive to heat. It should be used carefully as it is toxic if inhaled.

- **Glutaraldehyde:** Generally 2% glutaraldehyde solution is used for disinfection and the instrument or object should be placed 20 mins. It is preferred to formaldehyde as it is less toxic & less irritant, can safely be used with all kinds of instruments.

Chlorine products: Sodium hypochlorite solution is mixed with distilled water to prepare the disinfectant. It should be used after thorough cleaning of the surfaces. It acts by damaging the cell wall and blocking the enzyme system to protoplasmic poisoning. It is unstable and corrosive to metals and softens plastic. It produces constant odor and can irritate eye & skin.

Alcohols: Isopropyl alcohol (60-70%) is generally used as a disinfectant. It kills bacteria by denaturation of the protein. But to be effective the surface should be devoid of saliva or blood. It rapidly evaporates from used surfaces.

Synthetic Phenol: Synthetic phenols like Lysol and Cresols are commonly used as disinfectants. Chlorine compounds such as Chlorphenols & Chloroxyphenols have less effect as disinfectant & are less irritating. They damage the cell membrane and cause cell lysis. Its effectiveness depends on contact with bacterial cells.

Iodine products: Iodophores (*Povidone-iodine*), the most commonly used disinfectants are a combination of iodine compound & surface-active agents. These are more effective than aqueous or alcoholic compounds of iodine. Iodine binds with the bacterial cell protein and destroys them.

Surface-active agents: They commonly known as wetting agents. E.g. soaps/detergents & quaternary ammonium compounds/emulsifiers. Quaternary ammonium compounds (QAC) have *cationic surface* but soaps/detergents have *anionic surface*. Commonly available QACs are Cetrimide & Benzylkonium chloride. QAC decreases the surface tension between the bacterial cell wall and the object, so it helps in wetting the bacterial surface with the disinfectants and kills them. The effectiveness depends on the concentration, degree of contamination and presence of other compounds. According to the American Dental Association (**ADA)** alcohol/QAC/phenolic compounds should not be used as the only method of disinfection in dentistry as they are not effective against bacterial spores and viruses.

Vitawipe: It is a disposable disinfectant cloth, contains *alkyl dimethyl chloride* [7.1%], *poly hydrochloride* [3.2%] & inert ingredients [89.7%]. To wipe contaminated surfaces it should be dampened with water. It removes the microorganism physically without having any chemical effect. It should be discarded after the color change of the indicator or after use in case of a Hep-B virus infection.[4]

Infection control procedures:

Instrument disinfection: Instruments are the main media for cross-infection. So they should be disinfected & sterilized thoroughly or sterile disposable instruments should be used. *Milton Schaefer of the University of Southern California School of Dentistry* has divided and described the different pathways of cross-infection and the method to handle as follows:

1. **Critical:** Instruments (scalers, scalpels, and other tissue-cutting instruments) that goes into the mucosal tissue should be sterilized.
2. **Semicritical:** Instruments (hand instruments and pliers) that comes in contact with the mucosal tissue should be sterilized.
3. **Least Critical:** Instruments & Surfaces (Worksurfaces, three-way syringes, chair light handles) that comes in contact during treatment should be disinfected.

Instrument processing: Used instruments first placed in a solution consisting of detergents, enzymes, or detergents with disinfectants until it starts to disintegrate the organic tissue and sometimes begin to kill the pathogens. Then the instruments are cleaned either manually or with the help of an ultrasonic cleaning machine. Heavy-duty utility gloves and protective goggles must be worn during hand cleansing. But manual cleaning is time-consuming and there is a chance of an accident.

Mechanical Cleaning: Combining the use of powerful vibrations and disinfectant solution in an ultrasonic machine increases the effectiveness of cleaning. Continuous vibration makes proper contact of the instruments with the disinfectant solution.[5] The instruments should be kept submerged in the cleaning solution during the whole cleaning procedure.

Figure 2. Ultrasonic cleaner machine

It should operate for **6-10 mins** or until the surface is visibly cleaned but the time should be **15mins** if the instruments are placed in a cassette. Thorough rinsing of instruments is done after cleaning.

After cleaning the instruments should be packed & sealed in an appropriate wrapping material before sterilization to prevent recontamination. Cloth wrapping for autoclave/steam sterilization, polyfilm paper pouches that are self-sealed for chemical vapour sterilization and paper wrapping for dry heat sterilization may be used. Metal trays with lids that don't need any wrapping should be sterilized by dry heat. Perforated trays and trays without lids should be sterilized by chemical vapour or steam sterilization so that steam can pass through the perforation. According to ADA recommendations the sterilization method for different items used in the dental office are as follows;

Rubber items and saliva ejectors: It is always safe to use disposable one and dispose of after use. Because it may get damaged in the process of heat sterilization and cold sterilization with ethylene oxide is not effective.

Handpieces: Cold sterilization with ethylene oxide sterilization and dry or moist heat sterilization can be used.

Stones: Diamond stones are sterilized by dry heat/ chemical vapor/ethylene oxide gas except polishing stones which are sterilized by chemical vapour/ethylene oxide gas only.

Impression trays: Chrome plated trays are sterilized by any method of sterilization but plastic or acrylic trays are sterilized by ethylene oxide or glutaraldehyde.

Stainless steel hand instruments can be sterilized by moist/dry heat, chemical vapour/ethylene oxide gas. Three-way syringes, NiTi wires are sterilized by chemical vapour/glutaraldehyde. Chemical vapour is used in the case of E-chain & ligature wires. [6]

Orthodontic pliers: For high-quality stainless steel pliers all method of sterilization can be used. But for low-quality pliers dry heat sterilization is preferred. For pliers with plastic parts cold sterilization with ethylene oxide is used.

Ultrasonic tip, Gloves & gauze, Tongue blade, lip & cheek retractors, Matrix band, spatula & light cure tip should be autoclaved. Ultrasonic cord should be sterilized by vapoclave and glutaraldehyde. **Glass slab** & **dapendish** should be sterilized by dry/moist heat and vapoclave.

Staggers et al studied the effects of different method of sterilization on different orthodontic wires. They found that the tensile strength of TMA wire is increased in case of dry heat sterilization but moist heat & ethylene oxide sterilization had no effect. The tensile strength of Sentalloy wires is increased due to dry or moist heat sterilization whereas no effect found in the case of SS wire.[7]

Jones M.L found that Chrome plated pliers are more resistant to deterioration and maintained the original shape, size & looks better than SS pliers after various method of sterilization.[8]

Sterilization monitoring: ADA has recommended regular monitoring of sterilizers to maintain the quality of the dental treatments. It is appropriate for a dental office to monitor sterilizers every week.

Biological monitoring: The most important way called biological indicators is done by the use of highly resistant bacterial spores. Spores of *Bacillus stearothermophilus* and *Bacillus subtilis* are used as biological indicators for steam & chemical vapour and dry heat & ethylene oxide gas sterilization respectively. **Spore strips (**filter paper strips impregnated with spores**)** for dry/moist heat, cold sterilization**, Spore vials (**small paper or disk spores**)** for steam/ethylene oxide**, Spore ampules (**glass ampules of spore in culture medium**)** for moist heat sterilization.

Chemical monitoring: Chemicals are placed inside or outside of the packs or trays. It changes the color to indicate the efficacy of the sterilizer. Internal chemical indicators are more accurate.

After sterilization the instruments must remain

untouched, protected from the environment till it becomes cool. The sterile instruments & trays must be kept in clean, less dust place which must be dry & moisture-free. Sterile instruments & trays or cassettes should be opened up at chairside for use. In the process of cleaning & sterilization there is a chance of corrosion of instruments due to the contact of two dissimilar metals and different chemicals. Hence to prevent this, 1) instruments should be cleaned properly and rinsed with distilled water. The surface should be free of blood, saliva, or other contaminants. 2) good quality steam should be used in the autoclave and should be deionized. Below 6.4 pH of the steam can cause pitting and corrosion. 3) Chrome-plated and stainless steel instruments must be autoclaved separately to prevent any electrolytic action.[6]

Surface protection procedures: Surfaces like different handles, controls, light cure units, micromotor & ultrasonic handpieces, three-way syringe etc which are touched by the dental surgeon during treatment should be cleaned with disinfectants or protected with a barrier. After every patient the surfaces should be cleaned by using **disinfectants** like alcohol/iodophore/ glutaraldehyde/chlorine products/synthetic phenols. The chair surfaces can be covered by impermeable **barriers** and must be discarded after every patient. They can be of plastic films, laminated paper plastics, aluminum foil etc and different sizes and shapes. The merits of this method are its easy & speedy insertion and protection of equipment from the harmful effects of chemicals and body fluids. But the cost, storage & disposal difficulties are the main drawbacks.

Tubing and hoses: As the surfaces remain moist always it creates a good environment for the growth of the bacteria and forms a biofilm. So regular checkup of the tubing and hoses should be done even if, there is an anti-retraction system. The suction tube should be flushed with fresh water before each patient and disinfected at the end of the day with a disinfectant like sodium hypochlorite. All water tubings should be cleaned by flushing water for 3-5 mins if the system has not been used for long times. Similarly the handpieces must be cleaned for 30 secs with air & water to remove anything that has come inside during use. Air compressor or tank should be emptied daily to prevent the growth of microorganisms in the tank. **Rubber dam** is used as a barrier to control the airborne contaminants. It reduces the infectious particle in the aerosols to a significant amount.[9] According to **ADA** use of mouth wash just before the procedure can reduce the number of pathogens in the mouth but it does not affect the number of pathogens that could be aerosolized.

Disinfection of removable appliances: Removable appliances are always coated with saliva and plenty of microorganisms due to its continuous use in the oral cavity. So during any adjustment protective glasses and full face-mask should be used. It also should be disinfected by placing the appliance in a germicide container.

Oral Safe is a germicide-deodorant and it is safe if occasionally swallowed. In an earlier study it was seen that 99 % of microorganisms are destroyed if the appliance is submerged for 10 mins in Oral safe. **H. Petit et al** described a method in which they combined germicide-deodorant with ultrasonic cleaning for better effects. They found that in three minutes use of this procedure 10 times more microorganisms are killed than the passive submersion method.[10]

Dental laboratory practices: All Impressions, occlusal bite records and devices which comes in contact with patients' saliva, blood or debris must be thoroughly rinsed to remove them and then put in disinfectant solution like glutaraldehyde/formaldehyde before sending to the laboratory.

Conclusion

As a sterile environment is mandatory for dental treatment it is necessary that everybody in a dental office should have some knowledge about disinfection and should be maintained. The process of maintaining sterility in the dental office is more complex than it appears. So it is the responsibility of all (patient, staff & the professionals) to carry out their duty with utmost purity and clarity. Hep- B, pneumonia, AIDS and other serious contagious diseases can be contracted in a dental office. So it is indispensable to use proper sterilization procedures for moral, professional & medico-legal point of view. Technological advancement and invention of newer machinery made the sterilization and disinfection procedure easier. The use of disposable barrier technique and different chemical agents for disinfection has further decreased the responsibility of dental staff to create a pure aseptic condition for the dental treatment.

Impact of Yoga in Dental Practice

Karishma Rathore[1], Debasruti Naik[2], Sthitaprajna Lenka[3], Gatha Mohanty[4]

[1]Tutor, Department of Public Health Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, [3]Professor, Department of Oral Surgery, [4]Senior Lecturer, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dentistry is perceived as a profession that is more stressful than other jobs. Many occupational health problems persist in modern dentistry. It is high time we, the dentists, also inculcate the practice of performing Yoga in our daily life regime, to strengthen our muscles of neck, shoulder and back, to save ourselves from musculoskeletal pains. The "Asana" recommended in the Yoga, specifically for posture-related problems can be of great help to the dental professionals in managing their day to day muscular discomfort and pain. The need of the hour is just to modify our lifestyle to get the maximum out of our professional and personal life. This review article focus on the importance of yoga in dental practice.

Keywords: *Yoga, Dental Practice, Healthy Body and Mind.*

Introduction

In one of the holy texts of old times – the Rig Veda, the term "Yoga" was first mentioned which is a derivative of the Sanskrit word "YUJ" which means 'to join' or 'to yoke' or 'to unite'. Over 5 thousand years ago the foundation of yoga was laid down by the Indus – Sara swat civilization.[1]

Yoga focuson a healthy mind in a healthy body concept that helps in controlling an individuals mind, body and soul.[2] It builds confidence and helps in maintaining a healthy lifestyle. Yoga is versatile, pleasurable as well as highly beneficial for dentists to battle stress and apprehension and to decrease work-related musculoskeletal pain.

Dentistry, as a profession, is very demanding, in terms of the focus and precision required while performing the procedure, more so, because we are working on a very small area, which requires sheer attention. In doing so, many times, we forget or overlook the posture in which we are working continuously for long hours.[3] When the dentist is working in a sitting position, over half of the body muscles provide support, to enable the body to be in a static position. If the same posture is continued for a longer period, muscle ischemia happens. As a result, what we get in return is the musculoskeletal disorders that exhibit in the form of pain. The intensity of this pain can vary from mild discomfort in the neck, shoulder and back region to excruciating one, so much so that it leaves us with no choice but for placing a halt on our professional work and then rushing to the concerned specialists for management and respite.[4]

As a substance of fact, as it is said "small things can make a big difference," as a fact of our life like a simple change in our lifestyle, can make a huge difference in the way we can escape this health hazard which is gulping the entire dental fraternity worldwide, like a monster.[5] The "International Yoga Day" was celebrated worldwide on June 21, 2015, attracting everyone's attention on this indigenous tool in the prevention of various health-related issues.

Advantages of yoga[6]:

a. Improvement in cardio-respiratory efficiency

Corresponding Author:
Dr. Karishma Rathore
Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: krishrrathor@gmail.com

b. Improvement in exercise tolerance

c. Harmonious balance of autonomic function

d. Improvement in dexterity, strength, steadiness, stamina, flexibility, endurance, and neuro-musculoskeletal functioning

e. Increase in alpha rhythm, inter-hemispheric coherence and homogeneity in the brain

f. Improved sleep quality and improved cognitive functions

g. Alteration in brain blood flow and brain metabolism as well as

h. Modulation of the neuroendocrine axis.

It is high time we, the dentists, also inculcate the practice of performing Yoga in our daily life regime, to strengthen our muscles of neck, shoulder and back, to save ourselves from musculoskeletal pains. The "Asanas" recommended in the Yoga, specifically for posture-related problems can be of great help to the dental professionals in managing their day to day muscular discomfort and pain. The need of the hour is just to modify our lifestyle to get the maximum out of our professional and personal life.[7] This paper aims to stress the benefits of yoga for dental surgeons.

Why introduce Yoga for dental students and professionals?[8]:

a. Improved visibility is gained, sitting at one place for a long duration as well as working in the desktop and keyboards can very well put massive strain on the musculoskeletal system.

b. Mutual understanding with disobliging teammates and with fearful patients as well as job-related frustrations can become overwhelming.

c. Results in stress, anxiety, anger, and depression.

d. Prevalence of general musculoskeletal pain is estimated to be between 64% and 93%

e. Major issues : – back pain (36.3-60.1%) – neck pain (19.8-85%).

f. Risk factors include:

– static and awkward posture of clinical practice

– other non-ergonomic work practices.

It has been recently suggested that Yoga may be a good way for dentists to relieve stress and reduce the risk of repetitive strain injury and dysfunctional posture. Another survey amongst 220 dentists found noteworthy differences in existing cases of musculoskeletal pain among those who practice yoga as compared to those with no regular activity over 12 months.[9]

Yoga can improve your health in various ways like:

1. Yoga Stimulates Saliva Production:

- Bacterial count in the oral cavity increases because of the reduction in salivary production. Bacteria can thrive in an environment like dry mouth which later results in plaque formation, tooth decay, and gum disease.[10]
- Regular yoga with practicing breathing method can help avoid mouth and throat from drying. Increase saliva production is related to someyoga poses likeinverted poses, twists and forward bends.
- The Khechari mudra–is a type of attitude or honour which should preserve vitality. Method of performing the Kechari Mudra are simple -Rolling tongue backward as if it enters the nasal cavity to touch uvula inside the mouth. Breathe in as well as with a snoring type of sound from inside throat. Breathe outand swallow some saliva that was deposited in your mouth while releasing from the posture of your yoga style.[7,10]

2. Yoga Improves Posture :

- A good body posture gives us many benefits likegood memory along with brain functions, improved breathing, less stress, healthier mood, stronger core muscles, better confidence and more energy as well as better productivity.[11]
- Improper posture can affectthe spine and neck as well as the mouth. The mandible shifts forward after a person slouches causing the teeth of both the jawsin malalignment position. During this the head moves back and compress the spine. If left untreated, there will bestress on the surrounding muscles, bones and also in joints. It alsocan create pain and inflammation in the muscles and joints involved in the opening and closing of the mouth.[7,12]
- Jaw issues like temporomandibular joint disorder can also arise from improper continuous posture. This disorder can have common side effects that consist ofa clicking sound or pain while opening the jaw, tenderness in the face can be felt, chronic headaches and changes in jaw alignment resulting in

rough wear of the teeth. (13) Poor posture can also lead to poorly balanced shoulders causing stress on the ribs as well as the organs underneath.[14]

3. Bad breath:

- Also known as halitosis is a distinctly unlike able odour that can be felt while breathing. It results in fretfulness in exaggerated person. There might be various etiologies for halitosis that includes all improper oral hygiene habits but problems with our gut can also be a reason that leads to bad breath. This type of sign and symptoms is known as dysbiosis which is an imbalance between the good and bad bacteria in our gut, as well as the presence of yeast or candida in the gut.
- Certain yoga postures are there that can unswervingly involve the digestive as well as respiratory organs. By improving blood circulation and manipulating functions of the kidneys, lungs, stomach, kidneys or liver and also removing toxins is encouraged. All this may help cure and prevent bad breath. Yoga posture like Lion Pose or Simhasana– The Cooling Breath or Sheetali Pranayama – The Psychic Union Pose or Yoga Mudra, Kapalbhati breathing are some of the asanas that can help out in curing halitosis.[12,15]

4. Yoga reduces Stress:

- More stressed focus less on the maintenance of good oral health.[16] Stressed people have a habit of grinding their teeth resulting in micro-cracks and broken fillings and worn down teeth results in nerve damage; the teeth that are grounded down to the dentin results in sensitivity to heat and cold; gum recession because of pressure on the gum line; loose teeth and gingival pockets due to the motion of teeth grinding; headache and aching jaws because of overworked jaw muscles; and jaw impairment.[9]
- Stress causes the salivary glands by slowing down the production of saliva resulting in dry mouth andgives a suitable environment for bacteria to thrive. These kinds of bacteria cause serious dental issues like inflammation in the gums. Stress exacerbates inflammation in the gums which can lead to more serious dental issues and even general health issues. From regular yoga practice, stress can lessenthe body can be maintained mentally and physically healthy.[9]

Some other professional hazards for dental surgeons are:[13]

- Lower back pain
- Cervical spondylosis
- Eye problems because of continuous and constant focus into the oral cavity where light has less power
- Varicose veins in lower limb

Prevention and cure by doing yoga therapy[3,10]:

Bhujangasana: This pose lengthens and strengthens the back and shoulders caused due to improper flexibility of upper and middle back. It helps to reduce fatigue and stress. This yogasana has been shown to reduce chronic pain associated with Musculoskeletal and joint diseases. It also helps in treating Cervical spondylosis.

Padmasana: This Asana works wonders for the spinal cord by keeping it erect, healthy and flexible. In the Asana the lungs get packed with air-filled oxygen. By leg pulling the nerves, muscles and bones are stretched tight thus massaging the legs meticulously and keeping them healthy.

Sirshasana: This Asana helps in providing conditioning to the brain, eyes and ears due to increased blood pressure. It also helps in improving concentration and memory. This Asana improves blood circulation in the organ of both the normal and diseased eyes.

Vajrasana: This asana helps in the impediment of varicose veins which take place because of prolonged standing. This Asana helps in the majority of cases. Because of this asana, the blood flow to the lower limbs is reduced, muscles are stretched and these varicose veins are cured.[16]

Conclusion

Practicing regular yoga can help in preventing and treating many long term diseases as well as can helps in achieving good oral health. Yoga heals the body, mind and soul by stress reduction and also by increasing the motivation level. The inflammatory response decreases and increases in the immunity to attain good gingival health and healing after extractions and oral surgical procedures is achieved by performing regular yoga. The lifestyle of a yogic is always lean towards nature, it helps in the impediment of dental as well as soft tissue disorder of the mouth which are the result of the stresses of life.

It is high time that we the dentist include the practice of performing yoga in our daily life regime. Asana recommended in yoga especially for posture-related problems can be of great help to the dental profession in maintaining their day to day muscular discomfort and pain. By practicing regular yoga, it rejuvenates and revitalizes all the organs of the body. So devoting 40 to 50 minutes on an average day to yoga, we can remain fresh mentally and physically and it will keep us away from professional hazards.

Modified Semilunar Advanced Flap with Connective Tissue Graft Technique for Root Coverage: A Case Report

Anurag Satpathy[1], Bhagyashree Lenka[2], Rinkee Mohanty[3]

[1]Professor, [2]Post Graduate Student, [3]Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Gingival recession may not only result in aesthetically unacceptable results but also be associated with increased susceptibility to root caries and dentinal hypersensitivity. A novel technique for recession coverage by using a modified semilunar advanced flap technique with connective tissue graft is described. The technique involves placing of connective tissue graft underneath a semilunar incision which is made parallel to the free gingival margin of the facial tissue and its advancement over the denuded root. This technique has the advantage over conventional semilunar flap, in that benefit of connective tissue graft is combined for improved prognosis

Keywords: *Semilunar flap, connective tissue graft, gingival recession, coronally advanced flap.*

Introduction

Gingival recession (GR) is a common concern of many patients who visit a dental office, but despite the concern of patients, the practice of recession coverage often eludes general dentists owing to the need for superior skills. In gingival recession there is an apical shift of the marginal gingiva resulting in denuded root surfaces[1]. It not only is an esthetic concern but also causes dentinal hypersensitivity. Tissue destruction that takes place in periodontal disease or mechanical factors due to toothbrushing can cause GR[2,3]. Root coverage (RC) is indicated when there is an esthetic concern, dentinal hypersensitivity, root caries, cervical abrasion and prevention of periodontal disease progression[4-6].

Several surgical approaches have been put forth in the management of denuded root surfaces. Among these, the subepithelial connective tissue graft (SCTG) procedure, has been considered as the most efficacious and with most predictable outcomes[7,8]. Introduced for RC in 1985, SCTG has been performed by using a variety of flap designs[9,10]. In the following year, ie in 1986, Tarnow et al[11] introduced the semilunar coronally advanced flap (SCAF) procedure. Case reports with connective tissue graft for treatment of isolated gingival recession have shown a high success rate[12-14]. The present case report utilizes a modified semilunar advanced flap technique in combination with connective tissue graft in the management of gingival recession.

Case Report: A male patient aged 32 years was enrolled in the OPD of the Department of Periodontics, Institute of Dental Sciences, Bhubaneswar, Odisha,with a chief complaint of receding of gums in the upper central incisor (tooth number 11). The patient had no faulty tooth brushing habits or any parafunctional habits and hadn't taken any antibiotics in the preceding six months. He neither had any prosthesis in the anterior region nor did any tooth receivea restorative therapy. His medical history was non-contributory.

Intraoral examination: Class I Miller's gingival recession was observed in the tooth number 21 (Fig 1). Clinical measurements such as a recession defect of 2mm (Fig 2) and width of keratinized tissue of 4mm

Corresponding Author:
Prof. Anurag Satpathy
Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha
e-mail: drasatpathy@gmail.com

prior were measured using a UNC 15 periodontal probe. Clinical photographs were taken prior and post-surgical therapy. The intraoral periapical radiograph (IOPA) taken had no bone loss in the 21 region. A recession coverage procedure was planned, explained to the patient and a written consent was obtained.

Pre-Surgical Preparation: Scaling and root planing was carried out to render the surgical area plaque-free. Ademonstration of the correct tooth brushing technique to the patient was also done.

Surgical procedure: After anesthetizing the surgical site with lignocaine (2%), a crevicular incision (Fig. 3) was placed on 21. This was followed by creating a tunnel by separating the mucosa from the underlying periosteum (Fig 4). A semilunar incision (Fig 5) following the curvature was placed at an area apical to the marginal gingiva of the indicted tooth such that the apical most extent is in the alveolar mucosa. The incision curved laterally and lay coronally in the keratinized gingiva apical to the mesial and distal interdental papilla maintaining the vascularity of the flap. The harvested connective tissue graft (CTG) from the palate was then placed underneaththe coronally advanced semilunar flap (Fig 6 & 7).Advanced flap along with the CTG was stabilized by an anchor suture on the buccal surface of the tooth (Fig 8). The surgical site was covered by a periodontal dressing for mechanical protection and to control postoperative bleeding from the surgical site. Patients were given post-operative instructions and were prescribed with suitable antimicrobials and analgesics. Suture removal was done after 10 days and the patient was put on a periodontal maintenance regimen. An acceptable root coverage was seen after which was stable even after 6 months (Fig 9). Fig 10 provides a schematic diagram of the technique for visualization and better understanding.

Figure 1a Recession defect irt 11, igure 1b.Recession of 2 mm

Figure 2a. Crevicular incision given, Figure 2b Tunnel created

Figure 3a. Semilunar incision given, Figure 3b. Graft tucked underneath semilunar flap

Figure 4a. Connective tissue graft placed, Figure 4b. Suture placed.

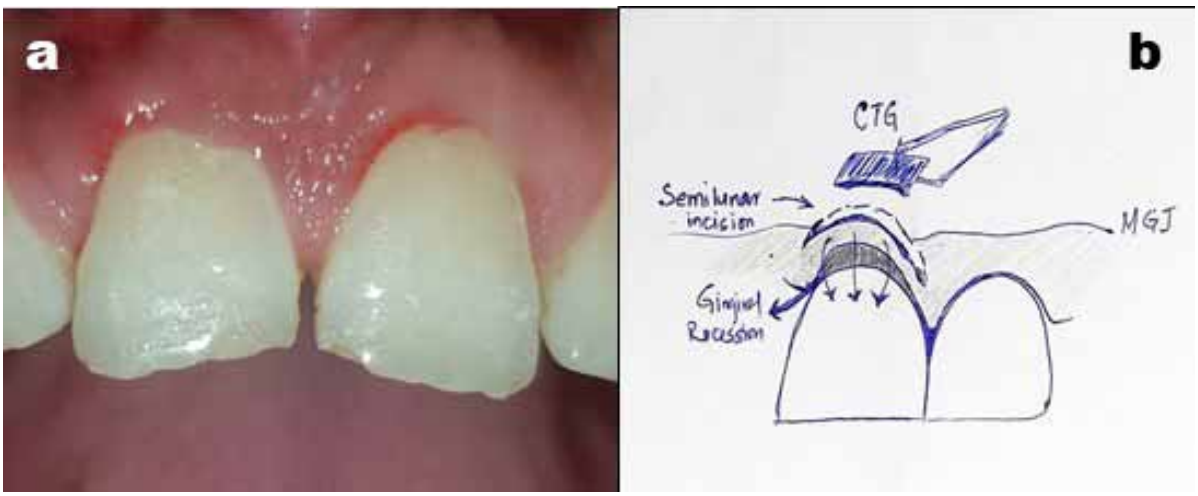

Figure 5a. Postoperative 6 months, Figure 5b. Schematic Diagram; CTG = Connective Tissue Graft, MGJ = Mucogingival Junction

Discussion

The presented technique utilized the combined advantages of the SCAF technique and SCTG technique in that there is no disturbance to the adjacent interdental papillae, there is no shortening of the facial vestibule and has least flap tension. This technique is preferably to manageisolated gingival recessions which serve as a predictable root coverage procedure. Apart from preserving the adjacent interdental papilla, this technique also applies less traction and preserves the gingival height. Minimal trauma at the recipient site due to minimal incision, may be advantageous in masking recessions as compared to the coronally repositioned flap. In this case we utilized one vertical incision to facilitate placement of connective tissue. This technique combines the benefits of subepithelial grafting along with semilunar incision and tunnel procedure, thus improving the outcome.

SCTG procedure is advantageous in that it provides a good tissue blending at the grafted site. Also, owing to its conservative approach, there is minimal trauma and discomfort at the donor site. The recipient site receives a dual blood supply from the underlying connective tissue base and the overlying recipient flap which contributes to the success of this procedure[15].

In the presented case which was managed by the novel technique of combination of SCPF and CTG showed 100% root coverage. The tunnel approach used in the technique is a modification of the pouch and tunnel technique which was designed specifically for isolated recession frequently found in the maxilla. There was a highly esthetic outcome and also increase the thickness of keratinized gingiva.

Conclusion

This present case report confirmed that a modified semilunar coronally advanced flap and in combination with subepithelial connective tissue graft technique is an efficient treatment option for the management of gingival recession defects and resulted in complete root coverage of the treated case.

Effect of Long-term Use of Steroidal Anti-inflammatory Drugs on the Periodontal State: A Review

Rinkee Mohanty[1], Rashmita Nayak[2], Gatha Mohanty[3], Abhaya Das[4], Utkalika Das[5], Aishwarya Bal[6]

[1]Professor & Head, [2]Professor, [3]Senior Lecturer, [4]Reader, [5]Tutor, [6]Postgraduate Trainee, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Corticosteroids are chemically similar to endogenous cortisol and mostly prescribed for their anti-inflammatory and immunosuppressive properties, which are due to the inhibition of phospholipase A2 activity. These drugs are extensively used in the treatment of a plethora of autoimmune disorders such as rheumatoid arthritis, various breathing disorders and also disorders of connective tissue. In the field of dentistry these drugs are prescribed in most of the mucocutaneous disorders such as they are mostly used in inflammatory diseases such as oral lichen planus, pemphigus, and oral stomatitis to alleviate post-operative discomfort and swelling. These drugs can be administered systemically,topically or asinhalational therapy. Evidence concludes that short term corticosteroids possess antiresorptive properties and its local application shows a favourable effect on the periodontal ligament, but when administered systemically for a long period could lead to periodontal diseases as it has shown to increase attachment with alveolar bone and destruction of transseptalfibers. Oral manifestations are dependent on duration,dose and frequency of use. It is commonly associated withmoniliasis, dental caries,altered taste sensation, ulceration of the tongue, buccal mucosa, and gingiva due to xerostomia,gingival inflammation, periodontal inflammation,and immune suppression. They can either cause dramatic improvement or dramatic adverse reactions which can lead to a considerable increase in the distributionof periodontal disorders. In patients on long-term corticosteroid therapy, oral health is generally not given importance during management. Hence this review explains about various effects of different types of corticosteroids on periodontium used in dentistry.

Keywords: *Corticosteroids, risk factors, mucocutaneous lesions, periodontitis, Bone mineral density.*

Introduction

Physiologically steroids (cortisol and aldosterone) are produced by adrenal glands and help in various physiological functions such as metabolism of fats, proteins and carbohydrates, immune mechanism, and saltwater balance.[1,2] Testosterone, estrogen, cortisol and aldosterone are the steroid hormones produced by the body.Corticosteroids are synthetic analogues of steroid hormones that are produced in the adrenal cortex of vertebrates.[1] In 1940s glucocorticoids were first introduced and since then it has become an extensively prescribed class of drugs to manage various disorders such as adrenocortical insufficiency, rheumatic diseases, asthma, and skin diseases.[2] They are available in different formulations like ointments,gels and tablets.[3] Due to their anti-inflammatory action, steroids were first used clinically to treat dermatological diseases. Corticosteroids are commonly advised as replacement therapy in treating various types of inflammatory and immunosuppressive disorders.[4,5]

Steroidal drugs are known to exert definite anti-allergic, anti-inflammatory and immunosuppressive effects.[1] However, despite these beneficial actions, corticosteroids are also known to cause adverse reactions likerashes, clouding of the lens, weakness in the muscles, GIT disorders and candidiasis. In dentistry, they are generally advised to reduce post-operative edema, postoperative pain, anxiety and for the management of oral inflammatory manifestations of systemic disorders like bullous pemphigoid, oral lichen planus, pemphigus, erythema multiforme, recurrent aphthous stomatitis, and hypersensitivity reactions.[2]

Research has proventhat the patients on corticosteroids often present with oligodontia or are characterized by dentition which is prone to dental caries.[6] Corticosteroids can cause osteoporotic changesin the alveolar bone due to the reduction of bone-forming cells and the amount of bone matrix. This results in a fibrous transformation of the periodontal ligament space and decrease of the alveolar bone height.[7] In periodontology, the use of corticosteroids is mostlyrestricted to its use for periodontal manifestations of systemic disorders, and not as a first-line treatment of periodontal disease per se. Nevertheless, it is necessary to know the uses and effects corticosteroids have, not only on oral diseases but also on the gingival and periodontal diseases and hence this review.[8,9]

Uses of steroidal anti-inflammatory (corticosteroids) in oral diseases: Corticosteroids are commonly administered in the topical, systemic, and inhalational form.[10] of these, topical corticosteroids are the ones that are commonly used for the treatment of oral lesions.[11] They have evolved and emerged as the mainstay of therapy for numerous oral lesions and conditions such as oral lichen planus, erythema multiforme, desquamative gingivitis and major aphthous ulcers.[12,13] Their use is mainly due to the anti-inflammatory, immunosuppressive, and anti-proliferative properties of corticosteroids.[14] These properties/actions are expressed as a result of a process called transactivation. It is mediated by the nuclear glucocorticoid receptors which arepresent in the cytoplasm which regulates the protein transcriptiontoinduce anti-inflammatory proteins and regulatory proteins.[15] Corticosteroids displace proteins like heat shock proteins from the inactive receptor site and bind to the receptor, and this corticosteroid-receptor complex then getstranslocated to the nucleus and binds to a specific sequence of deoxyribonucleic acid. The metabolic effects and some of the adverse reactions could be occurring through this process.[14,15]

Anti inflammatory action: This action is mainly brought about by topical corticosteroids which mainly function by inhibiting the formation of eicosanoids. Corticosteroids stimulate the production of various polypeptides, collectively called lipocortin which has inhibitory effects on phospholipase A2 activity.[16] They are also known to block the action of vasodilators such as histamine and bradykinin leading to vasoconstriction. This is clinically evident by a reduction in erythema.[17]

Immunosuppressant action: This is brought about by suppression of cytokines namely interleukin 1 (IL - 1), IL- 2–6, IL-8, and tumor necrosis factor-alpha, leading to a reduction of cell proliferation. They also affect the humoral immunity by reducing B cell expansion,destruction of T lymphocytes and antibody synthesis.[18]

Anti-proliferative action: This is seen as a result of a reduction in the mitosis in the epidermis which makes the basal cell layer, as well as the corneum and granulosumlayer of the keratinized epithelium thinner. The proliferation of keratinocytes is affected, there is a decrease in the keratinocyte growth factor, and inhibition of fibroblast proliferation, migration, and chemotaxis. This is followed by abnormal aggregation of the elastin and collagen fibers,which decreases the synthesis of collagen and glycosaminoglycans. For oral lesions,topical corticosteroids are most commonly advised and hence it is important to know the factors that need to be taken into consideration when prescribing or using them. The effectiveness of treatment with topical corticosteroids depends on the halogenation of its 6main ingredient, i.e., cortisol. This halogenation leads to an increased binding of cortisol to the glucocorticoid receptor. The penetration of the topical corticosteroid depends on the esterification of cortisol which increases the lipophilicity of the steroid.[17]Hence, the corticosteroids should be selected based mainly on their potency and the area of application.[19]

There are various classifications of topical corticosteroids based on their potency with or without using the vehicle. Among them, the World health organization (WHO) classifies the topically administered steroids into seven groups, with Group 1 which is the most potent and Group 7 being the least potent. Potency is determined based on the activity of the corticosteroid molecule, its concentration, and the nature of the

vehicle.[20] Highly potent concoctions are meant to used for a brief period only and are topically applied on the soles of the foot, and palms of the hands. It can also be used for the management of hyper keratinized lesions. For the management of the lesions on the face caused due to various acute inflammations low to medium potency formulations are used. They can be used for a longer period. Normally, high potency steroids are used for oral application for a short duration.[17]

Since the adventmany different delivery systems of these topically applied steroids have been developed such as Creams, ointments, lotions, and gel/hydrogel.[20,21] Vehicles are nothing but carriers. They carry the active steroid molecule which keeps the skin hydrated and moisturized and enhances the penetrative capacity of the drug. Creams are the vehicles that aremost preferred by the patients. Their occluding capability is less due to their water-based preparation. Hence, they spread easily, without anoily and sticky feeling.[21]Ointments are preferredin highly keratinized areas and for dry or scaly lesions. They enhance moisture-holding capacity and possess a good occluding ability. This aids in the penetrating capacity of the drug. Gels are prepared using a gelling agent.This makes the application of the dug more convenient. The shortcoming of using gels is that they have the possibility of inflicting pain and discomfort after the application. Conventionally, ointments have been considered to be more potent than the rest of the formulations.[22] The use of corticosteroids for treatment of periodontal disease is however limited. Corticosteroids are known to affect fibroblasts and bone remodeling, which may affect the periodontium and hence it is important to have a thorough knowledge regarding its application and the drawbacks of using these steroids on the periodontium.[23]

Effects of corticosteroids on the periodontium: Corticosteroids, when topically applied to the erythematous marginal gingiva suppresses the inflammatory process and masks the rate at which the bleeding should be occurring blinding the clinician with the false picture. It has been observed that,in cases where steroid anti-inflammatory drugs are administered topically or injected in the gingival tissues, there is a disturbance in the ability to percolate into the capillaries and formation of collagen, decrease in the b lymphocytes and granulation tissue.[24]

Researchers have established that a high dosage of hydrocortisone brings about an increase in the activity of various enzymes that help in the degradation of the collagen and enhance the fibro lysis.One of the major classes of enzymes is matrix metalloproteinases (MMPs). Marked increase is seen in the subtypes 1, 2,7 and 11, while low levelsthis steroid reduced the expression of the same.[22]

In chronic periodontitis patients, also diagnosed with asthma and under long-term inhalational steroid therapy pathological migration and loss of teeth (mostly mandibular anterior teeth) have been observed.[23,24] Research has proven that patients under the inhalational therapy are more prone to the diseases of the periodontium more prevalent in the mandibular jaw. It is more likely to be seen in the cases which are further influence by other debilitating diseases such as osteoporosis.[25] In the adolescent age group who are on long-term steroid anti-inflammatory drugs there is an increased risk of gingivitis and tooth decay due to xerostomia. Mouth breathers and those taking inhalers that have these steroidal formulations are associated with drastic variations in salivary pH, decreased salivary flow, increased accumulation of the dental plaque which further creates a cascade mechanism causing an increase in the rate of caries initiation and progress.[26]

Safkan et alconcluded that those who were under steroidal anti-inflammatory drugs are often predisposed to gingivitis.[27] It further evidenced that using corticosteroids for a longer duration (one year or more)led to a marked increase in the presentation of the clinical symptoms of periodontal inflammation.

Markitziu et al carried out a study to assess the periodontal changes in patients of pemphigus vulgaris undergoing corticosteroid therapy.[28] The results of the study have shown statistically significant differences in bleeding on probing and in gingival recession but no significant changes in alveolar bone height.

Despite their strong anti-inflammatory and immunosuppressive effects, long term application of corticosteroids can cause enhanced deterioration of dental health and hygiene. Misuse or overuse of steroidal anti-inflammatory drugs must also be taken into account as they may affect not only the teeth, but also the soft tissues and alveolar bone.[29] It has also been found that prolonged application of corticosteroids adversely affects the osseous metabolism, along with a notable decrease in the density of the inorganic component of the mandibular jaw.

Inhaled corticosteroids, sodium cromoglycate, anticholinergic bronchodilators, β-2 agonists are frequently administered alone or in combination in the form of inhalation therapy for the treatment of asthma and chronic obstructive pulmonary disease.[26] The dosage, duration and frequency of application of steroid anti-inflammatory drugs directly correlate to the severity of adverse effects seen in the oral cavity in general and the periodontium in particular. Several adverse reactions affecting the oral cavity due to long term inhalational Corticosteroid therapy include not only severelyaltered taste perception, ulceration, moniliasis, demineralization of the tooth and dry mouthbut also severe gingivitis and periodontitis.

Aggregation of plaque deposited on the tooth is directly proportional to the reduced rate in salivation. The unbalanced buffering capacity of saliva and constant low pH scores provides a conducive condition for the growth of acidogenic and acidophilic caries causing microbes such as *Streptococcus mutans and Streptococcus sobrinus*.

The adverse habit of breathing through mouth in the patients with long term corticosteroid therapy, contributes to the aggravation of gingival inflammation due to the loss of water from the alveolar mucosa. The disturbance in the pathophysiology along with disturbance in local and systemic immunity, provoked by long term corticosteroid therapy, has shown to considerably increase the distribution of periodontal disorders.[24] Taking into account the fact that saliva acts as a reservoir of the necessary factors required for protection against gingivitis and periodontitis, drugs affecting the qualitative and quantitative properties of saliva directly influence the severity of periodontitis.[23]

Conclusion

This review concludes that long-term corticosteroid therapy directly influences the oral cavity. It further leads to several adverse reactions from moniliasisto gingivitis and periodontitis to impairedosseous metabolism. Furthermore, a significant amount of reduction in the Bone Mineral Density (BMD) of the mandible. Therefore, patients receiving this treatment for a longer duration (oral, topical, inhalational) should undergo a thorough dental check-up, and regular follow-up. This is to check and prevent any disturbance in the dental health and to estimate the risk factors for gingivitis and periodontitis. However, it is still taxing to come to a definite conclusion on the relation of oral Corticosteroids with the loss of tooth and the status of the periodontium. More number of studies on the effect of the different forms of corticosteroids on the gingival and periodontal state are required to draw more definitive conclusions.

Health Hazards Due to Increasing Use of Mobile Phones in Children: A Review

Upasana Mohapatra[1], Susant Mohanty[2]

[1]Tutor, [2]Professor & Head, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

The excessive use of mobile phones and other wireless devices is seeing a steep rise among the general population in the present world. People, unaware of the hazards these might pose, are marching towards a great health risk. This article would focus on health hazards in children, which are brought about by the harmful radiation emitted by mobile phones.

Keywords: *Mobile Phones, Health, Harmful Effects, Radiofrequency.*

Introduction

In the present world, the most popular mode of communication is found to be mobile phones and tablets. These gadgets apart from being used for making calls are also being used for many other functions. They are used as texting devices, sensors, high definition cameras, internet surfing gadgets, gaming stations, GPS stations, calendars, calculators, source of internet connections for sending e-Mails among many other advanced functions. This is the reason why people tend to depend on this complicated device which serves the assignments of multiple devices. This leads the adults to use the mobile phones or such gadgets very frequently. Because of this increasing use among adults, the children too end up using them. They tend to imitate their parents and seem to act like them. They find it to be a very convenient and interesting mode of entertainment. Their age being at a very tender stage, they are yet to understand the harmful effects the use of mobile phones and tablets has on their mental and physical health. This radio frequency fields to which today's population is exposed lead them to be affected by the harmful radiations emitted by the mobile phones and tablets and these are the electromagnetic rays ranging in between the microwave wavelength of 850-1800.[1]

Effects of radiations emitted by mobile phones on health of children: The effects of the radiation may take years to appear. Hence, they are less visible. Some of them are degenerative neurological diseases, like, Alzheimer's disease, dementia, depression syndromes (mostly at the age of 50-60 years). But, amongst the most harmful effects that are visible, are the tumors associated with the brain because it is the organ that is targeted easily.[2] Some of them are glioma and acoustic neuroma associated with that part of the brain that is most exposed to radiofrequency, i.e. the ipsilateral part.[3] These effects are more pronounced in children because of their smaller head size and lesser skull thickness. The brain keeps developing almost till the age of 20 years and this is the period when the brain is most sensitive to toxins and environmental radiations. Moreover, children have a longer life to be exposed to any health risks. So, they are more vulnerable to the radiation that the adults.[2] The American Academy of Pediatrics agrees, saying that "when used by children, the average RF energy deposition is two times higher in the brain and 10 times higher in the bone marrow of the skull, compared with mobile phone use by adults."[4]it has been reported that

younger the children, the more is the harmful effect of radiations emitted from mobile phones in terms of brain tumors and cancers.[5] Some researchers have shown the link between pregnant mothers using mobile phones and the mental health of the children. Such children develop a tendency of hyperactivity, emotional disturbances and difficulty in mingling with other children.[6] A link also has been established between attention deficit hyperactivity disorder and the use of mobile phones. Children who excessively use mobile phones to make calls or entertainment or tend to spend a great amount of time with their mobile phones are seen to have developed this disorder.[7]

The international agency of research on cancer (IARC) at WHO in May 2011 conducted a study regarding the effect of mobile phones on children. They concluded that the radiofrequency in the range of 30 kHz – 300GHz might have the potential of a human carcinogen.[8] An ongoing study, MOBI-Kids by Sadetzki et al., 2014, has by far shown that regular users, who use mobile phones to make just 1 call per week have a very insignificant risk for developing brain tumors. They have also shown that the highest time lapse between the use of mobile phones for the first time and development of disease is 5 years.[2]In a report submitted by Russian National Committee on Non-Ionizing Radiation protection in 2008 to WHO, it was opined that the children who frequently use mobile phones would most commonly face mental and physical illness, like, memory disturbances, loss in concentrating abilities, increased levels of irritation, sleep disturbances, reduced stress management capabilities, increased risk of epileptic attacks, etc.

The radiofrequencies have their harmful effects on skin too. Skin cancers and contact dermatitis are some of the skin diseases associated with frequent usage of mobile phones and wireless devices. These diseases highly affects the way of life as they might cause pain and discomfort in a large percentage of the population.[9]A few of the less risky health problems that were found to be associated with phone calls were warmth behind and around the ears and burning sensation in the skin of the face. These symptoms were commonly found to be lasting till 2 hours after the phone call.[10]

Highlights of few harmful effects in adolescent:

Sleep disturbance is one of the major harmful effects of radiofrequency on adolescents. Sleep is mostly regulated by a neurohormone, Prostaglandin D2, whose synthesis is in turn dependent on an enzyme, β-trace protein (lipocalin-type prostaglandin D synthase). The concentration of this enzyme is markedly reduced by the continual use of mobile phones and wireless devices. This causes sleep disturbances in adolescents.[2]

Conclusion

With the increased use of mobile phones and electronic gadgets among the adults and children, the health risks associated with harmful radiations have taken its dominance in this world overtaken by technology. The children are the easy and the major targets of this storm of science. Both, physical and mental health mishaps are pronounced.

Teeth Mobility Cause and Management of Mobile Teeth in Dental Clinic

Priyabrat Sahu

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

By examining firm pressure with two metal instruments on teeth, the extent of vertical and horizontal displacement considered as tooth mobility, which is due to either periodontal disease or trauma. Nowadays teeth mobility is a common problem in dental scenarios, which results inocclusal problems, Dietary problems, and disturbances in mastication, aesthetic problem and worsening life quality. The treatment of tooth mobility is based on its etiology; it may be surgical or non-surgical. Surgically by Periodontal surgery, non-surgically by occlusal adjustment and splinting. Sometimes the Occlusal adjustment can be done by the surgical process. In the article, we discuss the cause of tooth mobility, relation between tooth mobility and occlusion including indication, contraindication and principles of tooth splinting. Our ultimate goal is to restore mastication function, good aesthetic, to improve patient comfort and good oral functions by various periodontal treatments for the management of mobile teeth.

Keywords: *Teeth Mobility, Adjustment Occlusion, Periodontal Splinting, Trauma of Periodontium, Types of Splinting.*

Introduction

Periodontitis is the most common and harmful disease among all periodontal diseases. It affects both soft tissue, hard tissue and tooth-supporting structures due to which tooth mobility occurs. By firm pressure of the dentist by using an instrument, the horizontal and vertical displacement of teeth is accepted as teeth mobility. Assessment of the mobility of the tooth is considered an integral part of the periodontal diseases as it is one of the essential signs of the diagnosis of periodontal disease. The primary objective of periodontal treatment is the reduction of tooth mobility.[1]

According to miller's tooth mobility index it is graded as Grade-1, Grade-2, Grade-3. By using miller's tooth mobility index, treatment plan and prognosisrate can be forecasted. Many factors are there which cause tooth mobility like inflammatory condition of periodontal tissue, PDL widening, alveolar bone loss, trauma from occlusion, loss attachment.[2]

Factors causing teeth mobility: Due to functional or parafunctional habits the force generated causes damages of periodontium which is otherwise called as occlusal trauma. Occlusal trauma is of two types.

i. Primary occlusal trauma

ii. Secondary occlusal trauma

Primary occlusal trauma: The etiology of primary occlusal trauma is due to the pathological occlusal forces which cause abnormality in the periodontium.

Secondary occlusal trauma: In some conditions the periodontium which is already inflamed, bone loss already occurred and there is a pre-existing disease in periodontium but still the healthy periodontium bears the occlusal forces. The mobility of teeth depends on the frequency and direction of the occlusal forces.Other factors that cause teeth mobility are accidental trauma, Periepical endodontic lesion, high filling, orthodontic treatment during pregnancy. Mobility also depends on the number and distribution of remaining teeth in the jaw. Root shape, number of roots, root position, inter radicular bone, and root amputation case also affect teeth mobility.[3]

Mobile Teeth Treatment: Mobile teeth treatment is based on its aetiology. Splinting occlusal adjustment and treatment is based on the stage of periodontitis. Reduction of mobility can be done by healing of the inflamed Periodontium or reduced Periodontal disease. Splinting is just a supportive part in periodontal treatment therapy. Periodontitis can be treated both surgically and non surgically. In some cases occlusal adjustment is enough. In miller Grade-II mobility teeth need both occlusal adjustment and periodontal treatment with splinting procedure. In some cases splinting is necessary where Grade-II mobility of teeth is seen but extraction is not indicated.[4]

Occlusal adjustment: Occlusal adjustment is the process in which by grinding the occlusal surface of maxilla and mandible free form contact between upper and lower jaw is created. To increase occlusal stability occlusal therapy is required in any stage of periodontitis.[5]

Indication:

- In Fremitus positive case within increasing teeth mobility due to traumatic forces.
- In case of occlusal discomfort and masticatory function
- Grinding and reshaping of teeth due to which soft tissue injury happens.
- Reshape and adjustment of marginal ridge, proximal contact and cusps where food impaction is seen.
- As an accessory therapy which can mitigate harm caused by para-functional behaviors.

Contra Indication:

- In the case where there are no signs, symptoms of occlusal trauma.
- In a mentally disabled, mentally abnormal patient.
- Occlusal adjustment has no effect where there is severe malposition of teeth and mobility.
- It is not applied as the primary treatment of microbial induced periodontitis.[6]

Splinting:

Principles of splinting: To reduce the three-dimensional movement of teeth splinting is required. Splinting is the clinical procedure in which adjoining the adjacent tooth using mechanical stabilization objects to control reversible and irreversible mobility of teeth. Splinting has the unique criteria of mobile teeth stabilization, decrease in tooth mobility and increase in masticatory and occlusal function. Due to good outcomes and better prognosis rates in periodontal diseases, splinting is most important due to its ability to give stability of teeth in between the surrounding periodontal structure of teeth. Before periodontal surgery and to improve the post-surgical healing splinting helps to the migrated teeth to reposition in a favorable environment by repairing periodontal tissue and tooth surrounding components. The skill of the clinician is needed for the successful splinting. The teeth marginal fit, contour of teeth, cleanability, retention, good joints of solder and esthetics are the technical elements of splinting. For the improvement of the masticatory force, occlusal force and patient comfort splinting has a great role. Splinting helps in deflecting the occluding and physiological force to other teeth which help in protecting the mobile teeth, reduction of traumatism, inhabitation of periodontal tissue regeneration and repairing. There is a previous history of healing of non-mobile teeth as well as mobile teeth, when mobile teeth are splinted. In the case of aggressive periodontitis by periodontal surgery and splinting help in the regeneration of bone and inhibit healing. The purpose of splinting is tissue protection, occlusal force distribution, mastication comfort, protection of investing teeth structure, pulp protection, stress, and force control. In performs in evaluation procedure anchorage, stabilizing in minor teeth movement. It helps in the prevention of teeth drifting while therapy is ongoing. In disease dentition it gives comfort by tooth stability.[7-8]

Indication and condition: In various clinical scenarios benefit of splinting is seen but the main objective of periodontal treatment is to create an environment where both movement occurs within the physiological limit for patient comfort and satisfactory function.

Indication: The main objective of splinting is to provide adequate rest while the healing process is ongoing and functional movement where the supportive tissue cannot perform satisfactorily.

- To relocate the teeth which is migrated due to periodontal problem
- When TFO is developing, In case of moderate to severe periodontal splinting required with addition to occlusal adjustment.

- In some surgical and non-surgical periodontal treatment procedures, where without stabilizing the mobile teeth treatment is difficult to operate. Before treatment by splinting extremely mobile teeth, it gives a good prognosis rate.
- After periodontal surgery the micro-movement of the teeth is seen in the healing area. So to eliminate the micro movement and increase the repair rate splinting is necessary.
- Splinting is done either for a single tooth or for entire dentition where extraction and implant is not indicated.
- After orthodontic treatment and after avulsion of teeth splinting prevent drifting of teeth.
- Splinting is helpful to increase the stability of joining, elimination, and reduction in teeth mobility and to get rid of pain and discomfort.[9-10]

Contra Indications:

- Without minimum periodontal condition and stability of occlusion splinting is not recommended.
- If the diagnosis of inflammatory periodontal disorder is not tackled splinting is not recommended.[11]

Biomechanics: In periodontitis associated teeth mobility the mesiodistal, lateral, occlusal and intrusive forces cause tissue destruction because all the forcesthey don't direct on the long axis of teeth and the forces alter the center of rotation of affected teeth. By occlusal adjustment the occlusal force is reduced which helps in the reduction of teeth mobility before splinting. By altering the center of rotation of every teeth and by creating a multi-rooted unit all the forces acting on teeth is reduced. Thus root resistance, mesiodistal force resistance and periodontal resistance are achieved. Splinting guarantees a fair distribution of force by focussing force over the dispersed region with sufficient periodontal help. When two single-rooted teeth are splinted, the mesiodistal force is well distributed. For splinted areas, invasive forces are easily accepted as the forces affect spreads over a small number of key periodontal fibers. Splinting stretches across the arch to connect posterior and anterior segments or to include teeth in the opposite side of the arch such that anteroposterior forces and faciolingual forces are counteracted to achieve a desirable stabilization in the faciolingual and mesiodistal direction.[12]

Splinting disadvantage: Oral hygiene accessibility and plaque control is difficult after splinting. It is noticed that due to plaque accumulation in the splinted margin it cause gingival irritation and periodontal problem in case of the periodontally compromised patient. Long term splinting causes dental caries in the proximal, gingival caries due to the accumulation of food debris. Crown loosing, fracture of anterior teeth sometimes happens. Splinting causes a phonetic problem.[13]

Requirements on splinting:

- Splinting will add as many strong teeth as possible to decrease the extra pressure on single teeth to a minimum.
- Teeth kept rigid by splint and splint does not place torsional stress on any portion of the teeth.
- By extend around the arch splint opposes the anteroposterior and faciolingual forces.
- Splint does not mean to mess with occlusion.
- Before splinting the teeth should reposition to a harmonic order if possible.
- Pulp should not be irritated by splint.
- Soft tissue, gingival, cheeks and tongue, lips should not be irritated by splinting application.
- The design of splint should be like that the patient can easily clean it.
- Splint should not block the interdental area between the teeth.
- Instead of the above-required criteria others are medically acceptable, inexpensive, ease of fabrication, easily removable by the operator and esthetically acceptable.[14]

Splints classification

- Various techniques are there for the splinting of teeth. Splinting is classifies according to its duration of use, purpose teeth location on the jaw, fabrication way. According to use length splinting is classified into short term splints, provisional splint and long term splints.
- Based on material splinting is of 3 types: metallic, non-metallic and combination of non-metallic and metallic type. The metallic is made up of chrome, cobalt, cast metals, stainless steel. Non metallic are made of composites and acrylic.

- According to the way of fabrication it is of 2 types: fixed and removable type.
- Based on the location of splinted teeth in the jaw, it is of 2 types: Extra coronal and Intra coronal. Extra coronal splints are stabilizing wire, fiber-reinforced ribbon, fixed orthodontic retainer, right guard and welded bands. Examples of Intra Coronal splints are inlays and nylons wire which make the splint place visible and superior esthetic.
- Based on the duration and purpose:
- **Temporary splinting:** Temporary splinting is used in periodontal treatments for less than 6 months. to reduce unfavorable occlusal forces, anchorage in orthodontic treatment and advanced periodontal disease as a support temporary splinting is used. It can be removable, fixed external and fixed internal. Removable temporary splints are acrylic Hawley, bite guard or night guard. Splint made with acid etchy, self polymerizing resin and composite materials are most popular.
- **Provisional Splints:** For more stabilization like permanent type, diagnostic purposes it is used for several months to a year. It is the phase of restorative therapy for immediate and temporary basis of treatment of teeth with dressing coverage and stabilization. Examples of provisional splinting are ligature wires, night guards, Interim fixed prosthodontic appliances and composite resin splints.[15]

For application of provisional splint, by using 35% Phosphoric acid enamel surface is etched for 10 seconds. Then the surface is wiped with wet cotton or rinsed using water. Then denting bonding agent is applied and polymerized by light. By using a suitable shade of composite the splinting material is placed and polymerized for 40 seconds. The splinting material is ligature wire and glass fiber.

Definitive splint: After the occlusal stability and the periodontal therapy completed, definitive splints are used. By definitive splint occlusal trauma is prevented, Functional stability increases and esthetic is improved.[16]

Conclusion

Tooth mobility is the common cause due to trauma from occlusion and periodontal problems. By eliminating trauma from occlusion cause mobility, bone loss and attachment loss can be reduced. Tooth with poor prognosis rate can be retained in the arch for long term until definitive treatment is planned by splinting. For periodontal maintenance and periodontal therapy splinting has a major role. Splint never eliminates the cause of teeth mobility. It is just a supportive method in the periodontal treatment procedure. To increase the prognosis rate of mobile teeth due to periodontal or other problems. Splinting is considered as an important part of dental treatment based on present data.

Abstract

Thumb sucking is a type of non-nutritive sucking that occurs in the early daysof the 29th week of gestation. Parents should be concerned about the health of their kids. Parents have to look after their children good health who should raisedevoid of developing any behavior that would endanger their suitable development. Thumb sucking is one of the concerned habitsthat makes every parents worry about as their babies grow and grow to be toddlers. Parents keep speculating if the habit will continue, or if they have to look for help to stop it. This review article discusses all the importance of habits related to the oral health of a child and focus on the need of awareness among parents about thumbsucking.

Keywords: *Thumbsucking, Parental Awareness, Management.*

Introduction

Thumb Sucking is also known as Finger/Digit Sucking Habit. This habit is the putting of one more fingers or only one thumb in varying depths of despair into the oral cavity. Moreover thumb sucking is the repeated and forceful sucking of thumb with associated strong buccal and lip contractions.[1] Thumb sucking is a type of nonnutritive sucking that occurs in the early days of the 29th week of gestation. The persistence of such kind of continuous oral habits regularly might be because of various emotional stimuli such as pleasure, sadness, hunger, boredom, hyperactivity stress and various kinds of physical disabilities.[2] These kinds of sucking habits in infants as well as in small children are primarily copied from the physiologic requirement for nutrients and these kinds of behavior are normal in the initial years of life, however, might result in enduring damage if continued beyond this age.[1] The present perceptive of the child growth suggested that sucking behaviors occur and continue because of psychological requirements along with some studies reported that grown-up infants have an inherent biological drive for sucking.[3,4]

Classification of Thumb Sucking[4]:

1. **Cook classification (1958):**
   - **A. ALPHA** Group pushes the palate inside the oral cavity in a vertical direction that displays only a little contraction of the buccal wall.
   - **B. BETA** Group shows strong contraction of the buccal wall as well as a negative pressure in the oral cavity. A posterior crossbite can be seen in the Beta group.
   - **C. GAMMA** Group shows alteration in positive and negative pressure. Among all the groups, the least amount of malocclusion can be seen in this group.
2. **Clinical classification of thumb sucking Clinical classification:**
   - **A. Normal Thumb Sucking:** Habit during first and second year of life is normal.
   - **B. Abnormal Thumb Sucking:** Physiological Habitual
3. **Thumb sucking by O'Brien:**
   - **A. Nutritive Sucking:** Breast Feeding, Bottle Feeding

B. Non-nutritive Sucking: Thumbsucking, Finger sucking, Pacifier Sucking

4. According to Subtelny (1973):

Type A: 50%: Thumb occupies a larger portion of the vault of the hard palate which was kept into the mouth. Thumb is in contact with the maxillary and mandibular anterior.

Type B: 13-24%: Without touching the vault of the palate, the thumb is placed inside the oral cavity. Thumb is in contact with the maxillary and mandibular anterior.

Type C: 18%: As in type A here also thumb passed fully into the hard palate. Contact with maxillary incisors only

Type D: 6%: Thumb retreat appreciably and the lower incisors made contact at the estimated level of the thumbnail.

Thumbsucking is a conduct found in humans, chimpanzees, and different primates. This more often than not includes putting thumb into the oral cavity and rhythmically continuing sucking. During childbirth, an infant will submissively suck anything set in its mouth which is called as sucking reflex in charge of breastfeeding.[3,5] As the child becomes more seasoned and is, in the long run, weaned the dietary sucking, they cancreate elective method to accept equivalent sentiments of physical and passionate satisfaction or they can keep encountering those agreeably mitigating encounters by starting to suck their thumbs or fingers.[1] Thumbsucking by and large stops by 5 years of age.[2] While many dental practitioners suggest bringing an end to the tendency as right, on time as could reasonably be expected, the harm is reversible.[3]

Etiological Factors[4]:

a. The socioeconomic status of the family-related with the parent's occupation.

b. Children of working mothers children get onto sucking habit to attain secure feeling.

c. More number of siblings in a family divides the attention from a child.

d. Scolding parents, as well as peer pressure, leads to stress and social adjustment.

Factors Affecting Thumbsucking: The severity of displacement of the teeth and investing tissue depends on these factors:

a. Duration- the amount of time spent on sucking; longer the duration of each suckling period, the greater is the damage.

b. Frequency of indulgence – number of times the habit is practiced; frequent and continuous sucking is more damaging than occasional, short-time practice.

c. Intensity of force – the amount of force exerted on teeth while practicing the habit.[2]

Apart from these conditioning factors, the type of malocclusion produced also depends on various factors is also mentioned:

a. Location of digit inside mouth

b. Involvement of orofacial muscle contraction

c. Position of mandible during sucking

d. Skeletal pattern of face[2]

Thumb Sucking: Effect on Oral Health: Parents should be concerned about the health of their kids. Parents have to look after their children good health who should become adults without budding any habits that would endanger their proper development. Thumb sucking among all the oral habits, is one of the concerning things that makes every parent be bothered about as their babies grow and become toddlers. Parents speculate if the habit will prolong, or if they have to look for help to stop it. Good advice from a dentist is required for both the child and parents. The good thing is that the habit will more often stop before a child starts going to preschool.[1, 3]

Normal Behaviour: Thumb suckinghabit along with pacifier use is atolerable behavior for infants in the society. As mentioned by the American Dental Association (ADA), this kind of behavior is a natural reflex for an infant that cannot be found in the womb during development. This type of reflex makes the baby feel comfortable, secure as well as happy. Many babies as well as toddlers use it as a recovering mechanism whenever anxious or they get separated from their parents then this habit encourages sleep.[5]

How Long Is Acceptable?: As mentioned by the ADA, the suitable time to discontinue thumb sucking is till age four. By this age, long duration sucking started affecting developing jaw and teeth as a result of which permanent teeth may be misaligned. If a child is a passive sucker then his habit can easily be discouraged whereas

prolonged sucking can result in the occurrence of changes in the palate that impinge on the bite and generally very difficult to quit without doing any intervention.[6]

When continuous habit starts to become physiologically need—in other words, craving starts when something is missing and this is what happens with thumbsucking.[6]

a. Sometimes addictions continue because they might give life-motivating purposes.

b. Since these addictions are gratifying that is why they can continue.

c. It has to take a firm decision before ending any habit.

d. When a habit is motivated by a combination of fear and desire then its ending starts more effectively.

e. To quit any addictive habit all of a sudden is very difficult practically, therefore keeping a record of the progress helps to motivate and reach the goal.

f. Complete blocking of the adaptive habit can help a bit in this process.

g. During the process of quitting the addictive habit, patience and continuous persistence are required.

h. Anything that can replace the habit will surely help in quitting.

Stepladders for Discouraging: Sometimes children will find out on their own onto which time they want to continue their behavior and their habit will not be accepted from any social situations and peer pressure. When the habit of a child sustains beyond kindergarten then steps should be taken to stop the habit.[4]

- A pacifier can be offered to infants, they might easily adapt to this replacement.
- For proper tracking, a chart can be established and rewarded from time to time for seeing the child's progress for quitting.
- A child should always be encouraged and praise for making any attempt to quit his habit.
- It should make sure that parents should visit their dentist about positive as well as beneficial effects of stopping the habit.

Some children may face difficulty in stopping their thumb sucking. In this kind of situation, it may be required to purchase replaceable products that can be placed on the thumb or fingers to discourage the habit. Parents can just be placing a bandage on the finger or socks or glove on the preferred hand is sufficient. Whatever method is chosen to employ to discourage the behavior, positive reinforcement to encourage children should always be used. Criticism or nagging may cause more anxiety and carry on the problem.[3]

Oral Effects: When oral habit keeps on going further age of five or six, the pressure and sucking motion will start to make changes in the oral cavity. As mentioned by the ADA:[7]

a. Front teeth of the upper jaw may come out for which the bite will remain open that will not allow the upper and lower front teeth to touch each other.

b. The skeletal effects of the mouth will start disturbing the alignment of the permanent teeth.

c. The dentist can evaluate the changes and then can give a referral to an orthodontist or pediatric dentist for a consultation.

d. As suggested by NYU's Langone Medical Center, in a very exceptional situation, a dental appliance or a cri**b**, may be required to be placed in the roof of the oral cavity to accomplish a modify in behavior.

e. To Correct the bite itself it is always better to start stopping the habit as soon as possible to get better results.[7]

Insights for Parents: It has been mentioned that 15-20% of children under age 6 engage in thumb or finger sucking habits. Even orthodontists' children suck their thumbs![5]

Below are 4 considerations for parents with a child who engages in thumb sucking. All of the following are evidence-based and established by clinical research, to help the child to avoid dental health problems while building self-confidence associated with overcoming a challenging task.

Impact on Dental and Facial Growth and Development: After age 6 and with the corresponding eruption of the first permanent teeth, sucking habits will begin to have an irreversible negative effect on the development of the jaws, bite relationship, and positioning of teeth. In most cases, the habit will contribute specifically to a narrow upper jaw (causing crossbite), protruded upper teeth (overbite), and a failure of the front teeth to bite together properly (open bite).[1]

Stopping By Age 6 or 7 Will Minimize Most Long Term Effects: In my experience as an orthodontist, I find that most children begin to establish social awareness of thumb sucking around age 5-6 and develop an internal motivation to cease the habit when it is observed that peers at school are not engaged in the habit. Fortunately for children and parents, this period coincides with the time in development at which irreversible negative effects can be prevented. Research has shown that cessation of thumb and finger habits before the eruption of the permanent incisors (central teeth) at age 6 or 7 will prevent lasting negative impacts on the development of the upper jaw and permanent teeth. This key age to stop also aligns with the American Association of Orthodontists' (AAO) recommended age for the initial evaluation of your child (age 7) by an orthodontic specialist.[9]

Techniques for stopping Thumb and Finger Sucking: The single most important aspect in helping a child to stop sucking a finger or thumb is to determine self-motivation. In the clinical setting, I typically begin by simply asking the child if he or she would like to stop the sucking habit. If your child is not ready and motivated, then it is not time to attempt to stop the habit. It will only lead to frustration and negativity. The focus, instead, should be on education. Explaining to your child how it would be helpful to them to stop and point out that others in their social group or class at school may be in the process of stopping. Acknowledging the difficulty in stopping is also very important. For example, if either parent had a sucking habit as a child, explain to your child how you recall how hard it was to stop, but how rewarded you felt once you were able to tackle the difficult challenge.[10]

Once established that the child is motivated, I recommend the following techniques to positively reinforce stopping the habit[3,8]:

1. **Continuously reaffirm the child's self-motivation and goal to stop.** Examples: "That is so great that you set this goal." and "You can do this, we are so proud of you."
2. **Set up a reminder system to help the child stop when the body may be unconsciously initiating the habit during sleep.** This can include sleeping with a glove or band-aid on the sucking hand and using nail polish on the sucking finger (Mavala Stop is one brand name). The goal is not to physically prevent your child from performing the habit, but to help to provide reminders so they canfully stop the habit in a positive, supportive environment. Positive reinforcement is the key.
3. **Use a reward calendar on the refrigerator.** Every full day/night your child goes without engaging in the habit, place a star on the calendar. Arrange for a reward after 14 consecutive days are achieved without the habit. After 14 consecutive days, the chance of relapse of the habit is very small. (Link: I Can Do It Reward Chart)
4. **In many cases, early orthodontic intervention will help your child if he or she is actively engaged in a sucking habit over age 7**. Most often, a constricted (narrow) upper arch and possible associated crossbite will indicate the need for a maxillary expander to orthopedically widen the upper jaw. In this case, this very common appliance will change the dynamics of the thumb habit just enough to serve as a reminder and aid the child in stopping the habit.

Conclusion

Your child will overcome this habit. Your role as a parent is to educate, to motivate, and to provide a positive and supportive environment. Keep in mind that this may be the very first conscious, difficult sacrifice your child makes to improve his or her health and well-being. It must be our goal as adults (parents and healthcare providers alike) to foster self-motivation, encourage that little girl or boy that they are up to the challenge, and celebrate with them when they achieve what they set out to do. Comments like "how am I going to get him to stop" or "she will never stop this" do little to motivate and will undermine the child's self-expectations. This habit should be looked at as a profound opportunity that can be used as a very important confidence builder for a young child. We adults must create an environment that encourages children in our sphere of influence to learn, to set goals, and to succeed- in thumb-sucking and beyond!!

Current Concept of Bruxism and its Treatment Options

Abhilash Mohapatra[1], Gopal Krishna Choudhury[2], Sangram Panda[3], Upsana Dhar[4]

[1]Professor, [2]Professor & Head, [3]Reader, Department of Prosthodontics, Crown & Bridge, [4]Post Graduate Trainee, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In our day to day clinical practice we come across a lot of patients suffering from occlusal parafunctional habits or bruxism. Bruxism can be described as nonfunctional abnormal, involuntary contact of teeth, if ignored it leads to occlusal trauma. So for correct diagnosis and treatment a multidisciplinary approach was required in which dentists, psychiatrists, neurologists and physiotherapists play an important role. Causes for bruxism were multifactorial and the treatment modalities were also various. Bruxism can be a major concern for the dentist as they were required to not only diagnose but also intervene in most of the cases of bruxism. And if untreated it leads to destruction of dentition, muscle fatigue & temporomandibular pain. This article discusses the history of the current concepts in the diagnosis and treatment of bruxism.

Keywords: *Bruxism, Sleep hygiene, Splint, Pharmacological, Contingent electric stimulation cure (CES).*

Introduction

Parafunctional habit bruxism has always been amajor concern for dentistsas it causes tooth attrition, fractured restoration, muscle soreness & TMJ pain. In common population bruxism ranges from 8-31% and 14-20% in children[1]. Bruxism was very rarely found in patients above 60 years of age[1]. Usually bruxism does not cause any serious complications in most of the patients, and they seek treatment only if heexperiences unbearable pain. Hence a proper diagnosis and multidisciplinary approach were required for the management of bruxism.

Marie and Pletkiewicz[2] coined the term "bruxomania" from the French word "la bruxomanie,". The term bruxism was coined Frohman[3]. Vanderas defined bruxism as the movement of the mandible which was non-functional and waswith or without an audible sound occurring during the day or night[4]. According to GPT 9, bruxism was defined as "the parafunctional grinding of the teeth; an oral habit consisting of involuntary rhythmic or spasmodic non-functional gnashing, grinding, or clenching of teeth, in other than chewing movements of the mandible, which may lead to occlusal trauma".

Bruxism can be classified into diurnal bruxism or awake bruxism and nocturnal or sleep bruxism. Bruxism during day time was known as awake bruxism and in night time was known as sleep bruxism. Awake bruxism was always related to stress, work pressure, & anxiety. Diurnal bruxism was more common in females than males. Whereas, sleep bruxism was considered as a sleep-related movement disorder. Sleep bruxersusually have sleep disorders like snoring and sleep apnoea. No gender difference was found in nocturnal bruxor. But it more prevalent in small children than in adults.

Figure 1: Causes of bruxism

Cause of bruxism:

- Central factors: As describe byMacaluso et al[5] bruxism was closely associated with an arousal response. And arousal response was defined asa sudden change in the depth of the sleep and it was associated with body kinetics, escalated heart rate, respiratory changes and increased muscle activity. In bruxism patients the five subcortical nuclei of basal ganglion were not in co-ordination[6].
- Psychosocial factors: A highly stressful life was a significant risk factor for bruxism. And intoday's prevalent social environment the inability of a person to reveal emotions such as apprehension, despise, & aggression leads to bruxism. And diurnal bruxism was associated with psychological tension due to responsibility & work pressure.

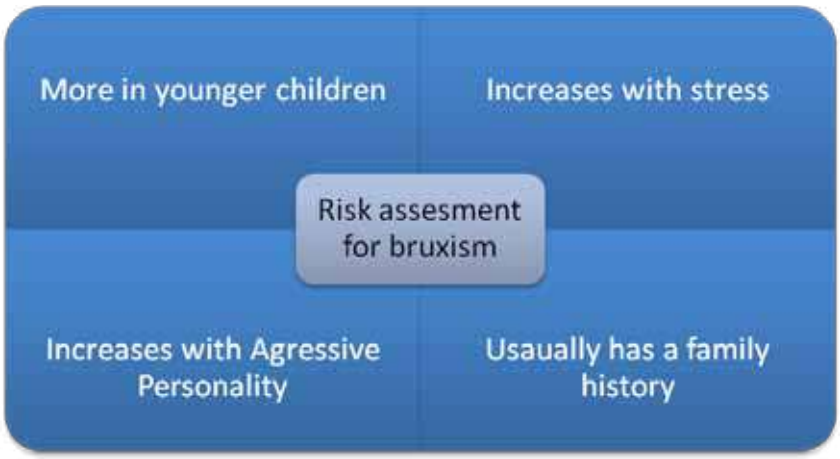

Figure 2: Risk factors for Bruxism

For a patient with bruxism clinical assessment and detection was the most important step in treatment. Because if it were left unattended it leads to depreciation of quality of life. As on long term basis bruxism leads to occlusal disharmony, TMJ disorder and damaged tooth[7]. The assessment method for bruxism were questionnaire form, scientific clinical evaluation, and electromyographic recording. In questionnaires assessments done were subjective and questions asked were related to signs and symptoms of soreness in gums or headache after waking up. It should be asked to parents, siblings or wife if they have heard patient grinding teeth. As for the dental clinic of North American the clinical evaluation[8,9] of bruxism can be done by taking a detaileddental history of the patient and evaluating the periodontal status, occlusal wear facets on teeth and abnormalities of TMJ[10].

Korioth et al. reported asymmetric occlusal wear out of stabilizing splint when used in sleep bruxism patients[11]. Forgione gave the Bruxcore Bruxism Monitoring Device (BBMD) to measure the nocturnal bruxism activity[12]. Takeuchi inventedan intra-splint force detector (ISFD) and it intraorally records the force being produced by tooth contact on the appliance during bruxism[13]. But the most tried and tested method of recording bruxism without any intraoral instruments were masticatory muscle electromyographic[14]. In a recent development a miniature self-contained EMG detector-analyser (grindcare, medotech Denmark) was developed to record biofeedback in sleep bruxorsby just attaching it to masticatory muscle. The EMG detector analyzer works by recording of EMG activity of the masticatory muscle, and then processing the EMG signals to detect tooth gnashing and clutching and give biofeedback stimulation for reducing sleep bruxism activities[15]. Sleep laboratory was another new advancement to detect sleep bruxism, in a controlled environment where brain waves heartbeats and breathing rate while sleeping were recorded. Simultaneous audio-video recordings were used to record any eye movements, limb movements and any deviation in the sleep pattern of the patient. Sleep disorders like sleep apnoea and insomnia were ruled out and sleep bruxism was diagnosed by this procedure. The major limitation of the sleep laboratory wasthat due to change in the environment of the patient the normal sleep pattern cannot be observed in some patients[16,17].

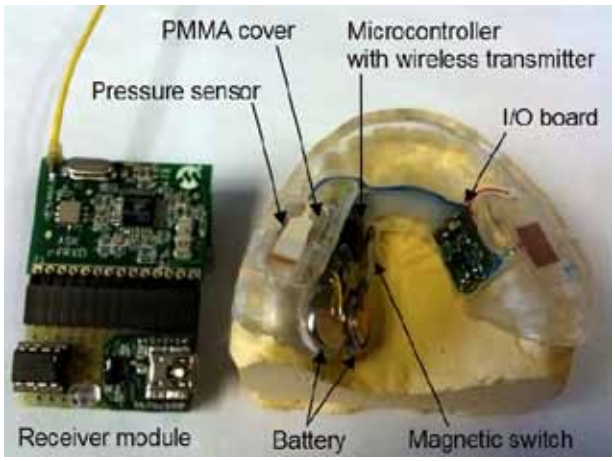

Figure 3. Contingent electrical stimulationapparataus

Table 1. Signs & Symptoms of bruxism

1	Iatrogenic sensitivity to heat and cold of the tooth
2	Muscle pain due to intense contraction in the morning.
3	The sound heard by parents and relative when the teeth were ground together
4	An uneven tooth wear with exposure of dentine
5	Micro-fractures on the tooth enamel
6	Fractured or broken teeth
7	Periodontally compromised teeth
8	Pain in the temporomandibular joint and restricted mouth opening
9	Earache

Effects of Bruxism on Fixed prosthesis: The effect of bruxism on prosthodontic restoration like single, multiple and full mouth rehabilitation was mechanical failure. The fracture of ceramic material and dislodgement of the crown was the most common failure in bruxors. Metal or metal-ceramic restorations seem to be the safest choice of prosthesis in cases of high load conditions[18]. But due to the risk of fracture of ceramic veneers in metal-ceramic restorations, many clinicians prefer metal crowns for heavy bruxors. The material of the present period zirconia, which has excellent strength,aesthetics,and claims mechanical property almost similar to metal crowns(International Journal of Applied Dental Sciences Zirconia) has been used in bruxers[19,20]. But on clinical use it has been found to have complications of fracture of veneered part[21]. So in bruxism patient's monolith zirconia crown should only be used.

Effect of bruxism on implant restorations: Bruxor who have implant prostheses were at a risk of loss of osseointegration. But systematic reviews have concluded that there was no relationship between occlusal forces and loss of osseointegration[22,23]. Studies by Elfelt A, De Boever AL have indicated that there was a higher rate of complication on superstructures of removable and fixed implant-supported prosthesis in bruxism patients[24.25].

Effect of bruxism on dentures: Inpatient wearing complete or removable partial denture the most common clinical problem was the soreness of denture bearing area. But there was no systemic review on the effect of bruxism in the partially edentulous patient and its effect on residual dentition and denture bearing tissue.

Current Treatments of Bruxism: To treat bruxism, we not only have to treat the effect of it but also eradicate the cause.

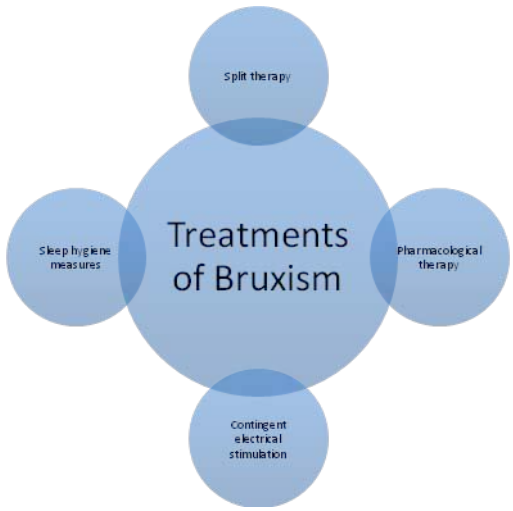

Figure 4: Treaments of Bruxism

1. **Sleep hygiene measure:** The term sleep hygiene means counseling the patient to ensure less physical and cognitive activity before retiring to bed. And to doze off within minutes of going to bed, the patient has to ensure a quiet and dark environment in the bedroom. In one randomized clinical trial it was found that there was no clinically significant difference between patients using sleep hygiene and control group[26]. But reducing the consumption of coffee, alcohol and tobacco had a positive effect on patients with sleep bruxism[27].
2. **Occlusal therapy:** The first line of treatment of bruxism was occlusal splints. These reduce the pain and prevent tooth wear inpatient with sleep bruxism. They were classified into hard splints and soft splints.

Okeson[28] had preferred hard splints over soft splints because soft splints were difficult to adjust than hard splints. It was found hard splints to be more effective in reducing the bruxism activity. But in a study by Madani et alfounda similar reduction in muscle activity associated with sleep bruxism after 2 months of therapy[29] in patients using occlusal splints and in patients taking medication gabapentin.

3. **Pharmacological therapy:** In a randomized clinical trial done by Mohamed et al. for evaluating amitriptyline in patients with sleep bruxism and temporomandibular disorder, found no changes in pain and masseteric muscle fatigue[30]. But in contrast to a study by Lobbezzo et al, it was found that levodopa used in bruxorsreduced pain and bruxism in 70% casein comparison to placebo[31]. In some patients with psychosomatic disorder, when clonazepam was given, it reported to reduce sleep bruxism along with increase REM sleep[32]. But to recommend clonazepam with clonidine (a α_2 adrenergic agonist used in hypertensive patient[33]) in routine clinical practice more randomized control trial on a bigger population has to be done.In recent studies Shim et al[34] used muscle relaxant botulinum toxin type A injection to treat masticatory muscle in sleep bruxism patients and found to reduce the amplitude of contraction in patients but there was no difference in number of contraction. Pathophysiology of botulinum toxin was inhibition of acetylcholine at the neuromuscular junction. So a more randomized control trial of botulinum toxin and placebo has to be done to recommend it in clinical practice.

4. **Contingent electrical stimulation:** In an attempt to treat bruxism contingent electrical stimulation(CES) has been tried by a lot of scientists. In this low-level electric stimulation was applied on the muscles when they became active i.e. during bruxism episode. Two studies were done on patients with myofascial pain and nocturnal bruxism, and it was found that EMG episode was reduced but no reduction in muscle pain[35,36]. So CES was found to reduce the sleep bruxism while in use but was not able to reduce it after discontinuation. So long term studies have to be done on CES and CES versus TENS and its effectiveness if done in combination.

Conclusion

The most common parafunctional habit was bruxism, which can occur during wakefulness and sleep. Usually the patient comes for treatment when there were in pain and discomfort. The side effect of bruxism was progressive dental wear, so to improve the quality of life, full comprehensive treatment has to be done. The etiology was multifactorial and there was no specific treatment option to reduce the effects of bruxism. Treatment has to be multidisciplinary with counseling and behavioral strategies, splint therapy, medication and contingent electrical stimulation. But all the treatments have shown mixed results in various patients. So clinical judgment was most important to treat symptoms and prevent tooth wear, reduce tooth grinding and improve muscle discomfort. So long term studies including a wide variety of bruxism patients and comparing the effect of different treatments on all of them has to do.To helpa clinician known when to treat the patient and when to leave it alone to resolve by itself.

Abstract

Oral squamous papilloma (OSP) specifies the non-neoplastic proliferation of stratified squamous epithelium giving rise to a verruciform or papillary growth on the surface of the oral cavity. Usually asymptomatic, OSP presents as soft tissue growth of the oral cavity exhibiting various clinical manifestations. Human papillomavirus (HPV) commonly HPV types 6 and 11 are believed to be the causative agents even though not detected in some lesions. Found in 4 of every 1000 individuals OSP ranks fourth among the common oral mucosal mass. It has equal predilection for both male and female and occurs within the age group of 30 to 50 years. Its clinical appearance imitates exophytic carcinoma, verrucous carcinoma or condyloma acuminatum raising concern amongst the patient as well as the dental surgeon. OSP measures up to one centimetre or so in diameter, but here we present a case where the lesion measures up to 5 centimetres in diameter along with review of literature.

Keywords: *Oral squamous papilloma, human papillomavirus, exophytic growth, koilocytes.*

Introduction

Oral squamous papillomas are generally benign, asymptomatic, exophytic growth in the oral cavity present in the form of numerous small finger-like projections which results in roughened, verrucous or cauliflower-like surface. Human papillomavirus (HPV) commonly incriminated as the causative agents in skin warts are mostly related to its pathogenesis. HPV type 6 and type 11 are commonly associated but have failed to be demonstrated in oral malignancies.[1-4]

The World Health Organisation (WHO) has defined papilloma as "a range of localized hyperplastic exophytic and polypoid lesions of the hyperplastic epithelium with a verrucous or cauliflower-like morphology".[5]Among the most common oral mucosal masses squamous papilloma ranks fourth. It is found in 4 of every 1000 individuals[4] and is frequently seen between the age group of 30 to 50 years [1]. Hormonal changes, deficiency in the diet, smoking and secondary residing infections influence the occurrence of these lesions[6]. Commonly affects the soft palate tongue and occasionally seen on the vermilion border of the lip and uvula.[1,2,7] Size of oral squamous papilloma commonly measures from few millimetres to one centimetre but bigger size lesion has also been documented in the literature.[8-10]

Ideal treatment is excision or laser ablation with the base of the mucosa into which the stalk or pedicle of the papilloma is inserted. Electrocautery, cryosurgery and injections of interferon into the lesion are some of the other treatment techniques. Frequently recurs in patients

infected with human immunodeficiency virus (HIV) else if properly excised recurrence is rare.[7] Though HPV lesions are infective, squamous papilloma appears to have very low virulence and infectivity.

In this article, we are presenting a case of Oral Squamous Papilloma with an unusual size and clinical looks mimicking carcinoma, along with review of the literature.

Case Report: 65-year-old male patient reported to the department with the chief complaint of an ulcerated growth in the left buccal mucosa. The ulcerated growth extended from the commissure of the lip till the retromolar area. The lesion has been present for 6 months. The patient gives a history that the lesion started as an asymptomatic slowly enlarging soft tissue mass eventually reaching the present size. As the lesion enlarged there was intermittent pain, discomfort and interference while chewing. The past medical and dental history of the patient is not significant. The patient was well oriented with no significant general findings and the extra-oral examination was also non-contributory. The patient has a habit of tobacco chewing from 20 to 25 years.

Intraoral examination revealed a big size exophytic lesion in the left buccal mucosa extending from the lip commissure till the retro-molar area not involving the sulcus. The lesion was pink and white in colour, sessile in nature with pebbled surface and papillary projections at places. The lesion measured approximately 5x2 cm and well-circumscribed [Figure 1]. The lesion was firm in consistency and there was bleeding on palpation. The submandibular lymph nodes on the left side were palpable and tender.

Based on the history given by the patient and clinical features a provisional diagnosis of verrucous carcinoma and carcinoma of the left buccal mucosa were given.

Under local anaesthesia,an incisional biopsy of the lesion was done along with the submucosa to a depth of one millimetre and sent for histological examination. Histological examination showed stratified squamous epithelium thrown as finger-like projection towards the surface with long slender fibro-cellular connective tissue core reaching very high in it [Figure 2]. Very few cells resembling koilocytes are seen in the stratum spinosum [Figure 3]. Minimal amount of chronic inflammatory cells are diffusely arranged in the moderately vascular connective tissue stroma. Histological picture was compatible with squamous papilloma. Excision biopsy was done with surgical removal of the lesion in toto along with the submucosa to a depth of one millimetre. Histological picture of the excisional biopsy again confirmed oral squamous papilloma.

The uniqueness of this case report is the size of the lesion which is unusually big and its clinical look mimics a malignant lesion. Literature says maximum size that a papilloma reaches is up to 0.5 cm with no subsequent alterations. However oral papilloma measuring up to 3 cm has also been reported[10]. In our case, the lesion is about 5 cm in its maximum length which is first of its kind to be reported. Though the look of the lesion is deceiving but both incisional and excisional histopathological report confirmed the lesion to be benign and oral squamous papilloma.

Discussion and review of literature: A papilloma (plural: papillomas or papillomata) is defined as a small firm non-neoplastic growth of the epithelium with a well-defined boundary that extends out above the neighbouring tissue[11]. The generic term *oral squamous papilloma* specifies a benign proliferation of stratified squamous epithelium giving rise to a verrucous exophytic growth or papillary growth on the oral mucosal surface with minimal amount of connective tissue core.

Aetiology: Oral squamous papilloma was first described by Tomes in 1848 as a wart limited to the gum and Human Papillomavirus (HPV) type 6 and 11 are the causative agents. They have low infectivity rate and are less virulent which is why squamous papillomas are always benign. The pathogenesis in the development of papilloma lies in that the double-stranded DNA of the virus merges with the host DNA.

Incidence and Occurrence in Oral Cavity: The incidence rate of SP is 4th among all the mucosal growths in the oral cavity and 1 in every 250 people exhibit oral squamous papilloma. Oral squamous papillomas make 3 to 4% of all the oral soft tissue biopsies and are most commonly seen within the age group of 30-50 years. Males and females are equally affected. Some literatures have documented OSP among children and it constitutes 7 to 8% of all oral mucosal growths. Whites are more affected than the black population. Generally, the lesion appears on the tongue, soft and hard palate, gingiva, buccal, labial or lingual mucosa and near uvula too.Oral squamous papilloma is the most common of all the soft tissue growths arising in the soft palate.[12,13] There are

certain notable differences between papillomas arising in the other body parts and papillomas of the oral cavity. Though benign OSPs have a higher neo-plastic potential compared to other papillomas if not properly excised they have a relatively higher frequency of occurrence and recurrence compared to other papillomas.[14,15]

Clinical features: Clinically OSP often is a solitary lesion presenting itself as an exophytic soft-tissue growth with a verrucous, roughened or cauliflower or wart-like surface. There are presence of many papillary projections on the surface or maybe blunted. The lesion is occasionally sessile and often pedunculated and has well-defined border. Depending upon the amount of keratinisation the lesion appears pink or white and is usually asymptomatic. Presence of trauma imparts red colour to the lesion. Generally size of the papillomas ranges from a few millimetres to less than one centimetre but big size papillomas have also been documented.[8-10]

Clinical Differential Diagnosis: When oral squamous papilloma is a single solitary lesion differential diagnosis includes *papillary hyperplasia, condyloma acuminatum* and *verruciform xanthoma.*[10] Gingiva and alveolar ridge is the specific site of occurrence for verruciform xanthoma. A causal-and-sequence relationship (for example: pathology under an ill-fitting denture) is blatant in *inflammatory papillary hyperplasia*. Condyloma will be bigger than the papilloma with a wider base and colour will be from pink to red due to lesser keratinization. Multiple squamous papillomas specify *focal epithelial hyperplasia (Heck disease*).[7] The other lesions suggested in the differential diagnosis include *nevus unius lateris, acanthosis nigrans, focal dermal hypoplasia (Gorlin-Goltz syndrome)*.

Histopathology: The histological description of squamous papilloma is a non-neoplastic proliferative exophytic or verrucous tumour which is lined by *stratified squamous epithelium* with organised stratification and showing acanthosis. Histopathological archetype put forward by Oliveria et al comprises papillary-like outgrowth of stratified squamous epithelium with usual maturation of cells and epithelium showing hyperparakeratosis. There is presence of Koilocytosis in which the cells of the spinous layer show perinuclear cytoplasmic vacuolisation and pyknosis. Occasionally basilar hyperplasia is noticed. The connective tissue stroma is fibrovascular and presence of mild degree of inflammation.[8,16,17]

Laboratory Diagnosis: Electron microscopic analysis can detect the viral particles. Immunohistochemistry, in situ hybridization and polymerase chain reaction (PCR), are the other laboratory techniques for identification of the virus.

Immunohistochemistry: There is over expression of *Tumor protein (TP53), Proliferating cell nuclear antigen (PCNA), Cell-surface glycoprotein (CD-44 involved in cell-cell interactions, cell adhesion and migration)* and*B-cell lymphoma 2)Bcl-2)* in case of neoplastic alteration and papillomas with epithelial dysplasias.[18]

Treatment: The ideal treatment is complete surgical extirpation of the lesion along with one-millimetre clearance around the base and one-millimetre depth into the submucosa. Very small sized squamous papillomas are excised using Liquid nitrogen and Lactic acid having keratinolytic constituents.[19]

Figure 1: clinical presentation intra-oral: exophytic lesion in the left buccal mucosa extending from the lip commissure till the retro-molar area

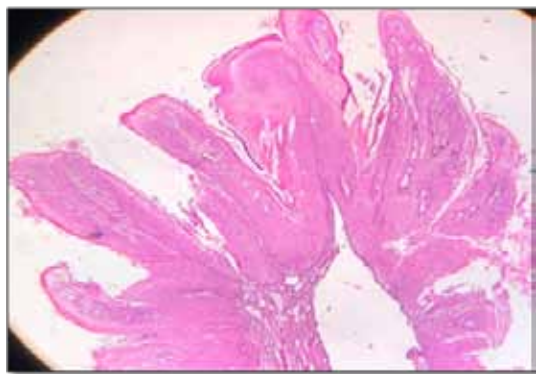

Figure 2: photomicrograph 4x: illustrates many finger like projections each made up of a continuous layer of stratified squamous epithelium and containing a thin, central connective tissue core

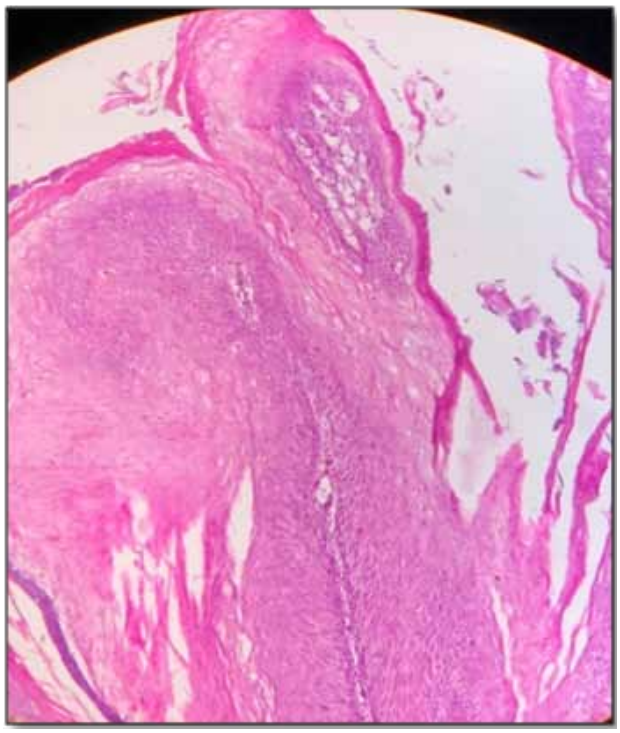

Figure 3: photomicrograph 10x: presence of hyperkeratosis, proliferation of spinous layer in a papillary pattern

Conclusion

The size and clinical features of papilloma presented here is very rare and mimics malignant lesion of the oral cavity through histological features confirmed otherwise. Papillomas in other regions have shown neoplastic transformation hence the potential neoplastic nature of squamous papilloma should be researched and explored.

Abstract

The prosthetic rehabilitation in temporomandibular disorders is a challenging task, This article reviews about the present condition and provides the data regarding the treatment needs of the TMD patients and what approach should be followed the practitioner. There has been tremendous development in Evaluating through MRI, it was inferred that the splint therapy through various means reduced the risk of the temporomandibular disorders by eliminating the etiological factor. Furthermore it allowed the patient to cope with the disease such as disk displacement with greater tolerance rate. Moreover, after treatment the patients are likely to cope with disc displacements with larger or smaller tolerance.

Keywords: *Temporomandibular Joint, Pain, Muscles of Mastication, Stabilization Appliance.*

Introduction

Temporomandibular disorders (TMD) is a vast term that deals with various clinical conditions and their pathology comprising of the masticatory muscles and/or temporomandibular (TM) joints and associated soft and hard tissue[1]. The Temporo-mandibular joint is a load bearing joint which entails the condyle, mandibular bone and the fossa eminence of the temporal bone separated by a fibrocartilaginous disc. The clinical conditions associated with the temporomandibular joint diseases were characterized by preauricular pain, pain the Temporomandibular joint area or soreness of muscles of mastication; limitation or deviation in mandibular movement and TMJ sounds[2] (clicking, popping, and crepitus) upon various activities . Symptoms most often found in the patients includes head ache, neck ache, face ache and ear ache .In clinical scenario the TMD are the most intractable problems. The primary approach in the TMD management is controlling the pain.[3,4] The clinicians should be cautious while diagnosing TMD in patients.

The diagnosis of TMD is based upon the chief complaint, past history that patient gives, thorough clinical intra and extra oral examination and the physical examination this helps in formulation of a diagnosis for the disease[5]. Most common findings that the patient present with are faulty mandibular movement,pain of masticatory muscles, pain on loading, signs of bruxism, and neck or shoulder muscle tenderness[6,7]. If there is presence of any certain type of malocclusion then the practitioner should address the problem. Crepitus, clicking, locking of the TMJ is accompanied with the joint dysfunction . Such as, if a single click Is heard during mouth opening, it can be associated with the anterior disk displacement[8,9]. But if there is a second click upon closing of mouth, then it is associated with disk displacement with reduction[10] with the progression of the disc displacement,the patient is not able to open the mouth (closed lock. The crepitus most often associated with the articular surface disruption that occurs in patient with osteoarthritis.[11,12]

Radiographic evaluation and Imaging can help in the diagnosis of TMD when we don't get much information form the physical examination and the history of the patient[13] . Plain radiograph such as an lateral cephalogram or orthopantograph can be used assess the joint area. CTscans are more superior which used for the evaluation of subtle bony morphology.[14,15] False positive findings occur in 20% to 34 %of asymptomatic patient . MRI is mostly done for patients with continous symptoms, those in whom conservative treatment approach was not effective, or in patients with internal disk derangement[16,17] when the MRI is not available, then the Ultrasonography can be used which is anon invasive procedure and is cost effective to diagnose the internal derangement of the TMJ[18].

Types of Oral appliance for Treatment of TMD:

Stabilization Appliance: It is a rigid appliance usually fabricated using acrylic and generally fabricated in the maxiilaryarch. It is fabricated in the centic relation so when the appliance is placed the jaws are separaed by 2 to 3 mm and the condyle is brought in centric relation. It eliminates any instability and other causative factors for TMD and improves the condyle fossa relationships[19].

Indications: It is used in the treatment of muscle pain disorders .Wearing it decreases the parafunctional activity. In cases of muscle hyperactivity such as bruxism, local muscle soreness, myalgia, retrodiscitis a stabilization appliance is considered.[20]. This appliance minimizes forces that damage tissues, thus efficiently improves the healing.[19]

Simplified Fabrication Technique:

Fabricating the Appliance: A clear sheet of resin is adapted to the maxillary cast . The lingual extension is about 10 to 12 mm from the gingival border runs throughout the lingual portion of the arch. Thelabialy it is extends upto the junction between the incisal and middle thirds of the anterior teeth. A small anterior stop is fabricated in the anterior region and the patient is made to bite on it in Centic relation. This procedure is repeated till the centic relation is obtained and the area is grooved using a round bur. Self cure acrylic resin is mixed and placed over the appliance except in the anterior stop area and the patient is made to bite in centric relation .After the acrylic sets it is removed and is polished.[21]

Anterior Positioning Appliance: It that encourages the mandible to be positioned anteriorly.. It is useful for the treating disc derangement disorders . It alters the position of mandible for short duration and thus It provides a better condyle-disc relationship and provides time for tissue repair and adaptation of retrodiscal tissues. After the tissue are adaptated, the usage of appliance is eliminated.[22]

Indications: It is used mainly in the treatment of disc displacement with reduction, joint sounds, Intermittent or chronic locking of the joint and few inflammatory disorders.

Simplified Fabrication Technique: It is also a hard acrylic device similar to stabilization appliance, that can be used in either arch. As a maxillary guiding ramp, helps in positioning the mandible, it is usually preferred over the mandibular arch.[22]

Fabricating and Fitting the Appliance: The initial steps inthe fabrication of a maxillary anterior positioning appliance are similar to that of fabrication of a stabilization appliance. A anterior stop is fabricated on maxillary central incisiors. The patient is asked to open the mouth widely and asked to close the mouth in forwarded position and the joints are evaluated for the symptoms. This step can be repeated and verified. Once the forwarded position is confirmed a groove is made in this position.[21] This groove helps in positioning of the mandibular incisiors . The appliance is placed in the mouth to the mouth with self cure acrylic resin on it except in the areas of anterior stop and the patient is made to close the mouth in the setting acrylic in the determined position

Adjusting the Occlusion. Excess of acrylic is removed, smoothened and polished using hard rubber wheel. A well fabricated appliance allows even and smooth contact of all the teeth in the desired position.[20] Flat occlusal contacts are developed for the posterior teeth, The appliance is returned to the mouth, and the patient closes in the forward position. Sound contact is checked using red articulating paper that should be visible on all cusp tips.

Anterior Bite Plane: It is a hard acrylic aplliance with contact is provided in the anterior region only without any contact in the posterior region[22].

Indications: It is used in the conditions of orthopedic instability causing muscle disorders or in cases of an acute change in the occlusal condition . Parafunctional activity is also treatablefor short

duration. Main disadvantage of this appliance is, if it is used for long time, it may cause supraeruption of posterior teeth leading to anterior open bite. It must be carefully observed during the treatment procedure and should be used only for short periods. similar results can be obtained using stbilizationappliance. More recently a device has been designed with similar cocepts of anterior bite plane to reduce the incidence of heeadache. It was marketed in the name of by its inventor the Nociceptive Trigeminal Inhibition Tension Suppression System (NTI TSS) or NTI[23]. It allows contact in the central incisiors. The initial studies showed that the NTI was only slightly more effective when compared to standard appliance therapy in reducing the headache

Posterior Bite Plane: It is a hard acrylic constructed usally in the lower arch in the posterior region connected by lingual bar.

Indications :They have been used in the cases of severe loss of vertical dimension or when severe changes are desired in the forwared positioning of the mandible It is also used as a protective appliance by athelets in few cases .However there is no scientific evidence for this . It helps in supra eruption of unapposed teeth or intrusion of apposed tooth. it is used in some cases of disc derangement however not much studies are present to support the fact[24].

Pivoting Appliance: It is a hard acrylic device that provides contact usually in the second molar region which act as a fulcrum and pivot the condyle in downward and backward position away from the fossa.

Indications . It was thought that it unloads the joint and provides time for tissue repair., It was used in the treatment for joint sounds. It is possible only if forces are located anterior to the pivot. As elevator muscles are present posterior to the pivot it does not allow pivotingaction. Anterior positioning appliances much more capable of as it provides better control in positioning the mandible[22].

However there are very few scientific studies that supports the success of treatment using this pivot appliance .In fact anterior positioning appliance has much more therapeutic value compared to the pivoting aplliance and is usually not used for the treatment clinically.

Soft or Resilient Appliance: It is usually made up of Resilient material that is adapted to the maxillary archto achieve even and simultaneous contact.[24]

Indications: It is usually indicated in athletic sports person to protect the teeth and tissues from damage due to trauma . But less studies are available regarding this. It is usually recommended in patients exhibiting clenching and bruxism. However soft appliances have not been shown to decreasebruxing activity. It is also recommended for patients suffering from repeated or chronic sinusitis resulting in sensitive posterior teeth due to heavy occlusal forces[24].

Conclusion

This paper is designed to give the dental practitioner an overview of splint treatment in the management of temporomandibular disorders. It is impossible to be definitive or prescriptive unless the TMD diagnosis has been made and it is not the remit of this paper to cover such diagnosis[24]. The overall benefits of splint therapy should not be underestimated a major benefit is that if splint therapy is beneficial if proper diagnosis is made and proper fabrication and regular follow-up done.

Conflict of Interest: There is no conflicts of interest.

A New Pioneering Advancement: Waterlase

Rinkee Mohanty[1], Bhagyashree Lenka[2], Rashmita Nayak[3], Anurag Satpathy[3], Abhaya C. Das[4], Gatha Mohanty[5]

[1]Professor & Head, [2]Postgraduate Trainee, [3]Professor, [4]Reader, [5]Senior Lecturer, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The Waterlase™ is a trailblazing tool for dentists which is an amalgamation of laser energy and water. This process is known as Hydro Photonics. This tool is proficient to perform many conventional dental procedures with less need for anesthesia. Hard and soft tissue can be cut using Waterlase without applying heat, vibration or pressure. The dental operator may easily carry out the procedure in the absence of anesthesia. Waterlase laser decreases post-operative bleeding, pain and swelling and the need for pain medication in many cases. It has been used for a variety of therapies such as hard and soft tissue procedures including caries removal, cavity preparation, endodontic therapy, designing and correcting smile, frenectomy, gingival excision, gingivoplasty, curettage, vestibular deepening, operculum excision, crown lengthening, flap surgery, and osseous surgical procedures,etc.

Keywords: *Waterlase, Lasers, Hard tissue therapy, Soft tissue periodontal surgery.*

Introduction

The diseases of the periodontium comprise of a group of inflammatory diseases. It is commenced by microbes that colonize the teeth and spread infection. Earlier, the local factors causing periodontal diseases were eliminated by the hand instruments and ultrasonic scaler.[1] However, calculus and plaque removal using traditional method has been considered to be insufficient and taxing.[2] For enhancing the usefulness and efficacy of debriding the root surface, different devices have been tried such scalers both ultrasonic and sonic. Recently lasers also have been used for the same.

Laser: Laser is the **acronym** for **L**ight **A**mplification by **S**timulated **E**mission of **R**adiation. It generates electromagnetic wave. The heat released by the laser converts the electromagnetic energy into thermal energy. The laser follows the principle first given in 1917 by Albert Einstein. He proposed that light consists of mass-less particles called photons. The energy of the photons corresponds to the wave's frequency. As the frequency increases, the energy carried by the waves becomes greater. This is the principle of laser. Charles Townes and co-workers first demonstrated the action of laser in the microwave region for which he was later awarded the Nobel prize. A beam of ammonia molecules was passed through a system of focusing electrodes. Amplification occurred when a microwave was sent through the cavity at an appropriate frequency. This was termed microwave amplification by stimulated emission of radiation (M.A.S.E.R.). The term laser was first coined in 1957 by physicist Gordon Gould a physicist in 1957 who coined the term laser. The first Laser beam was generated in 1960 by Theodore H. Maiman at Hughes Research Laboratories. It is a solid-statelaser, that uses a pink ruby crystal. It is encompassed by a flash tube enclosed within a polished aluminum cylindrical cavity. It is cooled by forcing air through it.

Parts of laser:

Laser comprises the following constituents:

1. Laser medium- Can be in any state gaseous, liquid, or solid.An external energy source was passed through it.
2. Resonating chamber- It is a tube with two reflecting mirrors. One mirror is completely reflective, the other one partly transmitting light. Both are placed at either side of the optical cavity.

3. Power source- It pumps the atoms in the laser medium so that they can attain higher energy levels. It is either mechanical, optical or chemical source of energy.

Three factors are essential for the characteristics of the laser light:

1. Composition of the laser medium,
2. Energy source, and
3. Design of the resonating chamber.

Characteristics of laser: When an excited atom is stimulated to emit a photon spontaneously it results in the release of a subsequent photon. A monochromatic, collimated and coherent form of light is produced by the energized emission. This laser light on contacting the tissues gets reflected, scattered, absorbed ortransmitted to the surrounding tissues. The free water molecules, pigments, proteins and other macromolecules present in the oral cavity are the reason for photonic absorption in the mouth. This absorption causes an intracellular or intercellular change in the tissues. Shorter wavelengths of 500- 1000nm are readily absorbed in blood elements and chromophores. The Argon lasers are highly diminished by hemoglobin. The Diode lasers and Nd: YAG lasers have an increased affinity for melanin. Longer wavelengths interact more with H2O andhydroxyapatite molecules. The maximum absorption for H2O is just under 3000 nm for Er: YAG laser. At 10,600 nm CO2laser has the maximum affinity for hydroxyapatite and water.

Different wavelengths can be classified as:

1. The ultraviolet spectrum i.e. 100- 400 nm
2. The visible spectrum i.e. 400-700 nm
3. The infra-red spectrum i.e. 700 nm to the microwave spectrum

Depending on the wavelength Lasers can be of two types:

(i) Deep penetrating ones, such as Nd: YAG and diode. The laser light enters deep into the tissues and scatters.

(ii) Superficially absorbed ones, such as CO2, Er: YAG and Er, Cr: YSGG lasers. The laser light gets absorbed in the superficial layers. It does not penetrate or scatter deeply.

Various periodontal laser procedures: Laser has proved to be an effective device in the recent dental practices. It has not only increased efficiency, and specificity but has also enhanced the ease and comfort of carrying out dental treatment at minimal cost. A few of the uses and applications of specific lasers in different treatments are mentioned below.

Table 1. Uses and applications of specific lasers in different treatments

	Er:YAG 2940nm	Er,Cr:YSGG 2780nm	KTP 532nm	Argon 488 and 515nm	Diode 810-980nm	Nd:YAG 1064nm	Helium-neon 633nm	Diode 635, 670 or 830nm	CO_2 10600nm
Calculus removal	✔								
Periodontal pocket disinfection	✔	✔	✔	✔	✔	✔			
Photoactivated dye disinfection of pockets							✔	✔	
De-epithelialization to assist regeneration	✔	✔							✔

Effect of lasers on bacteria and calculus: Most laser bactericidal studies reported that when the density of the energy is enhanced results in decreased bacterial load. Cobb CM et al 1992 reported that a decrease in period onto pathogens followed by the use of Nd: YAG laser shows reduction in *P.gingivalis, P. intermedia and A. actinomycetemcomitans*. However, recolonization of multiple morphotypes of bacteria was observed postoperatively in laser-treated subgingival root surfaces Moritz et al (1997) proposed that Er: YSGG laser in

adjunct to SRP enhanced healing of periodontal pockets. Aoki et al (2000) suggested that Er: YSGG laser has the proficiency to remove calculus which is at par with ultrasonic scaling.[3-5]

Latest Developments:

Periowave™: Periowave™: It is a system that is based on the principle of photodynamic disinfection. It uses non-toxic dye (photosensitizer) along with a low-intensity laser. This enables singlet oxygen molecules to eliminatemicrobes. Each site requires only one minute of laser activation, making it a swift and painless treatment(6).

Waterlase: Er, Cr: YSGG (Erbium-Chromium doped: Yttrium-Selenium Gallium-Garnet) laser is available commercially as Periodontal Waterlase MD™ and The Waterlase® C100 It utilizes a patented amalgamation of laser energy and water to perform various dental procedures. It is so precise that the dentist can restore the teeth, gums, and bones without damaging the surrounding structures.

What is Waterlase dentistry?: This dentistry is an alternative to conventional treatments. It works in the absence of heat, vibration, and drilling. Hence providing a minimally invasive, precise approach.

It uses advanced technology to:

- Alleviate patient's anxiety
- Carry out minimally-invasive procedures
- Significantly reduce the need for retreatment
- Comfortably prepare patients for invasive treatments
- Perform treatment without anesthesia
- Reduce post-treatment bleeding and swelling, and pain
- Provide effective treatment in minimal time

The handpiece resembles a high-speed handpiece but it has fiber optic tips instead of bur. This directs the laser energy at a focal point about 1 to 2 mm from the tissue surface. It weighs 88 pounds, and has dimensions of 12.5×26×32 inch. It needs about 80 pounds per square inch of air pressure provided by an external source. The water supply is placed in an attached bottle.[7] Hydrokinetic energy is generated by combining a spray of atomized water with laser energy. The resulting Hydrokinetic energy smoothly and precisely cuts hard and soft tissue such as tooth enamel and soft tissue.

Advantages of Waterlase:

- Itremoves hard and soft tissue without any discomfort
- It requires less anesthesia
- It decreases post-operative pain, bleeding and swelling,
- Waterlase precisely cuts the tissues leaving the surrounding areas unaffected minimizing trauma
- Treatments can be simultaneously performed in several areas of the mouth, resulting in a decreased need for multiple visits.

Hard tissue procedures: The YSGG laser generates optical energy to a user-controlled distribution of atomized water droplets. The hydrokinetic cutting effect occurs due to the absorption of the optical energy by the water droplets. The removal of tissues with highly energized water particles is the principle behind the hydrokinetic process. Enhanced absorption of laser energy by atomized water droplets results in an intense yet controlled water particle excitation and micro-expansion. The water vapor released causes an increase in the internal pressure within the tissue, resulting in an explosive expansion called 'micro explosion'. These results in 'thermomechanical' or 'photomechanical' ablationby mechanical collapsing the tissue. This process is termed as 'water-mediated explosive ablation'. Various studies have reported that Er, Cr: YSGG laser can be comfortably used on osseous tissue bone without anycharring or melting. No physical contact is made with the hard tissue while cutting it; i.e. the laser energy is transmitted to the water, which is further transmitted to the tooth leading to tissue ablation.[8,9]

Soft Tissue Procedures: These procedures are done using a different mode where direct Er, Cr: YSGG laser energy is applied to cut or ablate the soft tissues. Adequate anesthesia is needed to perform soft tissue procedures. The water is need for cooling, keeping the tissue moist and clean and for hydrating. Waterlase laser energy is delivered via a flexible fiber-optic device. The laser does the cutting while the water released acts as a coolant. For soft tissue procedures, the Waterlase® C100 utilizes direct laser energy to cut tissues, incise, excise, ablate and coagulate.

Two key features are:

1. Reduces bleeding in the operative field
2. Decreased post-operative pain and discomfort in comparison to traditional procedures.

The power source, the pulse energy, rate of repetition and rate of flow of air and water are adjustable in all the applications according to user requirements.

Uses in Periodontics:

1. Root planing procedures
2. While giving incisions in cases of Full-thickness/ Partial-thickness flap
3. In cases of curettage
4. Granulation tissue removal from the osseous defects
5. During debridement
6. While recontouring bone to restore its architecture
7. Respective osseous crown lengthening
8. Soft tissue procedures such as removal of the gingivaand frenum
9. Implant recovery
10. Painless excision of epulis caused by faulty dentures
11. Low-level laser therapy is used for early detection of caries
12. Lasers are used for providing restorative therapy having longer and better prognosis due to its microbial actions in caries removal procedure.
13. Dental lasers are also used as sealantsfor dentinal tubules that are the primary reason for dentinal hypersensitivity.

Waterlase with Emdogain™, is a regenerative gingival therapy. This device promotes the regeneration of soft and hard tissue that has been degraded due to chronic periodontitisand observed the combination of the two procedures for over nine years. He also concluded that this method of treatment has immense potential in the healing of the periodontal treated sites.

Drawbacks, Cautions and Contraindications:

1. The Er: YSGG laser has few drawbacks when used subgingivally.
2. While applying laser in the periodontal pockets, the visibility of the operator is compromised. Hence special tip designs should be facilitated for better insertion into the pockets. This can also aid in the detection of the subgingival calculus.
3. High-speed evacuation is necessary to pump out the water released during the explosive ablation causing splatter of blood and water from the pockets. This can be carried out by not only using an intraoral suction but also an extraoral evacuator. Thus cross-contamination can be prevented by the splashes of blood and water.
4. In cases of systemic health conditions extra caution and precaution should be exercised. In cases allergy to anesthesia, cardiac disorders, respiratory problem and blood disorders use of lasers can be contra indicated local procedure. Immuno-deficiency may also pose as a contraindication. Hence medical consent from the patient's physician is mandatory in the above-proposed cases or doubt.

Precautions:

1. Inadequate knowledge about the usage of controls or adjustments or performance of procedures may lead to harmful radiation exposure.
2. This device has been designed to meet the requirements of excessive electromagnetic, electrostatic and radio frequency interference testing. However, there remains the possibility of other interference persisting.
3. One should never carry out any procedure if he/she thinks that the device is not functioning properly.

Directions for safety:

These instructions should be strictly followed at all times:

- Highly reflective items in the vicinity of the operating field should be removed or covered.
- No explosive or flammable things should be present nearby.
- Protective eyewear must be worn by the operator and personnel surrounding the operative field suitable to block 2.78 μm wavelengths.
- One must make sure that Waterlase® C100 Handpiece Mirror is clean. There should be an absence of water or moisture.

Do not directly look into the beam or at specular reflection.

- The cutting spray should be directed towards the target tissues and not elsewhere.
- STANDBY button on the control panel must be pressed before switching off the unit.
- Before exchanging handpieces or removing the fiber optic connector from the unit press STANDBY.

Move the circuit breaker to the OFF (O) position (located on the rear panel) and remove the key before leaving the unit unattended.

Future developments: There is a great potential for laser systems to be developed further to include additional features and functions. The Alexandrite laser is a solid-state laser, which could remove dental calculus selectively. Mechanism of selective ablation has not been clarified yet. The development of this laser for clinical use is widely expected due to its excellent ability for selective calculus removal from the tooth structure. Solid-state lasers are being designed that have higher power, are faster, have shorter wavelengths, and better beam quality, which will expand their applications.

Conclusion

Er, Cr: YSGG laser effectively performs numerous soft tissue procedures with little or no bleeding and gives the dentist a new high-tech tool for many procedures that previously required referral to a specialist. Now one can have them performed during the scheduled appointment. Through this new innovative technology that seems to be extremely effective, there is a great need to develop an evidence-based approach to the use of Waterlase in periodontics. More controlled studies are needed to establish its usefulness in the field.

Mental Attitude in Complete Denture Patients: A Review

Debarchita Sarangi

Senior Lecturer, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Patient evaluation is the first clinical step of Complete Denture fabrication. Besides finding out intra-oral state, the clinician also evaluates general well-being and also extra-oral state. In general well-being, the psychological status of the patient should be evaluated. Evaluation of the mental attitude is a very important factor in determining the success of the complete denture. This begins immediately when the patient enters the dental office. Patients attitude and their expectations from the treatment should be understood. If required certain modifications and conditioning by the dentist should be done for better acceptance of the treatment and a good outcome. This article is a review of the classifications proposed for evaluating the mental attitude of the patient.

Keywords: *Mental attitude, Prosthodontic treatment, Classification; dentures; complete.*

Introduction

The loss of a tooth affects the physiology of mastication, speech, esthetics, and also on the patient's psychology, thus having an overall impact on the quality of life of patients, irrespective of age, gender, economic status, etc. This is even more obvious in completely edentulous patients, especially in the geriatric group. Therefore,De Van stated that we should meet the mind of patients before we meet the mouth of the patient which means that the psychological state should also be examined even before the procedures for treating the edentulism.[1,2,3] This determines the acceptance of the completely edentulous patient to the complete denture. Sometimes a patient with an ideal intra-oral condition may have less acceptance, but a patient with unfavorable conditions may have better acceptance and outcome. Thus, studying the mental attitude would determine the patient's acceptance for the treatment, patient's temperament towards the dentist and expectation from the treatment which will altogether determine the success of the treatment.[3,4,5] This article is a brief overview of the various classification of mental attitudes proposed for edentulous patients along with their clinical importance.

Various Classifications:

Ideal Patient: There are four traits of the responses of an "ideal patient" who needs denture, according to Winkler. They are: the patient realizes the need for the treatment; wants the prostheses; accepts them and learns to utilize the dentures by giving attempts.[6] O'Shea considered a geriatric edentulous patient "ideal", when the patient is compliant, sophisticated, and responsive to the treatment.[7] But, these cannot define the patient's attitude and dictate the very relative treatment outcome, rather the psychology should be analyzed and profiled.

M.M. House Classification[8,9,10]:

This classification has been described in TABLE I.

Table I: Types of patients and their clinical impressions in M.M. House classification.

Type	Clinical Impressions
Philosophical mind	- reasonable,calm, and involved in the treatment procedure at every step. - understand the treatment - listen to the dentist's advice and are willing to follow the instruction.

Type	Clinical Impressions
Exacting mind	- disciplined, strict,may have precise demand and may ask for a guarantee - dentist may have to give a little more effort after which the patient listens to him and follow his advice. - if the patient had a previous denture which was dissatisfactory, then he may doubt the present denture also. But, once satisfied, he would be the dentist's fan. - prognosis is usually good
Hysterical mind	- negative attitude - poor oral health and lack of effort for maintaining oral health - anxious and unstable emotionally - do not have realistic expectation - unreasonable complaints - poor prognosis
Indifferent mind	- not motivated for the treatment. - disinterested in the treatment - does not obey any advice of the dentist - prognosis is doubtful

Winkler's Classification[3,6]:

This classification has been described in Table II.

Table II: Types of patients and their clinical impressions in Winkler's classification

Type	Clinical Impressions
The Hardy Elderly	- physically and psychologically maintained - active in their professional life - active socially - adapt to changes and accept them
The Senile Aged Syndrome	- physically may be ill,disabled or aged - psychologically and emotionally weak - cannot cope with stress and vulnerable to ailments.
The Satisfied Old Denture Wearer	- adapted well and happy with old dentures, even though they are faulty - not motivated for treatment - poor prognosis
Geriatric Patient who doesn't Want Denture	- long-standing edentulism, without any treatment - no motivation for treatment and have a poor prognosis

Gamer's Classification[9,11]: Gamer classification is based on two factors, i.e: patient's engagement level to dentist and treatment procedure in a continuum from totally engaged (++++) to disengaged (+).

This classification has been described in Table III.

Table III: Types of patients and their clinical impressions in Gamer's classification

Type	Clinical Impressions
Ideal	Reasonably engaged i.e. (+ + +) Reasonably trusts the dentist i.e. (+ + +) May skeptically distrust also . Mature May ask questions and need satisfying answers for the same from the dentist May not be over suspicious or over accepting of the dentist's opinions. Similar to Philosophical type of patient in House's classification

Type	Clinical Impressions
Submitter	Highly engaged (+ + + +) trusts the treatment and the dentist(++++), considers the dentist as ideal. Engages in the treatment completely
Reluctant	Engagement level is + + Trust for the treatment is ++ skeptic
Indifferent	Engagement level is + i.e. minimum level of engagement. Trust for treatment is +; indifferent to the dentist's instruction Similar to Indifferent type of patient in House's classification
Resistant	Engaged with treatment but with an adverse mindset. Trust is very minimal or not there Question or doubt if they receive help from anyone in any situation Instead of acknowledging or accepting, they challenge the dentist.

Another Classification[11]:

This classification has been described in Table IV.

Table IV: Types of patients and their clinical impressions this classification

Type	Clinical Impressions
Cooperative	- may or may not recognize the need for dentures - Open to suggestions - After some effort by the dentist, these types of patients become cooperative.
Apprehensive	- Unreasonable - Acknowledge the need for dentures, but give an illogical problem that cannot be solved rationally.
a. Anxious	- Anxious and sometimes become neurotic - Focus on the uncertainties related to dentures.
b. Frightened	- Fear the denture therapy
c. Obsessive or exacting	- Aware about their wants - Exacting type - May dictate the clinician regarding the way to proceed.
d. Chronic complainers	- Dissatisfied with any kind of treatment - Find faults and problems in everything - Need appreciation, if they are willing and cooperating for the treatment.
e. Self-conscious	- Look-conscious - Need to be re-assured and should be acknowledged for their inputs in the final result.
Uncooperative	- Do not need dentures - Not motivated - Have a negative approach

Need of Understanding Patient Psychology: The patient's contribution to his or her treatment is vital for a positive treatment outcome. For the clinician to deliver good work and for the patient to adapt, there must exist a good relationship between the patient and dentist. Then only the patient will accept the treatment.[10] There are many factors that play a role in satisfying the patient. Among these factors, the most important ones are: type of treatment selected, psychology of patient, the personality of the patient, perception of the patient towards the dentist and treatment selected, the interaction between patient and dentist. Patient satisfaction level may be increased if there is a good dentist-patient relationship because the dentist understands the patient's needs and

delivers as per the patient's expectation whereas the patient builds an acceptable and realistic result.[11,12]

Conclusion

The clinician should understand the mental attitude of the patient, preceding general and oral examination. Proper time should be devoted to a thorough examination. This builds the patient's faith in the doctor. The doctor's attitude towards patients is also equally important. The dentist should be concerned about the patient's comfort, health, and well-being so that there is trust developed from both-sides and the patient is motivated to follow the advice of the dentist. This shall lead to a good outcome of the denture therapy.

Barodontalgia: Dental Implications at High Altitudes

Nikita Sahu[1], Debasruti Naik[2], Sudipta Sahu[1], Kajal Kiran Sahu[3]

[1]Tutor, [2]Senior Lecturer, Department of Public Health Dentistry, [3]Tutor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Barodontalgia is a symptom of a pre-existing subclinical oral diseases rather than a pathological condition itself. It was considered earlier as a "flyer's toothache," barodontalgia is described as pain that occurs in the tooth utilizing changes in ambient pressure usually in people who fly or dive. It is the whole responsibility of the dental health professionals to provide the aviators with the best dental treatment as well as awareness about the hazards to the dental treatments at higher altitudes. This piece of writing gives sufficient information about the need and protocols to be followed especially for the patients commonly at higher altitudes. This article aims at providing adequate knowledge about barodontalgia and the responsibilities towards its prevention both by the dentist and the flight crew members.

Keywords: *Barodontalgia, Ambient pressure change, Toothpain.*

Introduction

Dentistry has changed over some years from prevention to management of oral diseases. Considering from varied professions, some people will be there who "rise from the ground" commonly known as air travel crews, pilots, and persons who keep travelling always for work. The dental health professionals might more and more come upon flight-related oral conditions which require treatment for the rising number of flight attendant and leisure pilots, air passengers, as well as military and airline pilots. Barodontalgia also known as Tooth Squeeze; or Flyer's Tooth; or Aerodontalgia. It is the pain in the oral cavity that results because of the pressure changes usually found in case of far above the ground altitudes in pilots and also for the deep sea divers who also go through severe changes in pressure.[1] Barodontalgia is a symptom of a pre-existing subclinical oral diseases rather than a pathological condition itself.[2] It was considered earlier as a "flyer's toothache," barodontalgia is described as pain in the tooth that occurs with variation in ambient pressure usually in people who fly or dive. It can be severe enough to cause inflight vertigo as well as premature flight cessation.[1]

Aerodontalgia was named during the world war II because of the pain experienced by aircrew in the flight but, this type of tooth pain was found in divers, therefore an additional suitable word, barodontalgia, later given to this phenomenon.[1] Barodontalgia affects both aircraft passengers as well as aircrew and underwater divers. Due to the change in pressure gradients teeth are affected due to injury and pain.[3] According to Boyle's Law "at a given temperature, the volume of a gas is inversely proportional to the ambient pressure," which can be used to explain the concept of barodontalgia.[2]

The barodontalgia phenomenon starts occurring at an altitude of about 3,000 m and at a water depth of 10 m where the ambient pressures are 0.75 and 1 atmosphere, respectively.[4] Some people have reported that they have felt pain in a tooth because of the high rise buildings these days plus the powerful lifts that are used with travel at very high speeds to reach great heights.[5]

Prevalence:

- It ranked 5th as complaint and 3rd as cause of chamber simulation termination.
- Usually above 3,000 ft. with 11% of aircrew affected.[3]
- Seen at 5,000-35,000 ft. but more common 9,000-27,000 ft.[6]
- 3-37% of barodontalgia is non-dental facial barotraumas.[1]

In the 1940s, the prevalence of barodontalgia was within a range of 0.7% and 2% and in the 1960s it is 0.3%.[7]Similarly, in the Luftwaffe, several cases of barodontalgia reported in 0.3% of high altitude-chamber. It was also reported that there were cases of barodontalgia of about 1 case per 100 flight-years in the Israeli Air Force.[8]

Classification:

1. **According to Fédération dentaire Internationale (FDI):** It is divided into four categories such as:- a) acute pulpitis, b) chronic pulpitis, c) necrosis of the pulp d) periapical abscess or a cyst.[9]
2. **In 1972, The pathology of barodontalgia** was specified by Strohaver. He divided his description into two types: a) direct barodontalgia b) indirect barodontalgia. In the direct type of barodontalgia, the atmospheric pressure is decreased and then it results inan indirect effect and is localized into moderate to severe that is generally formed at some stage in take-off, whereas, in the indirect type of barodontalgia pain results because of the stimulus of the superior alveolar nerves during the period of maxillary barosinusitis which is dull and also poorly defined that involves the posterior teeth which occurs during landing.[10]

It should be kept in mind that teeth that are normal in condition and are devoid of anycausal pathologies that will not get exaggerated by any changes in pressure. Barodontalgia can be found commonly in teeth that contain pre-existing dental pathology or undergone with any inappropriate dental treatments such as:[11]

a. Chronic pulpitis

b. Restored teeth

c. Maxillary sinusitis

d. Default restorations

e. Periapical cysts

Barodontalgia hasa chance of occurringat the time of initial pressure reduction from 14.7 psi to 12-8 psi.[12] A distinguishable sign is the pain that is consistently relieved on repressurization, distinguishes barodontalgia from pain in the upper jaw because of maxillary barosinusitis.

Manifestations due to pressure change:

1. **Barotrauma:** This is a type of condition that results as a variation count in pressure flanked by a gas space surrounded by the body as well as the surrounding fluid because of the lower atmospheric pressure. This might give rise to conditions like dental barotraumas, barodontalgia, barotitis –media, external otitic barotrauma, barotraumas related headaches, barosinusitis.[13]
2. **Barodontalgia:** This is a kind of pain that occurs by a variation in barometric pressure in an asymptomatic organ. Here it can be expected of pain that is correlated to periapical disease that can occur during ascent as well as descent and also it can disappear on returning to the ground level. It is being reported that toothache in barodontalgia is because of the rise in atmospheric pressure that will lead to spreading out of trapped air bubbles.[14]
3. **Tooth outburst:** Also well known as odontocrexis or barodontocrexis. When exposed to sudden changes in atmospheric pressure then a tooth explosion will occur in teeth that have pre-existing leakage restorations or in recurrent carious lesions. This detonation happens because of the unexpectedspreading out of gas bubbles fascinatedinside and underneath these restorations.[15]
4. **Barosinusitis:** This barosinusitis occurs as a result of negative air pressure formation in between the sinuses that leads to tenderness that causes toothache.[16]
5. **Prosthetic Considerations:** There might be a retention problem in both upper and lower dentures that are being troubled because of the variation in barometric pressure. Due to the effect of gravity suchvariation is more distinct in upper denture than lower denture.[17]
6. **Restorative Dentistry:** Fracture of restoration can occur due to variation in thermal contraction in restorative materials and low temperature at higher altitudes as compared to tooth hard tissue.[18]
7. **Periodontal considerations:** Due to change in pressure xerostomia and hyposalivationcan be seen as an imperative risk factors for decayed teeth. This might increase the risk of occurring periodontal infection and dryness of the oral cavity which can occur because of inhaled compressed dry gases in the aircraft.[19]
8. **Surgery Considerations:** To avoid the growth of sinusitis at higher altitudes, care should be taken for

the existence of any oroantral communication while extraction of maxillary teeth.[20]

Reason of pain due to pressure change:

a. During any underlying pathology, spreading out of gas with compensating rise in pressure inside the pulp chamber and root canal can be seen because of changes in external pressure.[21]

b. Pain during ascent pressure along with relief on descent pressure - Pulpitis

c. Toothache on descent along with relief on ascent - Necrosis

d. Toothache can be seen usually in the maxillary posterior teeth along with adjusted blood supply to the tooth.

e. Exposed nerve endings by direct pressure.

f. Faulty restoration can leads to microleakage.

Hypotheses to this phenomenon by Kollman: First, intent air bubbles get expands underneath a root filling or against dentin to activate nociceptors; Second, with the pain in the referred teeth, stimulation of nociceptors in the maxillary sinuses; Third, chronically inflamed pulp stimulates the nerve endings. He presented histological substantiation that shows that chronic inflammation of pulp that can exist even after a thin dentin layer covers the pulp, for example, like in a deep cavity preparation and also he strongly supported his last two hypotheses.[22]

Flight Restriction related to dentistry: The flight restriction for any patient in the flight is enforced when any kind of intrusion in the flight capabilities is doubted for any aircrew member:[23-25]

- Patients under any medications might be a source of dizziness or lack of concentration or maybe the reason for diarrhea.
- Intraoral stress changes can be found in patients who have undergone tooth extraction or other oral/ periodontal surgery after several hours.
- Variations in hazard of emphysema.
- The jet and helicopter pilots might face difficulty in wearing helmets comfortably in case of face swelling.
- Alteration in pressure changes can hamper the wound healing in cases of oroantral communication.
- Aircrew has to reschedule his flight in anticipation of his endodontic treatment is finished to avoid in-flight barodontalgia.

The dental health professionals recommended the aircrew not to flight until the toothache is subsided so that the patient can rest well. It is also suggested that appointment for dental check-up and treatment can be scheduled for a date with enoughperiod before the next planned flight.[26]

Prevention from barondontalgia:

a. Professionals like pilots and deep-sea divers should undergo the Hyperbaric Oxygen Therapy (HBOT) whenever the individual is set in a 100% compressed Oxygen chamber that set the body for maximum stress as well as compression.[25]

b. FDI suggests a yearly checkup for pilots, divers and submariners with dental hygiene instructions from dentists.[9]

c. Patients within 24 hours of dental treatment must not dive or fly in non-stressed cabins having a requirement ofanesthetic.

d. Existing dental pathologies should be checked and treated properly.

e. Barodontalgia can be prevented by putting a zinc oxide eugenol (ZOE) base in case of a reversible pulpitis as ZOE is well known for its sedative effects.[26]

f. People subjected to long-duration pressure changes then procedures like pulpectomy or cases like pulp capping of an exposed pulp should be avoided and alternatives treatment should be done. [14]

Recommendations:

a. Dental conditions like periapical pathology, dentin exposure, caries, and fractured cusps should be paid attention closely by the patients involved in diving or aviation.

b. The dental health professional should examine properly and ask the patient about the history of recent flying or diving if the patient has any symptoms of barodontalgia.

Conclusion

By the passing time,a rise in the number of people traveling by air can be observed and this also leads to a gradual rise in the number count of aircrew personnel. Therefore, aviation dentistry has amplified, it has to be

given importance, so that suitable diagnoses should be prepared. Barodontalgia must not be underestimated because of its safety risk to pilots, submarines, divers,and airline passengers. Special considerations for aircrew patients have to be made when dental treatments are planned. It is the whole responsibility of the dental health professionals to provide the aviators with the best dental treatment as well as awareness about the hazards to the dental treatments at higher altitudes.

Oral Health Care in Infants and Deciduous Dentition: A Review

Upasana Mohapatra[1], Susant Mohanty[2]

[1]Tutor, [2]Professor & Head, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Oral health goes in a close relationship with the general health. Hence, bad oral health affects the personal life and the lifestyle too. It affects interpersonal relationships, concentration, and productivity. Hence, maintenance of oral health, not only maintains the oral cavity, but, also helps maintain a quality life. The process should start right from the prenatal period (oral care of the pregnant mother) and infancy. It has been found from surveys that the presence of dental caries in school going children affects their education as they tend to miss school due to pain and aesthetics.

Keywords: *Oral Health, Maintenance, Oral Hygiene.*

Introduction

Oral care in infants and children is an important aspect of the sphere of their health care. The parents, caregivers, and pediatric dental and medical practitioners play an important role in the maintenance of the oral health of this section of the population. Oral care practices in infants differ from those in case of deciduous dentition. These practices help prevent the most prevalent dental disease, i.e., dental caries.

Oral hygiene in infants:

Source of infection in infants: Though teeth are not present in the oral cavity at this age, but, still the maintenance of oral hygiene is very necessary. This would prevent the occurrence of dental caries when the primary teeth or the permanent teeth erupt.

Corresponding Author:

e-mail: upasanamohapatra.um@gmail.com

Vertical transmission in one of the major factors in the infection of infants with Streptococcus Mutans.[1] The high density of *Streptococcus mutans* in the saliva of mothers leads to the increased risk of infection in the early life of their children. This in turn leads to a high risk of dental caries in the primary and permanent dentition.[2,3] Infection from family members or the members of a group can also occur. This is called horizontal transmission.[1]

Few other sources of infection of Streptococcus Mutans in infants and children are diet including cariogenic foods, poor oral hygiene practices, bottle-feeding, and breastfeeding practices at night and on-demand. These are also found to be linked to the development of early childhood caries (ECC).[4,5]

Oral hygiene practices in infants:

Oral health in infants can be maintained by taking a few steps at home itself.

- Vertical transmission of dental caries can be prevented by reducing the cariogenic bacterial count in the mother, especially during pregnancy. This can be achieved by regular tooth brushing, use of fluoridated Mouthwash, and treatment of all the carious teeth, if any.
- horizontal transmission of dental caries can be

prevented by avoiding any habits that include the sharing of saliva (e.g., sharing of spoons) within siblings, parents or any other family members.[6] Regular maintenance of oral hygiene can be achieved by wiping the alveolar mucosa and the tongue with a moistened piece of sterilized gauze. This can be wrapped around a clean index finger and then oral tissues are gently wiped and gingival tissues are gently massaged. The use of dentifrices, such as fluoridated toothpastes should be avoided as its ingestion is a possibility.[7] Another important practice is weaning the child at the proper time. Frequent bottle-feeding or breastfeeding on demand or during the night in infants beyond 12-18 months leads to the development of dental caries at a very early age. The results are early childhood caries and nursing bottle caries.[7]

Dental home concept: According to AAPD, this concept is an ongoing relationship between the dentist and the patient, inclusive of all aspects of oral health care delivered in a comprehensive, continuously accessible, coordinated, and family-centered way. It should be established as early as 6 months after the eruption of the first tooth and no later than 12 months of age. It includes the referral to dental professionals as and when appropriate.[8,9]

Its objectives include enhancement of dentists' ability to assist the children, their parents and/or their caregivers for maintenance of child's optimum oral health; planning early oral examination schedules and preventive services for the achievement of cost-effectiveness; risk assessment of the individual child for dental diseases, monitoring growth and development and awareness of parents of proper time and frequency of paying a visit to the dental home for their child.[8]

Oral hygiene of deciduous dentition: The care for the deciduous dentition should be started immediately with the eruption of the first primary tooth in the oral cavity. Colonization of the deciduous teeth with Streptococcus Mutans leads to the development of dental caries in them and the non-maintenance leads to the development of dental caries in the permanent teeth in those children too. It has been reported that tooth brushing habits in children are viewed as the parents' attitude towards the importance of maintenance of oral hygiene.[10,11] Toothbrushing in children till the age of 7 to 8 years should be assisted or guided by the parents as at this age, fine motor skills develop in the children.[12]

Source of infection in children: One of the primary causes of infection of children with Streptococcus Mutans is the presence of active caries in the parents or caregiver.[13,14] Hence, the treatment of their dental caries is of utmost importance. High and frequent intake of sugars in the diet is another important source.[15] Some other factors are reduced salivary flow (including intake of medications those might result in xerostomia); premature birth leading to enamel defects; the presence of deep pits and fissures in the teeth, etc.

Oral hygiene measures in children:

Diet counseling:

- This is included in Anticipatory Guidance practiced by the dental professionals.
- Exclusive breast-feeding for 6 months of age and subsequent introduction of appropriate food.[16] Weaning of children from bottle and breast-feeding by the age of 1 year.
- Limitation of intake of sugary foods and beverages to only during meals and avoiding having them as 'between-the-meal-snacks'.
- Avoiding aerated and sugary juices and making the children to take pure juices.
- Making children drink only water, especially, fluoridated tap water between the meals.
- Maintaining a balanced diet.

Oral hygiene practices:[6,9]

- Discontinuing the habit of the bottle or breast-feeding during night.
- Tooth brushing twice a day with a proper amount (as appropriate for the age of the child) fluoridated toothpaste.[17] The use of fluoridated toothpastes is an easy means of delivering fluoride to the teeth. Other means of fluoride delivery is fluoridated drinking Water (can be obtained by community-based water fluoridation programs)[18,19], application of fluoride varnish (professional means).[20] Tooth brushing should be properly guided or done by the parents only for achieving an optimal result. This should be practiced till the child attains 7 or 8 years of age.[12]
- For children below 2 years, the toothpaste should be smeared on the toothbrush, and for children above 2 years, a pea-sized amount of toothpaste should be dispensed. Care should be taken or the child should be trained so that they don't swallow the toothpaste.

- Replacement of toothbrush every 2 months or on the appearance of the first sign of fraying, whichever is earlier. This increases the efficacy of toothbrushes.[21]
- The children should be made to rinse their mouth after every meal to prevent food lodgement, thus preventing the provision of a nidus for bacterial growth and subsequent development of dental caries.[22]
- Flossing and use of mouthwashes should be incorporated in the daily oral hygiene practice of the child.[12]
- The use of proper dentifrice is an important factor as well. Fluoridated toothpastes are the recommended dentifrices for prevention of development of dental caries.[16]
- Tongue cleaning also should be included as a regular oral hygiene practice. This reduces the count of Streptococcus Mutans and significantly reduces the plaque accumualation.[23,24]
- A proper brushing technique should also be incorporated.

Conclusion

Optimal oral health is not only obtained by maintaining proper oral hygiene in an individual, but it starts right from the prenatal period. The care of the pregnant mother is also a necessary step. Maintenance of the oral hygiene is not only practiced after the eruption of teeth, but also the oral cavity before the eruption of the deciduous teeth is essential as the colonization of the oral cavity with cariogenic bacteria begins as this stage. This would affect the caries status of both primary and permanent teeth.

Abstract

A child's behavior pattern in any situation is governed by his inherited physical and mental endowment and as he develops,by the conditioning he receives through contact from his environment. The former,except within normal limits,cannot be altered. The later can be controlled and developed so that the child will grow to have a well-adjusted personality to suit the society of which he is a part. Here we discuss how fear governs to a large extent the behavior being shown in a dental operatory by the child and the value of fear.

Keywords: *Behaviour,Child, Dental Fear, Management, Pediatric Dentist.*

Introduction

One of the physical needs of children,which is deemed necessary for the overall health of the child is dental attention whether the child accept dental treatment gracefully or refuse it entirely will depend on how they have been conditioned.[1] The emotional conditioning of children toward dentistry,as toward other experiences which make up their childhood,is primarily formed at home and under parental guidance.[2]

If the dentist is to perform satisfactory dental work on a child patient,he has to get his/her full co-operation. He can get their full co-operation only when he knows the emotional make-up of the children and their parents. Without this knowledge it will be difficult to treat the children. The pediatric dentist must acknowledge that he is emotionally involved with his patients and to handle them successfully,he must be aware of those psychological and sociological factors that have formed their attitudes and behaviors toward dentistry. This study of science which helps understand the development of fears,anxiety and anger as it applies to the child in the dental situation can be designated as behavioral pedodontics.[3] The proper handling of children in the dental office is the sole responsibility of the dentist only,and it is one that he should assume without hesitation if he is to fulfill his obligation to his patients and his profession.[4] It is equally clear that the conditioning of children to the dentist and dental services is entirely the parent's responsibility. They should accept this obligation as a parental duty. If the children enter the dental office for the first time with undue fear and an unwillingness to cooperate,one can assume that the parental conditioning has been faulty. Although it is the parents' responsibility to inculcate the proper attitudes in children of dentistry,the dentists can help by making sure the parents are fully informed of and educated in the necessary fundamentals of child psychology. Before a dentist is in a position to advise parents regarding proper psychological preparation of their children,he must understand the problems involved.[5] He must understand the fear involved and have an awareness of how parental attitudes may modify behavior patterns. He should be familiar with personality formation and how anxieties develop. If the dentist wants to be respected in his professional circle,he should be competent enough to discuss the problems tactfully related to his field. Parents are always eager to provide all the advantages of life to their children even if they didn't get. The dentist should be capable enough to provide advice on child behavior to parents as a physician.[6] Certainly management

e-mail: sonuacharya@soa.ac.in

problems are of greater concern to the dentist,who may see children under considerable stress-yet dentists hesitate to advise parents on child behavior. The parents will in turn apply this knowledge to their children,who will look with favor on dentistry rather than fear. This knowledge will help the child as well as the dentist. The anxieties we find in adulthood are formed primarily in childhood. In adults the fears and anxieties are usually latent and well hidden. Marked phobias related to dental treatment do exist among adults and they make up for a large segment of our population.[7]

The Nature of fear: The parents' responsibility in psychologically preparing the child for dental treatment is primarily, the emotional problem of fear. Fear is one of the major managing challenges to the dentist and a major reason for public neglecting oral therapies. Fear is a primitive emotion gained just sometime later than birth,the infant is not knowing the type of the action creating fear. When little one becomes big and his thinking capacity rises he comes to know what produces fear in him. He tries to adjust to the situation with a flight response,if not the fear intensifies. Fear is a primitive response gained for protection from trauma and mutilation.[8] The emotional stimulation is discharged by way of the autonomic nervous system through the hypothalamus and needs very little cortical integration.

The value of fear

Contrary to popular belief,fears are good if gone into proper channels and moment. The good value of this fear can be utilized to bring the kid away from notorious situations of any nature. When the kid is not fearful about being punished or parental disagreement this nature can make him a danger to societal norms in the long run.[9] Therefore the parents should not try to eradicate fear but to channel this scare towards the ill effects that are present and beyond things where no ill is there. This is a protective mechanism against serious threats. Kids should be made aware that dental place is not to be feared. Dentistry must not be utilized as a threat by guardians. Taking the kid to a dental surgeon must not imply punishment to him. Utilisation of fear as punishment will undoubtedly raise doubts of the dental surgeon. On the other hand, attachment of the child to the dental surgeon will lead to motivating the child in accepting office rules as he will dreading that he might lose his confidence of dental surgeon.[10]

Types of Fear:

A. Objective Fears: Objective fears are those that arise due to objects which stimulate the sense organ,not of family origins. These are responses to stimuli that are dependent on seeing,hearing,smelling and tasting which can be bad to taste. Kid having a bad experience with the previous dentist develops a fear of further oral therapy. It is a problem to get back a kid so disturbed to go back to the dental office of his free will. Even if he returns the dentist should be aware of the situation and should try to gain his confidence.[11] Objective fears are associative. A child who has been treated improperly by a pediatrician who wears a white uniform will create the same type of fear in the child when he visits a dentist. Fear reduces the boundary of hurt.

B. Subjective Fears: Subjective fears are that which are told to the kid by the people around him which he has never felt on himself. A little kid is prone to suggestion. A young child,hearing about a painful experience in the dental office by an adult starts fearing the dental treatment as a whole. The mental picture of the painful procedure remains in his mind and with varied imaginative skills of the child,it gets magnified and formidable. Kids have much fear of that thing which is not known. Anything which is novel and not known to the kid is going to instill fear till the kid gets evidence of no issue to his good being. The parents have to make the child aware of the situation and tell them before visiting the dental office,what are the things and procedures the child can encounter in the dental office. Suggested ones can be got by imitating others. A kid watching other kids who are fearful in operatory will get fearful for the same thing or place as realistic and with genuinity.[12] Immitative fear maybe got subtly and maybe showed my family and got by the kid with both not knowing about it. Generally,the long time the subjected fear remains in the brain,the more they get increased. As a result they will be more intense than objective fear. Suggestive fear can become so magnified that it might reach irrationality. The suggestions known most by kids have been made into studies and got no correlation between them and the bad experiences encountered in their natural livings. The worst fears were imaginative things and events. As the imaginary capability of kid

develops,imaginative fear also increases to a certain stage when reasons show them to be ill-gotten. The intensity of fear varies from child to child. The child who is deprived of sleep develop more fear than the ones who sleep adequately.[13]

Role of pediatric dentist: The pattern of fear in a child is quite unpredictable. It is to remember that,regardless of conditioning,normal children with the same experience will visualize a variety in their development of and reaction to fearful things. Each child is an individual and responds individually. The physically healthy child with normal endocrine function will respond more intelligently and swiftly than the mentally retarded individual. The dentists should teach the parents that growth and development are a great delineator of fearful things and it can modify the use of conditioner. The child's first fearful thoughts related to dental treatment are of not knowing and not expecting things. An intensified or fast stimulant for the sense organs is hurt increasing to the kid as it is non expected. The sound and vibrate of rotor and pressed exerting in the use of handheld instrumentation in carie cavities making are conductive of hurt in a very small kid. Unless the hurt is too much to take, he generally is fearful of the sound of dental motors more than he does any added hurt. Since the small kid also is fearful of fall down falling or fast and non-expected jerks, swiftly being reduced or being made back in children without any prior telling may instill fear.[14] Bright lights,especially intense operating light,if allowed to shine in a child's eyes are fear-producing. Before school kids may have fear of separation from parents. If the kid is sent into a novel scenario when he might be removed from parents, with whom he has dependency behavior and safety,he has a feeling of being abandoned. It might be preferable to have parents accompany the child to the operatory if the child is very young. The dentists should also avoid treating children during nap times as the child will not tolerate the situation well. The children should be given a little control while getting a treatment done as to, raise their hand if the treatment gets painful. Older children are more concerned about their looks and so they will cooperate with the dentist on their own will.[15]

Conclusion

Dentists along with the parents have a major role in making the dental treatment less fearful for the child. In subjecting the children to dentistry one must always weigh the possibility of psychological trauma against the necessity of treatment. Since dental treatment is needed by almost every child,it becomes important that psychological trauma to be minimal of all the problems associated with the treatment of children, the management of children becomes paramount,because without proper patient co-operation the dental procedures become almost impossible.

Hormonal Changes Across the Life Cycle of Women and its Effects on the Periodontium

Sourav Chandra Bidyasagar Bal[1], Sukhvinder Singh Oberoi[2], Radha Prasanna Dalai[1], Sashikant Sethy[1]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Professor Genesis Institute of Dental Science and Research, Firojpur, Punjab, India

Abstract

In recent years, it has been realized that women's oral health may differ from that of men in many areas. It is rightly said that the health of a woman's body and oral cavity are bidirectional, hence women need exceptional dental health facilities and attention. The role that different endocrine hormones imbalances during puberty, 1st to 3rd trimester of pregnancy, menopause, oral contraceptive use, and females reproductive cycle details has the main role in various sex data in orofacial health status is supported by different medical clinical trials. The oral conditions commonly observed during these phases of the lifecycle of females include inflamed gingiva, the formation of granulomatous tissue in the body, disease of periodontium,, and grade 1,2,3 mobility of tooth. The closest bonding between status and worst dental health condition in the female will need excellent care in investigation plan that assimilates and controls for the diverse array of lurking varying, such as dental diseases (gingivitis, periodontitis and missing tooth), the whole history of female's reproductive physiology, and benefaction communal and financial variables. Dental practitioners need to actively counsel female patients about general and oral health strategies so that they can maintain their oral health and maximize their quality of life. The effect of hormonal changes during the life cycle of a female affects the prevalence and intensity of the oral disease. This understanding is helpful for a clinician in rendering oral health care to these patients.

Keywords: *Gingivitis, Oral Health, Periodontal disease, Tooth loss.*

Introduction

Excellent oral health is mandatory for excellent general systemic health there is a close interlink among dental and systemic health according to surgeon general data.[1] WHO on its Oral Health data 2003 outlines the global burden of oral disease with particular emphasis on the important matter: oral health is vital and necessities to systemic health, dental health is essential for maintaining an excellent quality of life and oral and systemic health are two sides of a coin both are dependent on each other.[2] All these points emphasize the importance of oral health in connection with the general health as well. Good health status changes according to different phages of life of women widely in the entire population and to their economic status. Dental health condition declined to some state in between the 1st trimester to 3rd trimester of pregnancy and it is a matter of concern which has a bad impact on the lifestyle of human beings. [3] Females should need special oral care and attention due to hormonal imbalance and it has excellent effects on the oral environment.[4]

Nowadays, female's systemic health oral health has become a matter of a global focal point. Thus a

long term follow up research is mandatory in females dental health. The aspects of research study on the dental health of females are through clinical examination of oral physiology, long experiences on clinical practice, and dental health attitude knowledge behavior among various age groups between the circumstances of society transitions. It is rightly said that the health of a woman's body and oral cavity are bidirectional, hence they have special oral health needs and considerations. [4] Periodontal disease occurs due to a complex interplay between susceptibility of host and microflora of the oral cavity. Different internal variables of the host has a direct or indirect impact on different stages of various oral infectious disease.[5] Among these variables, sex hormones likely influence the pathophysiology of gingival inflammation, various periodontists like (ANUG), as hormonal changes have a great effect on the pathophysiological mechanism of human-parasite interlink inside the oral environment.[6,7,8,9] secretion of the endocrine gland is unique controlling particles that regulate the reproductive system, growth factors, and proper maintenance of internal systems of the body as well as generation of energy and its consumption and remaining for storage in proper form.[10]

We know it better than various changes that occur during 1st trimester to the 3rd trimester of pregnancy for which certain changes also occur inside an oral environment like gingival inflammation, periodontitis, pigmentation on the oral mucosa, etc most of these things are revers to normal form after some days. [11,12] The true causative factor behind these changes are not well mentioned anywhere. These endocrine secretion changes can cause certain complications during pregnancy.[13] The changes most commonly reported are pregnancy gingivitis and pregnancy epulis.[14] Also, an association has been reported between Poor oral health and premature births and low birth weight.[15,16,17,18]

When women reach their Menopause that leads to permanent stoppage of regular menstruation cycle which is next immediately stoping the ovulation mechanism. Non-inflammatory destructive periodontal disease (NIDPD) appears in old aged females through their menopause cycle or there is a tight bonding between menopause and on inflammatory destructive periodontal disease (NIDPD).[19] The marginal, interdental, attached gingival status became worst during menopause in the absence of secretion of hormone-like gonadocorticoids. The present review addresses the effect of puberty, pregnancy, menopause, post-menopause, and oral contraceptives and the changes in the hormonal level during this period of the life cycle of women affecting the periodontium.

Pathophysiology of Sex Hormones: Estrogen has a great impact directly on various cellular mechanisms, amplification, and development of body tissue.[19] Oestrogen is the main causative factor in the process of various physiologic interchanges in females in different aspects of their life span: starting the age of puberty, during every periodic cycle, 1st to 3rd trimester of their each pregnancy, after the starting of the menopausal cycle in old age.[19] Oestrogen and progesterone are the main sex hormones that can affect the periodontium by significantly influencing the different organ systems.[10,20]

Various important cells in the mouth deeply affected by sex hormone-like estrogen, progesterone etc.[19] through various cellular activities like the development of specialized cells of squamous epitheliallium the estrogen act. [20] various important receptors of sex hormone present in osteoblast has a great impact on compact bone, spongy bone in their development process. Some additional receptors of sex hormones which are mainly attached to different periodontal ligaments has some significant mechanical action on targeted periodontal cells.[21]

The sex hormone mainly estrogen hinder the progress of IL-1, IL12, TNF-alfa, and GM-CSF which has great hand behind osteoclastic activity leading to compact and spongy bone loss. When there is less synthesis of sex hormone its plays a key role in severe inflammation of attached gingiva, marginal gingiva in generalized periodontitis case. On the other hand it has some contribution to skeletal bone loss mechanism.[19]

Various sex hormones have a key role in different microvascular changes like inflammation of the endothelial layer of oral tissue, interruption in various mast cell formation, thrombi formation, the process of permeability of vessels became faster.[19]

Role of Different Phases of Lifecycle on Oral Health:

Puberty: Puberty is regarded as the very first sign of maturity in turn towards the adult age group. Puberty is always linked with more production of estrogen and testosterone in both gender men and women. A lot of prevalence and follow up survey data tells that there is an interlink between the development of gingivitis in the

absence of dental during the starting period of puberty. severity of gingivitis has definite bonding with serum sex which fluctuate mean plaque score.[22] Severe generalized inflammation of interdental gingiva, marginal gingiva, attached gingiva of maxilla and mandible sometimes associated with bleeding from the gingiva. Inflammation of gingiva (Generalised) is seen all around the labial surface and palatal surface of interdental, marginal, and attached gingiva in some case interdental gingiva is absent due to severe inflammation.[23] A significant increase in gingivitis in children has been reported during the starting phage of the menstruation cycle. There is severe gingival inflammation reported among females at the age of 12 years, 10 months, and among males at 13 years, 7 months. This has been seen to coincide with the onset of puberty which could strongly play a major role in changes in oral-microflora in the presence of gram –ve anaerobic bacteria P. Intermedia, which later helps for the production of BGF in proper suitable oral environment. The mass of dental bio-film increases rapidly with various types of spirochetes like Aa. Gingival bleeding also present.[23]

Menstruation: During the staring phage of the pubertal cycle there is a sudden increase in the release of sex hormone (estrogen, progesterone) in a regular manner.[24] The female periodic cycle goes through 4 phages- 1st- menstrual, 2nd follicular, 3rd ovulation and 4th one is luteal phages. During the ovulation period the amount of secretion of sex hormone rapidly increased than its normal secretion.[23] According to Lindhe et al at the time of ovulation the amount of secretion of GCF and exudate fluid of gingiva is more than normal days. [25] Holm et al concluded from their study that there is a presence of mild to moderate gingivitis who are running through their periodic cycle.[26] Data of Some studies say that most of the females developed minor or sometimes major aphthous ulcers during their periodic cycle. Some other surveys give data that minor aphthous ulcer develops in females only in the last phage of their periodic cycle that is the luteal phase where ovulation starts again. The study of Ferguson state that repeated aphthous ulcer develops in the oral cavity of the female during the periodic cycle but this data is still in controversy. [10]

Pregnancy: In between 1st to 3rd trimester of pregnancy there are many changes in the amount of secretion of endocrine fluids. Corpus luteum took the amount of sex hormone very high due to constant secretion.[23] There is a marked increase in the level of estrogen and progesterone to the level hundred and six nanograms per milliliter during the last days of pregnancy.[10] Changes in endocrinal secretion (release of sex hormone) during 1st trimester to 3rd trimester associated with marked increase in mild to severe gingival inflammation in some cases localize periodontitis seen.[10]

Pregnancy gingivitis is a common condition reported among pregnant women affecting between thirty to a hundred percent between all pregnant female cases. Pinard was the first person to disclose the fact that increase gingival bleeding, edema like symptoms are seen during 1st to 3rd trimester. The information of all types of gingiva (attached marginal and interdental) some times associated with moderate referred pain with mild gingival bleeding. Some clinical periodontal signs found like increase BOP, amount of GCF increase, severe gingivitis found, increase gingival pocket depth beyond 4mm. Most frequently lower and upper anterior region of tooth segments are affected and the interproximal gingival unit also. [27] A high amount of estrogen and progesterone found in oral fluid during 1st trimester to 3rd trimesters of pregnancy.[28] Chances to develop oral infection like mild periodontitis, mild to severe gingival inflammation is more during 1st trimester due to low immunity, associated with low production of suppressor T cell, early maternity stress, disruption in realizing of various body hormones.[23] A small majority of the pregnant women (0.5-9.6%) of which develop inflammation of gingiva which is associated with P Granulomatous tissue. This growth some times called benign tumor of pregnancy or pregnancy linked granuloma in reality these things are not true neoplasm. It cant be distinguished histologically nor clinically. This type of growth is painless, developed from marginal gingiva some times developed from interproximal area maxillary anterior tooth segments growth base is pedunculate type. [23]

Oral Contraceptives: Birth control method are important factors with association with human chorionic gonadotropin trigger every trimester of pregnancy to stop the release of eggs from the ovary.[22] Oral contraceptives tablets tries its best to make hormone level balance during the trimester.[23] Currently, oral contraceptives pills come with the doses point zero five milligram estrogen per day and one point five milligram per day dose for progestins.[22]

The clinical studies have reported that the use of

hormonal contraceptives in women influences periodontal disease progression in the form of a higher prevalence of gingival inflammation, loss of attachment, and gingival enlargement.[29] marginal attached Gingival have an great response to localize triggering factors. Mild to severe gingival enlargement associated with mild to moderate gingival bleeding sometimes with hyperplasia. Melanin pigments of skin occasionally reported. Establishment of close bonds found in between the use of contraceptive tablets and the development of excess melanin pigment on the skin.[22] A statistically significant increase in the prevalence of severe periodontitis was reported among Oral Contraceptive (OC) users, particularly smokers by Brusca et al.[30] Loss of attachment ≥2 and ≥5 mm were reported among OC users in comparison to the non-users. Maximum numbers of culture media were found +ve to Candida albicans. The link with sub-gingival *C. albicans* to *Porphyromonas gingivalis* more than eighty-five percent in patients who regularly consume Oral contraceptives.[30]

Menopause: When female reaches above 50 years menopause start which is also a natural process starting of menopause leads to permanent stoppage of females monthly period. Permanent stoppage of periods for a long period. A permanent interruptions around twelve months considered as menopause. [31] When menopause starts in females after fifty years of age it has a great effect on their intra-oral structures. Studies give data that various new oral sign symptoms appear intraorally in females due to insufficient release of estrogen from the gland. Deficiency of Vit-E, Vit-K, Vit-B, Vit-D, and calcium also found in some females after menopause start. [32,33] Xerostomia, burning mouth syndrome, alter in sensation of the test (most commonly metallic test) found in some females. Most of the females develop dental caries (mainly class 5 and class 2), mild to severe periodontitis in menopause. The maxillary and mandibular alveolar bone become unfit for endosteal implants in some cases because alveolar bone became very weak.[34]

In association with xerostomia, some patients develop breathing difficulty, difficulty in digitization, mild to severe intraoral and extraoral pain.[35,36] Periodontal problems can also be observed. Many females develop severe generalized gingivitis with mild bleeding.[37,38,39] There is a minute interlink in between osteoporosis of maxillary and mandibular alveolar bone, climacteric, periodontal gingivitis, and mild periodontitis, but there is no data about direct link in this case because periodontitis and osteoporosis are multifactorial.[40] Some changes found in the buccal mucosa, mucosa of tongue etc. Some autoimmune disorder li and mucosal lichen planus also found intraorally.[36]

Post-menopausal women: Females who receive HRT during post menopause to get rid of menopausal symptoms enjoying a good lifestyle.[41,42] Many menopausal signs and Symptoms disappear after taking combine sex hormone therapy (progesterone and estrogen combination). [43] The female who never receive HRT after menopause had developed lots of oral problems according to Allen NE study in the year 2010. Allen et al have published a systematic review on HRT vs dental outcomes with an emphasis on the costs of dental care.[44] According to Paganini-Hill study use of ERT for a longer period reduces the risk for tooth loss.[45]

Discussion

Different medical interventional research study gives new important data about oral health and its interlink with various sexual variation. The role that female sex hormones, pregnancy, and women's reproductive history play in contributing to the sex difference in oral health is supported by clinical research. [5] A causal relationship between parity and poorer oral health in women will require greater care in research design that incorporates and controls for the diverse array of confounding variables, such as related oral lesions (periodontal disease and tooth loss), the details of women's reproductive histories, and contributing social and economic variables.[46] Intersectoral approach between dental and other health departments can collect excellent data share among themselves for giving an excellent treatment plan.[47] Preventive oral health care services should be provided during the onset of puberty, early stages of pregnancy, menopause and post-menopausal women to improve their quality of life.

Conclusion

Dental practitioners need to actively counsel female patients about general and oral health strategies so that they can maintain their oral health and maximize their quality of life. Excellent knowledge about the systemic disease and its link with different oral lessons at different phases of a women's life cycle will help a lot in the diagnosis and treatment of disease for doctors like gynecologists, endocrinologists, specialized dental professional and at last fulfill the needs of the suffering patients.

Use of Robots in Dentistry: A Fact or a Fiction

Sangram Panda

Reader, Department of Prosthodontics, Institute of Dental Sciences,
Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Robotics is the most enthralling example of human invention which has the potential to replace the human factor altogether. Slowly but surely this invention is also making its way in dentistry too. The robotics coupled with artificial intelligence is being modified and customized to be used in the Dentistry. The advantage of robotic technology includes precision work delivered in a fatigue-less manner. This paper revisits the present use of robotic technology in dentistry and its future applications.

Keywords: *Robotics, Artificial Intelligence.*

Introduction

The traditional dentistry is increasingly becoming the object of past reconciliations as more and more clinicians are opting for new technologies to further their practice. The technologies which were previously just ignored based on the investment involved or the complicated training associated are now being increasingly getting incorporated in clinician's daily clinical regimens. Let it be intraoral cameras to the use of radiovisiography or use of lasers to microscope driven endodontics and digital impression, the technology-driven dentistry has arrived in our daily practice. But there is one more attribute to this modern era of practice that is robotics which is yet to make a grand entrance into this field but is already making its presence felt.

The world of robotics has lots of features that can be adapted & utilized in dentistry. Some of the Robotic technology which is currently being used is like placements of implants by a distant placed skilled clinician, who controls the robotic arm via the computer to place the implants. Robotic arm on the other hand eliminates human error by eliminating any hand tremors or fatigue which are usually associated with the human factor during surgeries. Even the surgical guides for the implant placement and the restorations which are milled post placement of implants are also done using an automated robotic unit only.

Dental use of robotics presently used:

Training robots for Pre-clinical dentistry: Earlier during the pre-clinical prosthodontics or preclinical conservative, the students used to practice their skills on the phantom head, which is nothing but an adjustable mechanical replica of cephalic region with a simple arrangement of teeth allowing for practicing crown and cavity preparations[1]. The phantom head was in no way able to improve the clinical skills of the student concerned as students could manipulate it in a manner convenient to them but not according to the mandatory clinical assertions.

But in Japan, they are already using a robot named Showa Hanako which has artificial intelligence to simulate different types of patient attitudes, gestures, and responses to make the student experience what it feels like to work on a real patient[1]. There is also a group of robots corresponding to the family of Geminoids which are equipped with advanced motion-sensor technology which allows the machine to mimic facial expression and precisely imitate head motions[1]. The robot is first in the series of personalities outside japan and is intended to push forward the android science and philosophy, in searching for answers to fundamental questions.

Endo microrobots: Endodontic mishaps can occur by even the best of the endodontists like file breakage, ledge formation, apical foramen perforation, and

excessive instrumentation[2]. To reduce the potential for human error and improve the quality of endodontic treatment, it is necessary to develop advanced endodontic technology innovation by applying advanced engineering and computer-aided technology [3,4]

This computer-controlled machine will be mounted on several teeth within the patient's mouth. With on-line monitoring and intelligent control, the micromachine or robot will perform the automated drilling, cleaning, and filling of the root canal. All other sub-project results will be incorporated into this robotic operation. Specific objectives for microrobot design include:

1. Reducing the reliance on the skills of the dentist,
2. Minimizing human error
3. Offering a method for precise diagnosis and treatment[5]

Dental Nanobots: Nanobots or nanorobots as they have come to be known are miniature robots of the size of nanometers that is of the scale 1 nanometer is equivalent to 1 millionth of 1 mm constructed with the help of nanoscale or molecular components[6]. The application of the nano-robot technology can be used in local anesthesia, re-naturalization of the original attrited or damaged dentition, orthodontic alignment in a single visit, curing hypersensitivity and maintenance ofthe oral hygiene using mechanical dentifrobots. Using computer technology for guidance these nanorobots can also be directed to kill bacteria in the cavity or repair the tooth damage hence occurred as a result of bacterial activity[7].

Surgical Robots: Robots can be used extensively in maxillofacial surgery in collaboration with a maxillofacial surgeon to correct the deformity or injuries to the face. A surgical robot programmed by the surgeon through interactive programs, does the pre-programmed task of repairing the human face[8]. Robotics have long been used in the milling of the bone surfaces, drilling of holes, deep saw osteotomy cuts, selection of osteosynthesis plates, and orthognathic surgery planning[9].

Sensor -Equipped Implant Set up: Dental implant is used to replace the root form of the missing tooth by placing a titanium implant body in the bone & allowing it to Osseo-integrate with the bone. Considering the mistakes done by a human clinician in the placement of these implant bodies into the bone, which also affects the overall prosthetic outcome a computer-assisted surgery has been developed for oral Implantology which includes pre and intraoperative procedures. The preoperative surgery is to use three-dimensional (3D) views as provided to enhance raw images obtained from the patient before the operation. The main aim of this technique is to render a target region and a pathway associated with relative organs from computed tomography (CT) data. It provides 3D orientation of surgical instrument position and trajectory displayed on a monitor in real-time within the patient's 3D imaging data[8]. Yomi a robotically assisted implant system that is cleared by FDA utilizes patients C.T scans to plan the implant procedures for the patients[10]. Recently a robot dentist installed two implants on a female patient using the same technology with an error margin of 0.2-0.3mm[11].

Conclusions

Although robotics coupled with programmable software technology provides humanity with precision and accuracy and is being implemented in many areas, it comes with its limitations per se. Apart from the extensive research and development still required in this area along with elaborate equipment requirements and ethics involved, the economic factors make it difficult for the developing countries to replace humans with machines. Although with changing times this may change soon and robotic dentistry may become a fact from fiction.

Hybrid Implant-supported Prosthesis in the Lower Arch: A Case Report

Sangram Panda[1], Sitanshu Sekhar Das[2], Abhijita Mahapatra[2], Abhilash Mohapatra[2], Pradyumna Sahoo[1]

[1]Reader, [2]Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

The protocols for the implant dentistry has improved at a very extreme pace. To conduct implant dentistry in a manner that is beneficial for the society requires an impeccable diagnosis, a treatment plan that takes into consideration surgical and prosthetic parts too. For any implant driven prosthesis to be successful requires that clinicians adhere to the basic principles ignoring which can lead to a prosthodontic nightmare. Following is a case report describing the methodology followed for hybrid lower implant-supported prosthesis.

Keywords: *Hybrid lower implant-supported prosthesis, Diagnosis, Treatment planning, surgical guide.*

Introduction

Modern dentistry requires that all the treatment goals like normal contour, function, esthetics, speech and health of the patient is achieved irrespective of atrophic changes, any underlying systemic diseases or trauma to the stomatognathic system.[1] Although, if fewer teeth are presently coupled with the fact that the ridges are highly resorbed then achieving these goals with basic Implantology is not possible. Implantology in its basic element means placing an alloplastic material in the jaws that provide anchorage and retention for the prosthetic part.[2] The experiences gained and the information acquired thus far has helped establish endosteal implants as a commonly used dental protocol. As a virtue of advancement in research, designing implants, dental materials, and techniques have aided in better predictability and outcomes as a result of which various types of implants and clinical techniques are available for rehabilitation of different clinical problems.[3] Implantology provides acceptable treatment outcomes that better the conventional and traditional restoration protocol.

Replacement of hard and soft tissue structures includes a lot of challenges and thereby requiring proper case selection, diagnosis, and execution of the treatment plan. Following is a case report describing the treatment protocols followed for one such case.

Case Report: The Patient, a 78 years old-man, wearer of a removable partial denture in the maxillary and mandibular arch, presented to the Department of Prosthodontics and crown and bridge, at Institute of Dental Sciences, to undergo rehabilitation of the loose lower removable partial denture with a fixed implant dental prosthesis.

Figure 1. O.P.G of the patient at the time of reporting to the department

Corresponding Author:

e-mail: sangrampanda@soa.ac.in

Patients case history revealed that he is wearing the upper and lower removable prosthesis for 7 years and has been facing problems with lower denture since the last 2 years like pain and mobility of the lower teeth along with loosening of the denture and inability to eat. The patient after clinical examination was advised with an Orthopantomograph which was duly carried out in the institution itself. Examination of the Orthopantomograph along with clinical correlation suggested a root stump in 38, vertical defect in 34 and 46 along with grade 2 mobility of 42 and generalized loss of lower ridge height. Upper dentition also suffered from supraeruption and cervical attrition in 15. The patient was given the treatment option of upper plane correction as well as replacement of the upper prosthesis but he insisted on the treatment of the lower arch only and to maintain the status quo in the upper arch as he was not facing any difficulties in the upper prosthesis and was satisfied with it.

It was then decided to extract 38(root stumps), 34, 42 and 46 while retaining 47 and 48 to provide stability to the prosthesis. An implant-supported RP-5 Prosthesis was planned for the patient which will be supported by both implants and soft tissues and will provide lower lip support as patients age ruled out any extensive ridge augmentation procedure given the high chances of morbidity.

Figure 2. Patients pic post-extraction and healing of 38, 34, 42, and 46.

Extraction of 38, 34, 42, and 46 was done along with curettage and irrigation. Interrupted suture with 3-0 mersilk was given to achieve uneventful healing. Complete oral prophylaxis along with pocket therapy of remaining teeth was also done during the post-extraction healing phase.

After healing based on the patient's C.B.C.T (Cone-beam computerized tomography) it was decided to put four I.C.E (Implant classic esthetics) internal hex designed implants of Alpha biotech (Israel) of the dimension of 3.7x 11.5mmin the region of 33, 34, 43 and 44. A Bone stabilized surgical guide was used for determining the exact position and spacing between the implants during implant placement surgery. Good primary stability of 45N was achieved during torquing of implants and alloplastic augmentation of the ridge was not required. Multi-unit temporary Healing caps were given along with interrupted mattress sutures that were given to contour the soft tissues around the healing caps to allow for uneventful healing.

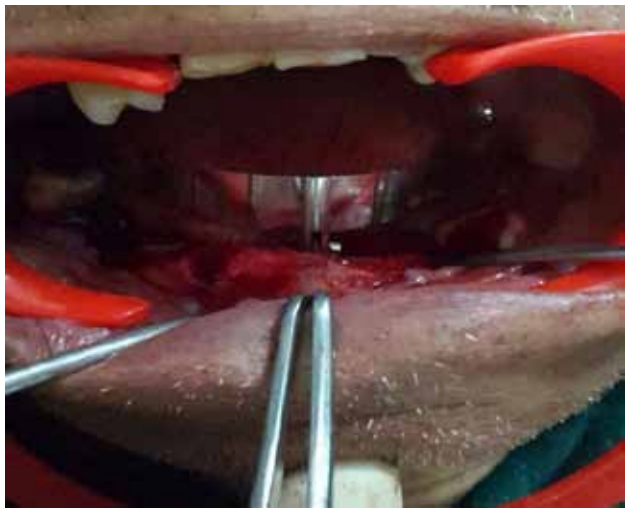

Figure 3. Bone stabilized surgical guide to ensure correct implant spacing and position.

Prosthetic phase: Post healing a preliminary impression of the upper and lower arch was taken with Chromatic alginate (Tropicalgin, Zhermack) and a special tray was fabricated for the lower arch. Borders were then molded using a green stick compound (DPI) and the second impression was made using medium body polyvinyl siloxane (Aquasil ultra monophase, Dentsply). A removable partial denture for the lower arch was prepared using the normal protocol and to match the upper occlusal plane. The coping cylinder was screwed onto implants and corresponding screw channels were made in the prepared removal partial denture to allow for the cylinders to pass through without any interference. These cylinders were then milled to the appropriate size to get incorporated within the removable partial denture. A 0.006 inch (adult size 6x6 inch, Nictone company) rubber dam was used to block out any undercuts and the screw channel access to prevent any self-cure resin to flow into it. R.P.D Prosthesis was placed over the coping cylinders and the pink color self-cure resin was used to fill up any gaps between the coping cylinders and the

prosthesis. Patient was asked to close his mouth in centric occlusion with articulating paper in place to identify any occlusal discrepancies if present. The prosthesis is then unscrewed with cylinder copings now attached to the intaglio surface of the prosthesis. The prosthesis was then screwed back into the patient's mouth after occlusal adjustments and any other discrepancies were corrected in the patient's mouth. Denture flanges were also reduced to prevent any soft tissue impingements. Composite resin (Te-Econom, Ivoclar Vivadent) was then used to block out the screw channels and maintenance instructions were given to the patient.

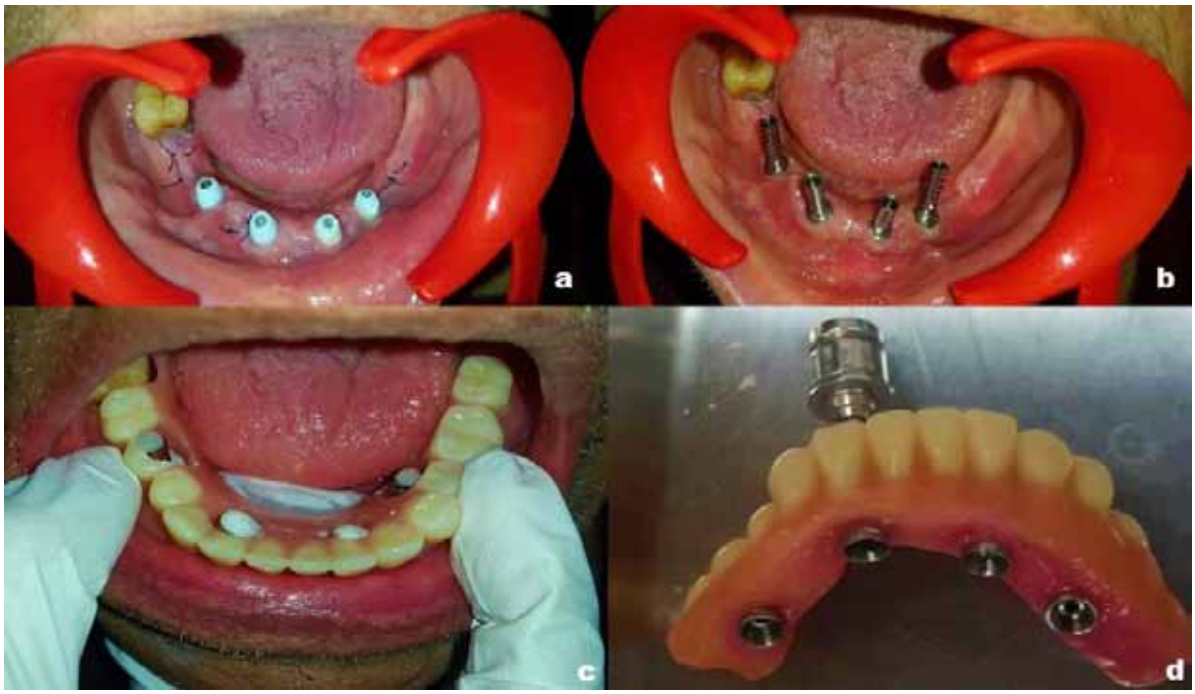

Figure 4a, 4b, 4c, 4d: Temporary healing abutment with continuous mattress sutures given.

Figure 5.

Periodic Recall: The patient was asked to come for a follow up at a frequency of 1,2,6 and 12 months after delivery of the prosthesis and Annual radiographic examination were also carried out. The following benchmarks for success were kept like lack of implant mobility, no tenderness or any symptomatic observations at each visit, Absence of peri-implantitis,and absentia of periapical lesion around the implants. Also, prosthodontic problems and outcomes were assessed. Very less bone deterioration was observed with radiological tools, but no implants failed after prosthetic rehabilitation after 1 year follow up. Occlusal access filling dislodged but was rectified and no other complication was noted during 1 year follow up. The patient also realized that his new denture looked good, his phonetics was vastly better and it was relatively easy to cleanthe prosthesis and his capability to chew had greatly increased. The progressive mentality of the patient and his happiness with the prosthesis that answered his main problems and requirement added to a fair prognosis.

Discussion

Dental Implantology requires exact and accurate planning to come over any clinical problems and to

foresee the final result before initiation of the treatment.[4] Planning for esthetic cases requires different diagnostic perspectives and includes additional factors like smile patterns and lip size etc.[5] Besides, the restorative space for the prostheses, which is measured from the platform of the implant to the opposing dentition, is often overlooked when the implant position is planned. The intra-arch distance which implants components, metal, the acrylic resin, and the denture teeth are placed plays a major role in selecting appropriate restoration. With mandibular implant-supported fixed prostheses, a minimum of 12–15 mm of space has been suggested.[3] When sufficient intra-arch space is observed, a hybrid prosthesis is recommended.[7] Reconstruction of the atrophic jaws for implant placements is usually staged with implant placement after graft healing.[7] Moreover, areas to be treated with dental implants are mostly affected with either acute or chronic infections.[8] Overall length of the cantilever is paramount for that itis to be assessed when constructing an implant-supported hybrid prosthesis.[9]The researchers suggested that the mandibular span should be between 15 and 20 mm to reduce the chances of failure of the framework.[9] Other researchers suggesta cantilever span of 1.5 or 2 times of the anterior, posterior curve of the implants.[3] Also to be considered is the opposing dentition and the number and distribution of implants, before the determination of cantilever span.[4] One more essential objective during the construction of implant-supported hybrid prosthesis is achievinga passive fit of the framework. If there is no passive fit then biological and mechanical problems likeperi-implantitis bone, screws loosening or fracture of the abutment or the implant were noticed.[3]No implant failure, peri-implantitis, soft-tissue complication related to prosthesis design, fracture of prosthesis frameworks, screw fractures or screw loosening, or difficulty in sustain ability were observed in the patient during the periodic recall time. Although, the occlusal access filling material dislodged it is considered to be the most common problem plaguing the mandibular hybrid prosthesis.[10] On an added note, it was also observed that, though the restoration survival rates remained high, the denture teeth underwent significant wear & tear.[10] Also, the clinicians found that tooth fracture anteriorly was more commonly observed than the posteriors.[10] In the present study, the loss of filling material from the prosthetic screw access occurred only once. These results are incomplete contra indications to the increased incidence of tooth fracture presented inthe previous report.[10]

Conclusion

The present case has shown that a very respectable esthetics and satisfactory functionality for a patient can be achieved with an implant-supported hybrid prostheses. The only drawback of this case study is the follow-up timeline of only 1 year which might undermine the proper assessment of these results. Although, it is safe to conclude that hybridrestoration can give optimum outcomes wherein implants were placed irrespective of careful treatment planning. It is also paramount to assess the patient not only with a surgical aspect, but also from a prosthodontic point of view.

Abstract

Majority of us spend very little time or else may be no time while choosing the right as well as the best toothpaste for our mouth because good oral health should be the prime importance. Everyone wishes to have an impressive personality, and for that attractive appearance, a beautiful smile is always required. Without proper oral care an attractive smile cannot be achieved. Toothpaste is not only a bathroom requirement; it is the most important material for maintaining good oral hygiene. All toothpaste that are available in the market commercially today is formulated and designed to clean our teeth and help in maintaining good oral hygiene, all the products do notachieve that need equally. Some of the commercial toothpaste products have the potential to damage our teeth, while others simply don't provide enough protection to our teeth as per requirement. This article highlights the toothpaste available in the Indian market so that one should be able to select the right balance of toothpaste according to his/her oral health needs.

Keywords: *Toothpaste selection, Good oral health, Indian market.*

Introduction

Dentifrice is the French word for toothpaste. Dentifrice is a type of paste, gel, or powder applied on a toothbrush as an addition to dirt-free and to preserve the artistic appearance and good physical condition of teeth. A dentifrice is a substance kept on the top of the bristles of a toothbrush to clean the visible surfaces of the teeth. Toothpaste composition are generally publicized on packs w/w' - that is weight for weight, or grams per 100 grams.[1]

Varieties of Toothpaste: Many varieties of toothpaste are now available in the market. But knowing the effectiveness of toothpastes is important by seeing their advertising or new formulations are "clinically proven" and approved by any experienced dental health personnel.[2]

a. Fluoridated Toothpaste: This type of toothpaste has taken 95% of the market sales. Because of this fluoride ingredient there is a decrease in the occurrence rate of oral cavities in industrialized countries for over the last 30 years. Sodium fluoride and sodium monophosphate are the most commonly used fluoride compounds having more than 1500 ppm F available in the market but can be obtained only with a prescription. The amount of fluoride content is written in the toothpaste tube.

Fluoride toothpaste for children: Fluoride toothpaste which contains 1000-1500 ppm F might cause enamel fluorosis for all the permanent incisors of

children below the age of 2 years as there are chances of swallowing toothpaste while brushing. Fluorosis of enamel is a form of condition varying from minor white spots to yellow/brown discoloration of the enamel because of too much intake of fluoride. Because of this fear over enamel fluorosis, a few production companies now promote low fluoride "children's" or "pediatric" toothpastes which contains less than 600 ppm fluoride.[1]

b. **Plaque and Gingivitis Prevention Toothpaste:** Marketed as antiplaque and gum protection toothpaste. They contain sodium lauryl sulfate, triclosan, zinc, and stannous ions. They have antibacterial properties as well as they put a stop to the formation of plaque.

c. **Anti Calculus Toothpaste:** Commercially available as anti-tartar toothpaste. They contain tetrapotassium plustetrasodiumpyrophosphates, sodium hexametaphosphate, and zinc. Toothpaste that contains anti-calculus agents helps in reducing the formation of calculus and also it will not reduce the levels of pre-existing calculus.

d. **Desensitizing Toothpaste:** Marketed as anti-sensitivity toothpastes. They contain Potassium nitrate, potassium citrate, and Strontium chloride. Desensitizing dentifrices can work:

   1. Bymisleading the transmission of neural signals, pain can be prevented
   2. By blocking the dentinal tubules.

e. **Fresh Breathe Toothpaste:** They contain peppermint, spearmint, or menthol. They contain enhanced flavoring agents along with antibacterial to fight halitosis.

f. **Tooth Whitening Tooth Paste (Cosmetic Toothpaste):** Whitening toothpaste is promoted because of its cosmetic benefits. Enamel tends to go down its whiteness with age, therefore these whitening toothpastes continue to take rise in the commercial market. These toothpastes have abrasion value that is higher than in normal toothpaste to manually remove the tobacco, food, smoking, and other extrinsic stains from teeth. Enzymes such as protease and papain create a whitening effect. There should not be any confusion between whitening toothpastes with hydrogen (or carbamide) peroxide whitening systems which can only be approached through a dentist.[3]

g. **Toothpaste for adults:** The majority of toothpastes come together with fluoride and other agents to improve their plaque control, calculus,and gum disease by the enclosure of uncontaminated agents. Most of the toothpaste include Triclosanthat are medically of use for enhancement in gum health. Some toothpaste intentionally target 'tartar' and make use of pyrophosphate to restrain the formation of dental plaque by building-up of tartar. There is an advanced strategy in the manufacturing of 'all in one' toothpaste that contains the maximum amount of agents that can cause a reduction in calculus formation, help in preventing dental caries, and can also improve gum health.

h. **Smokers Toothpaste:** Tar deposits are the causes of stained teeth for the people who smoke. Several toothpastes make use of stronger abrasives to remove the smoker's stains. Vigorous and forceful brushing with coarse pastes can harm the enamel over the long run.[3]

i. **Herbal/Natural Toothpaste:** Herbal toothpastes that are made from natural herbal ingredients like seaweed extract, propolis, essential oil of ginger, and much more. For all the natural toothpaste regarding health claim is still not clinically proven. Therefore, it is required to make sure if these "natural" toothpastes have fluoride or not for the prevention of tooth decay.[4]

Complete Guide to Choosing the Right Toothpaste: A toothpaste displaying the seal on its packaging should be chosen which are approved by Dental Association. We should not gamble with our health by choosing non sealed approved products.[5]

According to the need: Toothpaste should be chosen according to the need of the teeth.

1. From mild pain to severe pain along with sensitivity in the gums and teeth.
2. Kids, adults in a sufficient amount of fluoride indiet, and people with diabetes and other conditions should choose fluoride toothpaste.
3. Before choosing anti-cavity toothpaste, products should be checked.
4. Products having the properties of anti-gingivitis should also be preferred.

Look Out: Unwanted cosmetic products like whitening toothpaste should not be used without the prescription of any experienced dentist.

Picking a Toothbrush: A toothbrush is the right tool on which toothpaste can be applied to the teeth to effectively protect from cavities and gum disease. The incorrect toothbrush can scratch gums, damage enamel or might fail to remove trapped food in between the molars. Toothbrushes with soft-bristled brushes as advised bya dentist should be used. Every 3 months toothbrush needs to be replaced even if it still appears new and fresh as bacteria can grow up over time.[6]

How to Choose the Best Toothpaste?:

- Toothpaste should be selected that cleans your teeth, prevent cavities,and fights plaque.
- Dental issues like bad breath, cavities, sensitivity, yellow teeth, and tartarshould be taken into concern while choosing the best toothpaste.
- Flavoured and compatible taste can too be an important aspectof a toothpaste.

With all these requirements in mind, some might get anxious while choosing toothpaste for self. So here is a listof top varieties of toothpaste that isbased on several parameters which will help todecide on the best toothpaste as per the requirement.[7]

Commercial Brands of Toothpaste in India: The commercial companies of toothpaste in India geared up since the year 1975 when companies like Colgate and Hindustan Unilever's Close-up used to be the leading players in the Indian market. Each year several new industries continue entering the toothpaste commercial Indian market. As year pass by, the dental hygiene industry replace all the locallymade powders and herbs that were previously used to clean teeth.[3] The 10,000-crore market of toothpaste quite exhaustive is flooded with a variety of brands of toothpaste that claims to provide cavity-free teeth and healthy gums.[2]

1. **Colgate:** Colgate is a synonym for toothpaste for many of us as it had ruled the Indian toothpaste commercial market for decades. It becomes the world's No. 1 toothpaste in 1999 and becomes the world's highest-selling brand. Colgate toothpaste is ideal for kids, young and old persons in the market segments as it commits to build teeth stronger, whiter, and free from cavities. Several famous variants of Colgate are Colgate Max, Active Salt, Colgate Total, herbal, Colgate fresh, and Colgate Sensitive for sensitive teeth. Colgateshares the highest number of consumers.[8]
2. **Close-up:** The Hindustan Unilever market the Close-up toothpaste which was the first-ever gel-based toothpaste in India. Close-up is known as a youth-oriented company but is also has kids toothpastes. It has variants like active gel, whitening gel, deep action, zinc-menthol gel etc. It rules in the second position in the toothpaste industries and is famous to deliver fresh breath along with strong teeth and dealing with dental issues like bad breath, cavities, and yellow teeth.[2]
3. **Pepsodent:** Pepsodent is owned all over again by Unilever. Ingredients include manynatural ingredients like zinc, micro granule formula, and inactive triclosan, that claim to give us fresh breath and germ-free teeth as well as strong gums. It has anti-bacterial properties that protect teeth from cavities and avoid the growing of yellowish coating on the teeth. Various variants of our Enamel Safe Whitening Protection, Center Fresh, Cavity Protection,and Germicheck with salt and cloves.[9]
4. **Sensodyne:** People facing the problem of tooth sensitivity can go for using this Sensodyne paste that deals with the dental problem more efficiently and it is an economically affordable toothpaste in the Indian market. It is a trademark of Glaxo Smith Kline and is considered as the most preferred and clinically recommended toothpaste for sensitivity by many dentists in India since 1961. Because of its efficient formulation of bioglass known as Novamin, known for a reduction in sensitivity of teeth while in contact with sweet, cold, acidic, and hot foods, many people felt their sensitivity to get reduced after the first use itself. Sensodyneprovides three variants for dealing with sensitive teeth for the people – fresh gel, repair and protection,and rapid relief.[4,5]
5. **Oral-B:** This is an international brand of India's finest dental care brand. It deals with various dental care commodities but it focus more on toothbrush designing. The toothpaste consists of a complex patented formulation of Stannous Flouride Complex with the rationale of preventing tooth decay and cavities, building stronger teet has well as preventing enamel erosion. Oral-B Pro-Expert toothpaste with Oral-B toothbrush and mouthwash can be a great combination together that can help in fighting all our dental worries. Other varieties of this toothpaste brand also act well such as Pro-Expert Deep Clean, Extra White as well as Gum and Enamel repair, etc.[9]

6. **Meswak:** Considered as the best natural toothpaste for sensitive teeth, Dabur is the manufacturing company having a strong grip in Ayurvedicas well as natural commodities. An important element of Meswak toothpaste is meswak (Salvadorapersica) or the toothbrush tree. Various other components of this toothpaste arechlorides, fluoride, silica, flavonoids,and Vitamin C which are known ingredients for providing optimal dental health. Since this is a herbal toothpaste, its taste will be different than other toothpaste and it can also provide relief from gum problems, dental cavities, sensitivity, and plaque formation.[10]

7. **Patanjali Dant Kanti:** Since some years recently Patanjali has transformed Indian Ayurveda to the highest level in the toothpaste industry. The Patanjali product known as Dant Kanti also comes as aloevera toothpaste, advanced oral care, medicated oral gel, and Dant Kanti Junior. It is made using herbal ingredients that help to fight dental problems such as dental cavities, painful, swollen and bleeding gums, yellow teeth, and bad breath. The consumers of this toothpaste reviewed that the paste is having a strong, refreshing taste that reflects the dominance of herbal ingredients.[11]

8. **Vicco Vajradanti Ayurvedic Toothpaste:** Vicco toothpaste is marketed as an "Ayurvedic medicine for gums and teeth," The main ingredient of the toothpaste is turmeric which acts as asuperb anti-inflammatory product. The remaining components of ViccoVajradanti toothpaste can help people to consider it as the best natural toothpaste. This distinctive formula provides excellent benefits for teeth as well as gums making them plaque resistant and strong fighting the bacteria that can cause cavities, as well as bad breath Vicco toothpaste,which is helpful especially for people suffering from swollen gums as well as toothache.[3,10]

9. **Dabur Red Toothpaste:** For millions of Indians, Dabur Red has become the favorite brand for oral health care. Dabur Red, is a combination of natural toothpaste that includes a great Ayurvedicconstituents of cloves, mint, tomar and other herbal ingredients. Being a herbal paste,it fights all our dental worries away by giving us shinier and stronger teeth. Because of this rationale, Dabur Red has created its place as one of the highly demanded products in the toothpaste industry of India. Although this toothpaste formulation also comes in a powder (manjan) form, however using the red toothpaste is always suggested by the dental health professionals.[12]

10. **Himalaya herbals complete dentalcare:** Himalaya complete care toothpaste is known for its key ingredients like neem, pomegranate, meswak and false black pepper, Triphala,etc blendand act as specially formulated toothpaste for adult and oral care. Properties like antioxidant, anti-bacterial and anti-inflammatory helps discard toxic layers in the mouth giving fresh and clean breath as well as strong teeth and gums. People anguish from bleeding gums explicitlyget many advantages from using Himalaya complete dental care toothpaste. It is now famous with Indian folks as it is a natural as well as chemical-free toothpaste and people who prefer herbal toothpaste give guarantee for its action.[13]

Conclusion

An attractive and beautiful smile can never be achieved by improper oral health care. The majority of us spend little time or else may be no time while choosing the right as well as the best toothpaste for our mouth because good oral health should be the prime importance. Toothpaste is not only a bathroom requirement; it is the most important material for maintaining good oral hygiene. The clinical team has a responsibility to keep up-to-date with the ever-increasing development and marketing of dentifrices. Dentifrice recommendations should be patient-specific. Patients having an allergy to certain or any component of a toothpaste then all such kind of toothpaste should be avoided. Patients suffering from erosion should choose low RDA dentifrice. After all smile matters and everybody wish to boast upon an impressive personality with a pleasing appearance and therefore toothpaste should be chosen wisely according to the need of dental health care.

Improving Oral Health of a Child: A Parent's Guide

Debasruti Naik[1], Motirmoy Giri[2], Ramesh Nagarajappa[2], Sudipta Sahu[3], Kajal Kiran Sahu[4]

[1]Senior Lecturer, Department of Public Health Dentistry, [2]Senior Resident, Fakir Mohan Medical College, Balasore, Odisha, India, [3]Professor and Head, Department of Public Health Dentistry, [4]Tutor, Department of Public Health Dentistry, [5]Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

For every parent, the early phase of growing a child is one of their life's most challenging as well as responsible experiences that can bring out the very best in us our patience and our skill to provide them good health. This article will provide essential information to help out parents build knowledge about maintaining good oral health of their children and also will help to make out the vital building blocks of parent-child relationships. This article will also help parents reflecting their actions to better understand their children's oral health. Small children at their younger age are very sensitive to social stimuli such as praise as well as affection and they learn best by imitating their parents. This knowledge will help parents to guide their children as they grow towards handling their oral health. This article is meant for parents of children of all ages and in all cultures which will be helpful and may provide insight to professionals like caregivers, teachers and early childhood educators.

Keywords: *Parental Guidance, Knowledge on dental health, Child oral health.*

Introduction

Oral health is considered as an important aspect of general health; good oral health provides healthy mental, physical and social well-being of an individual as well as provides enjoyment of their lives by allowing them to eat, speak and socialize devoid of experiencing pain, discomfort or embarrassment. Every child should benefit from a high paradigm of health, including oral health but during the early ages of their childhood they are dependent on their parents only. The dental health profession has an accountability to promote the best possible oral health for all children. Kids less than 5 years of age usually invest maximum time with their parents.[1] Some researches reported that the maintenance and outcomes of young kid's health invariably are affected by their parent's knowledge.[1]

A child's well-being of psychological, functional, and social dimensions are affected by dental health. Because of dental pain, distressing effects on kids, including poor growth, lost sleep, behavioral problems, and learning can be seen. Proper health inconvenience leads to a substantial reduction in school attendance and simultaneously hampers in parental working days.[2]

children as they grow towards handling their oral health. This article is meant for parents of children of all ages and in all cultures which will be helpful and may provide insight to professionals like caregivers, teachers, and early childhood educators.

Baby's teeth begin forming: Months before birth Infant teeth begin to develop. Tooth buds start appearing by the 6th week of pregnancy and keep on forming till 6 months. By the time baby born the crowns of primary teeth formation gets completed and until the baby begins teething they will stay behind hidden the gums.[3]

Looking for the teeth to erupt:

- Primary teeth will appear out in the mouth as early as 6 months till 12 months of age.
- First the lower front two teeth will appear.
- There is nothing to be worried as in some babies few teeth might appear late and by the age of 3 years, all 20 primary teeth will be present.

New Permanent Teeth: In the late 6 years of age, an eruption of 32 permanent teeth (16 in each upper and lower jaw) occurs that are the substitute of 20 primary teeth. The oral cavity contains both primary and permanent teeth during this period that might be a reason for small kids at increased risk of caries. The enamel of newly erupted is inadequately mineralized after its formation and its surface remains porous. During the phase of permanent teeth eruption, occlusal surfaces of the new permanent teeth will be resting on the lower level than the primary teeth. And because of this toothbrushing becomes more difficult than before. With the increasing number of permanent teeth in the mouth, the maintenance of the narrower interdental spaces becomes very important and crucial.[4]

Why Parent should be Concernedon Taking Care of Baby Teeth?:

- Healthy teeth are required for the baby and toddlers to chew their food properly while eating.
- Teeth has an important role to play in speech development as they learn how to talk.
- Primary teeth are needed to be maintained till the eruption of permanent teeth because the early loss of baby teeth can cause crowding of the permanent teeth.
- There will be a hindrance in the learning procedure if the primary teeth will be affected by any kind of oral disease-causing pain and infection.[5]

Beginning of Dental Care: By the first year of age, dental check-up at regular intervals of at least twice each year should be recommended.[6]

1. Birth to 6 months old:

- Baby's mouth has to be cleaned with water and a gauze or a cloth or a soft infant toothbrush after feedings and at bedtime can be used.
- If a child is living in an area without fluoridated water then dental health professionals should be about the use of fluoride supplements and the application of fluoride varnish.
- Regular feeding habits (bottle feeding and breastfeeding) should be established.

2. 6 to 12 months old:

- During the child's first birthday, the first tooth should appear and the pediatric dentist should be consulted for an exam as soon as possible for confirming about no worries.
- Tooth brushing needs to be done twice daily and specifically after feeding at night with a small, soft-bristled brush.
- During the phase of learning how to walk, a child may undergo facial injuries that might include teeth as well as other facial structures. Therefore, the parents and caregivers need to stay alert during this period.
- Breastfeeding for at least 1 year is recommended and after that year whole that milk should be used for proper development body and brain.[7]

3. 1 to 3 years old

- The scheduled dental checkups should be followed every 6 months as recommended by the child's pediatric dentist.
- By the age of 3 years, a child should learn how to brush his teeth and how to clean and rinse.

Protecting Your Child's Teeth: Below are the following points which help the parents to improve their child's oral health and protect from getting affected by oral diseases: -

- Drinking water containing fluoride (optimal amount of 0.7 mg per liter) should be given to the

child to prevent tooth decay. In doubt of fluoride concentration, dentists, pediatricians or nurses should be consulted.[8]

- Parents should make sure that their child brushes their teeth twice a day daily.
- The teeth of a child should be brushed properly without toothpaste with a small, soft-bristled toothbrush and plain water.[9]
- Children below 6 years should brush their teeth under the supervision of parents or caretakers so that they can develop good brushing skills. It should be taken care that they only use a pea-sized amount of toothpaste and always spits it out rather than swallows it.
- Need for the application of fluoride varnish on the teeth as soon as the first tooth appears should be discussed with the dentist, family doctor, nurse or pediatrician.
- **Get a Check-up:** During the child's first birthday, the first tooth should appear and the pediatric dentist should be consulted for an exam as soon as possible for confirming about no worries.
- **Spreading of cavities to be prevented to your infant:** Mouth to mouth contact should be limited by not sharing food or eating utensils, and by not placing objects in your mouth and then in your infant's mouth.
- **Avoid 'Baby Bottle Decay:** A child should not be put to sleep with a bottle of milk or juice. Sugary liquids can stick to his teeth, feeding bacteria that can cause cavities.
- **Cut Back on Juice:** A lot of parents have some thoughts regarding juice that it is a healthier choice for a drink. Juice should be limited to no more than 4 ounces a day of 100% fruit juice. Preference for on-sugary drinks and foods at mealtimes should be given.
- **Control the Sippy Cup:** Over-using of a sippy cup can result in cavities on the anterior teeth if the drinks are sugary.
- **Teach Good Habits:** Washing mouth properly after every meal. Brushing twice a day. Limiting sticky and sugary foods.

Children and their daily food eating habits[10]:

- Fruit, green and leafy vegetables, grain,and healthy dairy foods including cheese, milk,and unsweetened yogurt should be served for a healthy body.
- Sugary foods should be limited. Foods like candy, cake, cookies, and sweetened drinks can only increase the risk of tooth decay.
- Sticky foods like caramels and fruit roll-ups should also be limited.
- Eating between meals need to be limited.

Oral Hygiene Maintenance for Kids[11]: It has to be mandatory for every child to have his or her toothbrush as soon as the child has teeth inside his mouth.

Toothbrush for your child:

- Toothbrush with soft-structured bristles has to be chosen as it cleans the teeth better.
- A small child-sized toothbrush with large handles should be chosen. For being more comfortable, children can choose from various colorful toothbrushes.
- Toothbrushes need to be replaced every 3 months or maybe sooner if a child chews her toothbrush bristles or has been sick.
- Children under the 3 years old should use a smear of fluoride-containing toothpaste in case there is inadequate intake of fluoride daily.
- Parents need to apply a pea-sized amount of the toothpaste and spread along the head of the brush.

Sealants Can Seal the Deal for the Teeth: To prevent decay, sealants are preferred as a preventive procedure. The sealant applied on the teeth acts as a hurdle that protects the cavities prone areas of the posterior teeth from acids and plaque. The sealants have to be checked regularly by the dentist, since they do tear out away and might require reapplication of the sealant. If lost, sealants have to be replaced immediately, as they are effective simply as long as they are retained on the teeth.[12]

Table 1. Caring for your child's teeth during a dental emergency.[13]

Condition	What should parents or child care providers do?
Knocked out (avulsed) tooth	1. Get back the tooth and grasp it by the crown. In case the tooth is dirty then gently rinse it, if possible in the child's saliva. 2. Tooth can be stored in a cup of cool milk. 3. Parents of the injured child need to be contacted first to take the child to the dentist immediately.
Broken tooth	1. Rinse with warm water. 2. Cold compress like ice cubes can be used on the area to keep swelling down.
Bitten tongue or lip	1. Pressure to the injured area should be applied using a clean cloth to stop any bleeding. 2. Cold compress to be placed to avoid swelling.
Objects caught between teeth	1. Careful and proper use of dental floss between the teeth to remove the object has to be instructed to the child. 2. A dentist needs to be consulted ifthe object is not easily removable.
Toothache	1. Mouth rinse with warm water and floss to remove any food that might be trapped should be done by the child.
Trauma to jaw/ broken jaw	1. Cold compresses need to be applied to swollen areas and any kind of cloth-like scarf, handkerchief or towel around the jaw and over the top of the head should be tied to hold the jaw in place. 2. Emergency treatment needs to provide at the earliest.

Conclusion

The groundwork and the basis for strong teeth in children, as well as teenagers, is set during the early years of life. The contribution of parents towards good oral health is immiscible. Poor oral hygiene practices and diet habits are the primary reasons for cavities and gum diseases in children. The formation of caries in primary teeth gradually increases the risk of caries formation in permanent teeth also. Hence it is required to set up a proper and routine oral maintenance at the earliest during childhood to make sure the growth of strong as well as healthy teeth. Parents are considered as the constant role model for their children and they are also the key to make sure of a daily practice and in making their children value the importance of oral hygiene. Small children at their younger age are very sensitive to social stimuli such as praise as well as affection and they learn best by imitating their parents. Therefore, every parent should understand the importance of healthy teeth and should take proper care of them during their development to ensure a healthy future of their kids.

Abstract

Sugar eating is highly prejudiced by several social cultures, activities, biological and ecological factors which results to be the leading risk factor for dental caries as well as other oral diseases. A diet has a complete consequence on the veracity of the oral cavity that includes oral mucosa, alveolar bone, teeth,and periodontal tissue. It is ahead of our debate that the sugar-rich foods consumed can result ina risk on the integrity of our teeth. There is a direct impact on oral health because of the consumption of sugar. There has to be a noteworthy impact on serving to restrain the global outbreak of dental caries if we can reduce the amount of sugar consumption that has been extensively ignored compared to other health issues and is a foremost global public health problem distressing individuals, health systems as well as economies. This review article discusses the consumption of sugars, various forms of sugary diets in our daily intake, and its effect on oral health.

Keywords: *Sugar rich foods, Oral Health, Dentist recommendations.*

Introduction

In the last 50 years, sugar consumption has increased drastically worldwide during all these years particularly in emerging economies. Sugar eating is highly prejudiced by several social cultures, activities, biological and ecological factors which results to be the leading risk factor for dental caries as well as other oral diseases. A diet has a complete consequence on the veracity of the oral cavity that includes oral mucosa, alveolar bone, teeth,and periodontal tissue. It is ahead of our debate that the sugar-rich foods consumed can result in a risk on the integrity of our teeth.[1] There is a direct impact on oral health because of the consumption of sugar. There has to be a noteworthy impact on serving to restrain the global outbreak of dental caries if we can reduce the amount of sugar consumption that has been extensively ignored compared to other health issues and is a foremost global public health problem distressing individuals, health systems as well as economies.[2] This review article discuss the consumption of sugars, various forms of sugary diets in our daily intake, and its effect on oral health.

Sugar can be described as a sweet crystalline-like material augmented from various plants, chiefly sugar cane as well as beet sugar that consists of essential sucrose, and it is used as an extra additive material as a sweetener in food and drink. Sugars can be classified into two types i.e.

1. **Intrinsic Sugars** (or natural Sugars) i.e. where the sugar particles are inside the cell structure of the food particles such as fresh fruits or sweet vegetables.

Debasruti Naik
Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: smilewithdebshruti@gmail.com

2. **Extrinsic Sugars** i.e. where the sugar particles are there outside the cell structure of the food particles or considered supplementary as an extra substance to the food. Extrinsic sugars again subdivided into: a) Milk Sugars (or natural Sugars) i.e. lactose in milk products (e.g. cheese, plain yogurt), which are less cariogenic and are accompanied by significant amounts of essential nutrients. b) non-milk extrinsic Sugars, also called added sugars and free Sugars (or hidden sugars).[3]

Free sugars are a type of extrinsic sugars considered as the primary factor responsible for dental caries. They are added to foods and beverages. They considered to all: monosaccharides such as Glucose, Fructose, Galactose, and disaccharides such as Sucrose and Table sugar. It is advisable for primary children that free sugars consumption should be proportional to about 30 g per person per day. Because it is reported that consumption of free sugars more than 4 times a day or intake of above 60g per person per day can result in an increased risk of dental caries.[4]

Recommended dose of sugar: According to the WHO guideline recommendation: Free sugar consumption daily should be restricted to less than 10% (or 50 g = around 12 teaspoons) in both adults and children. Also an additional reduction to below 5% (or 25 g = around 6 teaspoons) of total energy intake will provide additional healthiness along with minimizing the risk of tooth decay all through the life route.[5]

Form and Frequency of Sugars Consumed: Sugars-containing food in sticky form if remains in the mouth for a longer duration then there will be drop-in pH for a longer duration inside the oral cavity. This may enhance the cariogenic activity, thus increasing the risk of tooth decay. A high rate of recurrence of intake of sugars causes an increase in exposure duration to the oral cavity that is open to the elements of sugars and has a high retention causing maximum exposure on tooth surfaces.[6]

Amount v/s Frequency: According to the Vipeholm study, the findings are significant to date while taking into consideration the amount versus frequency issue. The addition of 300g extra sugar during a meal has less risk than adding up sugary snacks between meals which causes a significant increase in the risk of dental caries.[6]

Sugar effects on oral health: During the intake of food, sugar itself never harms the teeth directly, but it enables the bacteria and acids to get activated and do the work. Plaque formation occurs as the bacteria feed on the sugary foods that are inside the oral cavity and they create a bacterial community and it remains on the teeth for a longer duration in the form of plaque till the bacteria make acids resulting in enamel wear and causing cavities. Gingivitis also occurs because of the bacteria present in the plaque. The sugary foods releasing the sweetness and allowing the bacteria to get metabolized and later they involved in dental biofilm formation which further generates acids by-products leading to demineralization of the tooth structure.[7]

Persons in the threat of Tooth Decay: Every individual having food is at risk of tooth decay but children and adolescents are at more risk of having dental caries. People having missing tooth have at a young age are at more risk of tooth decay. People who do not maintain proper oral hygiene or do not rinse mouth after every meal are at high risk of dental diseases because plaque formation occurs at the earliest only 20 minutes after we eat foods so if the mouth is not rinsed effectively, tooth decay starts. Consumption of sugar regularly always have a maximum threat of developing oral diseases, if the consumed food eaten is sticky or taken in between mealtimes. People involved in smoking and drinking alcohol are also at more risk.[8]

Are all beverages bad for teeth?: No, all the beverages are not bad for teeth as it relies on the type of sugar consumed as well as the acid production inside the oral cavity. There are some food products containing calcium and phosphate example:- milk and yogurt which are meant to protect teeth from the harmful effects of acid. Milk product foods and beverages helps in making the teeth stronger and aids in remineralization process, whereas calcium and phosphate in milk help to put off the bacteria from adhering to the tooth as well as budding into plaque. Thus, drinking some of the beverages may act as beneficial to our body.[2]

Health implications for people who go for high-sugar diets such as Unstable Blood Glucose, Obesity, Heart Disease, Cancer, and Diabetes, Immune Function, Chromium Deficiency, Aging Acceleration, Tooth Decay, Children's Behaviour and Cognition, Stress and Anxiety, Replacing Important Nutrients.[4,9]

High sugar-containing Foods and Drinks[10]:

1. **Low-Fat Yogurt:** 1 single cup of yogurt (12 teaspoons of sugar) = 24 grams sugar exceeds the

daily restriction of sugar intake for a human being. Therefore, natural, or full-fat yogurt without added sugar should always be chosen.[8]

2. **BBQ Sauce:** Almost 2 tablespoons of BBQ Sauce contains 14 grams of sugar in it. Therefore, daily intake of more than the normal range can cause harmful effects for our body.
3. **Ketchup:** 1 tablespoon ketchup = 1 teaspoon sugar.
4. **Fruit Juice:** Natural fruit juice contains more fibers than sugars in it. So, drinking one fruit juice will not hamper much to our health. Rather, drinking preserved fruit juices in which added sugars are in it can harm more to our health. Drinks like coke or any fruit juice contain more of added alcohol, sugars, and preservatives inside it.
6. **Sports Drinks:** One bottle (570 ml) of sports drink contains 32 grams of added sugar which gets quickly absorbed and provides instant energy with added 159 calories.
7. **Chocolate Milk:** A full glass of chocolate milk with added flavors of cocoa contains 2 teaspoons of added sugar.
8. **Flavored Coffees:** The hidden amount of sugars inside the coffee can be confounding. It is expected that a good chain of coffee can give 25 teaspoons of sugar = 100 grams of added sugar per serving.
9. **Iced Tea:** Commercially prepared chilled ice tea contains sweetened sugar or flavored with syrup of 33 grams of sugar per (340 ml) serving.[2]
10. **Protein Bars:** Protein bar with high sugar should be avoided as it contains around 30 grams of added sugar in it.[9]
11. **Vitamin water:** Some vitamin bottles come with added sugar in it which contains around 120 calories and 32 grams of sugar per bottle of 500 ml.[11]
12. **Pre-Made Soup:** Packed soup contains high amounts of sugars and preservatives inside it.
13. **Canned Baked Beans:** 1 cup (254 grams) of regular baked beans = 5 teaspoons of sugar.
14. **Bottled Smoothies:** Commercially prepared smoothies in bottle contains upto 96 grams = 24 teaspoons of sugar in a single serving.[12]
15. **Breakfast Cereal:** Some breakfast cereals have 12 grams = 3 spoonful of serving per 30 grams.[13]

The most excellent way to steer clear away the threat of added sugars in meals is to prepare them at home as it is known exactly what's in them.

Sugar Substitutes: Non-acidogenic sugar substitutes (sweeteners) do not cause pH falls in dental plaque. Various sugar replacementsare of two types: intense sweeteners (noncaloric) such as aspartame, saccharin, glycyrrhizin, sulfame and so forth and bulk sweeteners (caloric) such as sorbitol, mannitol, xylitol, and so on.[14]

Advisory from dental professionals[15]:

- It is advisable to brush teeth twice a day properly with fluoride-containing toothpaste as well as dental flossing to be done daily.
- Rinsing the mouth with water frequently after consuming sugary foods.
- Reduce consumption of sugar-sweetened beverages and snacks; that helps decrease the production of acid in the mouth.
- Eat sugary foods at mealtimes only
- Do not add any sugars to baby's foods and juice drinks.
- More amount of vegetables, fruits and breakfast having less sugar content should be consumed.
- Long-lasting sources of sugar consumption should be avoided (dried fruits, fruit leathers and hard or chewy sweets) close to bedtime.

Conclusion

Sugars and oral health have a dynamic relationship. Health care sector professionals, specifically the dental as well nutrition professionals should understand the relationship between diet and oral health and its effects on our body. There is a need for oral hygiene instructions and oral health education for the people and this awareness has to be done by dental health professionals to minimize the risk of oral diseases because of sugary foods. Future research is required in this field to establish method to decrease the threat caused due to sugars and other fermentable carbohydrates. Dietary guidelines for the prevention and management of oral diseases gives a structured format for consumers and health professionals to utilize the guidelines and understand the harmful effects of the intake of excess sugars in foods. Various modifications and behavioral interventions in research are needed to restrain the rate of recurrence of added

sugars as well as to amplify with the food reference intakes.

Desquamative Gingivitis in Cicatricial Pemphigoid: A Diagnostic Paradox!

Satya Ranjan Misra[1], Pavitra Baskaran[2]

[1]Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, India, [2]Consultant Oral Medicine & Radiology Specialist, The Tooth World, Purushawalkam, Chennai

Abstract

Desquamative gingivitis or gingival desquamation represents a clinical sign seen in many diseases, especially of muco-cutaneous nature. One of the common diseases, in which gingival desquamation is present is Mucous membrane pemphigoid (MMP) and represents a variety of chronic auto-immune sub-epithelial bullous diseases affecting the mucous membranes and sometimes the skin. MMP not only affects the oral mucosa but ocular involvement is also quite common. The severity of the disease is variable, and the gingival desquamation may be the first sign of this otherwise indolent disease and early diagnosis can reduce the morbidity especially ocular changes which could be irreversible leading to blindness can be prevented. We describe a case for documentation while describing the differential diagnosis and management of the disease.

Keywords: *Gingival desquamation, muco-cutaneous disorder, ocular involvement, sub-epidermal bulla.*

Introduction

The word "desquamation" taken from the Latin word 'Desquamare', meaning scraping fish flakes. In the literal sense, desquamation implies loss of epithelium, peeling off skin or mucosa. Desquamative gingivitis was first described by Tomes in 1894.[1] It is not a disease by itself rather a manifestation of some disease. It can progress to vesicle formation, erythema, erosion and ulceration of the attached gingiva.[2] Glickman and Smulowin 1964 stated that desquamative gingivitis could be a clinical manifestation of many diseases.[3] Dermatologic diseases, hypersensitivity, endocrine disturbances and chronic bacterial infections are common causes.[4]

MMP or cicatricial pemphigoid accounts for the maximum number of cases of desquamative gingivitis and sometimes the gingival lesions are the sole manifestation of the disease, hence it requires meticulous history taking and careful examination by the general dentists as they have an important role in the diagnosis of this chronic muco-cutaneous disease.[5]

Case Report: A 53-year-old female patient reported with a complaint of redness and burning sensation in the gingiva. History revealed she had pain and bleeding while cleaning her teeth. Her medical, surgical, personal and family history were non-contributory. There were no lesions anywhere else in the body.

On clinical examination, the left sub mandibular lymph node was slightly palpable, movable and tender. The attached gingiva in the mandibular anterior region and the entire maxillary arch was erythematous and tender on palpation. (figure 1-5) There was desquamation and mild bleeding on probing. On applying compressed air to the apparently normal gingiva, there was desquamation. This elicited a positive Nikolsky sign in the oral cavity.

Since the patient had got gingival desquamation and

an erythematous area the lesion clinically was thought of as desquamation due to hormonal disturbances, lichen planus, pemphigus and lupus erythematosus. But the absence of white striae in the lesion, absence of any menstrual irregularities, and any other systemic signs and symptoms with a positive Nikolsky sign indicated towards MMP.

The patient was advised for an incisional biopsy and H & E stained section revealed sub-epithelial cleft and basal cell degeneration, with haemorrhagic areas, suggestive of mucous membrane pemphigoid. (figure 6) The patient was advised to apply a combination of Clobetasol propionate 0.05% and Miconazole 1% cream, thrice a day for a month and was to be reviewed. The patient was lost to follow-up.

Discussion

Mucous membrane pemphigoid is a chronic sub-epithelial bullous disorder mainly affecting elderly ladies.[6] However, there is no racial or geographic predilection. It has a rather complex aetiopathogenesis as it is a heterogenous disorder with the involvement of multiple antigens. The antibodies produced in MMP have been shown both in vitro as well as in vivo. Generally, there are IgG and IgA antibodies circulating in the blood directed against the parts of the basement membrane zone (BMZ) which show that humoral response against the antigens occurs in MMP.[7] Mislaying of immunologic tolerance to morphologic proteins in the BMZ leads to the formation of autoantibodies. Using immune-precipitation and immune-blotting mechanisms, many antigens have been discovered. The bullous pemphigoid antigen 2 (BPAg2) (a 180-kDa protein, BP180) is the most commonly targeted autoantigen in MMP.[8] When there is reaction between autoantibodies against antigens it results in detachment of the epithelium within the BMZ.

MMP affects different mucosal sites, rarely there is cutaneous involvement. It is a chronic, indolent disease which commonly involves the oral mucosa followed by the conjunctiva, nasal mucosa, genital mucosa, gastro-oesophageal mucosa and the lesions always heal with scarring.[9] The disease differs in severity ranging from localized to a diffuse disseminated involvement. Initially the disease may be localized and later there is extensive involvement. Since the lesions heal by scarring, it leads to significant morbidity especially in those patients with ocular involvement.[10]

Oral lesions frequently occur on the gingiva and the palate, followed by labial mucosa, tongueand buccal mucosa.[11] These lesions can occur as erythema, erosions, pseudo-membrane, and rarely intact bullae. The gingival involvement manifests as desquamative gingivitis, which is not specific for MMP but may also be seen in oral lichen planus and pemphigus vulgaris.[12] Ocular lesions manifest as conjunctival erosions and erosions, keratinization, symblepharon, enteropion, trichiasis, ankyloblepharon, ankylosis and even blindness.[13]

The diagnosis needs histopathologic evaluation of the tissue samples which needs to be taken with utmost care as the epithelium easily dislodges from the underlying connective tissue. H & E sections characteristically reveals sub-epithelial split with an inflammatory infiltrate of chronic inflammatory cells.[14] Another specimen may also be taken from perilesional tissue and taken in buffered hypertonic saline solution and submitted for direct immunofluorescence. A linear IgG and C_3 is seen along the BMZ.[8,15]

Therapy for MMP comprises of early treatment of the lesions and aims at preventing complications especially when there is ocular involvement. The scarring can be avoided by early therapeutic interventions. Treatment is tailor made for individual patients based on the severity of the disease considering the age, general wellbeing, medical issues and contra-indications to the use of systemic drugs. Multidisciplinary treatment with a team of experts consisting of oral medicine specialist, dermatologist, ophthalmologist, gastroenterologist typically improve outcomes.[16]

High-potency topical glucocorticoids remain the mainstay of therapy. Fluocinonide, clobetasol propionate and betamethasone dipropionate are the prescribed drugs. Gingival desquamation alone can be well managed using topical glucocorticoids alone.[17] Use of a splint or custom-made tray to hold the gel on to the gingiva may be more effective. However due to long term use of these steroids leading to possible adverse effects like candidiasis, concomitant of topical anti-fungal drugs also is prescribed as in the present case a combination of clobetasol and miconazole was used.[18,19]

Intralesionaland systemic glucocorticoids are used to treat recalcitrant lesions or as an adjunct totopical steroid delivery. For patients not responding to steroids, calcineurin inhibitors, which are potent

immunosuppressants like Tacrolimus is prescribed with good efficacy and safety.[19]

Palliative care is also required to alleviate the masticatory discomfortusing topical anaesthetics-analgesic-antihistaminic mouthwashes or gels and improve patient's capability to eat, swallow and perform oral hygiene. [17-19]

Figure 2: Gingival desquamation in the mandibular lingual gingiva.

Figure 3: Gingival desquamation in the attached gingiva labially and buccally.

Figure 4: Gingival desquamation in the attached gingiva labially and buccally.

Figure 5: Gingival desquamation in the attached gingiva labially and buccally.

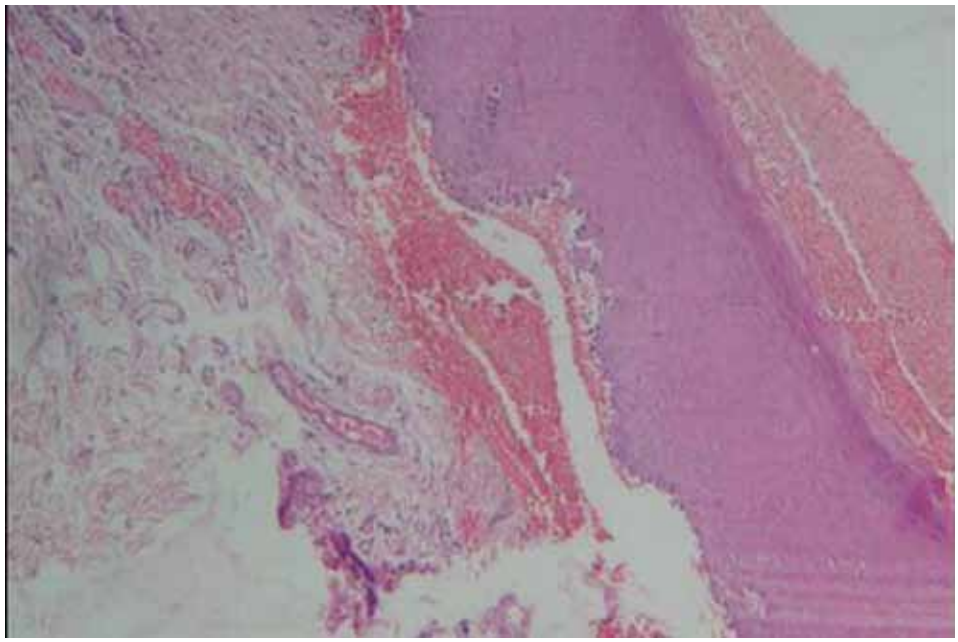

Figure 6: H & E (10 X original magnification) stained section revealed sub-epithelial cleft and basal cell degeneration, with haemorrhagic areas.

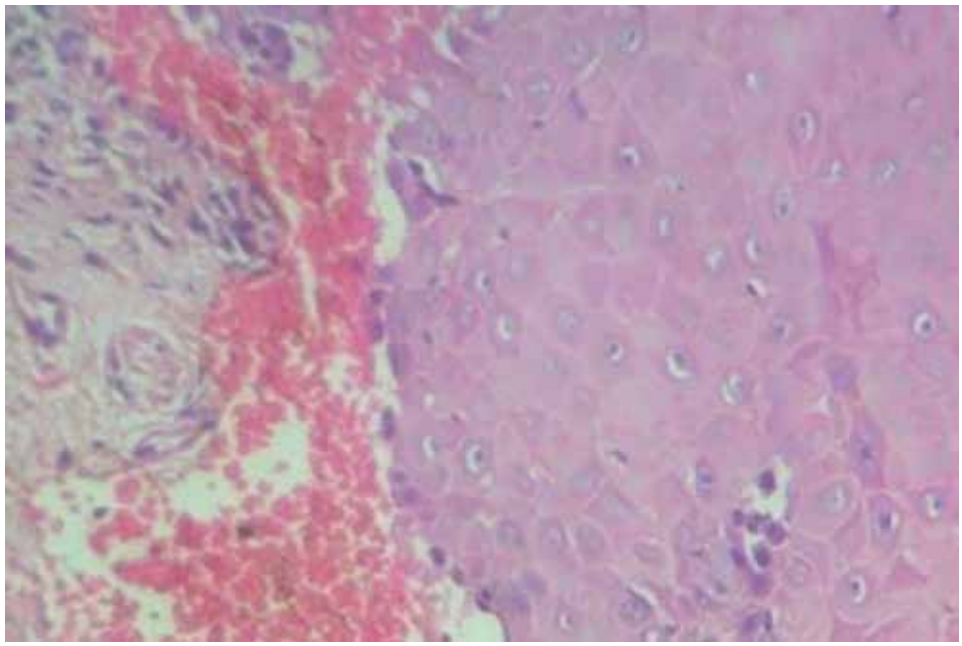

Figure 7: H & E (40 X original magnification) stained section revealed sub-epithelial cleft and basal cell degeneration, with haemorrhagic areas.

Conclusion

Dentists are often the first people to examine and diagnose this mucosal disease. Prompt diagnosis of mucous membrane pemphigoid requires taking a careful meticulous history together with a detailed oral mucosal examination along with checking the possible involvement of other mucosae and using histopathologic and immunofluorescent studies. Desquamative gingivitis may be the sole manifestation of the disease and usually heals uneventfully by improving the oral hygienic measures with topical glucocorticoidand antifungal therapy.

Complex Composite Odontoma: A Cause of Impacted Teeth

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, India.

Abstract

Odontomas are one of the most common odontogenic lesions, earlier considered as mixed odontogenic neoplasms but lately have been accepted as hamartomatous malformations. They are either detected accidentally on radiographs or when they are a cause of impeding normal eruption of teeth. Odontomas originate from the odontogenic tissue and contain enamel and dentine, hence are referred to as composite lesions. They can be of two types depending on the appearance. If they have masses of calcified structures resembling multiple miniature teeth then they are called compound odontomas and if they appear as an irregular disorganized radiopaque mass they are referred to as complex odontomas. A case if complex odontoma is reported herewith which led to impacted maxillary molar.

Keywords: *Harmartoma, denticles, odontogenic neoplasm, radiopaque mass.*

Introduction

The most common odontogenic lesions are odontomas which represent all odontogenic tissues i.e. Enamel, dentine, cementum and pulp tissue in one lesion hence referred to as a composite lesion.[1] Since they originated both from the ectoderm and mesodermal components of the odontogenic apparatus, they contain both enamel and dentine.[2] Although they can be detected at any age, being a developmental malformation, they are seen with twenty years of age and are generally asymptomatic lesions, unless associated with mild tooth pain or swelling, they are detected on incidental radiography.[3] There is a definite female gender predilection and also the maxillary arch, especially the anterior region is more frequently affected.[4] Odontomas are notorious for impeding eruption of nearby teeth. They are usually small in size though large sizes have been reported which can cause expansion of the cortex.

Corresponding Author:
Dr. Satya Ranjan Misra
Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (deemed to be University), Bhubaneswar 751003, Odisha, India
e-mail: satyamisra@soa.ac.in

Depending upon their radiologic appearance they may be classified into complex or compound odontomas.[5] Compound odontomas appear as miniature teeth like structures, known as denticles, where each structure has enamel, dentine, pulp and cementum like normal teeth.[6] Complex odontomas are disorganized irregular masses of enamel, dentine and cementum mixed up. Compound odontomas are commonly visible in anterior maxilla and complex odontomas in posterior mandible. Odontomas have also been associated with other odontogenic tumours like ameloblastoma[7] adenomatoid odontogenic tumour[8] and calcifying epithelial odontogenic tumour[9] and are then referred to as hybrid tumours.[10]

Case Report: A 28-year-old female patient reported with missing upper molar on the right side. History revealed the second molar on the right maxillary arch did not erupt in childhood. She did not have any toothache or swelling in the area. The medical, surgical, dental, personal and family histories were non-contributory.

On clinical examination, the maxillary second and third molars were missing, the alveolar ridge appeared normal without any bulge, swelling or tenderness on palpation.

A periapical radiograph was taken and revealed a single large well-defined irregular radiopaque mass

distally in relation to 16. Since the radiopaque mass was not fully covered in the periapical radiograph, maxillary lateral occlusal radiograph was taken of the right side which showed, a single large well-defined irregular radiopaque mass distally in relation to 16, with an unerupted molar displaced superiorly. A Panoramic radiograph was taken to screen the jaws for any other lesion and it revealed a single large well-defined irregular radiopaque mass distally in relation to 16, with an unerupted molar displaced superiorly. The radiographic features were suggestive of a complex odontoma and the patient refused any treatment after knowing the hamartomatous nature of the lesion and agreed for regular-follow-ups.

Discussion

The word "Odontoma" was given by Broca in 1867 to describe odontogenic neoplasm formed by the enlargement of developing odontogenic tissues.[2] The odontogenic tissues undergo morpho-differentiation to form enamel and dentine in teeth, but the tissues do not reach the normal level of morpho-differentiation and form abnormal enamel and dentine in the form of odontomas.[11] The aetiopathogenesis of this lesion remains unknown as yet but local infection or trauma may trigger its formation. Genetic mutation could also be cause where the normal tooth development is halted.[12] Odontomas are indolent and gradually grow in size and being a developmental lesion, they are most of the time detected within twenty years of age, though in rare cases like in the present case, they may be incidentally detected later in life.

As per the classification of the World Health Organization (WHO), odontomas are of two types, complex odontomas and compound odontomas.[13] They are bot to be confused with dilated odontomas which refers to dens invaginatus another developmental anomaly.[14]The former is rarer and is seen in the posterior mandibular region, however in the present case it is seen in the maxillary arch.About four-fifths of odontomas are associated with impacted teeth. [15] Odontomas can safely be removed surgically as they are generally encapsulated and easily come out as a single specimen and there is never any recurrence.

The radiologic appearance is very characteristic, the odontomas are well-defined radiopaque lesions surrounded by a thin radiolucent line denoting the capsule covering them. The appearance ranges from multiple miniature teeth like structures (denticles) to a diffuse, irregular, radiopaque mass. Enamel and dentine can be visualized on radiographs.[16] Though the diagnosis is often radiologic, histopathologic evaluation of the excised odontomas shows enamel, dentine, cementum, pulp, and cementum in haematoxylin eosin stained sections. While the compound odontomas resemble normal teeth, the complex odontomas look like masses of coalesced hard odontogenic tissue. Scanty, myxoid connective tissue stroma having epithelial odontogenic rests seen with the hard tissue mass resembling normal dental follicular pattern.[17,18]

Figure 1: Maxillary arch on the right side, missing maxillary second permanent molar.

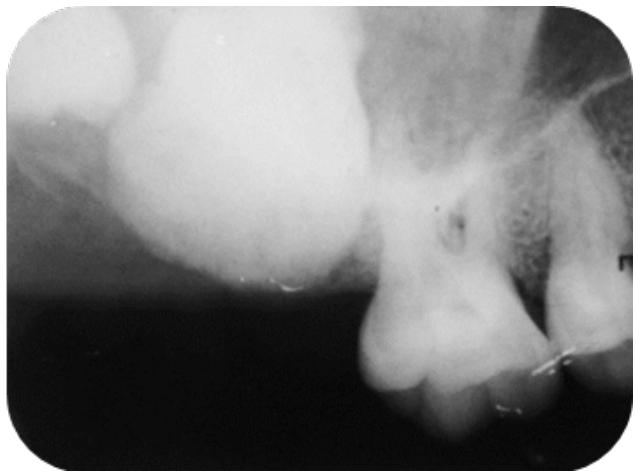

Figure 2: Intra-oral periapical radiograph of right maxillary molar region showing a single large well-defined irregular radiopaque mass distally in relation to 16.

Figure 3: Maxillary lateral occlusal radiograph of the right side showing a single large well-defined irregular radiopaque mass distally in relation to 16, with an unerupted molar displaced superiorly.

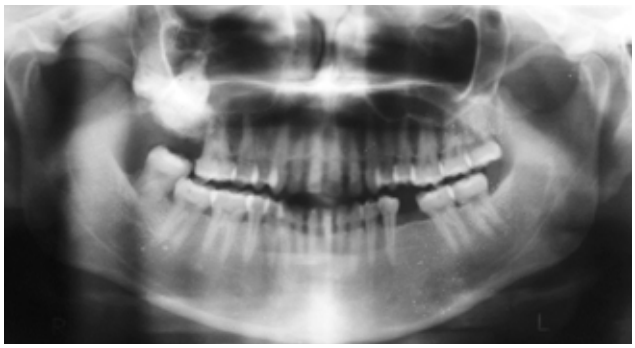

Figure 4: Panoramic radiograph shows a single large well-defined irregular radiopaque mass distally in relation to 16, with an unerupted molar displaced superiorly.

Conclusion

Odontomas have been often reported in the literature, complex odontomas of huge size, compound odontomas containing hundreds of denticles, odontomas erupted into the oral cavity and secondarily infected odontomas are some of them. As dentist's awareness regarding the presence of odontomas impeding the eruptive path of teeth is essential and their hamartomatous nature gives reassurance to the patient. Odontomas can be easily removed when required and it carries a favourable prognosis without any recurrence.

Ameloblastoma: A Common Benign Odontogenic Tumour with Multiple Manifestations

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (deemed to be University), Bhubaneswar 751003, India

Abstract

A myriad of odontogenic cysts and tumours both benign and malignant are seen in the maxilla and the mandible. One of the most frequently encountered odontogenic tumour is ameloblastoma and has different clinical and histologic variants which dictate the treatment plan. It has a properly documented inclination towards a local infiltration and tendency of recurrence. Ameloblastoma is a benign intraosseous odontogenic epithelial tumour which is locally invasive and locally destructive, non-functional, intermittent in growth, anatomically benign and clinically persistent. The tumour arises from the epithelial cell rest of malassez, from the walls of odontogenic cyst and from the basal cells.

Keywords: *Ameloblastoma, locally destructive, odontogenic neoplasm.*

Introduction

Ameloblastoma is a gradually progressing but locally infiltrating benign neoplasm of odontogenic origin affecting the jaw bones, more frequently the posterior mandible. It has high recurrence rate and was first explained in 1827 by Cusack.[1] It has been called by a variety of names including ''cystosarcoma,'' ''adamantine epithelioma,'' and ''adamantinoma''. Ameloblastoma is coined from French "amel,'' meaning enamel, Greek ''blastos,'' meaning germ or bud.[2] It is one of the most common odontogenic tumours probably second only to odontomas. Since the lesion is slow growing and asymptomatic, the patient reports only with facial asymmetry due to swelling in the maxilla or mandible, often growing to large sizes by the time of diagnosis thus jeopardizing the treatment plan and increasing chances of recurrence especially true in cases of maxillary ameloblastomas invading the base of the skull.[3]

Case report

A27-year-old male patient reported to the dental hospital with the complaint of large swelling in the right side of the face and discomfort on mastication for 6 years.

History revealed that six years back the patient had noticed a small swelling in the right side of the mandible in the region of third molar. It was painless swelling and was growing slowly for the past six years and attained the present size. The patient gave a history that during this period sometimes the growth was remaining as it was for some time and started growing again. No history of any numbness in the lip or pain and bleeding in the swelling. The swelling was a fresh swelling and not a recurrent swelling. Similar swelling was not found anywhere in the body. No history of any disturbances in the teeth like pain, mobility etc., Past medical history was not relevant to any disease.

Extraoral examination revealed a single large irregular shaped elevated swelling on the right side of the face involving the mandibular body on the

right side and extending downward along the lower border of the mandible. The swelling was large with well-defined borders and boundaries. (Figure 1) The swelling extended superiorly to the maxillary region and infraorbital region posteriorly 1cm in front of the auricle, medially it extended to the midline of mandible, inferiorly to submandibular region. The skin over the swelling was smooth and shiny but not stretched and no secondary changes like ulceration was seen.No visible pulsations or pigmentation was seen over the swelling. On palpation the swelling was lobulated, firm in consistency, not warm, not tender. The skin over the swelling was pinchable. The swelling was not reducible or compressible. No fluctuation was present. The mass was not movable and was fixed to the mandible.

Intraorally, the right side of the mandible was enlarged buccaly and Lingually. And the buccal extension appeared in the form of a swelling and extended from the midline to the retromolar area obliterating the sulcus (figure 2 and 3) The mucosa over the swelling was normal and the teeth were irregularly arranged with tilting. The lingual extension of the swelling was mild. On palpation the swelling was firm in consistency and in certain areas it yielded on pressure but no compressibility or reducibility. The swelling was fixed to the bone. The teeth were slightly shaky and tender. No mucosal involvement and tongue movements were normal. In the right-side floor of the oral cavity was partially filled with expansion of the swelling.

Since the swelling had developed after the mandible was fully formed, only 6 years back, growing very slowly intermittently without any inflammatory signs for the past 6 years, the swelling was a benign neoplasm. Further the swelling grew both intraorally and extra orally, was fixed to the mandible, firm in consistency and hence this benign neoplasm was a benign neoplasm of the bone. Since no fluctuation was present the question of a cystic swelling was ruled out. A differential diagnosis of Ameloblastoma and Ossifying fibroma were considered. Since the tumour had grown for the long time with intermittent growth and had enlarged to a very large swelling which appeared as multinodular and intraorally the swelling extended to a large area of mandible with areas of softness the condition may be provisionally clinically diagnosed as ameloblastoma.

Skull radiographs revealed that the right side of the mandible was destroyed up to the ramus. Lower border was irregular and destroyed. Areas of radiolucency and opacity were seen.(figure 4) In the panoramic radiograph a large radiolucency was seen on the right side from midline to the anterior border of ramus (figure 5) The normal bone pattern was destroyed. The radiolucency had a multilocular appearance with areas of opacity. The lower border was enlarged. Right lower third molar was floating in a mass.

Biopsy was taken in 46, 47 region. Histological features showed the mass consisted of connective tissue. The epithelium was in the form of follicles bounded by palisading ameloblastic cells with nucleus in the periphery enclosing stellate reticulum like cells. The connective tissue was fibrous with minimal vascularity. The histological picture suggests follicular ameloblastoma as the tissue contains follicle cells lined by ameloblastic cells. (figure 6)

In view of history, clinical findings, radiographic findings and histological appearance the condition was diagnosed as follicular ameloblastoma.

Figure 1: Facial asymmetry and huge diffuse swelling in the right side of the mandible.

Figure 2: Diffuse intra-oral swelling in the mandible obliterating the buccal sulcus, extending from 33 to 47 region mediolaterally.

Figure 3: Bicortical expansion in the mandible with lobulations.

Figure 4: Postero-anterior view of the mandible showing multilocular radiolucency extending from 47 to 35 region, crossing the midline, there are radiopaque septae present in the radiolucency.

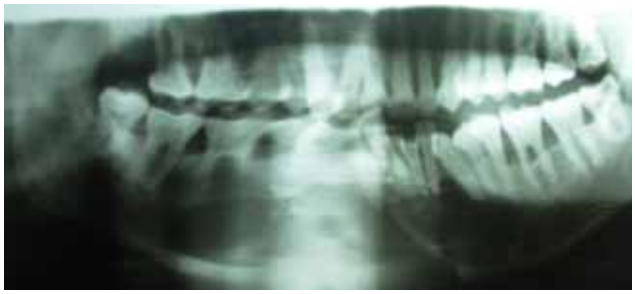

Figure 5: Panoramic radiograph reveals a multilocular radiolucency extending from 47 to 35 region, crossing the midline, there are radiopaque septae present in the radiolucency. Root resorption in 46 with displacement of 44, 43, 31, 33, 34, and 35. There is generalized alveolar bone loss.

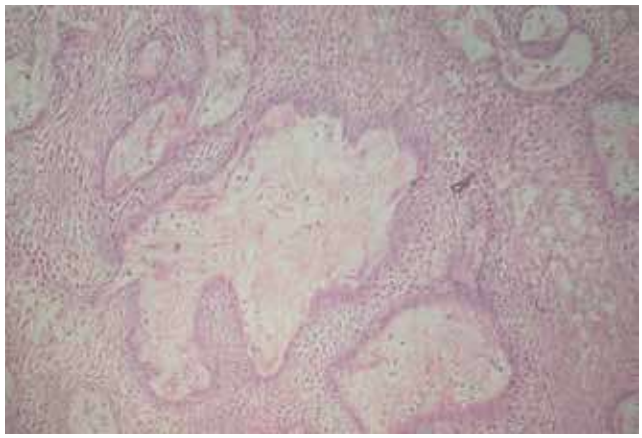

Figure 6: H&E stained section showing odontogenic epithelium showing peripheral columnar cells with reversal of polarity and central stellate reticulum like cells, in the form of strands and follicles within the connective tissue stroma with large areas of cystic degeneration associated with few areas of squamous metaplasia.

Discussion

The jaw bones have three tissues 1) odontogenic tissue – the tissue that is responsible for tooth formation 2) osteogenic tissue– the tissues responsible for bone formation 3) soft tissues within the jaw bone - blood vessels, nerves, ectopic salivary glands etc,. Tumoursare either benign or malignant and can develop from any one of the tissues.[4] Odontogenic tumours are the tumours that develop in jaws from odontogenic tissue- oral epithelium in tooth germ, enamel organ, dental papilla, reduced enamel epithelium, remnants of Hertwig's root sheath etc.,[5] This type of tumour doesn't develop in any other bone. The most common odontogenic tumour is ameloblastoma.

Ameloblastoma is a benign intraosseous odontogenic epithelial tumour which is locally invasive and locally destructive, non-functional, intermittent in growth, anatomically benign and clinically persistent. The tumour arises from the epithelial cell rest of malassez, from the walls of odontogenic cyst and from the basal cells. The proliferating epithelial cells are not ameloblasts but ameloblasts like cells with characteristics of short columnar cells with nucleus placed in the periphery. [4.5]

Clinically, the tumour develops in both males and females from 3rd decade onwards. It starts slowly, sometime stops in growth and recurs. The slow growth of tumour takes place over several years and can reach up to huge sizes invading and infiltrating locally. The

tumour expands both buccally and lingually and the teeth are irregularly arranged. [7]

Clinically the tumour is lobulated and hard in consistency and lower border is expanded. The tumour mass expands within the periosteal covering and it won't perforate the periosteum. Ameloblastoma may be monocystic or polycystic.[8] If it is monocystic it is a large cystic cavity. If it is polycystic it has a multilocular appearance with interlocular bony septa.[9]

Radiologically, ameloblastoma will appear as unicystic or multilocular (honeycomb or soap bubble appearance) and must be differentiated from other odontogenic and non-odontogenic tumours in the jaws. [9,10,11] Histologically ameloblastoma will have two components epithelial and connective tissue. The epithelial cells are arranged in alveoli which are separated by connective tissue. [12] The alveoli look like stellate reticulum and the peripheral cells appear as short columnar cells with nucleus placed away from the basement membrane and the cells look like ameloblasts. Histologically, follicular ameloblastoma, plexiform ameloblastoma, acanthomatousameloblastoma, squamous ameloblastomaand desmoplastic ameloblastoma are common varieties. [13]

Treatment varies from simple enucleation for uni-cystic amelobalstomas to resection for the multi-cystic ones. Reconstruction is also required to prevent gross facial deformity. [14]

Impacted Tooth: A Cause of Odontogenic Lesion in the Jawbones

Gayatri Potukuchi

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, India

Abstract

The dentigerous cyst is the commonest developmental odontogenic cyst encountered in the jawbones accounting for about one-fourth of all reported cases. As with other cysts, they present as asymptomatic lesions that are either detected on routine radiographs or when they cause swelling leading to facial asymmetry. Since the cyst is associated with an impacted tooth, the common teeth involved are impacted mandibular third molars or maxillary canines. This paper isan overview of the impacted tooth, which can be a cause of odontogenic lesion in the jawbones

Keywords: *Impacted tooth, odontogenic cyst, supernumerary tooth, unilocular radiolucency.*

Introduction

The term 'Dentigerous cyst' was coined by Paget in 1853.[1] Dentigerous cysts (DC) are the second most common developmental odontogenic cysts after the radicular cyst. A dentigerous cyst is defined as an odontogenic cyst that envelopes the crown of an impacted tooth.[2] It is almost always associated with impacted, unerupted, or embedded tooth, and may also be involved with a supernumerary tooth. They're usually unicystic but bilateral and multiple dentigerous cysts may be found associated with several syndromes.[2] They're most commonly associated with the mandibular third molars and maxillary canines, followed by maxillary molars and Mandibular premolars.[3]

These cysts are asymptomatic in most cases unless they are secondarily infected. Dentigerous cysts are usually detected on routine radiographic check-up, and are purported when-

- "The pericoronal radiolucency measures around 2.5 mm or larger in any dimension.[4]
- "The follicular space is more than five millimeters."
- "There is any associated tooth displacement or alarming expansion of bone found."

Also, Browne had pointed out that the literal meaning of the word 'dentigerous' means 'tooth-bearing' which is justified by its radiographic appearance as a dentigerous cyst is seen as a well-circumscribed unilocular radiolucency symmetrically surrounding the tooth, often with a sclerotic outline.[5] Several lesions first appear to fulfill the criteria for the diagnosis of the dentigerous cyst but later demonstrate features of something else like unicystic ameloblastoma, thus making the diagnosis of the lesion an important aspect.

A cyst is described by Kramer as, 'a pathological cavity having fluid, semifluid or gaseous contents and which is not created by the accumulation of pus'[1]. These are more commonly found in the orofacial region, and the cysts of jaws that develop from the tissues involved in tooth development are called the Odontogenic cysts. These cysts arise from the cell rests of odontogenic epithelium. These can be inflammatory or developmental, as given by Pindborg and Kramer in 1971. A dentigerous cyst is the one in which a crown or more rarely a part of the crown, projects into the cystic cavity. Various theories have been put forward as regards the origin of a dentigerous cyst. The strongest assertion is that the cyst initiates from the reduced enamel epithelium(REE) since the epithelial lining of the cyst is seen to be adjoined to the neck of the tooth, by the agglomeration of fluid between the reduced enamel epithelium and the enamel surface.[1]

Clinical Features: Dentigerous cystsare almost always involved with a normal permanent tooth that is impacted or unerupted, and rarely a deciduous tooth. Dentigerous cysts may be found anywhere in the jaws but are more frequently found in the angle of the mandible, canine region of the maxilla, and molar region of the maxilla. Dentigerous cyst is usually seen to be clinically present as an enlargement of the buccal cortical plate of the maxilla or the mandible.[6] Most lesions are said to be found in the second and third decade with a predominance among males.[2] It is highly likely that dentigerous cyst can become an aggressive lesion and its continued enlargement results in the asymmetry of the face, expansion of the mandible or maxilla, teeth displaced from their positions, and resorbed roots of adjacent teeth[7]. In case it is associated with maxillary canines, it leads to an expansion in that area, resembling sinus and skin infections. Unless infected secondarily, dentigerous cyst patients do not experience any pain,and on aspiration, yellow-colored fluid is obtained.[7]

Radiographic Features: As seen on a radiograph, dentigerous cysts typically have a well-defined border which may be absent in the case of infections. The internal structure is completely radiolucent except the crown of the tooth. Radiologic examination of a dentigerous cyst is the most important aspect in the diagnosis of this type of cyst as they give us a proper idea of the dimension and extent of the pathology. It is also important to keep in mind that we have to be able to distinguish between a merely enlarged dental follicle -an ectomesenchymal tissue that surrounds the tooth germ- which can be quite arbitrary unlike the smooth, well-defined borders of a dentigerous cyst. Also, the normal follicular space is seen to be around three to four millimeters whereas a dentigerous cyst is suspected when the follicular space exceeds more than five millimeters.[2]

According to the situation and form in radiographs, three variations of dentigerous cysts are seen. First is the central type in which the cyst is seensymmetrically enveloping the tooth. Here the pressure is directly applied on the erupting tooth thus preventing its eruption. It is the most common variety and the tooth appears like a candle flame. Second is the lateral type in which the cyst envelopes on the side of the tooth and is seen in the mandibular third molar region. This occurs when the follicle is dilated on one side. The third is the circumferential type which is very rarely seen. In this the follicle expands in such a manner it appears to enclose the entire tooth giving it an appearance of a lantern in the radiograph. However, it is wise to do a histological examination of the tissue associated with the affected tooth as we cannot dismiss the absence of any pathology based on just the radiographic methods as the absence of radiographic pathology may not necessarily mean the absence of disease.[8]

Histological Features: Microscopically we see that the cyst is composed of a thin wall of connective tissue with a thin layer of the stratified squamous epithelium lining the lumen. The dentigerous cyst has no characteristic microscopic features that can help differentiate them from other types of odontogenic cysts. The connective tissue is sometimes thickened and composed of loose connective tissue leading to misdiagnosis as an odontogenic fibroma or an odontogenic myxoma.[2] The connective tissue wall of normal dental follicle and dentigerous cysts has islands of odontogenic epithelium which can be sparse, but when present in significant amounts it again leads to its misdiagnosis as ameloblastoma. In the inflamed cysts there is the presence of hyaline bodies called Rushton bodies present inside the lining epithelium. They are of unknown origin and significance.

Dentigerous cyst is a common cyst but it has a few differential diagnoses which need to be kept in mind while diagnosing. Some of these are- Hyperplastic dental follicle, Odontogenic keratocyst, Ameloblastoma (unicystic), Calcifying odontogenic cysts, and Adenomatoid odontogenic tumor.

Table 1. Differential diagnosis of dentigerous cyst based on radiologic features.[9]

Lesion	Location	Periphery	Internal Structure	Effect on Surrounding Structures
Dentigerous cyst	Mandibular and Maxillary molar region, Maxillary canine region. Epicenter just above the crown	Well defined cortex unless infected	Completely radiolucent with the crown of the involved tooth	Apically displaced teeth, resorption of roots of adjacent teeth, inferior displacement of the inferior alveolar canal

Lesion	Location	Periphery	Internal Structure	Effect on Surrounding Structures
Ameloblastoma	Molar-ramus region of the mandible	Well defined cortex similar to a dentigerous cyst	Unilocular radiolucency, soap bubble appearance.[10]	Apical displacement of involved teeth
Calcifying odontogenic cysts	Incisor and canine region of maxilla and mandible	Maybe well-circumscribed or ill-defined and irregular	Completely radiolucent	Resorption of roots
Odontogenic keratocyst	Ramus-third molar area, anterior mandible, maxillary molar, and cuspid area	Well-defined peripheral, scalloped border	Unilocular radiolucency may sometimes contain the crown of the tooth	Displacement of adjacent teeth is more common followed by resorption of roots
Calcifying epithelial odontogenic tumor	Prevalence in the mandibular molar region is more than the bicuspid region	Appears either as diffuse or well-circumscribed	Appears as a unilocular radiolucency, sometimes seen as a combined pattern or radiolucency and radiopacity	Cortical bony plates are extended and weakened; both buccally and lingually
Adenomatoid odontogenic tumor	Mostly associated with maxillary canines	Well-demarcated smooth corticated border	Juxtacoronal radiolucency that is almost always unilocular sometimes extends beyond the cemento-enamel junction	Divergence of roots and displacement of teeth, maxillary sinus, and orbital invasion

The diagnosis of dentigerous cyst includes x-ray imaging, both periapical and panoramic. Another efficient method is the MRI-Magnetic Resonance Imaging as it helps distinguish cysts and tumors, but is very expensive thus limiting its usage.[11] The latest diagnosing technique is the CBCT-Cone Beam Computed Tomography that provides three-dimensional images with minimal distortion and significantly lower doses of radiation thus ensuring an accurate diagnosis.[12]

The dentigerous cyst gives rise to several potential complications apart from the possibility of recurrence. These include ameloblastoma, epidermoid, and mucoepidermoid carcinoma. Ameloblastoma and epidermoid carcinoma may develop from the epithelial lining or the odontogenic epithelial cell rests. The disposition of dentigerous cyst in the form of ameloblastoma is more profound than other odontogenic cysts. Mucoepidermoid carcinoma is principally a salivary gland tumor that develops from the epithelium of dentigerous cyst containing mucus-secreting cells.

The management of dentigerous cyst includes marsupialization and enucleation. The classic approach involves the enucleation of the cyst along with the removal of affected teeth. As this approach is too aggressive, more conservative approaches need to be incorporated such as Marsupialization, etc.[13,14] Marsupialization is the treatment of choice as it allows the eruption of the impacted tooth by deroofing the cyst along with adjoining bone and mucoperiosteum.[15]

Conclusion

Impacted teeth, especially mandibular third molars and maxillary canines are associated with dentigerous cyst and their evaluation using radiographs is important to investigate the correct method of enucleation, though they are least likely to recur.

Abstract

Maxillary jaw defect produced due to traumatic, surgical or congenital reason often creates communication between antrum and nasopharynx. The defect not only causes nasal reflux during swallowing but also interfere with articulation and production of speech. These limitations are commonly overcome by restoration of the defect with a prosthesis called an obturator. This case report focuses on the prosthetic rehabilitation of a post-surgical maxillary defect with cast metal definitive obturator.

Keywords: *Maxillary Defects, Definitive Obturator, Cast Metal Obturator Definitive Prosthesis, Interim Prosthesis.*

Introduction

Surgical rejection of maxillary jaw cancer often compromises the integrity and functions of the oro-nasal cavity.[1] The acquired defect formed due to hemimaxilloctomy, impairs the speech,mastication, swallowing and facial esthetic. Rehabilitation of such defect is essential to improve the functional quality of life and self-esteem of the patient.[2]

A multidisciplinary sequential approach involving oncologist, prosthodontist and speech therapist is required to handle such a case.[3] Surgical repair of such defects can be done with free micro vascular flaps or pedicled flaps, autogenous fibula free graft with or without dental implants.[4] However, in a patient with a large defect, history of irradiation, risk of advanced complications or financial issues surgical repair is avoided. Prosthetic rehabilitation of maxillectomy defect with obturator is the preferred option in such circumstances.[5] It recreates the anatomic barrier between the oro-nasal cavities, thereby improving the fluid intake, deglutition and speech of the patient.[6]

The success of an obturator is often subjected to the size of the defect, the amount of undercut of the defect and the number of remaining teeth. Patients with large intraoral defects have been found to have impair functional adaptability, owing to the bulky size of the obturator. The heavy size of the obturator put continuous stresses on remaining supporting structures jeopardizing their health. On the contrary, a hollow maxillary obturator can reduce the weight of the prosthesis by up to 33%, depending on the size of the maxillary defect.[7] This clinical report describes the step by step technique for fabrication of a lightweight, hollow type definitive cast obturator for a maxillectomy patient.

Case Report: A 34 -year- old female patient had reported to the Department of Prosthodontics, with a chief complaint of a loose obturator with difficulty in taking food with liquid coming out of the nose during intake. Past medical history of the patient revealed that she had undergone left maxillectomy approximately $2^{1/2}$ yr earlier, for inverted papilloma. Postoperatively, she had used an interim acrylic obturator for 1 year.

e-mail: mirnagarhnayak@gmail.com

The obturator was found to be ill-fitting and grossly undersized compared to the defect itself.

The extraoral appearance of the patient was found to be asymmetrical with a collapsed left side of the lip (Fig. 1). The mouth opening of the patient was normal. Intraoral examination revealed sub-total maxillectomy of left side crossing the midline and hence was diagnosed as a situation of Armany's Class IV (Fig.2).[8] Right side was partially edentulous with missing 16 and a metal crown of 17. All the walls of the defect were lined with healthy mucosa. Tongue function was normal and speech was altered.

Considering the large size of the defect, health of supporting structure and cost, it was decided to rehabilitate the case with a hollow bulb cast metal definitive obturator. The consent of the patient was taken for the same.

Procedure: The procedure was initiated with oral prophylaxis, followed by the removal of the existing metal crown of 17. The finish line of 17 was modified. Primary impressions of the upper and lower arch were made with irreversible hydrocolloid (Tropicalgin; Zermack Dental). Before this, excessive undercuts of the defect were blocked out with a petrolatum laden gauge. The diagnostic casts were retrieved from the impression and upper cast was surveyed and designing of the metal framework of the cast obturator was done on it.

A tripodal design was planned. Embrasure clasps concerning 14,15 and 17,18 were designed for the direct retention of cast framework. The rest seat for 17 was planned to be incorporated in the distal side of its crown. Indirect retention was intended to be obtained from the rest seat on 14 and the palatal extensions on the anterior teeth. Retentive loops were designed on the side of the defect, for attachment of the bulb of the obturator. A full palatal major connector was planned

Necessary mouth preparations were done accordingly followed by an impression of the upper arch with polyvinyl siloxane impression material (Aquasil, Dentsply/Caulk, Milford, DE). The secondary maxillary working cast was made with dental stone type III (Kalstone; Kala Bhai Pvt Ltd., Mumbai, India). It was subsequently duplicated with reversible hydrocolloid to prepare the refractory cast. Wax up of the cast framework on the refractory cast was done as per design, followed by casting with cobalt-chromium base metal alloy (Fig. 3). After proper finishing and polishing, try-in of the metal framework along with a metal crown of 17 was done. Then cementation of the metal crown of 17 was done and the metal framework was seated intraorally. A pickup impression was made with polyvinyl siloxane impression material (Aquasil, Dentsply/Caulk, Milford, DE) in a stock plastic tray, to incorporate the impression of the defect side.

In the final cast, the loops of cast framework were joined with auto polymerizing acrylic resin base covering the defect side. Jaw relation records, teeth arrangement, and try-in were done subsequently in a conventional manner (Fig. 4). After approval of the patient, waxed up prosthesis was processed with heat-cured acrylic resin (DPI-Heat cure; Dental Products of India, Mumbai, India). A sealing the lid with auto polymerizing acrylic resin was used to obtain a hollow bulb obturator.[9] The obturator was subsequently tried in the patient's mouth for adaptability (Fig. 5A,B,C). A permanent soft liner (Ufi Gel C) was applied around the bulb and border of the defect portion of the prosthesis. Necessary border molding was accomplished and the patient was asked to use the relined prosthesis for 1 week. Afterward,the relined permanent soft liner was replaced with heat cure denture material (DPI-Heat cure; Dental Products of India, Mumbai, India) The definitive obturator was positioned intraorally and assessed for nasal regurgitation and quality of speech production. Post insertion oral hygiene instructions and maintenance were given to the patient. The case was followed up for a period of 1yr, during which the patient was found to be satisfied with the prosthesis functionally and esthetically.

Discussion

The present case is a classic Armany class IV type defect, as it has crossed the midline and included the premaxilla of the opposite side. (Armany classification I) It was a 2yr old post-operative case with no recurrence of the disease. The wound had healed properly. So it was a favorable case for the definitive cast obturator prosthesis.[10]

Preservation of remaining structure has been the motto of Prosthodontic therapy.[11] This is arguably achieved with the cast metal definitive obturator. As the metal framework stabilizes the prosthesis, soreness and discomfort of soft tissue in the superior- lateral aspect of the defect are reduced. So the jaw relation record and wax try-in of the prosthesis are accurate in terms of esthetic and phonetics.[12] In comparison to the conventional acrylic obturator, it also provides maximum support and retention.[12] So the abutment teeth and soft tissue undercuts were subjected to less stress. Further, midline fatigue fracture is not an issue with cast obturators.[13]

A tripod design framework was planned for the prosthesis, as the remaining teeth were present in a curved manner, with 12 and 13 being still there. Primary retention, support, and stability of the prosthesis were provided by the remaining teeth.[14] Soft tissue undercuts of the defect were used for added retention. Support was obtained from the remaining teeth as well as palate. Definitive rest seats located on the premolars and molars provided the support. As the defect size was large, a full palatal major connector was used for the maximum distribution of functional load.

The definitive obturator design was made hollow to decrease the weight of the large prosthesis. Otherwise, the remaining teeth would have been subjected to persistent non-axial cantilever load, jeopardizing the health of supporting structures.[15] In contrast, a hollow bulb obturator is lighter and promote favorable palatal contour.[7] Moreover, the resonance of speech is achieved as it simulates the functional anatomy of the maxillary sinus. Proper nutritional intake and ability to communicate without nasality is achieved immediately with definitive maxillary cast obturator.

Conclusion

Prosthetic rehabilitation of maxillectomy defect with definitive obturator restores the mastication,swallowing, aesthetic, resonance and speech of the patient. This helps the patient to resume a normal social life.

Management of a Diabetic Patient with Philosophical Mental Attitude: A Case Report

Debarchita Sarangi

Senior Lecturer, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Diabetes Mellitus is a metabolic disorder. It has been recognized as a pandemic and is a nutritional disorder. It affects almost every organ system in the human body, including the patient's psychology. It occurs due to irregularity in the insulin secretion. The most characteristic feature is hyperglycemia. The underlying factors, contributing to this disease are age,genetics, obesity, lack of physical activity, etc. A prosthodontist should have a thorough understanding of the general considerations for diabetes mellitus patients as well as the prosthodontic consideration. This article reviews the prosthodontic management of a patient with diabetes mellitus, supported by a case report of a complete denture patient with a philosophical mental attitude.

Keywords: *Diabetes, Clinical features, Prosthodontic management, Dental.*

Introduction

Diabetes mellitus is a metabolic disorder. The abnormality in insulin secretion affects the carbohydrates, lipids, and protein metabolism. The most important basis of diagnosis is hyperglycemia. This is a chronic condition that may have other neurological, cardiovascular, cerebrovascular, nephrological, ophthalmologic disorders associated. The understanding of systemic effects of diabetes mellitus, its effects on the oral tissues, patient psychology and other complications associated with long-standing disease is essential to treat a diabetes mellitus patient, reporting in the dental office.[1,2] The onset of diabetes mellitus Type -2 is usually after 40 years of age and its prevalence increases with age. This is related to genetics, obesity and also lack of physical activity and not to the destruction of Island cells of Pancreas.[3,4,5]

Polyuria, Polydipsia and Polyphagia are the main symptoms for diagnosis.[6]

World Health Organization has predicted that by 2025, there will be a rise in prevalence of 300 million from 135 million cases, which is alarming .[7] American Diabetic Association recommends that the screening for Fasting blood sugar should be done for overweight individuals, no matter age, if Body Mass Index is more than 25 and every 3 years from 45 years of age, if the subject is obese.[8,9] The earlier the diagnosis is made, the better it is for the patient. The issue is patients report only after they have symptoms like polyphagia, polydipsia and polyphagia.[10]

Oral Manifestations:

The diabetic patients have the following oral manifestations:[8]

- Burning sensation of the mouth/mucosa
- Inflammation of gingiva and periodontitis
- Increased risk of caries
- Resorption of alveolar bone
- Delayed wound healing
- Opportunistic infections like fungal infections
- Xerostomia

The tolerance to removable prosthesis, like complete denture is also less.[11]

All the above oral manifestations occur due to:[8,12]

- Micro-vascular changes
- Increased concentration of glucose in saliva
- Impaired host-resistance which is a result of the defective function of Polymorphonuclear Neutrophils

Prosthodontic Considerations:

A few general dental considerations to be followed by the prosthodontist:[13]

- Proper history-taking of general health conditions and verification of blood reports
- A consultation with the patient's physician regarding his medications and dental procedure planned is beneficial.
- Radiological investigations should be done for all cases.
- Oral hygiene should be good, before starting any procedure. The patient should be advised to use anti-bacterial mouth-washes and gels.
- The procedures causing minimal trauma and that are minimally invasive should be carried out
- The procedures should be in a stress-free environment as possible
- Appointments should be of short duration
- If there is a chance of any pain due to invasive procedures, prophylactic medication is mandatory.
- Medication and dietary counseling is a must for every case.
- Hypoglycemic shock should be managed properly with proper monitoring of vital signs, depending on the severity. Nausea, perspiration, hunger, palor and tachycardia are indicative of it.

Following are the Prosthodontic Considerations:

- As mentioned earlier, general health history taking should be followed by dental history taking, assessment of the findings and thorough examination.
- Oral hygiene status should be evaluated before beginning any prosthetic procedure. The patient should be counseled for the maintenance of good oral hygiene and its importance.
- History of edentulism, cause of loss of teeth, type of prosthesis, etc should be noted.
- The number of appointments and duration of treatment should be planned and informed to the patient.[13]
- Recent reports of visits to the treating physician, along with laboratory investigation reports should be presented in the clinic. This should be brought to the clinic in every sitting.
- The blood sugar level should be checked with a glucometer, before starting the procedure, in every sitting.[14]
- Oral hygiene procedures like scaling and root-planing should precede removable partial denture therapy.
- The design of RPD should be appropriate, to make the prosthesis tissue-friendly.
- The prosthesis should be self-cleansing and should have point contact between natural abutments and prosthesis
- The occlusion should be freely gliding in all prostheses, thus the scheme should be carefully selected.
- In case of complete denture, the techniques that would retard resorption of bone should be followed. They are: mucositis impression technique; use of tissue-friendly material; verification of Vertical Dimension at occlusion; use of neutral zone concept wherever required
- Regular follow-ups are mandatory
- For Fixed Partial Denture prostheses: Supra-gingival margin with chamfer finish-line on the facial surface is preferable as it reduces stress-concentration; Crown-root ratio should never be compromised; Ante's Law should be mandatory; 3/4th crowns may be advisable in premolars;Periodontal therapy, Crown-lengthening, orthodontic extrusions may improve the prognosis of the treatment.
- Implant treatment should be planned only when the blood sugar levels are within permissible limits. Besides, the above points should also be considered .[9] Complete history taking, radiographic evaluation, implant site selection, abutment selection, prosthesis selection and scheme of occlusion determine the success of implant therapy . [15]

- The mental attitude and impact of the treatment on the psychology of the patient should also be tactfully evaluated in all the cases.[16]

Case-Discussion:

A 78-year-old man reported to the Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences with the chief complaint of difficulty in chewing and wanted a new pair of dentures. The detailed case-history was taken which gave the following findings: Patient was diabetic for more than 20 years and was under regular medications; blood sugar levels were remaining under control, according to last 3 years reports; the patient had taken prior permission from his endocrinologist for the treatment; all the teeth were missing; the patient was an old denture wearer; denture was fabricated elsewhere 4 years back and no follow-ups were done; on examination, it was found that the oral mucosa was in good condition, which suggests of maintenance of oral hygiene **[Figure 1]**. There were retention and stability issues in the old denture and the patient insisted on a new set of dentures. There was no history of any habits. The patient was under the regular supervision of a dietitian. He was aware of his meal timings and followed the dietitian's instructions. The treatment was planned with seven short, morning appointments, between 9:30 AM to 10:30 AM. The patient was explained about the procedure and also counseled regarding the importance of follow-up procedures. He had reasonable questions regarding the treatment which were satisfactorily answered, which indicated that he understood the treatment. He was very calm, willing to commit to the treatment and follow the instruction.

Figure 1: Intra-oral pictures of the edentulous arches

First Appointment: The perforated stock trays were selected. Impressions were made using alginate (Zhermack, Tropicalgin). The patient was recalled for the second appointment. The primary cast was poured using Type II gypsum (B.N. Stone Dental Plaster)in the laboratory. The markings for the spacer extensions and special tray extensions were done. The full wax spacer was designed.

Figure 2: Final impressions of the edentulous arches after the border molding

Second Appointment: Border-molding was done using the sectional method. The final-impressions were made with Zinc-Oxide Eugenol Impression Paste (DPI) [Figure 2]. This appointment was of the longest duration, i.e, 1 hour. The patient was given a break for 10 minutes after 30 minutes. The impressions were beaded and boxed in the laboratory. The master cast was poured using Type III gypsum (B.N. Stone Dental stone).

Third appointment: Adjustments on the temporary record bases with occlusal rims were done. Silvermann's closest speaking space was measured and Niswonger's method was used to record the vertical jaw relation **[Figure 3]**. Teeth set was selected in the clinic (Acryrock Teeth set). The pressure-less method was used to record the horizontal jaw relation. The related and sealed rims were transferred to the master casts. Articulation was done in a 3-point mean-value articulator. Anterior teeth arrangement was done.

Figure 3: Markings for jaw-relation

Fourth and fifth appointment: Trial of anterior teeth arrangement was done. The patient was recalled for the fifth appointment, immediately the next day. The posterior teeth arrangement was completed and the trial was done with necessary modifications. **[Figure 3]**. In the laboratory, carving and wax-up was completed. The dentures were processed, cured, and finished for the insertion step. The finished denture was remounted and corrections were done before the final appointment.

Figure 4: Wax trial

Sixth and seventh appointment: The finished denture was inserted **[Figure 4]** and all the necessary verifications were made. The occlusion was modified. The patient was instructed to use the denture for 24 hours and report for a follow-up the next day. Other post-insertion instructions were given. The oral mucosa was examined thoroughly for pressure sores. Modification to remove pressure points on the tissue surface of dentures were made. Final polishing of the dentures was done and dentures were re-inserted. The patient was asked for reviews and was also made to understand to report after a week and then after a month.

Figure 5: Intra-oral pictures after denture insertion

The patient had reported for the one week and one-month follow-ups. During the treatment, the patient would give his input regarding the steps. Every instruction was sincerely followed by the patient. He never reported with any attendant who speak for him, suggestive of his independent mind.

Conclusion

The prognosis of the treatment was good because the patient's mental attitude was the most important determinant. He maintained himself well, despite his long history of Diabetes mellitus, understood his needs and was committed to being treated. The patient's philosophical mindset benefitted him for a positive treatment outcome.[16] Diabetes mellitus is a complex disease and requires a multi-disciplinary approach in the treatment. Patient's motivation for treatment increases the chances of a better prognosis. The goals of prosthodontic therapy are also reached with proper treatment, counseling by the clinician, and a patient's positive approach towards treatment.

Conflict of Interests: The authors declare they have no conflicts of interest.

Tissue Engineering and Regeneration Therapy: A Boon for Periodontal Research

Gatha Mohanty[1], Rinkee Mohanty[2], Manoj Kumar[3], Saurav Panda[3]

[1]Senior Lecturer, [2]Professor and Head, [3]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Complete regeneration of the periodontium is the aim of any successful periodontal treatment. Recent Technologies have come up with many advances like cell-based therapy, peptides, genetic transfer, scaffolds, bone anabolics, and above all lasers. Four basic elements are required for periodontal repair and regeneration that includes adequate blood supply and wound stability, a source of bone and ligament forming cells, a supporting scaffold, and growth factors to regulate cell migration, synthesis and angiogenesis for revascularization of the site. The newer technologies not only offer unique opportunities but also enhance the predictability of regenerative procedures.

Keywords: *Periodontal Regeneration, Research, Tissue Engineering.*

Introduction

Chronic periodontitis is characterized by irreversible loss in connective tissue attachment and supporting alveolar bone. According to national surveys, more than 30% of adults suffer from moderate type of periodontitis, while severe generalized periodontitis affects almost 15% at some pointin time.[1] Scaling, curettage and open flap debridement are conventional treatment modalities that can control inflammation and lead to the long junctional epithelium formation but there is no regeneration. They have also improved the quality of life of individuals.[2] The main objective of periodontal tissue replacement and reconstruction is to restore mechanical stability and function and also relieve the pain associated with it.[3]

Regenerative Concepts: Melcher 1976, proposed that after flap surgery the curetted surface of roots might be repopulated by different cell types.[4]

Corresponding Author:
Dr. Gatha Mohanty

- Cells of Connective tissue in gingiva
- Epithelial cells
- Bone cells
- Cells of Periodontal ligament

The nature of the attachment depends on the cell type that starts populating the root surface after periodontal surgery.

Healing patterns of periodontal tissue damage:

- Down growth of epithelial cells results in a long junctional epithelium.
- Connective tissue might proliferate to cause tissue adhesion and thereby root resorption.
- If the bone cells are predominant,there may be root resorption,ankylosis, or both.
- A completely regenerated periodontium and new cementum can also develop.

How can the lost tissues be ideally replaced?: The concept of tissue engineering is based on the theory that an individual's damaged tissue is better to be replaced by the same natural healthy tissue. This concept has led to the formation of new tissue from preexisting tissues.

Tissue engineering, is a multidisciplinary field that

involves medicine, biology, and engineering. It is likely to revolutionize the quality of life and health of many people worldwide. It can maintain,restore and improve the tissue function respectively. This definition has been broadened recently to include the suitable attempt of tissue regeneration in the body, by the addition of specific biologic mediators,that might be cultured in or outside the body respectively.

Components of tissue engineering:

For the success of tissue engineering three components are needed:

1. To create new tissue: Implanted cultured cell
2. To act as a scaffold to hold cells: a suitable Biomaterial.
3. To form desired tissue type: Biological signaling molecules that can instruct cells.

Cells:

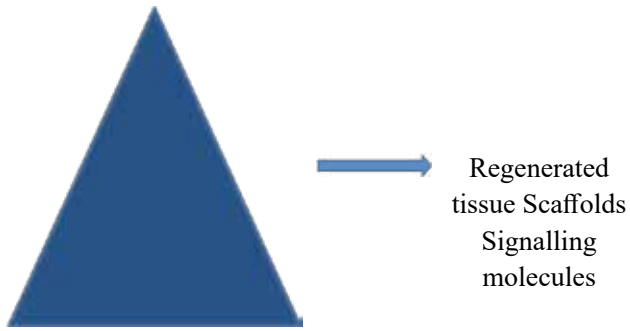

Figure 1. Triad

In vitro: In the laboratory, the construction of a vital tissue can be done and it can be subsequently implanted into the host body. This offers the advantage to examine the tissues as they are being formed and also measure the specific tissues.

In vivo: Properly seeded cell types, implantation of the porous matrix, & signaling molecules can facilitate tissue regeneration. This forms the basis of Tissue engineering.

Strategies to engineer tissues

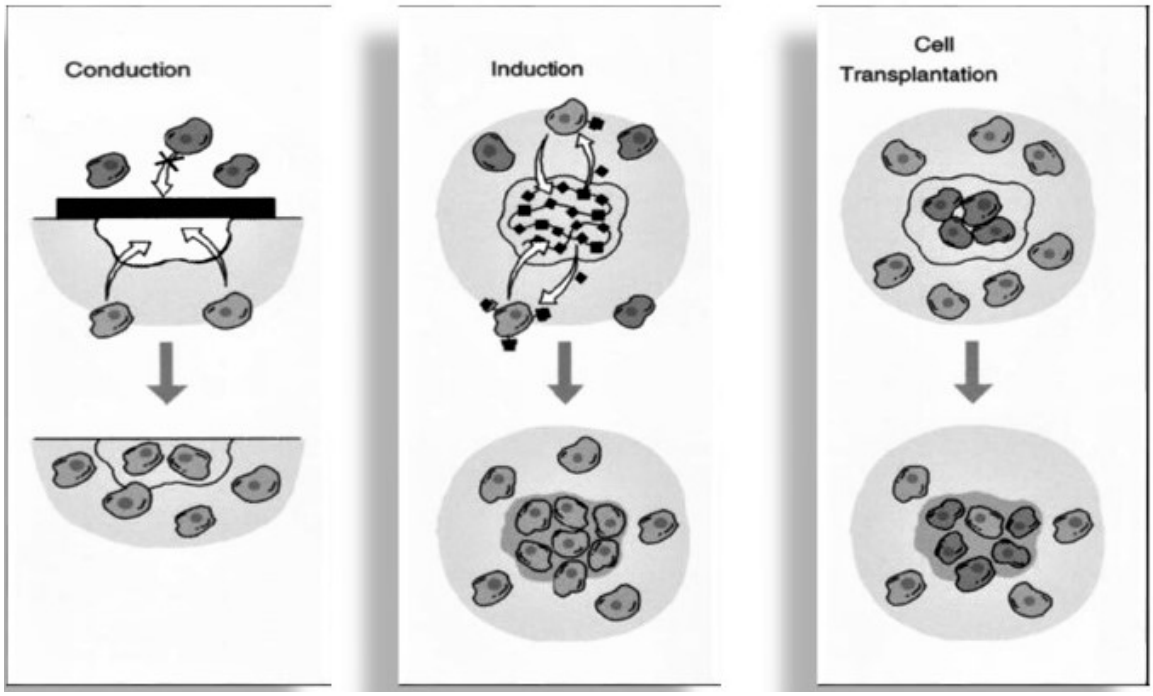

Figure 2. Tissue engineering process

Osteoconduction: "Trellis effect" is a physical effect where the graft matrix forms a scaffold. This scaffold favors cells from outside to enter the graft, thereby forming new bone.

It includes the growth of osteoprogenitor cells, new capillaries, and perivascular tissues from the recipient bone.

Eg: Jaw bone graft, xenograft

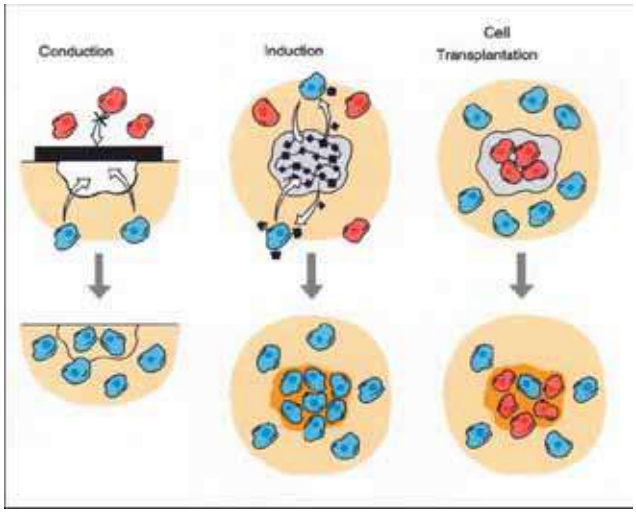

Figure 3. Osteoconduction

Osteoinduction: Biological signals are used to activate the cells close to the defect site.

Bone morphogenetic proteins (BMPs) are the key elements, inducing bone formation.

Limitation:

- It is not possible to know about inductive factors thatare specific for a tissue.
- For the delivery of genes and growth factors to the host site, a biodegradable polymer scaffold can be used as a vehicle.

Advantage:

- The release of growth factors or genes can be controlled based on the polymer breakdown rate.

Cell Transplantation: The cells that are grown in the laboratory are directly transplanted. A vehicle is also used for delivery so that cells and partial tissues can be transplanted to the host site.

Periodontal tissue regeneration:

- Grafts
- GTR
- Growth factors
- Cell sheet engineering
- Enamel matrix protein derivatives
- Stem cell therapy

Advanced regenerative techniques:

- Protein/peptide therapy
- Cell-based therapy
- RNA or gene therapy
- Lasers

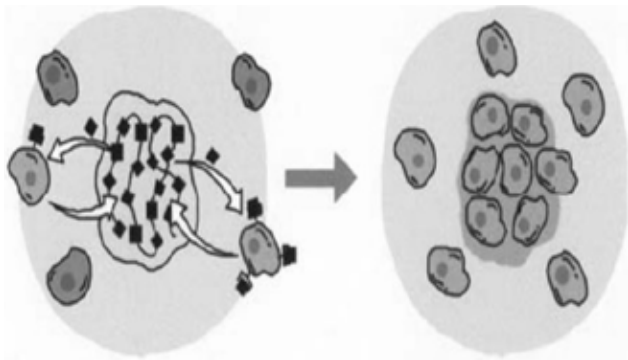

Figure 4. Osteoinduction

Scaffolds: Scaffolds provide and maintain the space that is needed for cell growth and also provide physical support to the process of healing.

Properties of a scaffold:

- To provide a 3D architecture for desired shape volume, and mechanical strength.
- To provide proper characteristics, likeporosity, hydrophilicity and to facilitate tissue infiltration.
- To provide biocompatibility.
- To provide controlled degradation rate coordinated with tissue regrowth.

Used to

- **Guide:** Growth & differentiation of cells
- **Organize:** Physical & chemical signals.

Types of scaffolds:

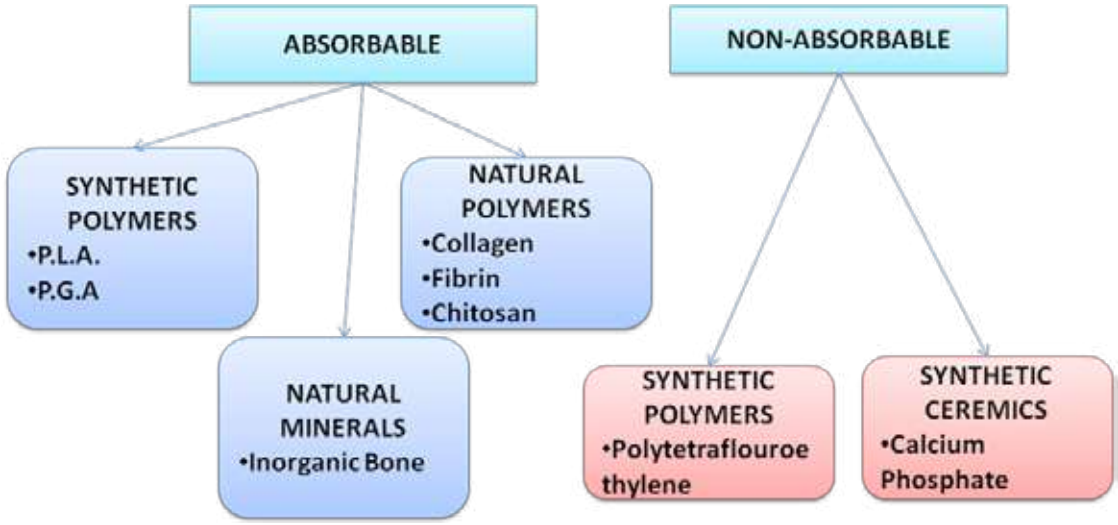

Figure 5. Types of scaffolds

Imaging-based, computer-aided design: According to Park CH 2001 CAD-CAM is one of the most recently developed techniques in scaffold fabrication, that provides a personalized solution for tissue engineering.[5] This technique acquires the 3D anatomic geometry of a defect by high-resolution CT or MRI and that is used as a template for a scaffold. Then 3D bioprinting with desired biomaterials fabricates the scaffold.

Natural minerals or bone grafts:

Bone graft:

Autograft (autologous graft): An organ or tissue transplanted from one site to another in the same person.

Isograft (Isogenic, Syngenic): Graft transplanted from one person to another with identical genetics (eg: identical twins)

Allograft (Homograft): An organ or tissue transplanted from one person to another of the same species but different genus.

Xenograft (Heterograft): A graft transplanted between members of different species (eg: ox bone to humans).

Alloplast: It is synthetic bone graft material or bone graft substitute.

Orthotropic graft: A graft positioned in an appropriate site (eg: bone placed in a bed of bone)

Heterotropicgraft: A graft positioned in an inappropriate site (eg: bone placed in a bed of muscle tissue)

Ideal requisites of bone graft material[6]:

- It should not impede bone growth
- It should enhance revascularization
- It should not elicit immunological responses
- Easy availability.
- Rapid osteoinductive, osteogenetic and. Osteoconductive effect.
- It can be help forming new attachment in periodontal defects.

Limitation of allografts and autografts:

1. There is no excess tissue store in humans for transplantation.
2. While replacing lost bone, donor site morbidity and problems in anatomy, might be there.
3. Immunologic response in allografts due to differences in genes, and can induce transmissible diseases.
4. Synthetic material replacements such as dental implants face a common problem with natural defense mechanisms.

Absorbable synthetic polymers:

They undergo degradation by the process of hydrolysis

Polyglycolic acid - faster degradation

Polylacticacid - this is most stable in-vitro

Polyglactin 910, a copolymer of glycolide and L-lactide – 90/10 molar ratio

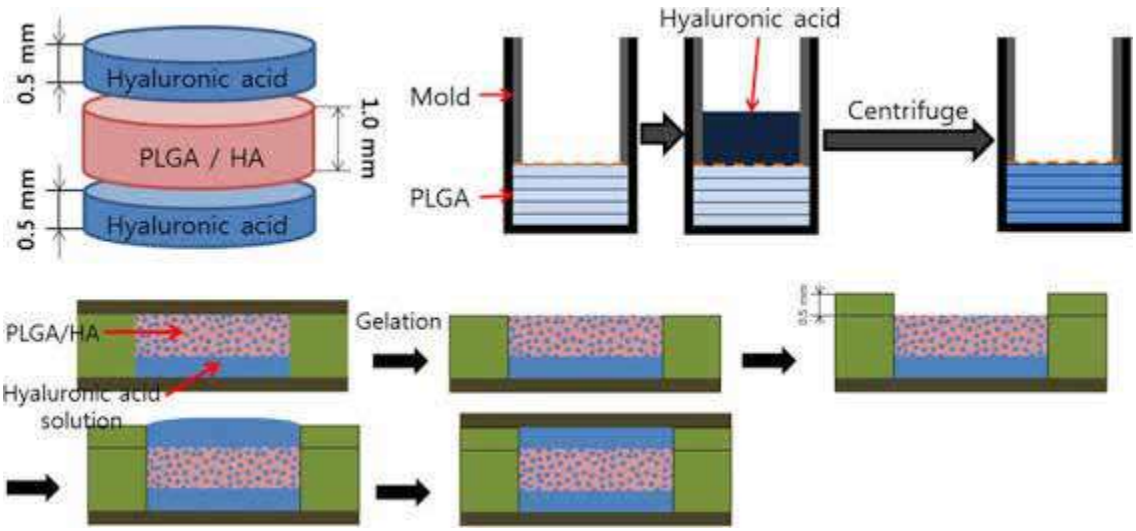

Figure 6: Manufacturing synthetic polymers

Synthetic ceramics(non-absorbable)

These are matrix materials used for facilitating regeneration in-vivo[7]

1. Tricalcium Phosphate:

This is a porous form of calcium phosphate

Ex: ß-TCP

But it undergoes physiochemical dissolution after implantation.

2. Synthetic Hydroxyapatite:

It is a secondary form of bio-ceramic.

Rationale for its use–the naturally occurring mineral in bone is hydroxyapatite

Guided Tissue Regeneration: GTR refers to the placement of a membrane that acts as a barrier between the flap and root surface preventing the gingival epithelium and connective tissues from contacting the root surface during healing.[8]

Design criteria for periodontal GTR devices:

- Easy usage
- Biological activity
- Cell exclusion
- Biocompatible
- Maintenance of space
- Tissue integrity

Barrier membrane for GTR Gottlow's classification:

- First-generation (Non-resorbable membranes)
- Second generation (Resorbable membranes)
- Third generation (Resorbable with growth factors or antibiotics)

Non-resorbable synthetic polymers:

Expanded polytetrafluoroethylene (ePTFE):

- This is the first commercially available barrier for GTR (Gore-Tex)

- Solid nodes and fibrils make itmicrostructure porous.
- The barrier is made of various sizes and shapes to exactly fit periodontal defects in different locations.

Titanium-reinforced PTFE membrane

- Titanium is reinforced between the two e-PTFE layers, thereby a device is formed.
- Facilitates improved space provision and maintenance
- Permits correction of larger defects

Miscellaneous membranes (Millipore membrane, resin-ionomer barrier, rubber dam)

Disadvantages:

- Require a second surgical procedure to remove the membrane and is done usually 3-6 weeks after the intervention when initial healing has occurred
- May interferes with healing by inflicting damage to sensitive regenerated tissue during removal.

Resorbable membranes:

Biomaterials: In cell-based tissue engineering, the expanded cells are seeded onto a scaffold synthesized with the best biomaterial available.

A. Naturally derived materials: Advantage: Along with cellular tissue matrices they offer the advantage of biologic recognition.

B. Synthetic polymers: Advantages: they can be produced in laboratories with the required properties such as increased strength, lowerdegradation rate, and improved microstructure.

Advantages of biomaterials: They mimic the mechanical and biologic functions of the native ECM. The ideal properties of biomaterial arethat it should be biodegradable and bioresorbable. It should also not cause inflammation of the tissue.Incompatible materials can lead to necrosis and foreign body reactions.

Natural biomaterial:

- Collagen (Biomend, Biogide, Biosorb, Ossix plus)
- Glycosaminoglycans (GAGs)
- Chitosan
- Alginates
- Duramater, Cargile membrane

Collagen: It is a major protein of the extracellular matrix, and it has a long triple-stranded helical structure which provides stiffness.

Type 1collagenis found in skin and bone,

Type II foundin cartilage

Type III seen in the blood vessels lumen.

Properties:

- has low immunogenicity
- Is hemostatic, inducing platelet aggregation, which facilitates early clot formation and wound stabilization
- Attracts and activates periodontal ligament and gingival fibroblast cells
- Inhibit epithelial migration

Advantages:

- Lysosomal enzymes sequentially attack and degrade the Collagen implants.
- By controlling the density of the implant and the extent of intermolecular cross-linking resorption rate can be regulated *in vivo.*
- A high rate of implant degradation is due to low density and increased interstitial space for cell infiltration.
- Cell-adhesion domain sequences are seen in Collagen that exhibit very specific cell to cell interactions.

Bio-Mend:

- Is a type I collagen GTR membrane
- Derived from bovine deep flexor tendon
- Is semi-occlusive with effective pore size 0.004 μm
- It is completely absorbed in four to eight weeks.
- Limitation- compromised space maintenance

Artificial biomaterials:

Synthetic polymers:

- Polylactic acid (Atrisorb, Epiguide, Guidor)
- Lactide/glycolide copolymers (Ethisorb, Vicryl mesh)
- Polyurethane
- Polyesters of naturally occurring -hydroxy acids, including PGA, PLA, and PLGA,

Synthetic membranes:

GUIDOR matrix barrier:

- First FDA approved membrane
- It is a double-layered absorbable device made of poly(1actic acid) and a citric acid ester?
- The external layer is designed to allow the integration of the overlying gingival flap.
- Containsrectangular perforations (400-500/cm^2)
- The internal spacers between external and internal layers create a space for the tissue can grow.

ATRISORB barrier:

- It is a poly(DL-lactide) polymer.
- This has been the only approved GTR device to be manufactured chairside.
- This is supplied in a flowable form.
- It can be cut into desired shape and size
- It can be placed into the defect using gentle pressure. Sutures aren't required.
- It is 600-750 μm thick and has properties like adhesion.

VICRYL Periodontal Mesh:

- It is a polyglactin 910 fiber, a copolymer of glycolide and L-lactide (90/10 molar ratio), that is used to prepare a tightly woven meshwork.
- Polyglactin sutures are placed through its coronal margin to anchor it to the tooth.
- Within two weeks of placement, it can lose integrity and resorption is within four or more weeks, depending on the host species.[9]

Polyurethanes membrane:

- These are organic polymers containing the urethane group. According to a study by Warrer et al. 1992 when polyurethane membranes were used for GTR in non-human primates, there was severe inflammation in the margins of the flap,and the recession was also more compared to the poly-(lactic acid) membranes treated tooth.[10]
- Therefore it was not suitable for GTR, as they did not possess all the necessary qualities.

Third generation membrane: They act as a barrier and delivery devices. Growth factors, adhesion factors, antibiotics etc., are released at the wound site.

Subdivided as:

Barrier membranes with Antimicrobial activity: ChengCFet al 2009concluded that the addition of "amoxicillin" or "tetracycline" is addedin GTR membranes,it improves the periodontal ligament cell attachment.[11]

Barrier membranes with Bioactive Calcium Phosphate: This is a three-layered membrane. There are two sides, porous side containing nano-carbonated hydroxyapatite that allow cell in growth and a pure PLGA non-porous side which doesn't allow cells to adhere. These two sides are separated by a transitional layer consisting of nCHAC/PLGA.

Barrier membranes with Growth Factor

Growth factors are proteins. They are naturally occurring and regulate various aspects of cell development.

Rathva VJ 2011 carried a study on bioactive molecules such as different growth factors and enamel matrix derivative (EMD).They concluded that periodontal regeneration is possible.[12]

Functionally Graded Multilayered membranes

Bottino MC 2011 designed FGM. This was fabricated via a multilayering-spinning process consisting of a "core-layer"and two functional surface-layers. [13]

Platelet-Rich Fibrin membrane

First developed in France by **Choukroun** et al.[14]

Characteristics: PRF has a fibrin network and that leads to more effective cell proliferation and migration and thus cicatrization.[15]

Many growth factors, such as platelet-derived growth factor (PDGF) and TGF-β, IGF, VEGF, and thrombospondin,etc., are released from PRF.[16]

Conclusion

Advances have been made in the treatment of complex alveolar bone wounds and periodontal wounds. Be it scaffolds for cell, protein delivery, or gene delivery to specific targeting of signaling molecules, all are in various stages of development. Providing growth factors to the periodontiumis considered as new knowledge revolutionizing the regeneration process.

Psychological Factors in Oral Lichen Planus

Abhishek Ranjan Pati[1], Rajat Panigrahi[1], Smita R. Priyadarshini[1]

[1]Reader, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

It has been known for centuries that mental/emotional factors are correlated to numerous physical diseases. Traditionally we regard mind (psyche) and body (soma) separate but where and how do they interact? The very idea of psychological medicines was told by Sigmund Freud, who used conversion hysteria in explaining the effects of emotional disparity turned into bodily or somatic symptoms

Keywords: *Oral Lichen Planus, Psychological Factors, Oral Health.*

Introduction

Fitness is a state of total"physical", "mental" and "social" wellbeing and not just the lack of sickness or illness.[1] "Oral health" is essential to all-purpose health and also a significant part of universal physical condition. "Psychosocial factors" are necessary and essential for health and are important in disease.[1,2] Psychosocial factors encompass both psychologic issues (those that arise predominantly from within the individual) and sociologic issues (external factors). Mental/emotional factors are connected to numerous physical diseases. Traditionally we regard mind (psyche) and body (soma) separate but where and how do they interact? The very idea of psychological medicines was told by Sigmund Freud, who used "conversion hysteria" in explaining the effects of emotional disparity turned into bodily or somatic symptoms.[3] In many illnesses, there is an interplay of psychological and physical factors. Frequently psychological disorders present in the physical guise of there may be a strong underlying psychological element in a somatic condition. It is now well recognized that psychological states can produce somatic symptoms, anxiety rates are shown to cause autonomic arousal, heightened muscle tone and over-breathing and hence a wide range of bodily symptoms. Depressive illness can lead to weight loss, tiredness, loss of appetite and pain or an existing pain can be aggravated. However, patients attribute these somatic syndromes to serious physical disease. The oral mucosa is very sensitive to psychological events and oral mucosal lesions can occur as a result of psychiatric influences. Psychological disorders may be manifested as atypical odontalgia, TMJ disorders, aphthous stomatitis,burning mouth syndrome."[4,5] In chronic pain syndromes, there is often a psychological behavioral overlay of symptoms that come part and parcel of the disease. Treating the psychological and behavioral problems with physical aspect may increase the chances of a successful therapeutic outcome.[6]

Classification: "Psychosomatic disorders"are widely classified depending upon the presence of tissue injury or not.[10] Under the category "Physiological malfunction arising from mental factors", these are regulated through the autonomic nervous system. Included in this group are breathing disorders, such as hyperventilation and psychogenic cough; cardiac problems, pruritis. The psychological factors are related to a disease succession, like asthma, dermatitis, eczema, stomach ulcer and ulcerative colitis.

"Zegarelli E.V., Kutscher A.H. and Hyman" G.A. (1978) Classified "psychosomatic disorders" as[11] Psychoneurotic disorder, Psychophysiological disorder, Personality disorder, Psychotic disorder

Classification:

- **Shklar et al. (1980)[12]:** Oral psychosomatic diseases; lichen planus; recurrentaphthous stomatitis; "glossitis and stomatitis areata migrant" psychologic factors can be aetiological factors in oral diseases like:"erythema multiforme, Mucous membrane pemphigoid" and Chronic periodontal disease.

- emotional stress serving as a contributing factor in "herpes labialis, Necrotizing ulcerative gingivitis
- neurotic habits leading to leukoplakia, "biting of the oral mucosa, (self-mutilation), physical/mechanical irrigation, dental/periodontal disease produced by "bruxism", "neurotic oral symptoms, glossodynia (glossopyrosis), dysgeusia, mucosal pain"

Bailoor and Nagesh (2001) classified oral psychosomatic disorders as [13]Pain associated disorders, MPDS, "atypical facial pain, atypical odontogenic pain", diseases related to altered oral sensation, burning mouth, xerostomia, idiopathic dysgeusia, miscellaneous, oral lichen planus," recurrent aphthous ulcers, psoriasis, erythema multiforme, hypochondriac disorder".

Review of Literature on Oral lichen planus: Oral lichen planus is a common chronic immunologic inflammatory mucocutaneous disorder. Many authors have concluded the association of psychological stress in "oral Lichen planus".Kovesi G. and Bancozy J. (1973)[16] were made the diagnosis of oral lichen planus on 326 patients between 1960-1969, and they found psychological factors appeared to be an important cause. Shafer W.G. et al (1983)[17] stated that lichen planus was associated with several stress-related medical disorders such as diabetes and hypertension. Lowental U., Pisontis (1984)[18] examined 49 patients with clinically diagnosed oral lichen planus. In erosive and bullous lichen planus, stressful events happened before the occurrence of lesions. Similar findings were shown by Scully M. and El-Kom M. (1985)[19], Hampt B. Goronc (1987)[20], Humphris G., Field E.A. (1992)[21], Sebastian J.V. Bogan (1992).[22] McCartan B.E. (1995)[23] studied 50 subjects with oral lichen planus for any"anxiety and depression" and for behavior problems. Nervousnesslevel, as considered on the "hospital anxiety and depression (HAD) scale", was eminent in 51% of subjects, while depression scores, were low in everyone. Sugerman P.B. et al (1995)[24] assessed the probablepart of stress derived HSP (Heat Shock Protein) expression using avidin-biotin complex immunochemistry with an "anti HSP-70" polyclonal antibody, in normal oral mucosa sections of OLP, "nonspecific oral ulceration" and dysplastic OLP. They established that there was a statistically significant difference in vertical and horizontal staining allocation when other groups compared with OLP. Chaudary S (2004)[27] Studied the importance of psychological stressors in patients with oral lichen planus.

Conclusion

The oral cavity is extremely responsive to psychologic stimulus, and in few subjects oral problems may be a straightappearance of psychological issues, while in somefactorsproblems of the oral mucosa may be the circuitouseffect of an emotional conflict. The fundamental concept in mental medicine was initially proposed by Freud, who coined "conversion hysteria" in unfolding the response in which disturbing conflicts are distorted into physical or somatic symptoms. Since the oral tissues have a high psychologic potential, oral symptoms are common psychosomatic manifestations.

The oral mucosa bears on an obvious role as on erotogenic zone, and oral manifestations resulting from emotional disturbance should be reasonably common. The overall relationship of psychologic factors to oral mucosal disease maybe representing different ways in which emotional stressful stimuli act on oral mucosal target sites.

A considerable evidence supports that psychological stress is a chief causativereason in these 3 disorders. In lichen planus and glossitis areata, burning tongue, and burning sensations of the oral mucosa are invariably neurotic symptoms and indicative of underlying psychologic problems, which are often severe and require appropriate psychiatric management.

"Burning" symptomatology in the absence of clinical disease must be considered to have a neurotic or neurologic origin. We should point out to the enduring that "neurotic is normal", and everybody is anxious to some extent, but that every person intuitive responds to emotional stress in different ways. Patients with oral featuresbecome visible to be suffering from sadness or other psychological disorders that require a mental status evaluation and psychiatric management.

The word"phobia", which means fear in Greek, are severalemotional and physiological problems that can range from grave disabilities to frequent fears to minor quirks. All fears and phobias, cancerophobia is shaped by the unconscious mind as a defensive mechanism.Several times, there may be an incident relating to oral cancer and emotional conflict, while the initialchannel may have been a real-life scare of some type, the condition can also be triggered by events like natural disaster, TV or perhaps seeing someone else experience trauma. It is an excessive and unreasonable fear of cancer in patients who have either a relative or friend who is suffering from

cancer or who themselves have a chronic oral lesion such as an ulcer, any growth or patch in the oral cavity which defies diagnosis or treatment.

When we focus on the etiology of the disease, many patients were relieved to know that the lesions were not due to some infection or neoplastic disease but as a result of "disease of civilization". Future studies to associate the psychological disorders with the immunological basis of the disease needs to be done for appropriate management and treatment planning.

Reattachment of Fractured Tooth-Series of 2 Case Reports

Satabdi Pattanaik[1], Shashirekha G.[2], Sumit Dash[3], Rini Behera[1]

[1]Senior Lecturer, [2]Professor & Head, [3]Professor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Most common consequences of trauma is the crown fracture, mainly maxillary anterior tooth due to its forward positioning in the arch. Understanding the outcome of the planned treatment gives an idea regarding the prognosis of that particular treatment. Various options are available for the treatment of fractured tooth. Among all reattachment of fractured coronal segment to that tooth provides instant esthetic, as it restores the original form, colour, contour, surface texture and also gives a psychological comfort to the patient. This clinical case report focuses on the successful reattachment of two fractured coronal crowns using glass-fibre reinforced composite post. Since, both of the fractured teeth were of complex type, endodontic treatment was performed for both of the cases. At the end, a natural-looking restoration is achieved.

Keywords: *Crown fracture; Fractured coronal segment reattachment; Glass-fibre reinforced Composite post; Natural-looking restoration.*

Introduction

Fractures of the coronal portion of anterior teeth are most common during trauma. Esthetic discrepancy due to fractured tooth may induce psychological distress to the patient. Retaining the natural tooth with the same quality and function is a challenge in the field of dentistry. Prognosis of fractured tooth also depends on the position of crack line. More apically the split of the tooth extends, poor is the prognosis of that particular tooth. Due to the lack of ability to explore and to seal the fracture line in splitted tooth, prognosis of the split tooth mainly anterior is considered as poor.[1] Out of all trauma to the dental hard tissue, coronal fracture of anterior tooth represents 18-22%, 28-44% are simple fracture (involves enamel and dentin), 11-15% are of complex fracture (involves enamel, dentin and pulp).[2] From which maxillary central incisors involves 96%, because of its position in the arch.[3]

Ideally, the broken part of the tooth should be restored with composites. Since colour mismatch, periodical wear and staining are the major drawback of composite, it would better to restore the tooth with its fragment, if the fractured segment is available, as it provides good and long term esthetics. Additionally reattachment permits restoration of the particular tooth with very minimal sacrifice of the remaining tooth structure. In case of complex fracture, endodontic treatment is required along with it post placement is required in some cases. Many other treatment alternatives are available for fractured tooth-like: orthodontic extrusion, flap surgery, crown lengthening, composite restoration, ceramic crown, etc. Few authors have shown that reattachment of fractured tooth provides, immediate esthetic (same colour, contour and surface texture), maintains occlusal function, provides excellent time management and also cost-effective than any other treatment.[4]

This article will discuss about two coronal fractured anterior teeth and their treatment using reattachment of the fractured segment.

Case Report 1: A 24-year-old patient named Deepu Prasad Sahoo reported to the department of conservative

Corresponding Author:
Dr. Satabdi Pattanaik
Senior Lecturer, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India
e-mail: satabdipattanaik@soa.ac.in

dentistry and endodontics, Institute of dental sciences, S'O'A University, Bhubaneswar, with the chief complain of pain and mobility of the upper front tooth. He gave the history of trauma due to fall from the bike before 2 days and immediately after the accident, fracture of the coronal segment of upper left incisor had occurred. On extraoral examination, no laceration of soft tissue or swelling was found. On intraoral examination, Ellis class III fracture was seen with the tooth 21. Fracture was of oblique type extending from the gingival third of labial surface to the level of CEJ in the lingual surface (Figure 1a, b). Radiographic examination confirmed the same (Figure1c).

After administration of local anaesthesia (2% lignocaine and adrenaline 1:200,000; Lox, Neon Laboratories, Mumbai, India), affected tooth and adjacent teeth were isolated with a rubber dam (Hygienic Dental Dam, Coltene Whaledent Inc., Germany). Fracture segment is carefully removed from the affected tooth (Figure1d) and was stored in a physiologic saline solution. Single sitting root canal treatment was performed for the tooth 21 along with sectional obturation (Figure2). Post space is prepared and the appropriate size of fibre post (Angelus, Londrina, PR, Brazil)was checked for the proper fit. In the centre of the separated fragment, a trough was created. Post size was adjusted in such a way that, it would fit properly into the trough. That means when the post is placed inside the canal, the emerging part of the post should adequately fit into the created trough when the broken fragment was attached to its original position of the tooth.

Dual cure luting cement (Para core resin cement, Coltene, Whaldent).was used for luting. Etching and bonding of both the root canal space and separated segment was done according to manufacture's instructions. Luting dual-cure cement was placed inside the root canal space and in the fractured segment. One coat of luting cement was also coated along the fibre post and was inserted into the root canal space and soon after this, the broken fragment was attached to the tooth and slight pressure was applied to tightly bind the fractured segment to the intact portion of the tooth (Figure2). Excess cement was removed at the whole tooth was light-cured (Figure 8, 9). Finishing and polishing of the complete tooth was done.

Figure 1a, b: Fracture was of oblique type extending from the gingival third of labial surface to the level of CEJ in the lingual surface; c. Radiographic examinationd. Removal of fractured segment

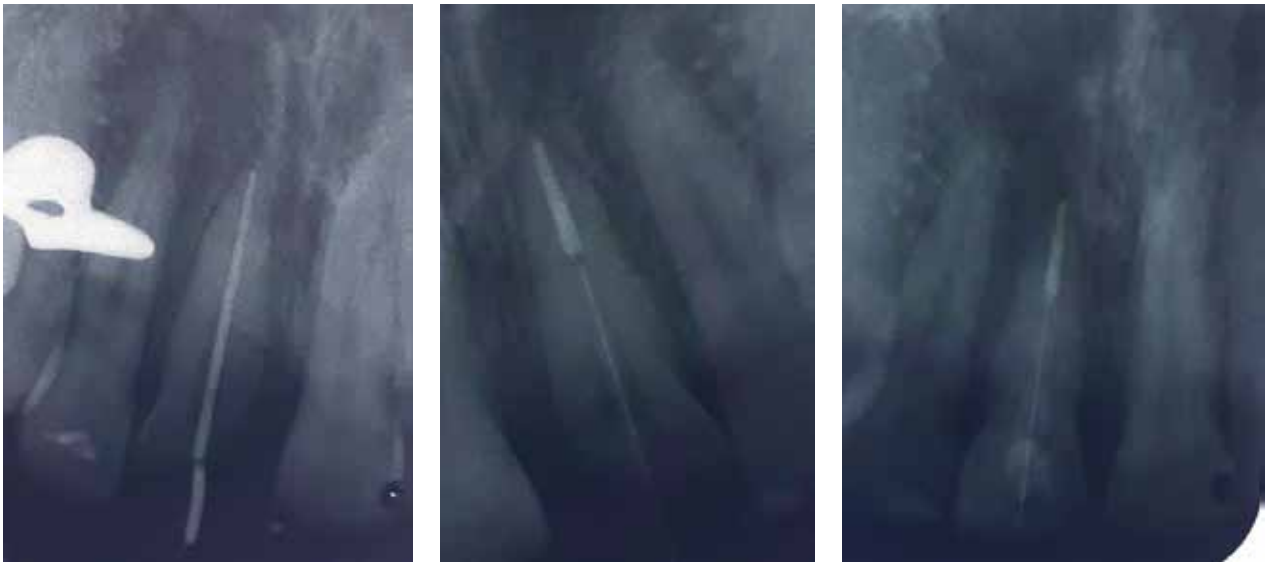

Figure 2. Post treatment radiographic examinations

Figure 3a, b. Reattchement of fractured segment 1

Case Report 2: Another patient named Sunil Biswal visited to the department of conservative dentistry & endodontics, Institute of dental sciences, S'O'A University, following trauma with fracture and pulpal exposure in the coronal segment of the right lower lateral incisor. No visualized trauma was seen in the intraoral and extraoral soft tissue regions. On clinical (Figure4a) and radiographic examination (Figure 4b), Ellis class III # was seen. Fracture line was of horizontal type involving gingival 3 rd of both the facial and lingual surface irt 42. Similarly, after administration of local anaesthesia (2% lignocaine and adrenaline 1:200,000; Lox, Neon Laboratories, Mumbai, India), fracture segment was carefully removed (Figure 4c) and stored in physiologic saline solutions. Complete root canal treatment was done for that particular tooth with MC selection (Figure 4d). Etching, bonding was done for the root canal space and intact coronal portion of the clinical crown and also in the fractured portion of the crown as per manufacturer's instructions. A fibre post (Angelus, Londrina, PR, Brazil) was placed exactly in the same manner as described in the previous case. Reattachment of fractured segment was done with the help of the fibre post (Figure 4e, f).

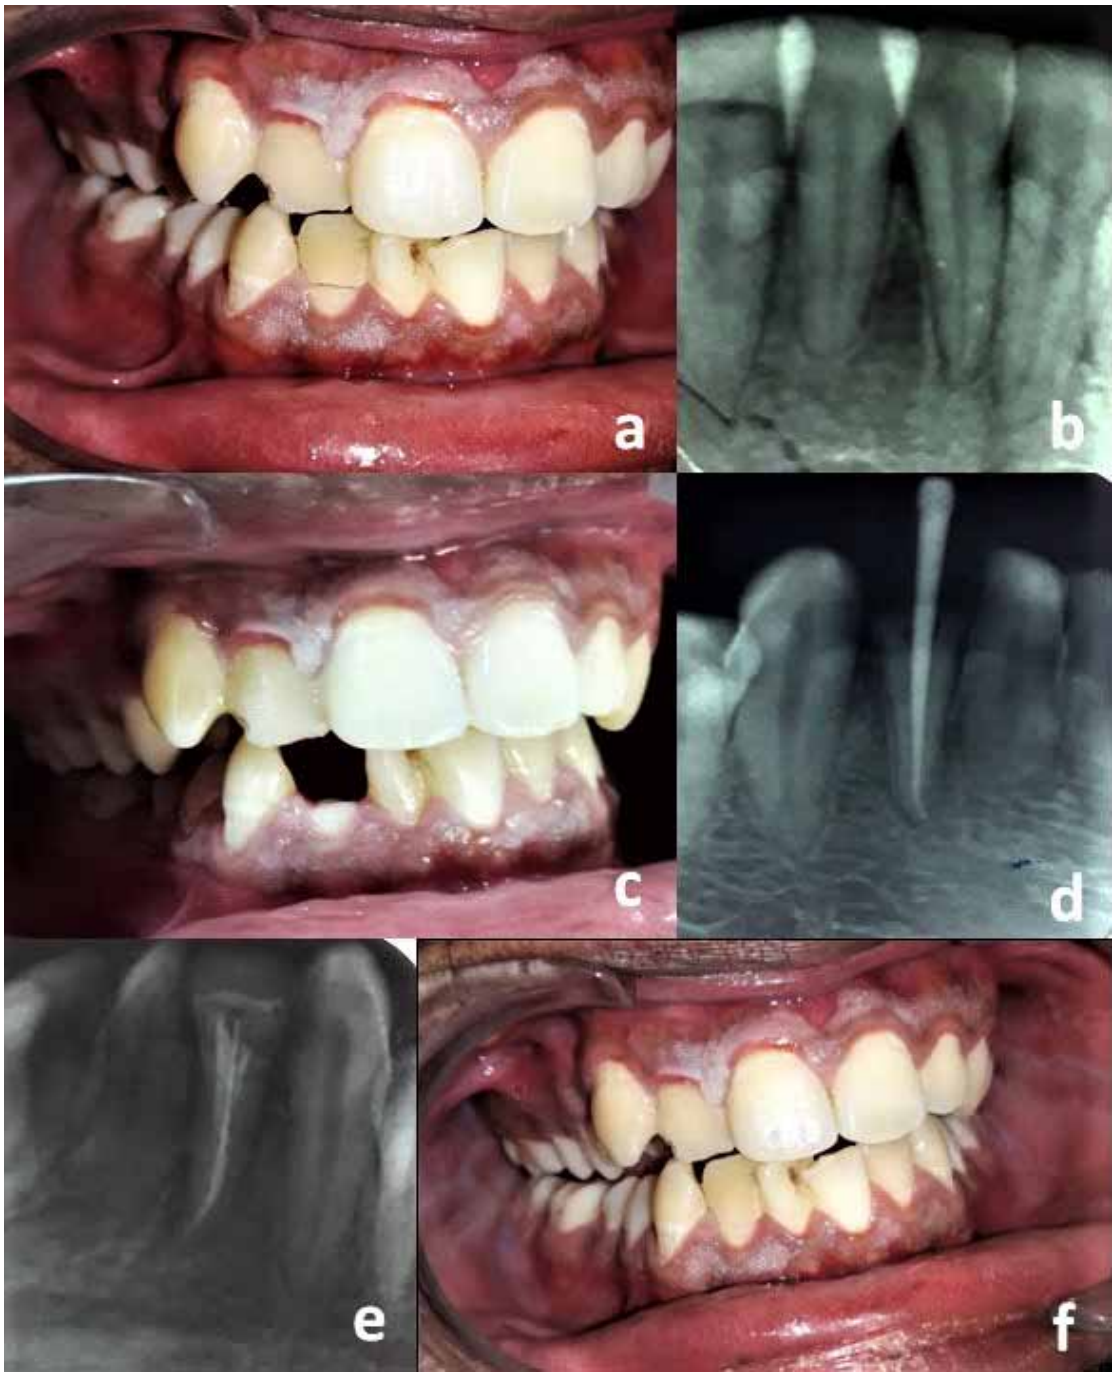

Figure 4a. Clinical examination; b. radiographic examination c. removal of fractured segment; d. complete root canal treatment; e, f. reattachment of fracture segment

Discussion

Treatment and prognosis of the fractured tooth depends on many factors like, patients age and habits, the thickness of enamel available for bonding, the property of the dentinal tubules in the young patients (wideness & wetness), size and thickness of fractured fragment for adhesion, bacterial contamination of the dentin and pulp.[5] A genuine dental treatment after trauma is a challenge for preventing the psychological & biological impacts.[6] According to many authors, reattachment provides an excellent result for the management of the anterior fractured tooth as it maintains the original colour, contour, translucency, surface texture, function

and occlusal alignment.[7-9] Clinicians follow many technical varieties for the reattachment of the fractured segment. The treatment options executed by the authors in the last 10 years case reports on- the reattachment of the fractured segment of anterior tooth,those were published in various journals (Table no. 1).

Table 1. Few case reports on reattachment of fractured segment of anterior tooth, those were published in various journals in last 10 years.

Type of fracture	Treatment followed	Reference
Case 1- Mid root fracture with grade III mobility. Case 2- Mid root fracture with grade III mobility.	Apical fractured segment was extracted and titanium endodontic implant was placed to preserve the natural tooth. Coronal segment was removed. The apical plug of MTA (open apex) with sectional obturation in the intact radicular portion. Reattachment of the coronal segment was done by fibre post.	10
Ellis class III fracture in both central and lateral incisors	Root canal treatment was done for both the teeth. Post space prepared in intact portion of the tooth. Fibre post were bonded to the fractured fragment and the whole thing was reattached to the intact tooth with dual-cure resin cement.	11
Crown-root fracture at the subgingival level with grade III mobility of fractured segment	1st line of treatment was Subgingival exposure of the fracture line. Root canal treatment was done followed by fibre post-placement along with GIC luting cement (Fuji II, GC International, Tokyo, Japan) for the reattachment of the fractured segment.	12
Two fractures in a single tooth- Ellis class III fracture (fractured segment was missing) and other line was on palatalside extending subgingivally.	Palatal fractured segment was first fixed to its original position with the help of composite resin followed by root canal treatment. 2mm post space was prepared and the composite resin was acted like a post and the rest of the tooth was build-up with composite resin.	13
Ellis class III fracture violating the biological width, where the fracture was extended upto the level of gingival in the labial aspect.	Osteoplasty and gingival recontouring were done to maintain the biological width. After root canal treatment post space is prepared. A hole was created on the fractured segment to fit the post and reattachment was done with the fibre post along with dual-cure composite bonding (Embrace WetBond, Pulpdent, USA).	14
Case 1- Ellis class III fracture at the cervical 3rd of crown. Case 2- Ellis class III fracture	Root canal treatment with fibre post for the intact portion of the tooth. Box like preparation was done on the fracture segment was reattached with the help of nanohybrid composite. Same as the previous one	15
Complicated Ellis class III fracture with mobile fractured segment	Root canal treatment of affected tooth followed by reattachment using composite resin.	16
Ellis class III fracture	Root canal treatment followed by post space preparation. Fractured fragment was prepared to receive the post which was 2 mm beyond the intact tooth surface after placement. Rest was built with a composite restoration.	17
Ellis class III fracture at the cervical 3rd level	Following root canal treatment reattachment was done with the help of fibre post and dual-cure resin cement (Para core resin cement, Coltene, Whaldent).	18
Ellis class III fracture involving middle 3rd of crown.	Root canal treatment followed by fracture segment reattachment with the help of flowable composite resin	19
Case 1- Ellis class III fracture at the cervical level and extended 2 mm subgingivally on the lingual aspect.	Case 1-Root canal treatment done followed by fibre post. Ginvial flap was raised to expose the fracture line. Fracture segment was reattached by preparing the segment to receive the coronal portion of the fibre post. Bonding was done by dual-cure cement.	20
Ellis class III fracture involving subgingival area on the palatal aspect.	Root canal treatment was done. The palatal gingival flap was raised to access the fracture line. Reattachment was done with the help of fibre post and dual-cure resin cement.	21
Split tooth involving the pulp with the loss of coronal tooth structure. Platally the fracture line was extended below CEJ.	Root canal treatment along with fibre placement was done for the tooth. Then the whole tooth was extracted and the fractured fragment was reattached to the tooth with the help of dual-cure resin. Tooth was repositioned back to its original position within 15.03 min and stabilized with fibre post and composite for 4 weeks.	22

Use of natural tooth to replace the missing part of the tooth structure eliminates the problem of shade mismatch and wear of restorative material. Additionally it provides fluorescence, opalescence and translucency. It was reported that reattachment of crown fragment provides long term prognosis than the composite restoration.[23] Amir *et al* reported there is no need of additional preparation over the tooth for retention purpose if the tooth is endodontically treated because; the space provided by the pulp chamber is enough to provide inner reinforcement.[24] Damaged tooth requires post-placement to retain the core, especially when more than half of the tooth structure is lost. Fibre post is mainly preferred by the clinicians because they are tooth coloured, has a modulus of elasticity similar to that of dentin, bonds to the tooth and have high fracture resistance. Fibre post along with the dual-cure adhesive creates a monobloc. Additionally, fibre post distributes the stress to the remaining radicular dentin. Resin luting cement provides good bond strength to the tooth. It has been suggested that surgery should be performed in those cases where the fracture line violates the biological width. Minimum of osteoplasty and osteotomy should be performed.[25] As described by authors from the above-mentioned table fibre post is the treatment of choice if the tooth is badly broken and it showed excellent result. Studies have shown that fracture resistance obtained from the intact tooth is greater than any other alternative technique and materials.[26,27] At the same time, the amount of strength required to maintain the function of the reattached fragment for long term use is not known. Bonding of post to the tooth structure increases the prognosis of the tooth by enhancing the post retention as well as reinforcing the tooth structure.[28] Overall resin-based adhesive along with the tooth coloured fibre post serves good esthetics, bonding and modulus between post and resin-based adhesives. Lastly, from the above discussion, we can say fractured anterior tooth can be successfully treated by using fibre post with the dual-cure resin cement.

Conclusion

Though various treatment options are available to treat the fractured tooth restoring the tooth by reattachment of the fractured segment is simple, economic and also provides good esthetics, translucency, contour, surface texture and function with a very conservative approach, most importantly patient's satisfaction.

Abstract

Traumatic injuries during early childhood interfere with root development leading to the formation of a tooth with an open apex. Apexification is considered as the best choice for the treatment of such cases. Use Mineral Trioxide Aggregate (MTA) as apical plug material optimizes the treatment outcome. Other than MTA different techniques are also used to restore the function and stability of the immature permanent tooth. In this case report 3 different techniques are used to treat the open apex. In the first case, MTA apical plug along with backfill was done. Complete canal obturation with MTA and custom cone technique were performed for the second and third cases respectively.

Keywords: *Apexification; Mineral Trioxide Aggregate; Complete canal obturation; Open acces management.*

Introduction

It is quite natural to achieve proper canal disinfection, adequate debridement and optimum apical sealing of the root canal in a completely formed and well-developed root, whereas achieving these parameters in a tooth with incompletely formed root is a challenge in the field of dentistry. Lack of apical stop in cases with open apex puts the clinician in an uncertain circumstance. In every step of root canal starting from chemo-mechanical preparation including irrigation till the apical sealing of the root canal clinician need to be very careful to avoid peri-apical extrusion of the materials, which may lead to post-operative symptoms like pain and swelling. Besides this an additional problem while treating this immature permanent tooth is the thickness of the radicular dentin, which may fracture during or after the root canal treatment.[1] These types of teeth are more commonly associated with periapical pathology.[2]

Early necrotized pulp and inflammatory apical root resorption are the most common etiological factors for the formation of immature teeth.[3,4] Apical barrier formation facilitates 3-dimensional cleaning and well adaptation of obturating materials leading to a successful endodontic treatment. Materials used for such cases should have properties like, antimicrobial, should be bioactive, should create a fluid-tight seal, should have high strength and should reinforce root dentin.[5] Earlier calcium hydroxide was used for the process of apexification, but it takes 5 to 20 months to form a calcific barrier.[6] This lengthy course of treatment offers a challenge like – difficulty in patient follow up management, increases the risk of tooth fracture with intracanal calcium hydroxide dressing for an extended period and also there is a delay in the completion of treatment.[7] Various authors have also confirmed that long term use of calcium hydroxide as intracanal dressing increases the risk of fracture in the future.[4,7,8]

Recently interest has focused on the use of MTA (mineral trioxide aggregate) for apexification. Its powder consists of hydrophilic compounds, which can set in the presence of moisture. Good biocompatibility, excellent sealing ability, high compressive strength, tissue

regeneration capacity are also added to its properties.[9] Importantly MTA reduces the appointment time, even allows single visit apexification. MTA offers a good apical barrier that allows vertical condensation of warm gutta-percha.

Technique 1: A 21-year male patient named Satyanarayan Sabat reported to the Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, SOA University, Bhubaneswar with the chief complaint of the discoloured tooth in the upper front tooth region. The patient gave the history of trauma 12 years back. Clinical examination revealed discolored tooth with open access and tender on percussion to the tooth 21. An intraoral periapical radiograph revealed an incompletely formed root apex with irregular periapical radiolucency (Figure 1a). Hence, the final diagnosis was pulpal necrosis with symptomatic apical periodontitis in tooth 21. After rubber dam isolation (Hygienic Dental Dam, Coltene Whaledent Inc., Germany), chemomechanical preparation of root canal was done upto F5 (Dentsply Maillefer, Switzerland) along with circumferential filing using # 80 K-file (Mani Inc., Japan). Chemomechanical preparation performed in conjunction with a copious amount of 3% Sodium hypochlorite (Prime Dental, India) and saline solutions. 5 ml of 17 % Ethylenediaminetetraacetic acid (Prevest Denpro, India) was used for smear layer removal. On completion of preparation calcium hydroxide dressing (Avue Cal, Dental Avenue, India)was given for 1 week.

After a 1-week tooth was again re-accessed under rubber dam isolation. 5 ml of 17 % EDTA and Copious amount of saline solution was used to remove the calcium hydroxide dressing from the canal. Canal was aspirated and dried thoroughly with absorbent paper points. MTA (Angelus, Londrina, PR, Brazil) was mixed according to the manufacturer's instructions and 4 mm of the apical plug was created using hand pluggers. A gutta-percha point was introduced into the canal to confirm the apical barrier (Figure 1b). a moist cotton pellet was placed over the MTA and the canal was sealed with a temporary restoration. Next day, the remaining portion of the root canal was coated with silicate-based sealers (MTA Filapex; Angelus, Londrina, SP, BR) and obturation was done by back-filling of gutta-percha using system B (Sybrondental, Orange, CA, USA) setting 200°C upto the level of CEJ (Figure 1c). Glass ionomer cement (3M ESPE, USA) was used for access cavity restoration (Figure 1d).

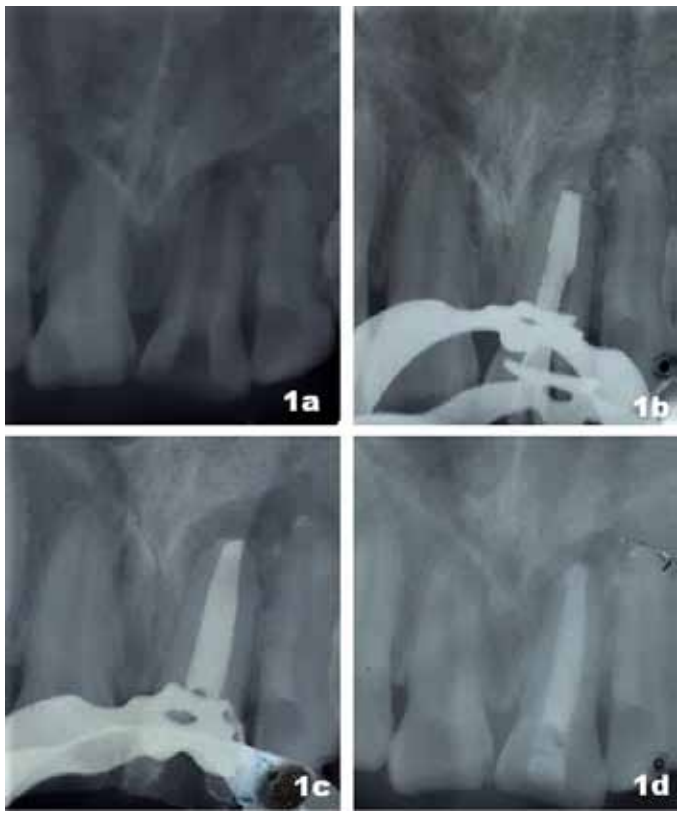

Figure 1: 4mm apical plug of MTA followed by backfilling of gutta percha

Technique 2: Another male patient aged 18 came to the Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Bhubaneswar, with the chief complaint of unpleasant smile and gave the history of trauma 10 years back. On clinical examination discolored tooth was noticed in 21. Intraoral periapical radiographic examination revealed a wide-open apex with a thin radicular dentinal wallalong with periapical radiolucency in tooth 21 (Figure 2a). Under rubber dam isolation chemo-mechanical preparation for the tooth was performed similarly as described in technique 1. Calcium hydroxide dressing (Avue Cal, Dental Avenue, India)was given for 1 week followed by temporary restoration. After 1 week of intracanal dressing tooth was irrigated with 17% EDTA (Prevest Denpro, India) and copious amount of saline solution to remove calcium hydroxide from the canal. Canal was aspirated and dried thoroughly with absorbent paper points. MTA (Angelus, Londrina, PR, Brazil) was mixed according to the manufacturer's instructions and the entire radicular portion of the canal was packed with MTA (Figure 2c). moist cotton pellet was placed over MTA and temporary restoration was used to maintain the coronal seal for the particular tooth. After 24 hours cotton pellet was removed and coronal restoration was done using glass ionomer cement.(3M ESPE, USA) (Figure 2d).

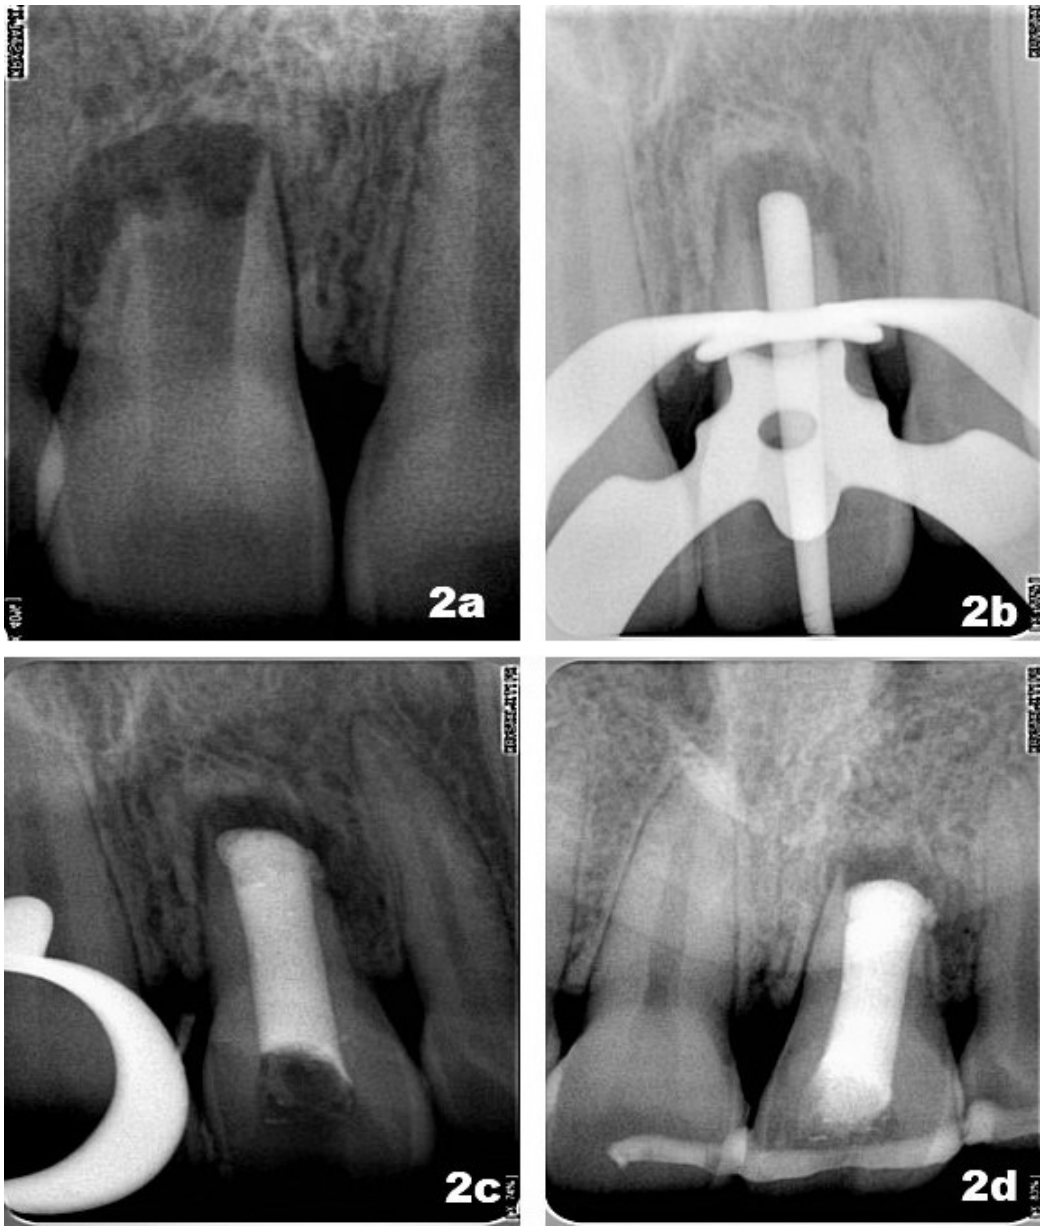

Figure 2. Entire canal was filled with MTA

Technique 3: A 14-year-old male patient requested dental treatment in the upper right central incisor following trauma before 5 years due to fall from the bike. Radiographic examination revealed incompletely formed root with no periapical changes (Figure 3a). Clinical examination revealed a discolored tooth in 11. All the necessary protocols were maintained under rubber dam isolation. Chemomechanical preparation of the canal including calcium hydroxide dressing was carried out the same way as described in the technique 1. After the removal of calcium hydroxide from the canal,it was obturated by the custom cone technique or roll cone technique using a resin-based sealer, AH Plus (Dentsply Maillefer, Switzerland). Gutta-percha points were softened by heat and rolled together between glass slabs. Tip of gutta-percha points were elasticized by using a heated instrument and then introduced into the canal to record the internal morphology of the apical portion of the canal (Figure 3b). This process was repeated till proper tug back was achieved. Canalwas sealed upto the level of CEJ and the access cavity was filled with glass ionomer cement restoration (3M ESPE, USA) (Figure 3c).

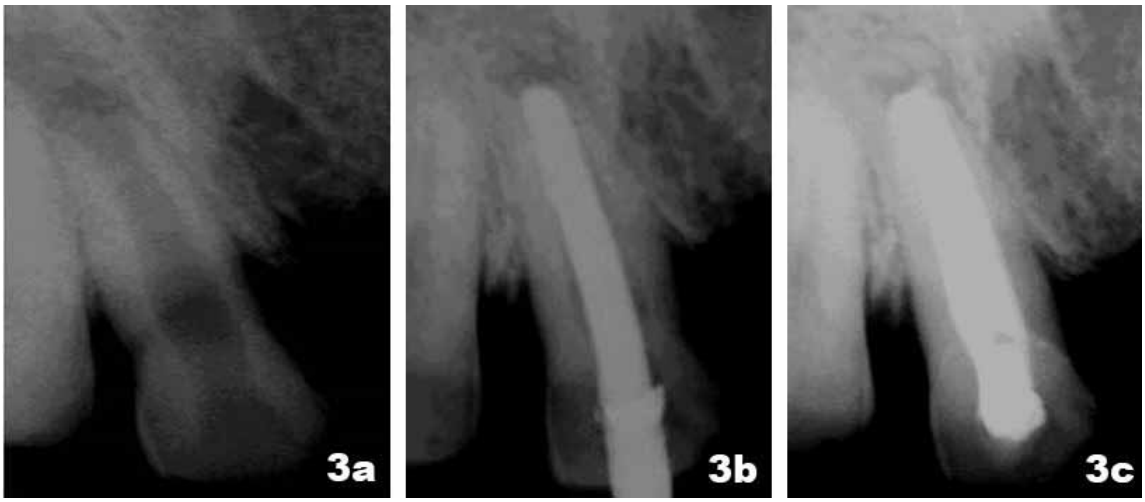

Figure 3. Custom cone/Roll cone technique

Discussion

Successful treatment of permanent immature teeth mainly depends on the proper cleaning of the root canal system as mechanical instrumentation can not be used appropriately. So, the disinfection of the entire root canal relies on the chemical action of sodium hypochlorite and on calcium hydroxide which is used as an intracanal medicament.[10] At high concentration Sodium hypochlorite is known to be toxic especially when it extrudes apically. Therefore, the use of a low concentration of sodium hypochlorite is advisable for disinfection in cases of immature teeth.[11] 17 % EDTA solution was used to rinse the canal before placement of calcium hydroxide as it removes the smear layer and opens up the dentinal tubule for penetration of calcium hydroxide through the dentin.[12] Along with this use of EDTA ensures better removal of calcium hydroxide from the canal before obturation.[12] Initially calcium hydroxide was used to form the apical barrier in non-vital immature teeth. One study has investigated thatfor apexification, apical barrier formed by calcium hydroxide is porous and even contains some amount of soft tissue.[13]

MTA has excellent biological properties and has the potential to create a good apical seal, therefore it has been strongly recommended to use as an artificial barrier in the teeth with open apices, thus reducing the treatment appointment to 1-3 visits. High pH of MTA allows it to destroy surrounding microorganisms and its bioactive nature encourages blastic cells to promote the process of healing.[5,15] Along with this, it also facilitates the deposition of cementum on it because of the presence of calcium and phosphorous ions (15). In a prospective study apexification using MTA has shownan increased prevalence of healing and apical closure.[16] Thus, an apical seal with MTA favours regeneration. Taking all the advantages of MTA into consideration, it was used

for the apexification process in the first two cases of this case report.

In the first technique-the apical plug of MTA was given and obturation was performed by backfilling of soften gutta-percha. 4-5 mm of MTA apical barrier has proven to be significantly stronger and showed less leakage than a 2 mm apical plug. In this case,a 4 mm apical barrier of MTA was given. MTA apical plug facilitated obturation by condensation without any over extrusion of gutta-percha. In technique 2,the tooth was very immature and the thickness of radicular dentin is less, thus making the tooth more vulnerable to fracture. In such cases adaptation of gutta-percha master cone to the dentinal wall would be difficult. Additionally, it has been confirmed the use of MTA strengthens root dentin.[17,18] Considering the above-mentioned factors root canal was completely obturated using MTA. As an experiment, a conventional method of obturation (tailor-made gutta-percha obturation) was attempted in technique 3. Rootend closure was achievedby customized gutta-percha cone. Considerably successful treatment along with complete resolution of symptoms was observed when the tooth was obturated with a custom cone technique.[19] The choice of treatment for teeth with open apex depends on the selection of case, operator's experience as well as on the handling of various materials.

Conclusion

There are various ways to manage a tooth with an open apex. MTA has numerous applications in the field of endodontics starting from pulp capping including pulpotomy to apexification. Due to its excellent biocompatibility and strength it is used for apical barrier formation in immature young permanent teeth. Apart from all the advantages of apexification materials, proper canal disinfection, achieving a fluid-tight seal, limiting the apical barrier and obturation within the canal, play an important role in a successful endodontic treatment.

Palatal Lift Prosthesis for Velopharyngeal Incompetence: A Case Report

Mirna Garhnayak[1], Lokanath Garhnayak[2], Kajal Kiran Sahoo[3]

[1]Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Associate Professor, Department of Prosthodontics, SCB Dental College & Hospital, Cuttack, Odisha, India, [3]Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Velopharyngeal incompetence often distorts the voice quality making it difficult for the listener to comprehend. A cost-effective treatment approach for this is palatal lift prosthesis. This prosthesis enables the incompetent soft palate to approximate with the posterior pharyngeal wall. As a result articulation of speech is improved.

Keywords: *Palatal lift appliance, velopharyngeal incompetence, speech.*

Introduction

The velopharyngeal mechanism plays a crucial role in the clarity and acceptability of speech.[1] It involves a sphincter, comprising the lateral pharyngeal walls, posteriorpharyngeal wall, and the soft palate (velum).[2] The contracture of the apparatus principally controls the oro-nasal sound pressure and amount of airflow in speech. Dysfunction of this mechanism due to congenital craniofacial syndrome, head and neck cancer, neurogenic injury, velopharyngeal insufficiency,or velopharyngeal incompetence may result in compromised voice quality.[3] It may be attributed to nasal air emission, reduced oral pressure, impaired articulation (weak consonants),and hypernasality (Figure 1).[3]

Though surgical correction of velopharyngeal dysfunction with a pharyngeal flap or pharyngoplasty is preferred, it may not be possible in a patient with a cardiovascular or neurological problem.[4] Such cases can be treated with velopharyngeal or palatal lift prosthesis (PLP) in combination with speech therapy.[5,6]

The palatal lift prosthesis was originally designed by Gibbons and Bloomer to uplift the neurologically weakened soft plate to a normal level. The aim was to decrease the size of palatopharyngeal opening during consonant sound production. This, in turn, improved the resonance and decreased nasal intonation of speech.[7] Subsequently,the velar lamina portion of the prosthesis has been made movable using a hinge, orthodontic wire, wire spring, or ageneric button attached to a single connecting wire. This facilitated the movement of velar lamina inferiorly-superiorly.[8,9] This clinical case report focus on the stepwise fabrication of a palatal lift prosthesis for a patient with hypernasal speech.

Case Report: A 20-year-old male patient reported to the clinic with a chief complaint of nasal intonation in his speech since childhood. The speech of the patient was dysarthric. Intraoral examination revealed a normal velopharyngeal structure with a flaccid soft palate (Fig. 2). Velopharyngeal orifice closure was inadequate due to impaired movement of the soft palate during speech and swallowing. Both the maxillary and mandibular arch were completely dentulous with all teeth in good condition. So it was decided to treat the patient with a combination of palatal lift prosthesis and speech therapy. Counseling of the patient was done and consent taken for the same.

Procedure: The procedure was initiated with primary impressions of the upper arch using irreversible hydrocolloid (Zelgan, Dentsply, Constance, Germany) and working cast fabrication. Before this, the stock tray was modified with impression compound (Pinnacle, DPI, Mumbai, India) to cover soft palate posteriorly.

The PLP used for the patient had two parts: an anterior denture base for retention of the prosthesis and a posterior velar lamina to uplift the soft palate. Initially, the denture base portion with four pin head clasp and two C clasps was fabricated using heat cure acrylic resin (DPI heat Cure, DPI, Mumbai, India). The posterior extension of the denture base was kept up to the junction of the hard and soft palate.

For the velar lamina portion of the prosthesis, a segment of 21-gauge stainless steel orthodonticwire (3M Unitek, Monrovia, CA) was adapted in the form of a loop on the master cast. The loop was attached to the posterior portion of the denture base and adjusted in the patient's mouth, till the soft palate is slightly elevated. Due care was taken to avoid gag reflex. The gradual uplifting of the soft palate was done by molding the loop with a green stick modeling compound. Molding was done by asking the patient to breathe through the nose and pronounce plosive sounds like 'b' and 'p'. These sounds require to increase intra-oral pressure and aid in decreasing hypernasality. The procedure was repeated, till the soft palate came in light contact with the posterior pharyngeal wall (Fig.3).

The efficacy of the molded prosthesis was assessed by asking the patient to blow out air, with the mouth being closed. Once air outflow through the nostril was greatly reduced,a satisfactory lift of the soft palate was assumed to be achieved. Then the velar lamina portion of the prosthesis was relined by zinc oxide eugenol impression material, which was subsequently replaced with heat cure acrylic resin (Fig.4). Insertion of the final prosthesis was done after proper finishing and polishing to ensure smooth and round border (Fig.5). The patient was advised to wear the prosthesis consistently except during sleep. Follow up of the patient was done in a weekly interval for a period of 1 month.

The speech therapy session was given to the patient by a speech therapist throughout the procedure. Audiometric analysis of the patient was performed periodically in the Department of ENT using the Temple Street Scale. After a post-insertion period of 3 months, the speech pattern was found to be improved with decreased nasal intonation clarity of speech.

Discussion

A palatal lift prosthesis was preferred in this patient as, the velopharyngeal closure was compromised, despite its normal structures. The soft palate was class II type, flaccid, and having inadequate movement vertically.[10,11]

This prosthesis uplifts the velum in superior-posterior direction to the level of normal palate closure, aligning with the palatal plane.[12] Consequently, pharyngeal muscles are activated, decreasing the size of the palate-pharyngeal opening and the nasal intonation.[13] So clarity of speech is improved.[14] Even prolonged use of PLP might also reduce the disuse atrophy of soft palate and enhance its function.[15] But the sudden and strong lifting of the soft palate is not recommended, as it might cause soreness. An interim PLP was planned for the patient, as he was a first time user. As it was made with PMMA, the palatal extension portion was gradually adjusted according to the patient's need. This resulted in better patient compliance. Once the patient is motivated and accustomed to the interim prosthesis, a definitive prosthesis can be planned for him.

The clinical efficiency of the prosthesis was assessed for nasal intonation, resonance, articulation, and clarity of speech in each visit. They were gradually found to be improved with the use of prosthesis. Effectiveness of prosthesis can also be assessed using the lateral cephalograms, video fluoroscopy, naso endoscopy, nasometric analysis, and aerodynamics.[16,17] Palatal lift prosthesis alone is effective in mild velopharyngeal insufficiency case. But in the long-standing case and repaired congenital cleft palate case require a combination of speech therapy along with palatal lift prosthesis.[10] Patient compliance is crucial for the success of PLP. They often complain of dysphagia and lack of immediate improvement in speech.[18]

Conclusion

A team approach comprising surgeon, prosthodontist, and speech therapist are beneficial in the management of a patient with velopharyngeal insufficiency. Depending on the severity of the case, palatal lift prosthesis should be used alone or in combination with speech therapy. A definitive prosthesis should be delayed until the patient is comfortable with the interim prosthesis.

Saliva as a Diagnostic Tool in Orofacial Disorders

Abhishek Ranjan Pati

Reader, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar 751003, Odisha, India

Abstract

Saliva is formed by major exocrine organs, namely the parotid gland, "sub-mandibular" gland and "sublingual glands" and many minor "salivary glands." Nature has bestowed saliva "The natural source" with many functional capabilities that have a crucial value in maintaining the well being of mouth. Saliva plays a major role in the protection of oral tissues, food preparation, digestion, lubrication and speech.[1] But one purpose not given by life is the utilization of saliva for investigative value, it is the human who has to explore this precious wonder fluid marvelously studded with clues about the human body in health and disease. Saliva as a diagnostic aid in orofacial disorders is the traditional monitoring tool for various diagnosis.[2]

Keywords: *Saliva, HIV, orofacial disorders.*

Introduction

Nature has bestowed saliva "The natural source" with many functional capabilities that have a crucial value in maintaining the well being of mouth. Saliva plays a major role in the protection of oral tissues, food preparation, digestion, lubrication and speech.[1] But one purpose not given by life is the utilization of saliva for investigative value, it is the human who has to explore this precious wonder fluid marvelously studded with clues about the human body in health and disease. Saliva as a diagnostic aid in orofacial disorders is the traditional monitoring tool for various diagnosis.[2] Saliva is formed by major exocrine organs, namely the parotid gland, "sub-mandibular" gland and "sublingual glands" and many minor "salivary glands." The total saliva produced during a 24 hr period is about 1000 to 1500 ml. The approx 0.4 ml per minute.[3]

Historically[4] the diagnostic value was recognized by the prehistoric legal center of the population who engaged salivary surge as the foundation of anancient"lie detector"examination, but now with endless, untired efforts of dental investigators in finding change in saliva stream speed and constituents by means of investigating and checking in several mouth disorders, it is established that saliva is valuable in the analysis of general disorder of salivary glands like inflammatory as well as autoimmune disease, by nurturing a known volume of saliva, a quantitative determination of specific organism can be made which is employed in identifying risk for caries and as an indicator for infection. The buccal mucosa cells are used for getting DNA for gene analysis, the list keeps growing.[5,6] Saliva is more and more used in the analysis and evaluation of ailment but the possibility of physiological difference within several constituent whose inference is projected as an analytic assist ought to be investigated sooner than it is utilized.

Saliva as a diagnostic tool in various disorders:

Autoimmune disorders - Sjogren syndrome:[7,8,9,10,11,12]

Saliva in infections:

- Viral: HIV, Herpes, Mumps
- Bacterial
- Fungal

HIV: Groopman JE, Salahuddin (1984)[13] demonstrated that HIV-1 was detected initially in whole saliva, at frequencies ranging from 1 to 45%. David HO, Roy E et al (1985)[14] conducted a study for the isolation of HTLV- iii(human T-cell lymphotropic virus) from saliva of infected patients. 83 saliva samples were collected from 71 homosexual men seropositive for HTLV-iii. Saliva samples were cultured within 60 minutes after collection and blood was collected from 50 of 71 for virus isolation. It was concluded that the HTLV-

iii titer of patients saliva was substantially less than that of blood. Thus this study indicates that transmission of HTLV-iii does not occur if exposed to the saliva of infected persons so useful in allaying public concern regarding the causal spread of AIDS. Yapijakis C, Panis V, Koufaliotis N, Yfanti G, Karachalios S, Roumeliotou A, et al (2006)[15] conducted a study investigate the finding possibility of "human immunodeficiency virus (HIV)" in the salivary sample,sixty-eight subjects were investigated, consisting of thirty-four"HIV" carriers and thirty-four non-carriers (controls) of coordinated sex and age. The mouth assessment revealed the saliva and blood sample of study subjects. Every subject was investigated andscreened for "HIV"by means of 2 method "Oraquick-compatible enzyme-linked immunosorbent assay (ELISA) and a fluorescent immunoenzymatic method (ELFA)", long-established by "western blotting", and a simple molecular method "(polymerase chain reaction amplification of a relatively constant viral DNA region)", long-established by "DNA hybridization". They investigated that the detection of anti-HIV in saliva mightattainthe accurateness of 97.1-100%, analogousby way of blood.

Hepatitis: Hutse Vet al (2005)[16] conducted a study on 43"HBsAg" positive and 73"HBsAg""negative paired serum samples" were investigated. These were gathered from subjectscoming to college outpatient department. The samples were stored using the "Oracol collection device" and they were passed through the "IgG quantification assay" to guarantee their fineness and amount. The finding of HBsAg in oral solution was done with"ETI-MAK-4 ELISA". The corroboration of this test gave a sensitivity and specificity around 90.7% and 100%.

Varicella-zoster infection: Talukder Y et al[17] investigated by means of matching serum as well as oral solution form fit grown-up subjects (n = 205) in addition top lay school kids (n = 98), saliva collection for regular"measles, mumps and rubella" tests (n = 537) and samples from subjects of atopic dermatitis (n = 252). When it was compared to paired sera tested by the same ELISA the sensitivity of the oral fluid assay was 93% and specificity 95.7% overall, varying slightly with the age group. The analysis was revealed to have good quality possibility for utilization in major epidemiological settings.

Herpesvirus infection: Blackbourn DJ, Lannette ET (1998)[18] conducted a study on "14 HHV-8-seropositive subjects, as well as 8 Kaposi's sarcoma subjects, to determine the growth of Human herpesvirus 8 by "polymerase chain reaction" in nose secretion and salivary fluid of patients. They concluded that HHV was present in solitary or equally body fluids in eight (57%) of fourteen subjects. They further determined that "parallel PCR testing revealed the concomitant presence of cytomegalovirus, Epstein-Barr virus and HHV-6" in a variety of amalgamation in these body fluids. Thus data indicates recurrent detaching of numerous herpes – viruses within saliva predominantly Kaposi sarcoma patients. Yildirim S et al (2006)[19] reported a case and found that "EBV was detected in baseline samples of saliva from the "Kostmann syndrome patients".

Mumps: Thomas Thieme, Stephen Piacentini et al (1994)[20] conducted study on 157 asymptomatic subjects to decide if oral liquid samples are capable to be used to constantly measure defensive blood quantity of antibodies to "measles, mumps and rubella", and to compare coordinated serum and saliva samples from eleven subjects after "measles-mumps-rubella immunization. They concluded that the incidence of antibodies in "oral fluid specimens" correlated with that of serum with 94% sensitivity and 94% specificity for mumps, thus protective levels of antibodies assessed by means of an oral fluid with good consistency. Muhels R.L et al (2000)[21] evaluated that in viral mumps the saliva shows an increase in the sodium values and a very less potassium level, which approaches its plasma equivalent. Sodium valuesincrease to 90-120 mmol/l and potassium values dropunder 10 mmol/l.

Bacterial infections:

Dental Caries: J Van Houte, HV Jordan (1990)[22] carried out a study on 273 subjects for the detection of the alliance of microbacterial concentration of teeth tartar and saliva with human root surface dental cavity and saliva samples were collected from one-third of the patients for determining of the concentration of streptococcus mutans and lactobacillus and they concluded that saliva populations of mutans streptococci had positive correlation by way of the occurrence of tooth root surface dental caries.

Fungal infection: Hicks MJ, (1998)[24] carried out a study to determine the prevalence of fungal organisms in whole unstimulated saliva from children with vertically acquired HIV infection. 27 HIV infected and 11 HIV exposed, but uninfected subjects were studied and the

whole unstimulated saliva was collected. The results were, yeast and hyphae were present cytologically in 19% of HIV infected and 9% of HIV-exposed but uninfected children and thus they concluded that fungal organisms in the saliva reflected oral carriage or mucosal colonization, influenced the development of clinically significant candidiasis in the immunocompromised children.

Saliva in malignancies:

Head and neck cancer: Jiang WW, Fmasayesva B (2005)[25] conducted a quantity PCR of "cytochrome oxidase I and cytochrome C oxidase II (Con II)" genes in mouthwash samples of 94 subjects having "head and neck squamous cell carcinoma" and 656 controls were considered. They evaluated the "mitochondrial DNA/nuclear DNA" in salivary samples from HNSCC subjects and controls in association to "smoking, ethanol intake and tumor stage". The mean values of "COX I and COX-II" in saliva samples have considerably elevated in comparison with controls. On univariate investigation, smoking, age, HNSCC analysis, and higher stage of HNSC were associated with higher levels of mt DNA contact in saliva.

Saliva in immune-related disorders:

Multiple sclerosis: Frena Adamashuilli, Aliraza Minagar (1993)[26] carried out a study for the quantity of soluble "HLA" in body secretions and to found that a possible function in assessing illness. "Enzyme-linked immunoassay" was used to gauge soluble "HLA class I and class II molecules" in saliva and cerebrospinal fluid in 13 non treated subjects with multiple sclerosis and saliva of 53 healthy controls is also studied. They concluded that soluble HLV in saliva specifically HLA 11 correlated with the levels formed in CSF, thus saliva provided a noninvasive correlation of CSF measurement.

Graft versus host disease: Patients with "graft versus host disease"experience from xerostomia and augmented levels of oral injections and mucosal pathologies. Izutsu KT, Menard TW (1985)[27] carried out a study on 42 subjects at 90 days to 2 years following bone marrow transplantation. They studied labial gland IgA, rather than whole saliva. It was concluded that there was a decreased concentration of IgA, 90 days after transplantation, and was suggestive of immunocompromised status. Morhang G, Engstron PE (1994)[28] demonstrated that the subjects of"GVHD" had a smaller amount of saliva IgM one year after "bone marrow transplantation". Maglu RS (1996)[29] demonstrated there is a mean decrease of 55-90% in the "salivary flow rate of patients" with graft versus host disease.

Drug monitoring: Similar to other body fluids, saliva is proposed for the monitoring of systemic levels of drugs. A requirement for this investigative purpose of saliva is a definable associationamidthe absorption of a curative medicine in blood and the absorption in saliva. Amedicine to appear in saliva, medicine molecules in serum have to cross through the salivary glands and into the oral cavity.

Antipsychotic drugs: Ben Aryeh (1980)[31] conducted a study on 118 manic-depressive patients, "salivary and serum lithium" concentration were calculated. The results were lithium concentration was higher in saliva as compared to serum. A method to measure serum lithium levels from salivary measurement was extracted from serum = 0.364 saliva. The results demonstrated the likelihood of through salivary lithium capacity for checking patients on long-lasting lithium treatment.

Antiasthmatic drugs: Krik JK, Dupnis (1994)[34] concluded saliva theophylline conc. established an improved association with serum levels of free "theophylline than with serum concentration of total theophylline."

Immunosuppressive drugs: Coates JE, Lam SF (1988)[35] demonstrated that a lesser association (r = 0.68) was established between salivary and whole serum levels of immunosuppressive drugs.

Antiepileptic drugs: Rosenthal E, Moffr E (1995)[36] evaluated the saliva evaluation of anti-epileptic medicines. Salivary carbamazepine levels were found to be 38% of serum carbamazepine level and a constructive correlation between salivary and serum carbamazepine levels was observed.

Alcohol and tobacco: Luepkar RV, Pachauk TF (1981)[37] evaluated that salivary thiocyanate level was established to be a pointer of smoking. Istvan (1982)[38] carried out a study on cigarette smokers between the age of 35 and 59 and investigated the relation of salivary continue and no of cigarette smoked per day to body mass index.

Discussion

Saliva is easilyavailable, which can be stored by

various method and it contains many hormones, drugs, and antibodies of interest in screening and diagnosis.[40] It is collected in distant areas by inexperienced persons and, by way of assured compilation instruments, is steady at optimum temperatures for few weeks Absorbing specimens on cotton may contribute interfering substances to the extract. A major advantage is that blood-borne diseases associated with blood collection are not relevant to saliva (noninvasive). Due to less quantity of harmful antigens in saliva, "HIV and hepatitis" diseases are much less of a danger from saliva than from blood.[40] Hocini et al. (2000) investigated that secretary"leukocyte protease inhibitor (SLPI- antiviral activity against free HIV-1)" can be an additional reason causative to the safety of saliva as an analytical sample.

Understanding of saliva assays is hard. Because blood levels of steroid hormones are several-fold higher than saliva levels, much has been written about the problems of contamination from bleeding gums. The use of saliva as a diagnostic fluid has become a successful research story during the past 10 years. Recent and most advanced technologies have enabled the salvia to be used to diagnose some of the diseases and prediction of disease progression, to be enhanced by future research activities.

Abstract

The most common carcinoma affecting the oral mucosa is oral squamous cell carcinoma, with prevalence seen in the age groups above 50 years in males and with rare occurrence below 30 years. Studies reveal approximately 30-40 % of deaths in oral squamous cell carcinoma occur due to various tissue abuse habits. The present case definesa classic incident of oral squamous cell carcinoma concerning the alveolo-buccal sulcus in a male having 50 years of age.

Keywords: *Alveolobuccal Sulcus, Oral Squamous Cell Carcinoma, Mandible.*

Introduction

One of the potential scarring and incapacitating disorder which harms the physical stature and mental health of patients is Oral Squamous cell carcinoma (OSCC).(1) It is the most familiar malignant mucosal neoplasm of head and neck accounting for over 90% of all malignant neoplasm.(2) The frequency and mortality rates of OSCC arise with the age of the patient and males are affected more than females.(1) It typically affects the older age groups throughout the fifth-eighth span of life with less occurrence reported in the younger age groups below 40 years.(3) The maximum prevalent threat for the occurrence of oral SCC is due to the habit of tobacco or betel intake, ingestion of intoxicating drinks, and contamination with human papilloma virus (HPV) having high-risk factors. Also a nutrition comprising of inadequate fresh fruits and vegetables was reported in OSCC patients.(4)

Since, the oral mucosa is more approachable to the comprehensive investigation; early perception of potentially malignant and cancerous lesions can be easily marked. But sometimes due to unawareness or unapproachability of therapeutic facilities, the carcinoma gets diagnosed in the advanced stages. Thus, an enhancement in primary recognition of oral carcinoma should be adopted, by adopting the chairside diagnostic procedures like toluidine blue, brush biopsy, etc.(5) In the current paper, we represent a case of a small swelling which grew to a larger size after 2 months.

Case Report: A male patient of age 50 years came with a history of pain in the left side mandibular back tooth region for 8 days. The patient had tuberculosis and is under medication for 2 months and he has undergone extraction in the left side mandible before 12 years. The patient had a habit of pan and khaini chewing 10-15/day for 20 years and has left the habit since 4-5 years. Extra-orally there was presence of a single, submandibular lymph node measuring approximately 1x1cm in size, non-tender and mobile on palpation. Intraoral examination showed localized growth present in the left lower edentulous region on the alveolar ridge with relation to 36, measuring 1x0.5 cm approximately having

irregular borders. On palpation, the tumor was soft in consistency, non-pedunculated, tender on palpation which bleeds on probing with slight obliteration of gingivo-buccal sulcus.(Figure-1.1)

Hence a provisional diagnosis of gingival epulis was given along with differential finding of pyogenic granuloma and peripheral giant cell granuloma, but patient didn't reported to the department, had not taken any medications, or performed any investigations advised. After approximately 2 months,the patient again reported to the hospital with the same complaint (as he had previously) of pain along with swelling in the mandibular left side back tooth region. Extra-orally swelling present in the left lower 1/3rd of face measuring 2x2 cm in size approximately of normal skin color, appears shiny and stretched. On palpation swelling was firm in consistency and tender with no secondary changes or symptoms associated with it. Skin over the swelling was warm to touch and was non-pinchable. (Figure-2.1)

Left submandibular lymph node measuring 1x1 cm was palpable which is tender on palpation and fixed to the underlying structures. A single, ulcero-proliferative growth present in the left gingivo-buccal sulcus with relation to 34 35 36 37 region, measuring 3x2 cm in size having irregular margins and erythematous in appearance with no secondary changes present. On palpation, growth was firm to touch, having indurated margins and remained tender on palpation with obliteration of gingivo-buccal sulcus with relation to 34-37 regions. (Figure-2.2)

Figure 1. 1. Extra-oral view of patient; 1.2-Intra-ora view showing a localized growth

Figure 2.1. Extra-oral view of patient after 2 months; Figure 2.2. Clinical view of ulcerative growth which increased in size in the gingiva-buccal sulcus.

The patient was further advised to do radiographic investigations. An intraoral periapical radiograph and panoramic radiograph was done.Intraoral periapical radiograph reveals a single diffused radiolucency with relation to 34 35 36 measuring 1x2 cm in size. There is vertical and inter-radicular bone loss,with widened pdl space i.r.t 35 36, and loss of lamina dura i.r.t 34.(Figure-3.1)

Panoramic radiograph reveals a localized, ill-defined radiolucency involving the left side body of mandible, measuring 3x2 cm in sizewith loss of buccal cortical plate and intact lingual cortical plate.Missing tooth present i.r.t 36 with mesially tilted 37.(Figure-3.2)

Figure 3.1-Inra-oral periapical radiograph; Figure 3.2- Panoramic radiograph

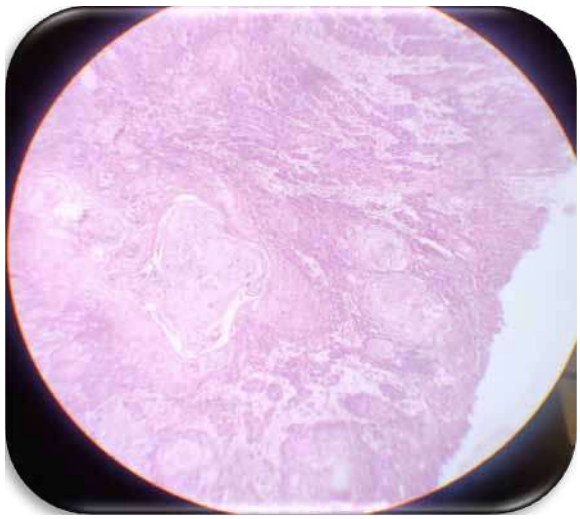

Figure 4. Histopathological slide showing para-keratinized stratified squamous epithelium, withtumorislands, nests and cords along with diffusely arranged chronic inflammatory cells.

Correlating the clinical features, radiographic findings a provisional diagnosis of Malignant ulcer-proliferative with clinical staging of tumor T1N1M0 was presented. A chairside investigation was carried out by applying toluidine blue staining which showed the presence of dysplastic cells. Further incisional biopsy of the lesion was done under local anesthesia and was submitted for histopathological examination. Histopathology revealed hyperplastic proliferated para keratinized stratified squamous epithelium invading into the underlying moderately dense fibro collagenous stroma as strands and cords.(Figure-04)

The definite diagnosis was moderately differentiated SCC patient was further sent for complete excision of the lesion to the department of oral surgery.

Discussion

This case report described an unusual case of oral SCC of alveolo-buccal sulcus of a 50-year-old male patient who has previously reported with a small growth which gradually increased in size over 2 months. World Health Organization(WHO) described carcinoma of the oral cavity as the 6th most commonest cancer in males in developing countries, the first being lung, followed by prostate cancer and involvement of carcinoma of other organs, while studies revealed that in women, it is the 10thusualspot for cancer, the first being breast cancer, followed by colorectal cancer and carcinoma of the stomach.[6]

Risk factor associated are tobacco (smokeless and smoking), alcohol, betel quid, agents containing phenols, emission of radiation, lack of iron and Vitamin A in diet, syphilis, environmental and occupational factors, oncogenic viruses (HPV and EBV), Candidial infection, genetic predisposition, immunosuppression[2]. It has been reported that tobacco and alcohol intakeis not only prime risk factors for oral carcinoma but also hasrobust effects on the morbidity, mortality, recurrence and second primary tumor in patients.[3]

A plethora of clinical forms of Oral SCC have been reviewed. It may be in the form of leukoplakia, leukoplakia with verrucous growth, an erythroplakia[7] some of them may exaggerate in the future into a necrotic type of ulcer comprising of indurated edges. It may perhaps give rise to a comprehensive mass having papillary projections with irregular superficialtexture.[4] There is the presence of bleeding in oral SCCin case of trauma with pain after they become superficially secondarily infected whereas otherwise oral SCC is usually painless in nature[4].

The sites with the most frequent occurrence of OSCC are the inner side of the tongue along with the floor of the mouth due to the presence of thin non-keratinized epithelium. The oral sites with less frequent occurrence are the gingivae, palatal mucosa, retromolar region along with the buccal and labial surface of the oral cavity.[4] Patients who have a positive histopathologic report for oral squamous cell carcinoma should undergo contrast-enhanced computed tomography of the head and neck to help in the physiological examination to know the extent of tumor and involvement of lymph node. Magnetic resonance imaging should be indicated in case of involvement of soft tissues especially in the tongue.[9] Surgery is considered the first line of treatment. Always a multidisciplinary approach should be made including chemotherapy, radiotherapy or surgery or a combination of all of these for the better prognosis of Oral SCC.[9]

Abstract

It is not possible to reach into the final diagnosis by only noting the patient history and clinical examination. Appropriate diagnostic aids are mandatory to co-relate the history with the clinical findings to reach into a correct final diagnosis. It is seen mostly the diagnosis of endo-perio lesion becomes difficult and complicated, unless the clinician possesses sound knowledge regarding the basic diagnostic procedures. Or else, there is a fair chance to miss the findings, small though relevant which would lead to an inaccurate diagnosis. Hence, this review topic is taken to help the practitioners with simple basic procedures to make the diagnosis of the endo-perio lesion made easy.

Keywords: *Endo-perio lesions, Periodontal, Pulpal, Diagnosis.*

Introduction

There is a close inter-relationship among the dental pulp and the periodontium. Anatomically,there is a communication between the same via the apical foramina, dentinal tubules, and lateral or accessory canals. This makes pulpal inflammation gives rise to the inflammatory changes in the periodontal ligament much earlier than the pulp could turn into a full necrotized tissue. The toxic and the by-products of the bacteria, tissue,and food debris from the pulp attain the periradicular area via any foramina of the root canals giving rise to inflammatory and reactions.[1-5] Pulpal disease can undoubtedly lead to periodontal diseases, however, the concept that periodontal disease cause pulpal disease remains controversial. If cementum getsexposed by progressive recession, it can become more readily penetrable by repeated scaling, curettage, or by direct bacterial action. Thus, the pulp may be affected in a few instances when large numbers of dentinal tubules become exposed through advancing pocket depth. Two usual routes are available for the entry of injurious agents into the pulpal tissue.[1, 2]

1. Exposed canals (including those of the furcation) allow direct access of microorganisms and their toxic by-products to the pulp.
2. Dentinal tubules,exposed by repeated instrumentation, causing damage to the cementum, or diseased cementum can become an avenue of direct microbial load entry into pulpal tissues.

True combined perio-endo lesions occur when independent periodontal and periapical or lateral lesions are present and do communicate resulting in perio-endo lesions.[1]

Correctsteps to achieve endo-perio lesions diagnosis easily:

1. **Patient History:** Maximum data can be gained if history is noted carefully with attention. A single point missed can lead to a wrong diagnosis which can jeopardize the next process, the treatment plan, which could have easily achieved. For the pain history, leading and precise form of questions are put to the patient to get a clue to find whether the case is pulpal or periodontal. If it is a case of early pulpitis, pain would be of mild degree and short

duration. And in the case of pulpal involvement, pain would be of acute onset with severe in degree. In the case of only periodontal involvement, as it would be chronic, the degree of pain varies from mild to moderate. And lastly, in the case of pulp periodontal lesion, pain would be of very minimal in degree as the drainage occurs via the periodontal pocket which reduces the pressure leading to a reduction in pain.[5-8]

2. **Visual examination:** It should be carried out thoroughly with proper digital pressure on both the hard as well as the soft tissues of the oral cavity. Sufficient illumination with enhanced magnification is a must during the visual examination. The tissues are examined visually well to detect the presence of dental caries, fractures, development defects, denuded enamel and dentin, cracks, erosion, faulty restorations, abscess, sinus fistula, pink spot, discoloration, in the tooth crown.[3]. To check for any swelling present, seen on the mesiobuccal fold, it would be of pulpal infection and whereas on the attached gingival would indicate of periodontal lesions.[9]

3. **Clinical examination:**

a. **Swelling:** Periodontal Probing is carried out to check the origin of the swelling. In case of a localized swelling, around or near the gingival sulcus, it becomes very difficult for the clinician to differentiate the origin of the swelling or the origin of the abscess.[10] The swelling is then probed with the help of a periodontal probe. Somewhere, if the probe drops down to the apex of the tooth and if the full width of the swelling comprises the entire pocket depth till the apex, the abscess would be of endodontic in origin. This type of swelling can be named as "blown-out". In such cases, the endodontic treatment if attempted, it results in successful periodontal reattachment within a week.[11]

b. **Mobility:** Two ends of the instrument are usually used to check the mobility of the tooth. If an isolated tooth is mobile, it can be endodontic in origin or even periodontal. It the phase is active, it is often considered as endodontic. And if there is mobility generalized, it is said to be periodontally involved.[1]

4. **Clinical Tests:** Certain tests are carried out to reach an accurate diagnosis.

(a) **Percussion Test:** If the percussion test is positive vertically, the lesion would be of periradicular infection, and if positive horizontally, it relates to the periodontal involvement.[4]

(b) **Palpation Test:** Periradicular abnormalities or "hot zone" quickly respond to the palpation method. However, it is not possible to confirm as endodontically involved or periodontally involved.[6]

(c) **Pulp vitality test:** It is an accurate test, to find the type and origin of the lesion. If there is pulp necrosis, the patient produces no response. On the other hand, if the pulp is vital, the patient gives a moderate transient response. In the case of reversible pulpitis the patient gives an immediate painful response whereas, in the case of irreversible pulpitis, the patient gives a lingering painful response.[8]

There are four various method of pulp tests are there: 1. Electric Pulp Test 2. Test cavity 3. Either Heat or Cold Test 4. Both the Heat and Cold Test. Sometime, false positive and false negative responses from the patient may confuse the clinician, hence it is advisable to add a combination of different test method to ensure a correct diagnosis.[5]

i. Electric Pulp Test: This device applies an electric shock to the tooth to check the vitality of the pulp. From the patient sensation arising from the sensory nerve of the pulp, when it comes in contact with a part of a sound tooth, the pulp is said to be vital. If there is no response, the pulp is said to be necrosed. False-positive response indicates partial pulp necrosis, and it happens due to the high anxiety of the patient and could be also of ineffective isolation. False-negative indicates obliterated root canals and it happens in case patients taking drugs to elevate the pain threshold, or poor electrode tooth contact, or recently traumatized tooth.[9]

ii. **Heat Test:** When hot stimuli are applied to the tooth structure with the help of a hot spatula, the patient sometimes complains of lingering pain which is suggestive of an irreversible pulpitis and periodically involved tooth. But if the patient pain is persistently even after the removal of stimulus, it indicates of endodontically involved tooth.[9]

iii. **Cold Test:** Few cold stimuli agents like ice sticks, ethyl chloride, dry ice (carbon dioxide), refrigerate like dichlorodifluoromethane (DDM) are used to carry this test. If the pulp is vital, the patient complains of sharp pain but for very few seconds.

If the case is an irreversible pulpit, the patient may complain of intense and prolonged pain response. If there is no response by the patient, the pulp is very likely to be necrosed. However, false positive and false negative creates hindrance especially if the tooth is multi-rooted or calcified root canals.[9]

iv. **Test cavity:** This is indeed a highly trustable device to check the pulp vitality. With the speed of a high handpiece a minute cavity is prepared on the crown surface of the targeted tooth, without local anesthesia. If the patient gives a positive response to severe pain or severe sensation, then the pulp seems to be vital. The negative response of the patient indicates pulp necrosis and completely no response from the patient indicates the tooth to be endodontically involved.[7, 8]

d. **Selective Anesthesia Test:** When there is a confusion of the origin of pain regarding the location of the arch it belongs, a specific arch block is injected at both the arches. The disappearance of pain indicates the particular arch involved and also reflects the origin of the pain.[8]However, it does not help in diagnosing the type of lesion whether it is endodontically involved or periodontally, which seems to be a big disadvantage of this test.

e. **Cracked Tooth Testing:**

a. **Illumination test:** This test is carried out to find any cracks or fractures on the tooth surface. High power light source with a fiber optic tip is used for providing illumination. The contrast is seen between the fracture lines as black shadows which will outcast the fracture line. The size position and the extent of the black line will suggest the type of fracture.[5]

b. **Wedging Test:** This test helps to recognize or identify the vertical crown fracture or crown root fracture. The patient is asked to chew a cottonwood stick or any rigid material to induce the wedging force. If there is a presence of a fracture, the patient complains of pain on chewing it. And the fracture indicates the origin to be endodontic.[6]

c. **Staining method:** This test is accompanied along with the wedge test. The dye (methylene blue dye) is used on the occlusal surface with the help of a thin brush. When the patient bites the cottonwood stick, the dye gets penetrated the area of the fracture is present. The patient is asked to gargle well and a visual examination is accompanied after it with a very magnify loops, if possible. The presence of fracture indicates with a darkened line with dye.[11]

4. **Radiographic examination:** Radiographic examination is done basically by inserting a radiopaque material like gutta-percha (GP) points inside the gingival sulcus or the periodontal pocket. On the insertion of the (GP) points, the GP points reaching till the fistula which is observed in the radiograph, the case is said to be endodontic in origin. If the GP points reach to the furcationarea or the mid-root, the case is said to be periodontal in origin. And lastly, if at all the GP points reaches till the apex region, it does not always alarm to be pulpal involvement; rather a pulp test should be carried out to finalize the diagnosis. (9). For the fistula Tracking method, once again the usage of GP points are suggested. The fistula can be seen extra orally and intraorally also. This method is performed by inserting a semi-rigid radiopaque material like GP points, deep into the sinus track till the resistance is felt. With the help of the radiograph, the course of the sinus tract and the origin of the infection is decided.[5] And also, in the radiograph, if an apical radiolucency is seen surrounding a particular tooth, it indicates that the tooth to be of primary pulpal disease. Similarly, if a furcation involvement is seen in a particular tooth radiographically but not clinically, it may be either of pulpal origin or a case of traumatic occlusion.[8]

Latest tests for pulp vitality:

1. **Dual Wavelength Spectrophotometry (DWLS):** This test is independent of the pulsatile circulation. It measures any change in oxygenation in the capillary blood rather than in the supply vessels. It has the capability of detecting the presence or absence of oxygenated blood. The major advantage of this test is the visible light is used which is filtered and then guided to the targeted tooth withthe help of fiber optics. It is a non-invasive test, small, portable, very much handy to carry, and also not expensive. It is very much suitable for the private dental office.[12]

2. **Pulp Oximetry:** This is a completely objective test, requiring no subjective response from the patient. This test can be an idle chairside screening test. It is a non-invasive, machine that measures the oxygen saturation in blood, used to detect pulpal blood circulation.

3. **Laser Doppler Flowmetry (LDF):** It helps in the measurement of the blood flow in a very small blood vessel of the microvasculature. It is a non-invasive, painless,and an electro-optical technique.
4. **Transmitted Light photoplethysmography (PPG technology):** It is an optical measurement technique used for monitoring the pulpal blood flow. It guides to find out the healthy pulp and the non-vital pulp by its pulsatile waveforms.
5. **Xenon Isotope:** It is also used to monitor the pulpal blood circulation and helps in differentiating the healthy pulp from the non-vital pulp.[6]

Conclusion

Endo-periodontal treatment is mainly indicated for the preservation of the remaining tooth structure and to safeguard the same in the future. Both the specialty, Periodontics and Endodontics are crucially concerned with the health of supporting structures of the teeth. The possibility of Periodontal and Endodontic varies only by the location of the involved portion of the tooth and surrounding periodontal structures. The role of the periodontal treatment aims at the safeguarding of the periodontium and the other hand, the endodontic treatment is carried out to maintain theshape of the root canal space followed by its 3-dimensional obturation, to re-establish or preserve the apical periodontium to a biologically acceptable condition.

Sterilization in Endodontics: A Newer Concept

Debkant Jena[1], Sumit Dash[1], Siba Prasad Jena[2], Naomi Ranjan Singh[2], Swapna Kumari[3]

[1]Professor, [2]Senior Lecturer, [3]Tutor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In the endodontic procedure the treatment consists of different types of working procedures, such as isolation in the area of a tooth by rubber dam, opening access cavity with burs and cleaning and shaping of the canal after that compact obturation of canal. In every phase of treatment sterilization instruments are needed to prevent blood born diseases like HIV, Hepatitis B, and other blood-borne infections. In-depth knowledge of sterilization protocol in every step to clean the instrument is the key to infection control. Sterilization refers to the process in which complete removal microorganisms and spores from the surface treated. The widely used method is heat-based sterilization by autoclave. Till the invention of autoclave, dry heat method was used for sterilization in all areas of dentistry. This review article describes the various method used in endodontics for sterilization.

Keywords: *Sterilization; Infection; Control; Blood; Endodontics.*

Introduction

One of the most important regions of cross-infection in the dental clinic was due to improper handling and sterilization. Control of infection was an important factor in providing comprehensive dental care. Another important matter of concern was the prevention of cross-contamination to dental staff and the other patients in daily dental practices by contaminated instruments.[1]

Blood and saliva are important carriers of infection such as Hepatitis B, HIV and other blood-borne diseases. In endodontic treatments includes various procedure which involves blood contamination during the procedure therefore making it sterilize every instruments both rotary and hand files after every patients.[2]

Sterilization is the procedure that kills the bacteria and another microorganism, pathogenic and non-pathogenic in vegetative or spore form the surface of the material to be sterile. The item free from living microorganisms is defined as sterile.[3] Chemical sterilization was used for the thermosensitive instrument, which cannot go for moist heat sterilization. For other than thermosensitive instruments all other instruments can be sterilized in an autoclave. An autoclave was used for sterilization for all instruments used in dental clinic.[4]

It was important to ensure that all microorganisms are killed after the sterilization process. So the quality management on time to time basis was an important part of the sterilization procedure.[5] To check the reliability of the sterilization the biological indicators are used such as spore strips which changes color after completion of sterilization if the autoclave is working in good condition. The indicator strips check the efficiency of the sterilizer to kill the bacteria.[6]

Sterilization of the instruments used in the operatory will only prevent the cross contaminations. If these instruments not sterilized properly may lead to cross-contamination. Most common method used for sterilizing these instruments are autoclave, ethylene dioxide gas, glass bead sterilizer and dry heat sterilizer.[7] Chemical disinfectants have the bacteriocidal effects on

e-mail: debkantjena@soa.ac.in

microorganisms after 15 minutes of exposure but not effective against spores and viruses. The most common method for sterilization was autoclave in a short period. Critical instruments are those that are used to penetrate soft tissue and bone. These types of instruments has to be sterilized after each use.[9]

Difference between Disinfection and Sterilization: It is important to know the difference between disinfection and sterilization both procedures can remove pathogens from the treated surface.[10] The process of removing pathogens but leaving the spore was known as disinfection and process to remove both pathogens and spores called sterilization.[11]

Cleansing and Disinfection (Presterilization): After completion of the patient first step of the sterilization process is to remove blood and debris from the endodontic instruments. Debris consists of protein and residue of blood and dentinal shavings.[12] Washing can be done by hand with disinfectant liquid or ultrasonic washer. The ultrasonic process is better as compare to hand washing because it can break the organic component.[13]

The study conducted by Sureshchandra et al[14] compares the various method of cleansing and disinfection with use of 3 material like 3% hydrogen peroxide, manual brushing and 70 % alcohol and in test group manual brushing 1% sodium hypochlorite and ultrasonic bath in the result showed that test group were more efficient. Azarpazhooh et al[15] Showed that the ultrasonic group has more potential to clean the endodontic instruments.

Disinfection of Root Canal Filling Materials: Materials used for sealing root canal are gutta-percha. Before using the GP points in the canal the GP points dipped into 5% Sodium hypochlorite sterilizes the points. Gutta-percha cones contains zinc as a component which helps the cones to inhibits some amount of bacteria to adhesion.[16]

Some studies show that during the production of GP points in the factory unit 30% of samples are contaminated with bacteria (staphylococcus spp). So if the GP point crosses the apical foramen chances of infection are more if not sterilized before placing it into the canal. Sterilization with the heat may alter the size and shape of the cone, so autoclaving is not indicated. Can be done by Sodium hypochlorite in concentrations of 0.5–5% (NaOCl), Chlorhexidine, 2% (CHX), Hydrogen peroxide, 3%.[17]

Sodium Hypochlorite and Chlorhexidine: 5% Sodiumhypochlorite was used for sterilization of cones. One of the main side effects was corrosive effects on most endodontic instruments. Rutala et al[18] who showed in the SEM scan that the use of both solutions can alter the tensile strength when placing the cone for 10 min. Eldik et al observed that 5% sodium hypochlorite for 5 min is one of the most effective method of reduction of bacteria from the surface of Gutta Percha points.[19]

Sterilization of Endodontic Instruments: After cleaning the instruments by hand washing or ultrasonic wash. The drying and wrapping should be done to all the instruments, the most common method from last twenty-year used are autoclave, glass bead sterilization for 45 seconds at 240°C, UV lights, Laser sterilization and glutaraldehyde. Many authors showed in their study that autoclave remove all bacteria and spores and virus with temperature 121 ºC for 15 min for endodontic instruments.[20]

UV light lamps sterilization works on thermal heat which causes activation of nucleic acid through the induction of thymine dimers. The disadvantage of UV lamps is they act only on the surface where direct there is contact to the light. 2% glutaraldehyde was a suitable method to sterilize the endodontic instruments and other dental instruments. The disadvantage is highly toxic in nature and it requires 12hr duration to sterilize the instrument which is difficult in clinical practice.[21] In the advancement of sterilization protocol the Laser was used as a chairside tool to sterilize reamers by CO_2 laser published in the work by Boyd at al.[22] the author found that complete sterilization of reamer was observed using argon laser. Various studies showed that the autoclave process of rotary instruments may lead to fracture during biomechanical preparation in the root canal treatment due to cyclic fatigue. To preserve the fracture 6% hypochlorite was used to reduce the microbiological load.[23]

Burs: Decontamination and Sterilization: Diamond burs used in the endodontic process to remove the caries and initial access cavity preparation after use can be dip into the ultrasonic bath for 15 min and after that can be autoclave prevent cross infection to other patients.[24]

Changes in the Physical and Mechanical Properties of Endodontic Instruments Subject to the

Sterilization Process:

Cyclic Fatigue and Torsional Stress[25]: One of the main reasons of the fracture of endodontic instruments is due to cyclic fatigue during root canal treatment. The instrument goes under cyclic stress followed by compressive loading stress which led to the fracture of instruments which again depends on the number cycles i.e., more cycles leads to more chance of fracture. Other stress was torsional which leads to complete rotation inside the canal and fracture in the endpoint where the canal is blocked or calcified. To overcome these effects NiTi files have evolved now have shape memory.

Roughness, Corrosion, and Reduction of Cutting Capability[25]: Roughness and corrosive effect on NiTi instruments during irrigation by Sodium Hypochlorite cause micro pitting phenomenon and oxygen in the autoclave causes formation of nitric oxide which causes roughness on the instruments and it may also cause a reduction in the cutting ability of NiTi instruments.

Conclusion

Based on various studies done by the author the most effective method for sterilization of endodontic instruments is the autoclave process. The glutaraldehyde sterilization was more potent to kill the pathogens from the treated surface as compared to the glass bead sterilization. Presterilization is help full in removing the debris and pathogens from the surface to 40 % in the count. Ultrasonic bath better than the handwashing technique.

Endocrowns: A Comprehensive Review

Sumit Dash[1], Debkant Jena[1], Sashirekha Govind[2], Siba Prasad Jena[3], Naomi Ranjan Singh[3]

[1]Professor, [2]Professor & Head, [3]Senior Lecturer, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Endocrown are indicated after every endodontic treated tooth. For good stabilization of endocrown prevention of healthy tooth structure was essential for tooth stabilization and adhesion of tooth. Due to biomechanical preparation the chances of failure of crowns in case of endodontic treated teeth than vital teeth. In recent years there are various advancements in endodontic materials like new adhesive systems which reduces the need of post-core restoration in the tooth. In excessively damaged teeth, endocrowns are used as an alternative method of partial denture and post-core. The advantages of endocrowns are aesthetical good, increase mechanical performances, and cost-effective. This article provides areview of endocrown used for endodontically treated teeth in the clinical practice.

Keywords: *Crowns; Post; Root Canal Treatment.*

Introduction

During the endodontic treatment, the complete removal caries by air rotor in first sitting is needed to further decay of tooth.[1,2] In this process of removal of caries leads to a considerable amount of enamel and dentine was lost during the initial access cavity preparation.[3] This process leads to insufficient tooth structure to support the filling material. The one most common complication in these type cases is the increasing chance of crown or root fracture due to chewing forces.[4] The type of dental filling material used for restoration depends on the position of the tooth anterior or posterior because in posterior teeth there are heavier forces seen as compare to anterior tooth and amount of tooth structure left after root canal therapy.[5]

To treat these type cases there is clinical protocol were suggested like in anterior teeth with small access cavity which can resort by simple composite material and there is no need of placement of crown.[6] In posterior tooth after endodontic therapy need coverage of cuspal area because of its help to bear mechanical forces.[7] In case of less amount of healthy tooth structure left behind need a post and core procedure before crown placement.[8] In case where post and corenot indicated use of extra retentive features are usedas pins and castable posts give extra retention to the filling and crown. Post can be two types of prefabricated metal post or one-piece custom made post and core.[9-11]

Most of the studies showed that post preparation leads to loss of radicular structure to place post might weaken the root which leads to fracture of the tooth.[12] One most important complication of post was retreatment of endodontic treated tooth. Adhesives play an important role in the restoration of endodontic treated teeth.[13] In the year 1995 Pissis present a new technique with combined porcelain to metal crown in a single unit and the technique called monobloc which replaces the previous tradition technique metal post.[14] Based on the concept of Pissis, the Endocrown technique was introduced by Bindel et al. in the year 1999.

In various studies, the results show that endocrowns

in molar are high success rate and higher fracture resistance as compared to posts.[15-19] Endocrowns are easier to prepare and apply and require lesser clinical time and visits. Endocrowns have superb esthetic properties, and in cases of adhesive restorations decrease the penetration of microorganisms in apical and coronal part to improve the clinical success of endodontic treatment. Endocrowns are a greater advantage as compare to post because posts are not indicated in short and narrow canals.[20]

Changes Occuring in Endodontically Treated Teeth: The factors associated with endodontic treated teeth are more prone to fracture resistance due to loss of tooth structure due to caries, trauma and cavity preparation. Appropriate selection of restorative materials is important for the longevity of endodontic treatment.[21] The integrity of the left tooth structure would be preserved for a solid base required for restoration and increase the strength of endodontic teeth.[22] The strength depends on hard tissue and the anatomic form of the tooth is the principle of biomechanical tooth preparation. Studies showed that there was no influence of variation in tissue on tooth biomechanical behavior.[23] Minimal access cavity preparation helps in the decrease the chances of fracture resistances.[24] The other important factor for decrease durability was the loss of marginal ridge in tooth. Another important study done by Gohring et al[25] showed that loss of dentine during the endodontic access cavity and root canal preparation after biomechanical preparation increases the brittleness of tooth. Guzy and Nicholls[26] observed that in the study decrease in the durability and strength by 5%, 20%, and 63% due to access cavity preparation, restorative procedure, and occlusal cavity preparation on Tooth cusp.

Restoration of Endodontically Treated: The remaining tooth structure left after caries removal and completion of endodontic treatment tell the suitable dental filling material, choice of material was controversial it was choice of treating dentist which material he placed according to his choice no special guidelines are given by American Association of endodontics. Function requirements are one of the important factors for deciding the choice of material for treatment planning.[27]

Risks and shortcomings in conventional post and core:[28-30]

- Perforations during the post and core procedure leads to further endo-perio lesion and sometimes leads to fracture of root.
- In prefabricated post made up of glass fiber reinforced posts (GFRP) in the root canal some time not bond to radicular dentine and in long loss crown due to heavy masticatory forces.
- The limitation of amalgam core build-up material was if there was less tooth structure additional pins were placed which further decrease the strength of the tooth. It was not indicated in the esthetic area because after 5-7 years it gives discoloration in the gingival margin.
- Glass ionomer cement lack of adequate strength.
- Composites material has good strength and has the ability to binds with the surrounding tooth structure and the disadvantage of composites is polymerization shrinkage leads microleakage which causes further plaque and calculus formation and these leads to treatment failure.

Preparation Technique for Endocrowns[31-35]

Occlusal Preparation:

- Overall reduction of 2mm in the axial direction
- Diamond wheel bur was used for the occlusal surface
- Bur used parallel to occlusal plane
- Cervical margin should be supragingival, in area estherics require subgingival margin angle below 60°
- 2mm thick enamel walls will be removed

Axial Preparation:

- The first step after occlusal reduction was removing all the undercuts in prepared access cavity.
- The convergences angle was 7°for both access cavity and coronal pulpal area.
- The depth of cavity between 3mm to 5mm.
- Avoidance excessive removal of coronal dentine which leads to endocrowns in future.

Polishing the Cervical Band:

- In this step, we remove all the irregularities from the tooth surface
- Large diameter fine particle bur was used for polishing

Figure 1. Removal of irregularities from the tooth surface

Figure 2. Polishing

Figure 3. Bondning

Bonding

- Adhesives such as self-adhesive and composites such as are used for bonding the endocrown to the prepared tooth.

Impression technique/Manufacturing: As compare to conventional rubber bass impression digital impression are more helpful to these types of case because it takes accurate record of prepared preparation of crown and it's to send the scan for CAD/CAM crown preparation. These digital impressions tell us if there any undercut present in the cutting to its easy to correct the preparation and make it less time consuming and no need for a diagnostic wax-up trial.

Indications of Endocrowns:

- Successfully treated endodontic treated tooth.
- In case less interproximal space and occlusal hight.
- In case were post and core not possible
- In the case of calcified, curved canals.

Contraindications of Endocrowns:

- In case of parafunctional habits
- In case of were proper isolation is not possible due to excessive saliva
- Cervical margin less than 2mm and depth less than 3mm.

Advantages of Endocrowns:

- Less complex to perform and easier to perform in patients
- Allow less reduction of radicular dentine so the strength of the tooth was not hampered
- Allow retreatment of a root canal if indeed in future
- Less chair side time and cost to the patient

Disadvantages of Endocrowns:

- Risk of debonding of crown and root fracture

Conclusion

An endodontically treated tooth in those cases where post and core was not indicated in these types of case endocrown. Endocrowns preserve the tooth structure and has several mechanical and aesthetic advantages. It's indicated in posterior teeth and showed better performance in molars than premolars.

Basic Package for Oral Care: A Means to Tackle Community Dental Needs

Dharmashree Satyarup[1], Manish Kumar[2], Radha Prasanna Dalai[3], Karishma R. Rathor[4]

[1]Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Professor & Head, Department of Public Health Dentistry, GITAM Dental College and Hospital, Visakhapatnam, Andhra Pradesh, India, [3]Senior lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [4]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

There exists a gaping rift between the available dental services and the need for dental care in communities, giving rise to the 'inverse care law'. WHO in collaboration with the University of Nijmegen, worked along the principles of Primary Health Care (PHC) to give the Basic Package of Oral Care (BPOC) which is designed to cater to the dental needs of outreach populations within the confines of minimum resources such as lack of electricity and dental setup, for a maximum effect of providing emergency, preventive and curative dental care. Implementing BPOC with prudent use of existing PHC workforce, local resources and collaboration with NGOs could be the best answer to tackling the dental needs of communities.

Keywords: *BPOC, ART, AFT, OUT, PHC.*

Introduction

Health is considered a fundamental human right. Various attempts have been undertaken by international health agencies such as the World Health Organization (WHO), and by individual governments to make this a reality but still have a lot to make up for. Primary health care was proposed by WHO and UNICEF in the Alma Ata declaration.[1] This recommended reliance on local, easily available means of healthcare to address the felt needs of the local population. Though tremendous improvements are observed in the form of a fall in mortality and morbidity rates, oral health often remains disregarded. Oral health often is considered a luxury, is ignored in health planning by most governments.[2] Hence the Basic Package of Oral Care (BPOC) was developed in collaboration with WHO in Nijmegen. The BPOC was deemed to be a means of effective, feasible and affordable oral care that would address the essential oral health needs in any community.[3]

Premise for introducing BPOC: People from low and middle-income countries that comprise of more than 70% of the world's population have very inadequate access to oral health care. India with its varied population faces the challenge of unequal distribution of health care with 700 million of its population in rural areas but only 25% of doctors practicing in semi-urban and a meager 3% in the rural parts.[4] The oral health scenario is further worsened by the fact that dentistry is considered a domain of private practice confined to urban areas. Oral health is also overlooked by policymakers and is not included as a part of Primary Health Care (PHC).

Primary Health Care philosophy was developed with an emphasis on redirecting the control and prevention of commonly occurring diseases away from healthcare based on hospitals. PHC primarily aims to provide for

Corresponding Author:

Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: dharmashree_s@yahoo.com

all basic preventive and curative care at a cost that the community can afford.[5] Presently basic oral health care is not included in PHC due to various factors;

a. Dentistry is commonly perceived as a specialty targeting individual care rather than a community.
b. Oral health is assigned low priority compared to general health.
c. Lack of judicious use of non-dental personnel and auxiliaries by dental professionals to address the dental needs of a community.
d. Perception that most dental treatments require sophisticated armamentarium.
e. Cost of dental is often beyond the economic means of a rural population.[6]

But oral health is found to influence the quality of life of all populations urban and rural alike. Dental caries is a common chronic disease that is on a rise in the low income countries. It accounts for loss of school days among children and missing work in adults due to unmet dental needs.[7] Even in high-income countries, oral diseases contribute to higher expenditures on treatments in comparison to other major diseases like stroke, cancer, and heart diseases.[8] Hence oral health pleads for substantial consideration in health policies of countries due to the following factors;

a. High prevalence: It is almost universal in its occurrence.
b. Effect of dental ailments: in terms of discomfort, pain, social and functional limitations caused.
c. Effect on general health.
d. Deterioration of quality of life associated with dental diseases.

Keeping these in mind, WHO and FDI (World Dental Federation) set global goals to be achieved by the year 2000. Later WHO, along with FDI and International Association for Dental Research (IADR) formulated oral health goals to be achieved by 2020. These goals required particular oral health programs targeting providing oral health care to those who need it the most.[9] This required a strategy that could use the prevailing community health structure. And also conform to with the principles of PHC i.e., an approach that was practical, scientifically sound and socially acceptable.[10]

Rationale of BPOC: A plan of action that is affordable, following the ideologies of PHC, that brought dental care within reach of disadvantaged communities. The idea is to reach all communities at costs more affordable than traditional dental health services. The BPOC comprises of;

a. Oral Urgent Treatment (OUT)
b. Affordable Fluoride Toothpaste (AFT)
c. Atraumatic Restorative Treatment (ART)

WHO suggested that every country's government could use BPOC based on the needs of its communities either with the aid of existing health care or external resources such as Non-Governmental Organisations (NGOs). (10) The use of BPOC along with oral health promotion and education could prove as a coordinated effort towards better oral health.

Components of BPOC:[2,10,11]

a. **Oral Urgent Treatment (OUT):** Based on the felt needs of a community, it is an emergency oral treatment provided on demand that differs from one community to another. OUT comprises of the following;

- Pain relief from oral causes.
- First aid treatment for relief of oral infections
- First line of treatment for oro-facial trauma
- Provision of referral services for complicated cases

Most commonly pain is the reason for dental visits. Pain from dental issues affect the quality of life, accounting for the loss of days from work and school. Hence handling of pain is one of the important aspects of BPOC. The treatments under OUT include;

- Extraction of severely damaged teeth.
- Handling of post-extraction complications such as bleeding and dry socket
- Drainage of dental abscess
- Medication for acute dental infections
- First-line for treatment for oro-facial trauma
- Referral of complicated cases

Pain is commonly from decayed teeth. Hence extraction of the affected tooth or draining of the abscess would provide the relief. 90% of decayed teeth are often left untreated and handled with prescription of medication. However, prudent prescription is advised in

lieu of increasing drug resistance of micro-organisms.[12] Oro-facial trauma is the second most common cause of availing dental treatment. Trauma involving tooth structures are more frequently seen among children and younger adults.[13] Delay in treatment of these could result in loss of vitality and root resorption. In developing countries, road traffic accidents most often cause facial trauma. Appropriate treatment at the earliest prevents further complications. A proper referral chain ensures the provision ofsuitable dental treatment. Referral for complicated cases should be done to the nearest dental facility. OUT incorporated at the sub-district level in the PHC system would make oral emergency care available to all.

b. Affordable Fluoride Toothpaste (AFT): As salt and water fluoridation is not possible in developing countries, the most feasible and effective fluoride delivery is through the use of fluoridated dentifrices. Hence it's the preferred anti-caries agent especially in rural areas. Reasons for using AFT are;

- Cost-effective and equitable means of caries prevention
- Effect of AFT is predominantly topical
- Extensive well-documented trials have proven a steady decline of caries in developing countries from DMFT of 8 to 1.5 in 12-year-olds.
- When the use of fluoride dentifrice is adequate, the diet has a lesser role to play in the prevention of caries.

Affordable fluoride toothpaste could be the most cost-effective and appropriate means of caries prevention in countries that otherwise lack access to specialized preventive care.[14] Proper packaging with information regarding the date of production and expiry is mandatory. Package should also display the fluoride compound used and its concentration. A concentration ranging between 1000-1500 ppm is recommended as, a concentration below this would notbe effective in preventing caries while higher content would increase the risks of dental fluorosis when used in children.[15] Toothpaste that meets the recommended standards could be made tax-free by the governments to encourage its widespread use.

Efficient collaboration among the manufacturers, advertising agencies, government, and dental professionals is mandatory to promote optimal use of fluoridated toothpaste. Long-term reinforcement programs at an early age are necessary to initiate use AFT and ensure it life-long use.[14] Brushing in children should be supervised by adults to minimize the chance of fluorosis. Using a pea-sized quantity of toothpaste along with making sure the tube of toothpaste lasts longer, guarantees a lesser risk of fluorosis. Brushing twice a day with fluoridated toothpaste effectively can prevent both dental caries and periodontal disease, thereby reducing the burden of dental diseases in a population.[16]

c. Atraumatic Restorative Treatment (ART): In the case that dental caries cannot be prevented, the affected tooth needs to be treated. Restoration of teeth relies on expensive electric driven equipment, thereby limiting treatment procedures to those who have access to the dental clinic. To overcome this, ART was proposed as it requires no electric equipment. ART consists of the use of hand instruments to excavate caries and restoring with material that bonds with the tooth structure. The cavity is overfilled and the excess material is then flowed to seal adjacent pits and fissures.[17]Therefore, it conforms with the concepts of preventive and restorative care. It avoids the sacrifice of healthy tooth structure and provides prevention with minimal intervention.

The survival and effectiveness of ART has been ascertained by various studies. 90% of dental caries in primary teeth and 54% in permanent teeth among a high-risk group in Syria could be treated with ART.[18] Medium strength GIC was the restorative material used. Single surface restorations were found to have of 95% - 100% one-year survival rate, whereas 2 year and 3-year survival rates are at 92% - 94% and 85% - 89% respectively. Failures of ART in the first 3 years are limited to 4-5%.[19]In primary teeth, single-surface ART restorations had a survival rate of 86% in contrast to 80% in amalgam restorations at the end of 3 years among Syrian school-going children.[18] The sealing of adjacent pits and fissures with GIC prevents dental caries and hence this fact needs to be considered while evaluating mechanical retention of restorations. It was found in children who underwent ART restorations in Zimbabwe, had four times lesser chances of developing caries.[20]

Factors favouring acceptability of ART:

- Reduced discomfort during treatment procedure:

Studies conducted have reported discomfort experienced is minimal in ART as compared to

conventional restorations where drilling is used. The discomfort was reported in only 19% undergoing ART as opposed to 36% of conventional amalgam fillings in 6-16-year-old children of Pakistan. Whereas, only meager 7% of the pre-school children in China felt discomfort while ART was performed. Hence, making it the treatment of choice in children who have limited access to dental care.[10]

- **Negligible post-operative sensitivity:** Sensitivity associated with the ART after the procedure is only 5% in Chinese adolescents and 6% of teenagers in Zimbabwe.[21,22] Therefore it can be safely said that sensitivity associated with ART is less and it can be used as acceptable form treatment of dental caries.
- **High satisfaction among patients:** 91% of Chinese and 95% of Zimbabwe secondary school students very satisfied with the operational procedure of ART and believed, that they would not mind undergoing the procedure once again.[21,22] This reinforces the fact that ART can be performed as a substitute for conventional restorations in areas with restricted access to dental treatments.

It has been found that because of the above-mentioned factors, ART works as an efficient means of treatment delivery. ART can be done through mobile dental units or the system in place for the delivery of health care. Because of its ease of sterilization and acceptability, it was observed that in a school in South Africa, the percentage of extractions came down by 17% in permanent teeth and 36% in primary teeth. It also saw an increase of 33% in restorative care, one year after administering ART.[23]The cost of ART using GIC is much less compared to that of a conventional amalgam restoration. Thus all the above-stated facts make making ART the clear choice for rendering restorative in outreach areas.

Requirement of personnel for carrying out OUT and ART: While promoting and dispensing fluoride toothpaste requires the teamwork of dentists and policymakers, the provision of emergency oral care and ART entails a team of well-trained workforce in place. This team differs from place to place based on the characteristics of the population that they will be serving, health strategies and the legislation of every country. For providing emergency oral health care under OUT, the following personnel can be utilized based on examples from different countries.

- Nurses from primary health care centers: Cambodia sourced their workforce from the PHCs. The nurses undergo a period of training for five months, after which they are employed at the district referral center until they are proficient in carrying out all the procedures included in BPOC.[24]
- Rural medical aid: In Tanzania, rural medical aids are trained for three years, after which there is dental training. They then provide relief of pain through extractions and the provision of medications.[25]
- Health assistants: Nepal, trains its health assistants to handle extended duties such as oral health education, first aid for oro-facial trauma and extractions.[26]
- Dental therapists: In countries like Vietnam, Zimbabwe, and Malawi, dental therapists are trained to provide OUT services.[10]

In the Indian scenario, dental auxiliaries such as dental hygienists and health care workers like ASHA and Anganwadi workers can be given additional training to handle dental emergency services. Also rural postings in PHCs can be made compulsory for interns of very dental college to help in rendering these services.

The personnel required for ART pose tougher challenges than those needed for OUT as, carrying out the procedure of ART requires an in-depth knowledge about dental structures and dental materials. Hence training courses of short duration are not sufficient. It was found that dental therapists, students studying to be dentists, and dentists could be efficient in ART procedures, with dentists being the most competent of them.[10]However, the decision regarding which personnel to use is the prerogative of every country and its governmental policies.

Requirement of equipment for OUT: A basic set of dental instruments and means of sterilizing them is necessary for the provision of OUT. A judgment regarding type and number of extraction forceps required has to be taken base on the local scenario. Usually, 2-4 types of extraction forceps and 1-2 types of elevators are considered sufficient. Apart from these, the following equipment is necessary;[10]

- Bed or chair with head support.
- Chair or stool for the dental personnel.
- Table for medicines and instruments.
- A source of light, preferably battery operated.

- Washbasin
- Means of storing water.
- Heat source and pressurized container for sterilizing instruments.

Requirement of equipment for ART:[17]

Equipment essential for ART are:

- Bench or chair for the patient
- Stool or chair for the operator
- Source of light
- Hand instruments - Mouth mirror
- Explorer
- Tweezer
- Excavators
- Dental hatchet
- Applier/carver
- Consumable items such as -Adhesive material, usually GIC
- Cotton for making rolls and pellets
- Petroleum jelly
- Wooden tips and matrix bands

Equipment requirements for ART have been kept to a minimum to cater to treatment without the use of electricity and sophisticated armamentarium. Thus making ART accessible and affordable even at most isolated locations.

Course of action for implementing BPOC:[2, 11, 27]

1. Identifying a local partner: Having a local body to aid in the identification of the specific needs of the population, providing support for planning and implementation of BPOC would make the process easier and hassle-free.
2. Gaining decision maker's approval: Involving the policymakers from the level of Ministry of Health right from the outset and their consent at every stage is essential for the successful execution of the program.
3. Involvement of other possibly interested parties: Participation of NGOs and other local political, medical and educational systems would give the necessary boost for the program in the form of funds and required manpower.
4. An in-depth comprehension of the local situation: The program must be based on the needs and expectations of the community that it is catering to. Various factors such as the oral health status of the community, their perceived and normative needs, awareness and habits related to oral health, financial and manpower resources influence the operation of the program.

How can BPOC put into action in India?

1. Involvement of NGOs: There is a surge of non-governmental organizations that are aware of their social responsibilities and are financially transparent. Their support can be the boost required for initiating and supporting BPOC implementation. However, certain factors need to be considered such as the extent of organization management, quality control and accountability of the organizations, limited financial resources and problems regarding integrating these personnel into the existing communityhealth care system.[6]
2. Integration with health workers from PHC: India has a competent system of primary health care in place efficiently catering to the health needs of the communities in rural areas. Health workers in this set up can be trained to deliver emergency dental health services. Oral health care needs to be integrated at all three levels; Macro-level (health system), Meso-level (Organisational system – by meansof inter-organizational relationships) and Micro-level (coordination at a personal level). Integration must be both horizontal and vertical for a capable incorporation. (28) The non-dental workforce that is available in the form of teachers and community health workers can be used to provide a range of dental services ranging from emergency care to prescription of medication and promoting the use of fluoride toothpaste. These personnel can also be used to generate a competent network of referral systems by creating a pathway for referral of complicated cases to nearby dental setups.[3]
3. Responsibility of local dentists: Dentists from the nearest localities can volunteer to meet the dental needs of an outreach facility individually or in partnership with an NGO. Dentists could also help the training of local health care workers in providing BPOC.

4. Role of dental institutions: Institutions can take up the responsibility to address the treatment needs of rural communities without access to dental care. This can be further facilitated by incorporating BPOC as a part of the dental curriculum. Studies evaluating awareness regarding BPOC among dental students found poor knowledge.[9,29] Hence steps to make them proficient in services provided under BPOC and then posting them to these areas could help in rendering dental care. Conducting workshops for training of local PHC workers such as ASHA and Anganwadi workers in BPOC could also be undertaken by dental institutions to makethe local community self-reliant.

5. Partnership between Public and Private sectors: Collaboration between local communities and governmental institutions have been purported to be the most important area to work on to increase access and affordability to dental care. The advantages of both these sectors can be combined to work complementary to each other. Areas such as conducting awareness programs, provision of manpower through outsourcing could be done to work in the best interests of both sectors.

Conclusion

Since oral health is important for general health and wellbeing, BPOC provides the best way of reaching the unreached at a cost that communities can afford throughout every stage of their development. The burden of oral health care in the communities can be addressed through proper implementation of BPOC. Oral health promotion is thought to be effective when both upstream and downstream interventions work complimentarily.[30] BPOC can act as a primary source for preventive and curative treatments which are a part of the downstream approach, this combined with upstream interventions such as health education could be the answer to tackling oral health problems competently in the communities.

Challenges in Regenerative Endodontics: A Case Report

Debkant Jena[1], Sumit Dash[1], Siba Prasad Jena[2], Naomi Ranjan Singh[2], Swapna Kumari[3]

[1]Professor, [2]Senior Lecturer, [3]Tutor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Regenerative endodontics is a part of the advanced endodontic procedure for the well being of immature teeth with root canals that are infected and it can be called as "paradigm shift" in the ideal approach of treatment for continued root maturation and apical closure. It is a procedure which is clinically oriented to disinfect the root canal system without damaging stem cell present in the apical papilla and dentinal wall. By instrumentation process bleeding induced in the apical area to induced new stem cells in this area followed by intracanal cement placement to prevent microleakage. The mechanism of REP was to make triad by biomarkers, stem cells, Scaffold which works on the regeneration of lost tissue of pulp dentine complex and further root formation. Many authors suggested that the REPS procedure is the definitive treatment of immature teeth with pulp necrosis.

For a dentist it is a unique challenge to treat an immature tooth with apical periodontitis and pulpal necrosis. For endodontic treatment the options available are apexification, apical barriers and revascularization of the permanent tooth. 16 years old boy comes to a comprehensive college clinic with the complaint of pain and swelling in the lower posterior tooth region. On clinical examination lower premolar with apical periodontitis was treated with revascularization protocol irrigating with normal saline and sodium hypochlorite, an antibiotic paste (triple), mineral trioxide aggregate and then a coronal seal with a dental composite. In a follow up of one year there was an evident resolution of radiolucencies in the periapical area and root development was appreciated.

Keywords: *Revascularization; Immature tooth; Antibiotic paste*

Introduction

In the year 1960, Dr. Ostby first proposed the theory of regenerative endodontic procedure. The theory says that the vitality of the pulp is directly dependant on the presence of blood clots in the canal which helps in promoting healing of the pulp.[1] The process was similar to other parts of the body like blood clots help the injury site to repair itself.

Authors suggested that REPS can be performed in infected immature permanent tooth because in a clinical trial and histological examination they found mesenchymal stem cells on apical end of the root.[2-4] These stem cells have the ability to differentiate into odontoblastic cells that helps in forming root dentin and these cells are called SCAP (stem cells of apical papilla) and other cells present in pulp are called dental pulp stem cells (DPSCs).[3] They both can form dentin pulp complex. Both cells are potent to differentiate as mesenchymal cells from the bone. The difference between in these cells like, SCAP showed a greater proliferation of the cell, number of population doubling and tissue regeneration as compared to DPSCs.[4]

Factor affecting the revascularization is related to infection in the root canal. It is difficult to treat infected canals with the REPS technique. In these types of cases triple antibiotic paste or CaOH paste are used to disinfect the canal. The second important factor was the size of apex during REPS is more than 1.1 mm apical diameter then revascularization increases in about 18 - 34% of teeth with immature root development. The 3rd factor is age which is considered between 8 to 16 years which is more considerable to the REPS procedure. REPS procedure should be avoided in the deciduous tooth as there is potent risk of impairing the eruption of permanent dentition.[5,6]

Regenerative endodontics procedure (REP) is the biological procedure in which damaged tissue can be replaced by newly formed cells (Dentin and root structure). REP is part of tissue engineering, which was adopted by the American Dental Association in the year 2011. Root canal is the definitive treatment in the case of pulpities or apical periodontitis patients.[7] The RCT procedure involves the complete removal of pulp tissue by biomechanical preparation, so that the bacterial and toxin load will reduce in canal in adult patients.[8] In children absence of apical constriction can be seen which can lead to RCT procedure problematic. For these types of case, apexification can be the best option, but there are some disadvantages like treatment time, compliance of the patient, risk of fracture of bone associated with tooth.[9]

So, recent advancement in endodontics, for the treatment of immature tooth regenerative endodontics procedure is used. REP is a biological replacement of dental tissue and makes the tissue in a functional state. MTA was the material of choice.

Case Report: A 16-year-old male patient reported to the dental clinic with the chief complaint of pain accompanied by swelling in the lower back tooth region. The patient has no previous medical and dental history. On clinical and radiography examination large carious lesion found in tooth number 34. On intraoral soft tissue examination reddish-pink gingival, soft and edematous with rolled out margin, no periodontal pocket was appreciated, on palpation was mildly painful with sinus tract. On radiography examination (Figure 1) secondary caries under the restoration and radiolucency and widening of Lamina dura were present on the apical area of the root. The final diagnosis tabulated was chronic apical periodontitis after clinical and radiographical considerations. Thereafter informed consent was taken from the patient and treatment was initiated.

Figure 1: Showing a carious lesion in lower left second premolar

Local anesthesia 2% Lignocaine with epinephrine, was administered isolation was done by rubber dam. Access cavity was performed, bleeding and purulent exudates were seen in the canal. Proper irrigation protocol was followed by 5.25% Sodium Hypochlorite, 20 ml of normal saline followed by 10 ml of 2% Chlorhexidine.

The canals were dried, and a triple antibiotic paste consisting of ciprofloxacin, metronidazole, and minocycline (100 mg of each drug in a 0.5-mL total volume) was placed. After three weeks the patient was symptomless. Local anesthesia without epinephrine was administered and then removal of triple antibiotic paste was done. Bleeding was induced by hand file in the canal, bleeding was controlled and then MTA was placed over the clot.

Figure 2: A radiograph showing placement of MTA and completion of composite restoration on tooth.

Figure 3. Healing of the radiolucent lesion, 1 year follow up.

On one year follow-up during clinical examination patient was asymptomatic, no bleeding, no swelling and no sinus tract was detected. Radiographically there was no visible lesion appreciated.

Discussion

Regenerative endodontic procedures also known as REPS is defined as a procedure that is biologically designed to replace damaged structures dentin, root structure and cells of the pulp-dentin complex.[9] It is a new modality to help the normal function of the pulp. It has become an alternative method to heal apical periodontitis. REP is an extension of root canal therapy with specially designed method. In conventional treatment the dentist cleans the root canal and fills the pulp chamber with inert material after cleaning the root canal.[10] As compared to conventional root canal, REPS replaces the live tissue cells in pulp tissue. The main goal of REPS is to regenerate tissue present in the pulp and modify the function of the pulp dentin complex. [6]

Before the introduction of REPS apexification procedure was used in the treatment of immature permanent teeth with the use of mineral trioxide aggregate and long term use of calcium hydroxide.[11] This treatment cannot resolve complete signs and symptoms of pathology. They affect the root development procedure. One of the options for the treatment of immature teeth with open apex can be Regenerative endodontics procedure (REP) because it has a great ability to affect the size of root length ratio and thickness of root wall by biomechanical process.[12-14] Apical bleeding initiated by the hand file in the root canal, making a feasible environment for pulp regeneration with host endogenous stem cells and growth factor in a bioactive scaffold.[15]

A study done in the year 2002, showed that the use of CHX as irrigation material caused detrimental effects on stem cells. The role of triple antibiotic paste has reduced the bacterial and toxin load in the canal. Many recent research articles show that inclusion of blood clot in the canal space help in revascularization and bleeding produces predominant mesenchymal stem cells which can form dentine complex.[16] The placement of MTA helps in making the apical barrier so that bacteria cannot enter through apical constriction. Many researcher suggest that use of $Ca(OH)_2$ in the tooth before placement of MTA as $Ca(OH)_2$ make the clot settle in the canal and prevent the movement of MTA, the coronal end 2-3 mm apical to cement enamel junction after which Glass ionomer material is placed over the MTA.[17]

Regenerative Endodontic Treatment in Maxillary Central Incisor: A 6-Month Case Report

Sumit Dash[1], Debkant Jena[1], Lora Mishra[1], Satabadi Pattanaik[2], Pratyaee Basu[3]

[1]Professor, [2]Senior Lecturer, [3]Post Graduate Trainee, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

The most important cause of pulpal necrosis was trauma during an eruption of the tooth, trauma cause delayed root formation, which leads to fracture of root. In recent advancements in the field of dentistry we can convert non-vital teeth into vital once again by regenerative endodontic procedure. There are many procedures we can included in the regenerative are root canal revascularization, pulp implant, stem cell therapy, gene therapy and injectable scaffolds. In this case report we discuss the successful regenerative endodontic treatment of necrotic permanent maxillary left central incisor. On clinical and radiographic examination the large periapical defect in respected tooth end. After local anesthesia administration, rubber dam placed, access cavity preparation will be done with sterilization protocol, irrigation with the irrigation material for the choice was 1.25% of sodium hypochlorite with saline after proper irrigation no filing will be done at this point of time after this calcium hydroxide will be placed in the dry canal after 3 months follow, intraoral periapical radiograph shows less radiolucent area as compare to baseline radiograph and no visible inflammatory sign seen in the surrounding tissue then filing will be done in the canal to induce bleeding after visible bleeding visible in the canal after canal dry MTA will be placed. During the following period the patient as asymptomatic and after a 1-year x-ray the lesion was subsided and followed by root canal treatment completion.

Keywords: *Regenerative, Root canal treatment.*

Introduction

Regenerative endodontic procedures (REPS) is defined as biologically based procedures designed to replace damaged structures such as dentin, root structures, and cells of the pulp-dentin complex. It is a new modality to help the normal function of the pulp, it become an alternative method to heal apical periodontitis. REP is an extension of root canal therapy. In conventional treatment the dentist cleans the root canal and fills the pulp chamber with inert material after cleaning the root canal shape. As compared to the convention root canal, REPS replaces the live tissue cells in pulp tissue. The main goal of REPS is to regenerate tissue present in the pulp and making the function of pulp dentin complex.[1,2]

Before the introduction of REPS in the dental filed apexification procedure was used in the treatment of immature permanent teeth with the use of mineral trioxide aggregate and long term use of calcium hydroxide.[3] This treatment cannot resolve the complete signs and symptoms of pathology. They should affect on root development procedure.[4] In children traumatic injuries are more common in the age group of 8-13 years. The effect of trauma lead to loss of pulp vitality, pulpal necrosis causes difficulty in root formation.[5] The treatment of pulpal necrosis in an immature tooth with an open apex is a challenge for treating dentists due to

e-mail: sumitdash@soa.ac.in

the open apex it was difficult to obtain an apical seal with conventional obturation technique.[6]

In recent years, we are come across with different new treatment procedures in the field of endodontics. Regenerative endodontic treatment procedure help in root formation and apical closure in immure tooth.[5] Regenerative endodontics is defined as "restoration of tissue architecture and biological function of damaged tissues by tissue similar to the original tissue" Revascularization is a regenerative treatment modality and method to biologically replace a diseased dentin and root structure procedure.[7]

This case reports the successful neurogenesis of permanent necrotic central by revascularization approach.

Case Report: A 10-year-old boyreported to the dental clinic with the chief complaint of swelling in the upper front tooth region. The patient has no previous medical and dental history. The patientgivesa history of trauma 2 days ago, which leads to a crown fracture in the upper permanent maxillary left incisor. On extraoral examination, swelling in the upper lip and it will extend till the base of the nose and left eye. On intraoral examination discoloration of the maxillary central incisor was seen, on soft tissue examination reddish-pink gingival, soft and edematous in nature with rolled out margin, no periodontal pocket was appreciated, on Palpation was mildly painful. On radiography examination(Figure1) large encircled lesion was present on the apical area of the root. After clinical and radiographic examination the final diagnosis was made chronic apical periodontitis. Before starting the treatment informed consent was taken from the patient.

Procedure: After local anesthesia 2% administration, rubber dam placed, access cavity preparation will be done with sterilization protocol, irrigation with the irrigation material for the choice was 1.25% of sodium hypochlorite with saline after proper irrigation no filing will be done at this point of time after this calcium hydroxide will be placed in the dry canal after 3 months follow, intraoral periapical radiograph shows less radiolucent area as compare to baseline radiograph and no visible inflammatory sign seen in the surrounding tissue then filing will be done in the canal to induce bleeding after visible bleeding visible in the canal after canal dry MTA will be placed. During the following period the patient as asymptomatic and after a 1-year x-ray the lesion was subsided and followed by working length was taken with apex locator and verified by x-ray+ tooth was filled with MTA root canal treatment completion. During the follow-up appointments, the patient was completely asymptomatic.

Discussion

REPS procedure was founded by Dr. Ostby in 1960. The theory he suggested that the presence of blood clots in the canal promotes healing of the pulp, which helps in the vitality of the pulp. The process was similar to other parts of the body like blood clots help the injury site to repair itself.[8]

To see the above hypothesis, the above case diagnosed with the apical periodontitis received cleaning of canal space followed by placement of medicament after initiation of intracanal bleeding. After 6 months obturation placed coronal to formed blood clot.[9,11]

In various study, authors suggested that REPS can be performed in infected immature permanent tooth because in a clinical trial and histological examination they found mesenchymal stem cells on apical end of the root.[12-16]

These stem cells have the ability to differentiating into odontoblastic cells that helps in forming root dentin and these cells are called SCAP (stem cells of apical papilla) and other cells present in pulp are called dental pulp stem cells (DPSCs). They both can form dentin pulp complex. Both cells are potent to differentiate as mesenchymal cells from the bone. The difference between in these cells like, SCAP showed a greater cell proliferation, number of population doublings, and tissue regeneration as compare DPSCs.[17-19]

Factor affecting the results of revascularization is the degree of infection of the canal, it is difficult to treat the infected tooth with REPS procedure in these types of case triple antibiotic paste or calcium hydroxide paste are used to disinfect the canal.[20] The second important factor was the size of apex during REPS more than 1.1 mm apical diameter is beneficial and the possibility of rev revascularization increases in approximately 18 - 34% of teeth with immature roots. The third factor is age consideration between 8-16 years is more considerable to REPS procedure seen in this group give good results. REPS procedure cannot perform on deciduous teeth because of the possible risk of impairing the eruption pattern of permanent teeth.[20]

In 1996, Hoshino et al. recommended a tri-antibiotic paste, which was composed of ciprofloxacin, metronidazole, and minocycline, to disinfect the canal, and this medicament can be used effectively in regenerative endodontic treatment. On the other hand, Chueh et al. reported that complete disinfection of the canal and regeneration can be achieved by using calcium hydroxide alone.[21]

This case report highlights regenerative endodontic treatmentin maxillary central incisor using $Ca(OH)_2$ and MTA. The most important factor for the successful outcome of the case was the selection of that case and choice of medications used and the technique of sealing the apex. In young children RET shows better results compared to apexification. The disadvantage of apexification was surgery time is more than RET. Postoperative complications are noticed in the apexification like swelling and bleeding.[22]As per the guidelines by the American Association of Endodontists instrumentation in regenerative endodontic procedure are contraindicated because of the chance of fracture in the dentinal wall.

The most common and potent intra-canal medicament used in dentistry was $Ca(OH)_2$. The benefit of $Ca(OH)_2$ prevent infection and have the ability to improve the length of root and thickness of the wall as showed in the study done by Bose et al and MTA was used in RET cases. MTA has sealing properties and excellent biocompatibility makes it the material of choice in RET procedure.MTA is composed primarily

of Portland cement and bismuth oxide such as other MTA products. MTA contains calcium carbonate and a chloride accelerator.[23,24]

Conclusions

Case shows the management of an immature maxillary central incisor reported on successful regenerative endodontic procedure done using calcium hydroxide and MTA. For future clinical studies the comparing RET with $Ca(OH)_2$ and apexification techniques are needed to see the better effect of RET on periapical healing in the central incisor.

Abstracts

Oral candidiasis, commonly referred to as "thrush," is an opportunistic fungal infection that commonly affects the oral mucosa. The various forms of oral and maxillofacial candidiasis are pseudomembranous, acute, chronic, median rhomboid glossitis, perioral dermatitis, and angular cheilitis. The main causative agent Candida albicans, is a highly versatile commensal organism that is well adapted to its human host, continuing rise in the development of pathogenicity and resistance to traditional antifungal agents. Thus needto develop novel therapeutic strategies that can find the early resistance to particularantifungal. So the clinician can be better able to prescribe effective antifungal for oral candidiasis.

Keywords: *Oral candidiasis; Candida albicans; anti fungal treatment.*

Introduction

The species of Candida is present inside the oral cavity together as an opportunistic and commensals pathogens. In the current years, incidence noteworthy in the state of pathogenic of commensal been seen and reflected by increased escalation of infrequent and common candidiasis forms.[1] The morbidity in oralcandidiasis may as discomfort, chronicpain, limiting mastication especially in immune-deficient and in elderly patients. There exist clinical multiple presentations of oesophageal and oropharyngeal Candidiasis created by candidaalbicans both alone/in infection of mixed type. The treatment is based upon the Candidiasis type-(pseudomembranous, acute, chronic, angular cheilitis etc.) and severity of infection. Hence the review presently comprehends opportunistic pathogen oral Candida.[2] The Candidaalbicans exists primarily as a fungus of dimorphic form. The ability of Candidaalbicans is transforming into various forms morphologically like hyphae, yeast & psuedohyphae by the signals from the environmental perception which is significant for virulence.[3,4] The psuedohyphae are referred to ellipsoidal, elongated cells which are adherent to each other, while the true type of hyphae cells characterized with a morphology of cellular cylindrical and the walls of septal are perpendicularly separated.[5] Infection of fungal type is the thrush or Candidiasis which is attributable to any species of Candida genera among which is Candidaalbicans, the causative common species.[6,7]

Scientific classification of Candida species:

Kingdom: Fungi, Phylum: Ascomycota, Subphylum: Saccharomycotina, Class: Saccharomycetes, Order: Saccharomycetales, Family: Saccharomycetaceae, Genus: Candida

Formation of Germ tube -The germ tube arises from the Candidaalbicans as lateral short filamentous form growth cells.[8,9] It's mentioned that tube of germ, grows as Candida being cultured on medium of solid example Sabouraud Dextrose Agar (SDA) & depending on formation of germtube leads to the character for identification of *Candidaalbicans*.[10,11] According to Davis 1972 germ tube of C. albicansis opportunistic, which increases its virulence. And it is the most important factor in virulence by giving mechanical power to resist the phagocytic cells of the host.[12,13]

Antifungal therapy: According to Nguyen 1996 incidence for fungal severe infections is due to opportunisticfungi which raised in about previous years particularly those with mycoses of endemic and the patients who are immunocompromised with the main problem of the public related to health in many countries of the world can give rise to seriousside effects on the host. The points majorly attacking are the cell wall which is rigid and the metabolism of their sterol with peculiarities by this all of the fungi is distinguished from the cells for potentialhosts.[14-16]

Although fewer studies were done comparing directly to azoles, related to treatment for endemic mycoses,the oral azoles have availability which ensures tolerated better treatments for the Candidaalbicans. This is useful particularly for diseases of fungal which need longlive courses therapeutically, like coccidimycosis/ for mycoses of endemic occurring in AIDS.[16,17] Tortora 1995 reported that many drugs that inhibit or kill fungi are therefore quite toxic for humans. Besides, most fungi have a detoxification system that modifies many antibiotics, probably by hydroxylation, as a result; the added antibiotics are fungistatic only as long as repeated application maintains high levels of unmodified antibiotic.[18] There are reports for fungal increased infections along with that resistance to several antifungal, leading to the demand to develop and discover effective new drugs for antifungal.[19-21] The chitin enzyme synthase target of active fungal antibiotics- polyoxin D along with Nikkomycin.[22] Therapy of antifungal was categorized into tropical and systemic agents.[23] According to Uzun 2014 the patients with immunocompromised diseases or patient's having underlying severe diseases, the prognosis is poor of these patients and this generally comes under fungal systemic infection.[24]. But a rapid and reliable method for determination antifungal susceptibility that would hence needful in patients management along with the fungal invasive diseases.[25]

The primary antifungal agents for oral candidiasis:

Azoles: Azole medications are a family of antifungal drugs which are use full and important drugs of antifungal ending with"-azole" as suffix. The azole exists in class for members of five heterocyclic nitrogen ring compounds comprising of one atleast another atom of noncarbon for sulfur, nitrogen, or oxygen.[26] The important two diazoles comprising of fluconazole and itraconazole.[27,28]

Fluconazole: It an antifungal drug, used to treat fungi. And it's drug of antifungal used for treating fungi along with bistriazole fluorinated that's unusual as being soluble in water at pH neutral solubility which permits administration orally or intravenously.[27,29] Fungal systemic infections also are effectively often treated with Fluconazole. The Fluconazole effective for oral Candidiasis andcandidiasis of the oesophageal in the patient's suffering from AIDS, along with that its also useful among the patients who are immunocompromised[25,30,31] and patients suffering from AIDS along with blastomycosis and cryptococcosis,[27] it also has an activity which is good for dermatophytes.[32,33]

Side effects: Fluconazole in lactating mothers is not recommended since in the human milk the fluconazole secreted at about concerntrations same to that of plasma. The Fluconazole's has rarely also been related with lethal or severe hepatotoxicity. Along with this it's used cautionly in the patients already suffering with disease of the liver, preexisting in human beings. But few people allergic towards azole, therefore who all allergic for azole of other kind drugs maybe allergic for flucanazole. Few drugs of azole have side effects that they disrupts the production of estrogen during pregnancy.[34]

Drug susceptibility and drug Resistance: Susceptibility of *C.albicans* and non albican Species of Candida-Itraconazole, Amphotericin B, Fluconazole, Echinocandin, Candidaalbicans, Flucytosineand Candidatropicalis is susceptible to above antifungals

usually. While *Candidaglabrata, Candidakrusei, Candidadubliniensis* shows various ranges from Susceptible; Susceptible dose-dependent; Susceptible-intermediate to Resistant. The species of Candida causes infections that is treated by various drugs of antifungal available, but resistance of drug poses problem seriously to patient's individual health and nowadays the health system management been difficult. Several studies have shown that several factors responsible for drug resistance includes the pumping of drugs out from the cells of fungal type, the targets are modified by the incorporating point mutations in the genes the modification of main enzymes by pathways of biosynthetic and the modulation for factors of transcription plays.[35]

Historical perspective: The fungi occur as eukaryotic, free living organisms, those exist like moulds- filamentous fungi, yeasts-round fungi/ combination of the two- dimorphicfungi. According to Terezhalmy 2011 Candidiasis found orally is the commonest infection of fungal type, affecting mucosa of the oral cavity. And the lesions caused from yeast (Candidaalbicans).Candidaalbicans one components for oral normal micro-flora along with (30%-50%) of people. The rate increases by patient's age. These Candidaalbicans recovered by 60% patient's with dental problems in the mouths above 60 yrs of age. According to Prasanna 2012 the species of Candida are of different types–seen inside oralcavity.[36, 37] Mostly the oral species of Candida consists of: *Candidaglabrata, Candidakrusei, Candidapsuedotropicalis, Candidaguillermondii, Candidatropicalis, Candidaparapsilosis, Candidaalbicans, Candidastellatoidea*.[38]

Biology of *Candida albicans:* Candida albicansis true and most common opportunistic fungal pathogens. It is termed as "commensal" organism because it can found in the normal flora of skin, oral cavity, gastrointestinal tract, vaginal and the urinary environments. According to Ellis1994 and Ferreira 2010 it is found in the all environment, on leaves, flowers, water, and soil.[39,40] The *Candidaalbicans*–a yeast fungus,grampositive, thin walled, morphology which is microscopic showing spherical – oval about diameter of 5 um. It's larger to bacteria, that is reproduced by the process of budding as Yeast.[41,42] *Candidaalbicans* grows in moderate temperature's at a temperature ranging from (20-38) degrees centigrade and can resist pH to ranges (2.5-7.5).[43] According to Ellis,1994 the agar of dextrose Sabouraud containing gentamycin or chloramphenicol flavored to isolate Candida.[39] *Candida albicans* can grow better oncormeal, 72hours following with incubation of 25°C forming branched abundantly pseudo hyphae along with the blastoconidia and truehyphae are represented. These blastoconidia formed are clusters of grape like along the length of hyphae. If incubation period is extended a terminal chlamydoconidia may be formed.[44] *Candida albicans* have more than one wellknown and important features that it has ability of fermenting the sugars along with fermenting other kind of carbohydrates to produce ethanol.[45] The *Candidaalbicans* are fungus (dimorphic) which gives rise to two types of forms—Invasive & noninvasive. The form of yeast is the noninvasive and form of hyphal by which it can penetrate mucosa; is invasive. Under different environmental conditions the *Candidaalbicans* shows variant which are morphologically different forms: the forms that include are—yeast budding cells (blastoconidia, truehyphae, blastospores, clamydospores and pseudo hyphae along with this which are used in identifying *Candidaalbicans* among the different types of species for Candida. The C. albicans produces these germtubes and transition to hyphal form. However, ability in assuming different forms that is related towards pathogenicity for organism.[46,47]

Life as a successful commensal: The *Candidaalbicans* which is largely fungus of asexual type; but by physiologically and morphologically is variable highly along with that the fungus's adaptability and is of pleomorphic type which is capable of growing like budding yeast/as pseudo mycelium for conjoined and elongated cells of yeast or truehyphae which consists of generated parallelsided with growing-tip filaments.[48] And also exhibits nonsexual variation form called switching of phenotype that is able to generate cells which are stable and variant colony with properties i.e. distinctive.[49] According to Vautier 2015 *C. albicans* that adapted of commensalism & which thrive in various host of niches (mucosa of the oral cavity, vagina, skin, gut).[50] Hence state of host immune response & along with this mediated specific organism adaptations is responsible for the change in host related state of commensal.[51] According to Yamaguchi 2005 Changes to the availability for nutrients inside gut by intake through diet, further can impact in abundance for Candida[52] & due to diet change/fungal gut microbiota leads to dysbiosis & pathologies of inflammation origin like Crohn'sdisease.[53,54] Hence commensal for Candidiasis status is also related with micro biome host as whole & immunestatus for host.

Life as a successful opportunistic pathogen: Throughout the infection pathway the colonized *Candidaalbicans* different hostniches, comprising of differences as eg. Changes in pH, carbon dioxide levels, hypoxia, availability of nutrient in the medium.[55,56] According to Sokol 2016 that the one important features of Candidaalbicans like that of a pathogen which is successful adaptability in various other conditions.[55] It has been seen that the microenvironment of the host have sources of carbon that is heterogeneous therefore the adaptation of candidaalbicans for using simultaneously the sources of carbon alternatively for the virulence and survival.[57,58] The metabolic characteristic and Candida's flexibility also leads alterations in cellular secretome and proteome[59] and the ability of undergoing yeast into hyphaltransition, opaque, white with switching[60] formation of biofilm also the characteristic of adhesive property,[59,61] and capacity of remodeling.[56-52] The changes within composition of cellwall's polysaccharide changes the pathogens susceptibility to stress from environment & antifungals.[55-61] apart from the environment effect's immunogenically along with altering presentation and expression of critical pathogen associated molecular patterns(PAMPs) so the *Candidaalbican's* makes a target to move for the recognition along with immunesystem of the host.[56-63] As per Crawford 2015, humanhost retains micronutrients (Zn, Mn, Fe,Cu) from pathogen by the process called as nutritionalimmunity.[64] Within the pathogen such micronutrients essential towards various cellular vital functions.[64] These adaptive evolutionary traits makes Candidaalbicans survival possible in different hostniches; countering the host immunity defence's and makes the *Candidaalbicans* itself to establish as pathogen which is successful. Mandell 1994 reported that Candida is a fungus and was first isolated in 1844 from the sputum of a tuberculosis patient.[65] Andseveral studies have demonstrated that infection with candida is associated with certain pathogenic variables. Pathogenicity of candida depends on local and systemic factors of host.

Akpan 2002 reported that the gland of salivary functions which is impaired is susceptible to candidiasis in the oral cavity. Whereas proteins of antimicrobial saliva like sialoperoxidase, lactoferrin, histidine rich in polypeptides, lysozyme and antibodies for anticandidal that is specific, interacts to the mucosa of the oral cavity and inhibit the overgrowth for Candida.[66] According to Epstein 1990 and Guida 1988 by which there is adherence for Candida with acrylic is enhanced when the flow of saliva under fittings of denture surfaces is reduced, denture fittings improper and with the poor oral hygiene.[67,68] Dreizen 1984 reported that the wearing dentures increases theinfection with candida is as many as 65% of elderly people. Since wearing of synthetic products produces a microenvironment conducive to the growth of candida with low oxygen, low pH, and an anaerobic environment.[69] According to Brassart 1991 Candida adhesing onto the epithelial surface, is an important step, this promoted with definite components of fungal like C3dreceptors, mannose, saccharins, and mannoprotein.[70-72]

Different Drugs such as inhaled steroids have been shown to increase the risk of oral candidiasis.[72] by possibly suppressing cellular immunity and phagocytosis and drugs such as broad spectrum antibiotics alter the local oral flora creating a suitable environment for candida to proliferate. According to Garber 1994 the mucosal local immunity changes towards normal by discontinuating the steriod's inhaled.[73] Ohman 1988 reported that the Candida growth within the saliva is enhanced with glucose being present & adherence with epithelial cells in the oral cavity.[74] According to Guida 1988 those who are having low immunity they mostly prone to Candia disease.[68] Thus the various factors be diabetes, smoking, immunosuppressive state like malignancies (leukaemia, infection HIV etc) and deficiency of nutrition intake have been implicated particularly to change of commensal candida to pathogenic candida that leads to onset of candidiasis.

Conclusion

In recent period fungal infection is risen up enormously. Most of the people of many countries are suffering from Candidiasis. Sometime different antifungal agents failing to treat the fungal diseases completely. Due to this ineffectiveness of drugs they became side effects to the human. This appearance of resistance to antifungal drugs, which demands to discover and development of new effective antifungal drugs for this we have to search gene which could be responsible to develop drug resistance in Candidiasis, more often for *Candida albicans*. Also with molecular tools, we can know the effective antifungal at the earliest. These novel strategies will overcome the oral candidiasis problems in the near future.

Abstract

In the 21st century where science and its technology have revolutionized the world, there has been also a remarkable increase in the infectious diseases which have disastrously affected mankind. From the past when millions of people die due to chickenpox and measles in America till today when a virus like the SARS, Coronavirus (COVID 19) has challenged the world, which is a highly infectious disease. Infectious disease reports the main cause of death in this global world. Despite high equipment facilities and technology, this type of disease has regularly challenged the global scenario. Infectious diseases are particularly important causes of death among the people who are elderly, immunocompromised, already having a chronic disease and also to whom who are suffering from malnutrition. The article focuses on the mechanisms by which the infectious agents cause pathology, various routes of infection and also throws light on the different microbial agents which are causing various infectious diseases.

Keywords: *Infectious Disease, Pathology, Microbial Agents, Infection.*

Introduction

Infectious disease has always a adverse effect to human beings as it is a pathological condition which is caused specific infectious agents which can be virus, bacterium, fungi or protozoan that affects the body parts or tissues, characterized by a group of signs and symptoms. As we all know bacteria were discovered by A.V. Leeuwenhoek in the year 1675 but the German physician named Robert Koch discovered that specific organisms are associated with a particular disease, after which the physician-developed four criteria to demonstrate that specific agents caused a particular, which he called Koch's Postulates that takes medical diagnosis to another level as it becomes accurate to find out the proper medication of different disease.[1] Infectious disease is always associated with infection, host, pathogen and virulence. There are different routes of transmission of infectious disease and different phases involving in this disease. Modern microbiology which is based on molecular genetics is the key to defeating this infectious disease. When it was discovered that DNA was the responsible material for the transmission of genetic traits which was the turning point in the medical research history that has continued to this day. In today scenario modern and improved techniques lead the advancement in controlling and detecting the various disease.[2]

Classification of Infectious Disease[3]:

The classification is based on a different basis, which includes:

By location: It is divided into 2 types – Local: The disease is curbed to a specific area of the body.

Systemic: It is a generalized disease that affects most of the body parts and its pathogenesis distributed thoroughly in the tissues.

By Duration: It is divided into 3 types- Acute: It develops quickly and fastly spreads.

Chronic: Chronic disease develops very slowly and it mild but it may last for a long time, it has an indefinite period.

Latent: This type of disease is characterized by periods of no symptoms in the outbreak of illness.

By timing: It is divided into 2 types – Primary: It is an initial infection which has affects previously healthy person.

Secondary: This infection occurs in a person who has weakened by a primary infection.

Types of Infectious Agents

These are different agents which are very small in size and thus can be noticed in a microscope that includes:

Bacteria: These are the most common cause of diseases. They are generally 0.8-1.5µm in size. The bacteria cells are prokaryotes in nature and have cell membranes but lack membrane-bound nuclei. Their cell wall consists of peptidoglycan and most of the bacteria synthesize their RNA, proteins & DNA, but depends upon the host for their nutrition. The bacteria which retain crystal violet stains are Gram-positive & those do not retain are Gram-ve Bacteria. Most of the bacteria are extracellular but few survive within host cells like as obligate intracellular bacteria.

Prions: These are found in neurons and they are abnormal forms of a normal host prion protein (PRP). The accumulation of abnormal PRP will lead to distinctive spongiform changes in the brain and also can cause neuronal damage. They are intracellular. These are associated with diseases like Creutzfeldt-Jakob disease.

Chlamydiae: These organisms divide by binary fission like bacteria and they are sensitive in binary fission but the feature that distinguishes it with the bacteria is that they cannot synthesize ATP (Adenosine triphosphate). They are obligate intracellular microorganisms. Chlamydia trachomatis is the common cause for the female sterility and blindness. They are normally 200-1000nm in size.

Viruses: These are obligate intracellular organisms having size 20-30nm. They consist of a capsid which is a protein coating that surrounds the nucleic acid genome. Viruses are classified under the basis of their nucleic acid genome combination i.e. DNA or RNA, but not the both. They contribute to the huge allocation of human infections.

Fungi: These are eukaryotes having 2-100µm in size. Their cell wall contains thick chitin and their cell membrane containing ergosterol and these constituents are the most targeted area for the different anti-fungal agents. A fungus grows by hyphae or like budding yeasts forms. Their site of propagation includes cutaneous, mucosal, extracellular and facultative intracellular. They can cause superficial or deep infections.

Protozoa: These are single-cell eukaryotes which are the most common cause of infectious disease in developing countries. They are 1-50µm in size and can replicate intracellularly in many types of cells like parasitic protozoa which includes microorganism likes malaria in erythrocytes and leishmania in macrophages.

Helminths: These are highly differentiated parasitic worms having complex life cycles varying 3mm-10m in size. They consist of 3 classes which include Roundworms, Flatworms & Flukes.

Different Routes of Infection[3-5]: Microbes can enter the host in many ways which includes through the air, through the body fluids, by the animal vectors such as insects, birds, bats,etc, by the direct contact, or through the contaminated food. To enter in the host and to infect an individual, microbe's virulence factors are responsible which can break the host barriers and colonize the host. The barriers in host includes:-

- **Skin and oral mucous membrane:** The outer layer of the skin is dense and keratinized and its low pH 5.5 with its fatty acids content helps to inhibit the growth of microbes. Although skin and oral mucous membranes are very effective barrier but some microbespenetrate through due to cuts

or abrasions. Some of the examples of microbes include Staphylococci in wounds, Pseudomonas aeruginosa in burns and multibacterial infections in diabetic ulcers.

- **Respiratory Tract:** Many microorganisms' are inhaled by human beings causing pathological condition, which includes different forms of viruses, bacteria or fungi. The size of microbes is inversely proportional to its traveling distance in the host. Large microbes are been trapped in the nose with the help of goblet cells by the action of respiratory epithelium goes back of the throat where they are swallowed and cleared and the alveolar macrophages or neutrophils phagocytes the smaller microbes less than 5μm in size, but some of the microbes like M. Tuberculosis can escape the phagocytic killing by alveolar macrophages and can cause severe respiratory infections.
- **Intestinal Tract:** Some of the pathogens which are transmitted by contaminated food or drink breaks the barrier of the intestinal tract, but there are some normal defenses against these pathogens which includes acidic gastric pH, immunoglobulin's like IgA which is secreted by B cells located in the mucosa-associated lymphoid tissue, viscous mucus secretions, the bile detergents or lytic pancreatic enzymes and the normal gut flora. These barriers also weaken in some cases due to the loss of gastric acidity or the antibiotics which unbalance the normal bacterial flora like in Pseudomembranous colitis or syndrome like blind loop syndrome. Most types of viruses are killed by bile and digestive enzymes that are mostly enveloped but few which are nonenveloped like Hepatitis A or rotaviruses, etc are resistant towards these barriers.
- **Urogenital Tract:** Many pathogens cause urinary tract infection but as the urinary tract is sterile as it is flushed many times per day but few like E.coli pathogen adhere to the epithelium successfully causing UTI. Women are more prone to UTI as compared to men as the urinary bladder and bacteria-laden skin which is length of urethra is less as compared to men. The distance in the women is 5cm and in men it is 20 cm. Obstruction in the bladder and excessive bleeding in menstrual leads to infection of the genital tract.

Mechanisms Associated with Infectious Disease[6,7]:

There are 3 general mechanisms by which viral, fungal and bacteria attacks host; which include:

- The Pathogens enter to host cells or bind them and directly cause cell death.
- The endotoxins or exotoxins which are released by infectious agents kill cells and damage blood vessels leading to ischemic injury.
- The pathogen induces the host immune and inflammatory responses causing additional tissue damage.

Viral injury mechanisms: When the viruses enter inside the host cells then they can damage or kill in many ways:

Lysis of host cells: The replication of the viruses which interferes with the host cells because cell death-like as influenza virus kills the respiratory epithelium.

Alteration in apoptosis Pathways: Apoptosis is a common process by which the host inhibits the pathogen route and eliminates the virus but some viruses inhibit apoptosis by encoding some genes like BCL-2gene and damage the cell in the cases like virus-induced cancers.

Viruses induce the cytotoxic T lymphocytes attack and cause damage to host like in liver cell injury during HBV infection.

Viruses like HBV, EBV induces the proliferation of cells and transformation that leads to cancer.

Mechanism of bacterial injury[8,9]:

The mechanism includes a simple process by which bacteria causes diseases includes:

- **Adherence to Host cells:** It includes the invasiveness which is the ability to invade tissues and encompasses the mechanisms for colonization with the production of the extracellular substances that facilitate the invasion.
- **Toxigenesis:** Bacteria can produce toxins which include exotoxins & endotoxins. The bacterial endotoxins which are a lipopolysaccharide present in the cell wall of gram-negative bacteria which contain

long-chain fatty acids. This LPS is both harmful and beneficial to the host. However high levels of LPS induces cytokines such as tumor necrosis factor, IL-1, and IL-2, etc and will cause septic shock, acute respiratory syndrome, disseminated intravascular coagulation, etc.

The exotoxins are released from the bacterial cells which are bacterial enzymes like coagulase, protease hyaluronidases, etc that targets the substrates and damage the host cells. Some of the neurotoxins which are released by pathogens like C. botulinum or C. tetani inhibit the release of neurotransmitters leading to paralysis.

Cytokine storm can be appreciated which is caused by superantigens that are bacterial toxins that have the potential to stimulate the large population of T lymphocytes.

Table 1. Examples of some recently introduced important infectious Disease

Agents	Disease
Corona Virus	COVID-19
Staphylococcus Aureus	Toxic shock syndrome
Hepatitis E virus	Enterically transmitted hepatitis
HIV	AIDS
Hepatitis C virus	Chronic hepatitis
Hantavirus	Hemorrhagic fever with renal disease, Hanta virus pulmonary syndrome
Vibrio cholerae O139	New epidemic cholera

Different phases of infectious disease[9]: The stages involved are: Incubation period – It is the time from the occurrence of pathogens in the body to the appearance of first symptoms. In this phase the microbes grow and rapidly multiply.

Prodrome Period: In this phase nonspecific symptoms like fever, fatigue and malaise can be noticed with the starting of specific symptoms.

Illness Period: It is time in which symptoms of specific infection occurs. In this phase pathogen is at peak level.

Convalescence: In this phase acute symptoms disappear and returning of the immune system occurs.

Some techniques for diagnosing infectious disease[11,12]:

There are some method to detect this infectious pathogen which includes histopathological process, PCR test which is useful in the amplification of nucleic acids. Different staining process which diagnosed infectious pathogens includes:

Gram staining process which reacts to most of bacteria, Acid-fast stain for Mycobacteria and Nocardia, silver stains and periodic acid -Schiff for the fungi, Giemsa for campylobacteria and malarial parasites, DNA probes for viruses,bacteria and protozoa & Mucicarmine process for cryptococci. These staining processes have played a crucial role in detecting these pathogens as well as controlling infectious diseases.

Conclusion

According to WHO the 10 most disease which cause maximum death in the world population includes 5 infectious diseases like Influenza, chickenpox, tuberculosis and new coronavirus which is giving disastrous impact to the global world causing COVID-19 disease and declared as a pandemic. Various advance technology and medical research have to control the infectious disease with a proper medication of it but in today world also there isan infectious disease like COVID-19 which is highly transferable and yet its proper medication is not discovered or made, different infectious pathogens like coronavirus or hantavirus can be used for bioterrorism which is very dangerous to mankind as it can be used as a biological weapon. Infectious diseases are challenging the world from long back history to present scenario and preventive care and social measures are highly impactful to controlling these severe diseases.

Confounding and Effect Modification in Research

Dharmashree Satyarup[1], Manish Kumar[2], Radha Prasanna Dalai[3], Karishma R. Rathor[4]

[1]Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Professor & Head, Department of Public Health Dentistry, GITAM Dental College and Hospital, Visakhapatnam, Andhra Pradesh, India, [3]Senior lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [4]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

An association that is not causal (Alternate explanations) is seen between outcome and exposure whenever the study has confounding factors, bias and random error/chance error. Bias in any study leads to systematic variation of inferences or results or interpretations from the true picture. One of the most important bias encountered during research is confounding. Confounding is seen when a variable is observed to be associated with both the exposure and the outcome but is not a part of the causal pathway. Confounding factors, when present, in any study, are the "Nuisance" and can be the cause in part or in full of the observed association between the disease and exposure. Effect modification, on the other hand, is seen when various effects are brought about among different subgroups by an exposure and this can be handled by doing stratification. It is the outcome that is linked to the effect modification and not the exposure. This article will define and discuss in detail confounding, and the concept of effect modification so that drawing conclusions of a study can be done after considering these errors.

Keywords: *Effect modification, Matching, Restriction, Confounding factors.*

Introduction

Bias is defined as any deviation of results or inferences from the truth, or processes leading to such deviation. Any trend in the collection, analysis, interpretation, publication, or review of data that can lead to conclusions that are systematically different from the truth.[1] There are a plethora of biases mentioned in the literature which an investigator might encounter during research.[2] All types of study design, be it case-control, cohort,or experimental are prone to one or more types of bias. A false picture of association is observed due to bias or they can even hide a true association when it is present.

Internal validity of a study is threatened by the presence of confounding, random error/chance error and bias. A researcher's unintentional mistake usually leads to bias, whereas, confounding occurs due to the presence of an extra variable that affects the outcome positively or negatively apart from the exposure. Random variation/ chance can be reduced to a greater extent by increasing the sample size; but, on the contrary, bias and confounding cannot be reduced by merely increasing the sample size.[3] This paper emphasizes only on confounding and the bias associated with it. The paper also attempts to throw some light on effect modification.

Confounding: The word is derived from Latin "confundere" meaning to mix or muddle. It means a distortion in an association that is seen when the exposal factor of interest is muddled with other factors that are

related to the outcome.[1] As a researcher, we ought to be careful to avoid confounders in a study as much as possible otherwise it may lead to "False Positive" (Type–1 Error) ie, conclusion of a spurious relationship. In simple terms, it undermines the internal validity of the study, as the confounder rather than the exposal agent seems to be associated with all the effects observed.

Example: A researcher wanted to find out the association (primarily) between physical activity (Exposure) and lung cancer (Outcome). Confounding factor in the given example is age as it is associated with exposure (Old people tend to be more physically inactive), and also associated with outcome (Lung cancer is at higher risk to develop among old age).However, race cannot be considered a risk factor for lung cancer. Adjustments to accommodate variables that might not be cofounders can bring in bias and compromise the precision of a study.

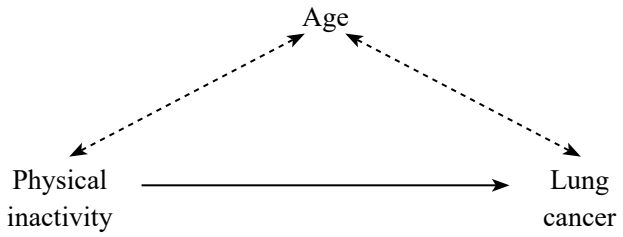

Figure 1: Understanding Confounding:

To understand confounding in a simplified manner, Rothman and others have investigated and illustrated an association between Down's Syndrome and birth order.[4]

Figure 1 shows that with an increase in birth order, the chances to develop Down's syndrome among the children also increases roughly around 4 – fold. This type of analysis did not take other potential risk factors/ confounders into consideration, making a researcher believe that birth order is associated with Down's syndrome.

But, when maternal age was used for children with Down's syndrome, it demonstrated that the age of the mother was more important in the causation of the disease i.e. as the age of the women increased to give birth, the prevalence of Down's syndrome also increased proportionally. (Figure 2)

Women who are mothers for the first time are much younger than women having their fifth child. In other words, maternal age is mixed up with the birth order of the child. There is a stronger correlation between maternal age and Down's syndrome prevalence than the birth order of the children and Down's syndrome. In lieu of this, it can be stated that the occurrence of Down's syndrome in relation to the order of birth is confounded by the age of the mother.

Investigators also tried to find if maternal age was confounded by birth order i.e. if birth order had an independent effect on the causation of Down's syndrome. Rothmansorted this by putting both effects i.e. maternal age and birth order v/s Down's syndrome prevalence. (Figure 3) (4).

The figure amply demonstrates that Down's syndrome prevalence is not associated (has no impact) with increasing birth order when observed from the side. But, when the figure is observed from forwards to backward, for every order of birth, an increase in the age of the mothers at all five levels of birth order can be observed, i.e. even after controlling for birth order, there is a strong association between increased maternal age and Down's syndrome among the children. Hence, the apparent association between birth order and Down's syndrome observed in Figure-1 was due to the confounding effect of maternal age completely. On the contrary, the association between Down's syndrome prevalence and increasing maternal age is not confounded by the birth order of the children.

Confounding Factor Criteria:

For a factor to be termed confounder, the following three criteria have to be met:[5]

1. Both the risk factor under study and outcome should be related to the confounder.
2. The groups under comparison should have the confounding factor among them, albeit it is distributed unequally.
3. A confounder cannot be an intermediary step in the causal pathway from the exposure of interest to the outcome of interest. In the pathway of causation from exposure to the outcome, the confounding factor cannot be a transitionary step.

The first two of these conditions can be tested with data. The third is more biological and conceptual.

To ascertain if the association shown between the exposure under study and the variable is independent, there should be a plausible biological or social explanation. These decisions should be best made

based on the basic science, psychological, sociological, or clinical data (i.e. non – epidemiological). In a nutshell, the confounding factor should precede the outcome of interest and not be an intermediary step. For example: To prove a relationship betweenlack of exercise and cardiovascular diseases, overweight might be an intermediary step between lack of exercise and cardiovascular diseases. Hence, bodyweight should not be controlled.[6]

However, bodyweight can be considered as a confounder if it is not a part of the causal pathway. Hence, controlling these intervening variables during analysis may mask a true relationship between exposure and disease.

Most of the diseases have multiple risk factors i.e. confounders. Confounder in a research study can be of any of the types mentioned below.[7,8]

- **Confounder as risk factor:** For example – In an epidemiological study to associate diabetes and exercise, age as it is a risk factor for diabetes, can be a confounding factor.
- **Confounder as a preventive factor:** For example – People who exercise regularlyon the prescription of aspirin, and being on aspirin decreases the risk of heart disease. Thus, the benefit of exercise would be exaggerated for reducing heart disease by regular use of aspirin (Confounder).
- Confounder as ***a marker or a surrogate***: For example – For most of the systemic diseases, socio-economic status would act as a confounder. Lower socioeconomic status (Marker) forms a collection of factors that are not understood completely and hence pose a high risk for many systemic diseases.

Effects caused due to confounding:

- An apparent association may be in part or wholly caused by a confounder.
- Can cause over-estimation of true association (Positive Confounding) or under-estimation of true association (Negative Confounding)

Identifying Confounders:[9]

- The best way to is to observe for the difference in the association before and after modifying for the confounding agent in a study. If the association between the two measures differs by ten percent or more, it confirms the presence of a confounder. On the contrary, if the difference is lesser than ten percent, then there is little or no role of the confounding agent.
- With the prior knowledge or experience of the investigator, if the variable is common to the exposure and outcome of interest, then the variable is believed to be a confounder.
- Test of hypothesis can be done to establish if the confounder is present in exposure and outcome.

Controlling for confounding during research:

The strategies employed to control confounding are:

1. Restriction
2. Matching
3. Randomization

} During the designing of the study

4. Stratified analysis
5. Multi-variable regression analysis

} During the analysis of the study

1. Restriction: A factor must be unequally present among groups being compared to be considered a confounding factor. Hence, a common method used to avoid confounding bias in the research is to restrict the selection and entry of participants by adhering to strict inclusion and exclusion criteria having the same levels of confounding factors.[10]

To understand simply, let us take an example of smoking and lung cancer, with age and gender being confounders of concern to the investigation. Restriction in this example, would be to select only male participants in the age group of 50 – 60 years. This will minimize the confounding to a greater extent as both the groups are comparable with similar characteristics.

Limitations to restriction technique:

- The problem of sample size might arise as the eligibility of the number of subjects will be reduced.
- If restriction is not done narrowly, then the problem of residual confounding might arise. The distortion that is still observed in study design or analysis even after controlling of the confounder is called residual confounding. For example, in an investigation of the association between smoking and lung cancer, if the investigators choose male participants between the age of 50 – 75 years, the occurrence of lung cancer varies widely in this age range as cancer might be more among the older adults.

- The effect of factors that have been adjusted for cannot be evaluated. For instance, the effect of men aged 50 – 60 years on lung cancer cannot be evaluated.
- Generalizability is limited by restriction considerably. For example, if a study only men are included, then the results cannot be generalized to women.[10]

2. **Matching[11,12]:** Matching is another straight-forward approach and commonly used method for reducing confounders in the research design especially in case-control studies. For instance, age groups among the cases and controls have to be matched in research to study the association between physical inactivity and cardiovascular disease. If not done, younger aged people might be mainly controlled strata and have fewer cases (suffering from heart disease) among them, on the contrary, older aged individuals might be forming up cases strata with fewer controls. Thus, by matching the age stratum, i.e. for every case aged 40–50 years, a matched control aged 40 years is chosen, thereby reducing the confounding to a great extent. As the analysis of unmatched study groups is different from than when matching is done, researchers should include matching during the study design to prevent confounding.

Applications of matching:

- Multi-faceted and complex variables need to be controlled (Example: Environmental factors, genetic factors, etc)
- In a case-control study, where the sample size for cases is less with many possible matched controls.

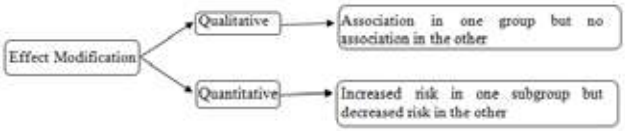
Limitations of Matching:

- The sample size is sometimes inadequate.
- Might be expensive and takes a long time to find exact matches
- Effect of the factors that are matched cannot be evaluated

3. **Randomization[13]:** To control both known and unknown confounders, the most powerful and ideal method is randomization. Selection bias by the investigator is prevented/reduced considerably by randomization, as it allocates subjects to control or experimental groups. Before randomization is conducted, the investigator should ensure all the participants are equal at baseline, to create comparability across groups. Similar distribution of known and unknown confounders is ensured by randomization to the control and experimental groups. Randomization also guarantees that any differences found between the two groups is due to chance and not due to the investigator.

4. **Stratified Analysis[13,14]:** Stratification permits an investigator to examine the difference of the confounder among the strata between outcome and exposure. For example: alcohol and smoking consumption, socioeconomic status, age, etc. In a hypothetical study, to find the association between air pollution and Chronic Obstructive Pulmonary Disease (COPD), smoking was the confounder to be controlled. The population under study was stratified based on their smoking status. Assessment of the association between COPD and air pollution can then be made within each stratum. Stratification allows us to examine the effect of smoking on the association between air pollution and COPD.

   The issue of simply creating strata, in general, is that, there will be more individuals in some strata giving an accurate estimate of the association. But strata with fewer individuals, the association estimate might not be accurate. Hence, the weighted average is calculated so that strata with more data gets greater weight. Mantel-Haenszel Method is the most common weight scheme used during the analysis. A single, summary measure of association providing a weighted average of the relative risk or odds ratio is produced by the Mantel-Haenszel method across the different strata of the confounding factor.All the usual statistical packages allow calculation of the estimates by the Mantel-Haenszel method. The major limitation of the stratified analysis is, if there are multiple confounding factors then it is very difficult to control all of them simultaneously.



5. **Multi-Variable Regression Analysis[10]:** If only one or two confounders have to be controlled, the best way is to conduct stratified analysis. Multivariate analysis is the only possible way to control simultaneously multiple confounders or if their grouping is large. For example: In a hypothetical study to find an association between smoking and oral cancer, we can control simultaneously other confounders (covariates) in the same model like age, gender, alcohol consumption, gutkha consumption, exposure to sunlight, sharp teeth, sepsis, etc. In

regression models (Linear and logistic), multiple confounders can be investigated at the same time by adjusting the odds ratio. Adjustment is the process of accounting for confounders followed by comparing simple and multiple regression results to get a clear picture of the quantum of distortion the confounder has made in the relationship between the exposure and outcome.

Effect Modification (Interaction): Effect modification, is seen when various effects are brought about among different subgroups by an exposure and this can be handled by doing stratification. Effect modification is associated only with the outcome of the study, but not the exposure. It is not considered a nuisance as it often brings to light significant information. The presence of a third factor determines the strength of effect an exposure on an outcome. For example, when a new drug is introduced called drug A. If this drug A works only in males but does not work in females, then gender is the effect modifier and its an example of effect modification.

Confounding is considered as muddling of effects, on the other hand, effect modification is a property of the effect.[15] Effect modifier is defined as a factor that modifies the effect of a putative causal factor under study.Effect modification is detected by varying the selected effect measure for the factor under study across levels of another factor. Hence, effect modification is a change in the effects caused by one or more factors due to the presence of the remaining factors.[1]

Types of effect modification[16]: Effect modification is generally classified into two types: Qualitative and Quantitative.

When the direction of effect (nature or quality) depends on the effect modifier, it is qualitative effect modification. On the other hand, if the strength (quantity) of association differs across strata of the effect modifier without a change in the direction of the effect modifier, it is quantitative effect modification.

Reasons for finding effect modification during research:

- For preventive actions, high-risk sub-groups can be defined appropriately.
- The precision of effect estimation is increased among the groups that would have been differently affected.
- The ability to compare across studies having different proportions of effect modifying groups is increased.
- Causal – The hypothesis of a disease can be developed.

Effect Modification Identification: The potential important effect modifier should not be matched during the study, as its effect on the outcome then cannot be determined. During the design and conducting a research study, the method employed to identify effect modifiers are: prior knowledge of potential effect modifiers and power of the study. The method usually employed to identify effect modifiers in research is generally done during the statistical analysis of the study i.e. stratification and regression (Already mentioned).

Conclusion

When a variable is observed to be associated with both exposure and the disease, confounding occurs causing confusion regarding the outcome. Hence it is imperative on the investigator's part to identify these confounders, otherwise, the study will be replete with bias. Randomization atthe design stage and regression models during the analysis stage are the best ways to prevent/reduce confounding in the research. On the other hand, effect modification does not create 'nuisance' in the research. In fact, effect modification helps the researcher to find the effect of one more variable on the outcome and hence are beneficial to the research.

Orthodontic Considerations for Traumatized Teeth: An Overview

Karishma Rathore[1], Debasruti Naik[2], Stithaprajna Lenka[3], Ramesh Nagarajappa[4], Utkalika Das[1]

[1]Tutor, Department of Public Health Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Professor, Department of Oral Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [4]Professor and Head, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

This article reviews the orthodontic consideration for the proper management of traumatic dental injuries which requires an understanding of the immediate and short- term response to the involved tissues: the periodontal ligament (PDL), pulp, and alveolar bone. This document discusses a few protocols required for orthodontic management of traumatically injured teeth.

Keywords: *Traumatized teeth, Orthodontic Management, Precautions.*

Introduction

Dental trauma mostly occurs in the age group of 7-19 years and is most prevalent in boys. Most commonly involved teeth during dental trauma accidents are the maxillary incisors. Commonly associated risk factors during trauma for class 2 patients division 1 malocclusion are increased overjet and incompetent lip coverage.[1] If there is an increase upto 0–6 mm, then it increases the threat of dental injury due to trauma which makes incomplete or partial lip closure resulting in unsupported maxillary incisors which is also said to be one of the majority factors in escalating the occurrence of traumatic dental injuries.[2] According to the Children's Dental Health Survey 2003, it is being reported that from 5% at age 8 to 11% by age 12 have undergone accidental damage to their permanent incisors. Data shows that many of them are remaining untreated. There is also evidences that 10.8% of orthodontic patients have a history of dental trauma.[3]

Types of dental trauma: It includes lateral luxation, avulsion, concussion, subluxation, extrusion, intrusion.

Dental trauma and orthodontics: During orthodontic treatment, if dental trauma occurs then there is a risk of root resorption associated with other dental problems. Every patient should be asked about any previous dental trauma before doing any kind of orthodontic treatment. By knowing the history of dental trauma, the orthodontist will prevent themselves from any potential complications to occur.[4]

Concussion

A concussion is a type of injury to the tooth and its supporting structures with an increased percussion that doesn't involve anyasymmetricaldisarticulation of the tooth. On examination plus radiographic findings suggested that the concerned tooth has high sensitivity on percussion but devoid of any increased mobility. There is no abnormality in radiographic findings. According to clinical guidelines there should be a record of the condition of the pulp of the tooth till 1 year. And according to orthodontic protocol, the patient needs to

e-mail: smilewithdebshruti@gmail.com

wait for 3-5 months to start any kind of orthodontic treatment. There has to be the maintenance of a record of radiographs throughout 1 year after trauma. In such cases, mild and intermittent forces can be used.[5]

Subluxation: Subluxation is a type of injury where the supporting structures of the tooth along with unusual loosening of tooth takes place, however, there will be no displacement of the tooth to be found. According to clinical findings, the concerned tooth will be having tooth sensitivity along with an increase in the grade of mobility. Also, there will be bleeding in the gingival crevice in this case but there will be no abnormalities in radiographic findings.[6]

Extrusive luxation: Extrusive luxation also known as peripheral dislocation or partial avulsion. It refers to the incomplete dislocation of the tooth that is exposedout of its jaw socket. According to the clinical signs there will be an elongated tooth that will be excessively mobile. The immature teeth will have revascularization of pulp. The radiographic examination in this case will show an increased space in the periodontal ligament area apically. Therefore, according to clinical protocol there should be the relocation of the tooth into its jaw socket to be done very gently. By using a flexible splint, stabilization of the tooth can be done for 2 weeks by utilizing flexible splint while keeping an eye onthe condition of pulp and radiographic control for 5 years. If we stick to the protocols of orthodontics criteria then, the patient should wait for 6 months to begin the orthodontic treatment. And during orthodontic treatment, radiographic control has to be performed every 3 months. Mild as well as intermittent forces has to be used. If necessary then the orthodontic treatment should be simplified.[7]

Lateral luxation :When the tooth is displaced in a particular direction other than axially then the displacement of the tooth is called lateral luxation which is associated with comminution or the fracture of the alveolar socket. In this case, clinical findings like the displacement of the tooth take place buccally or lingually/palatally which is immobile as well as tender on percussion that gives a metallic sound. The immature teeth will have revascularization of pulp. The radiographic examination in this case will show an increased space in the periodontal ligament area apically wide in an occlusal radiographic view. Therefore, according to the clinical code of behavior, the tooth should be repositioned gently by stabilizing tooth for 4 weeks using a flexible splint while keeping an eye on the condition of pulp through radiograph for 5 years. If we see the protocols of orthodontics criteria then, the patient should wait for 6 months, to begin with, the orthodontic treatment. And during orthodontic treatment, radiographic control has to be performed every 3 months. Mild as well as intermittent forces has to be used. If necessary then the orthodontic treatment should be simplified.[8]

Intrusive luxation (central dislocation): The least common displacement injury in the permanent dentition is known as central dislocation or intrusive luxation where dislocation of the tooth into the alveolar bone occurs. Such type of wound is combined with the fracture of alveolar bone. If we see the clinical findings then, the displacement of the tooth takes place buccally or lingually/palatally which is immobile as well as tender on percussion that gives a metallic sound. The immature teeth will have revascularization of pulp. The radiographic examination in this case will show anabsence or partial absence of the periodontal space in an occlusal radiographic examination. Therefore, according to guidelines, the tooth should be repositioned gently by stabilizing the tooth for 4 weeks using a flexible splint while keeping an eye on pulpal condition and radiographic control for 5 years. According to the clinical protocols, for 3 weeks, waiting for spontaneous re-eruption is indicated only for immature teeth with intrusion <3mm. cases of intrusion >3mm and <6mm may be treated by orthodontic repositioning, while surgical repositioning is recommended for teeth with intrusion >6mm. If we see the protocols of orthodontics criteria then, the patient should wait for 6 months to begin the orthodontic movement. And during orthodontic treatment, radiographic control has to be performed every 3 months. Mild as well as intermittent forces has to be used. If necessary then the orthodontic treatment should be simplified.[9]

Avulsion (exarticulation): Avulsion injury is seen in 0.5% to 3% of all dental injuries and is characterized by an absolute dislocation of the tooth out of the socket. This wound is accompanied by comminution or by fracture of the alveolar jaw socket.In this case the clinical, as well as readiographic findings like absolute dislocation of the tooth from its jaw socket, is found. According to the clinical protocol, the treatment of tooth placement is the alternative option, but proper prognosis of the tooth should be present for better orthodontic treatment. Prescription of antibiotics and anti-tetanic vaccination. If we see the protocols of orthodontics

criteria then, the patient should wait for 6 months to start the orthodontic movement. And during orthodontic treatment, radiographic control has to be performed every 3 months. Mild as well as intermittent forces has to be used. If necessary then the orthodontic treatment should be simplified.[10]

Significant risk factors due to dental trauma[11]

(a) It can be seen in the face i.e. increased overjet

(b) Maxillary incisors will be having inadequate lip coverage.

(c) Children who undergo treatment for dental injuries are usually at risk of getting injury to teeth repeatedly if the trauma occurs at an early age.

Considerations of a traumatized dental patient before orthodontic treatment: Before proceeding for any kind of treatment for traumatized teeth, a dentist need to take care of the complete profile of the patient. A comprehensive dental history including earlier episodes of dental distress and the treatment should be recorded.[12] Sometimes patient may not recall their history of trauma, therefore in such cases, a radiographic examination aforementioned to the beginning of any orthodontic management should include all these following points below:[13]

1. For assessment of colour, it has to be kept in mind about the transillumination seen in the radiograph which will disclose enamel infraction lines along with colour changes in the concerned injured teeth which are indicative of pathology or repair.[14]
2. Before proceeding towards the treatment examination for sinus or any kind of swelling should be done.
3. If there is any tooth mobility then the examination for the concerned tooth has to be done in both a horizontalas well as vertical direction. [15]
4. During the clinical examination palpation over the tooth apex for tenderness should be checked.[16]
5. Diagnostic tests for ankylosis can be done by the method of percussion tests in which a high metallic percussion note can be felt, while a duller note can suggest of a root fracture.[17]
6. For accurate diagnosis of dental trauma, radiographs like reproducible long cone periapical radiographs are the best. In such cases, radiographs at different angulations can be taken.[18]
7. Test like sensibility tests can be done for diagnosis of the teeth involved in dental trauma which is currently the most useful test to assess the neurovascular supply to the pulp of a traumatized tooth by the use of an electric pulp tester (EPT).[19] Before the commencement of orthodontic treatment, Proper detailed history of the tooth should be confirmed about any kind of existing root canal filling. Every patient should be asked about any previous dental trauma before doing any kind of orthodontic treatment. By knowing the history of dental trauma, the orthodontist will prevent themselves from any potential complications to occur.[20]

Precaution to be taken due to the dental trauma[21]

(a) Interceptive treatment can be opted.

(b) Use of mouth guards during sports can be used to prevent trauma to face and oral cavity structures.

Impact of orthodontic treatment on the tooth and its supporting structures[22]

(a) Loss of pulp vitality

(b) alternative resorption can be seen

(c) Non-responsiveness to sensibility testing

(d) Inflammation of supported gingival to the concerned tooth

Conclusion

Traumatized dental teeth should always be carefully examined regularly. In every month on a regular interval basis teeth should be monitored for the status of the traumatized teeth. Before commencing any kind of orthodontic treatment proper detailed history has to be recorded for avoiding any complications before the orthodontic treatment.

Management of Endo-perio Lesion by Guided Tissue Regeneration: A Case Report

Abhaya Chandra Das[1], Sourav Panda[1], Manoj Kumar[1], Gatha Mohanty[2], Utkalika Das[3]

[1]Reader, Department of Periodontics and Oral Implantology, [2]Senior Lecturer, Department of Periodontics and Oral Implantology, [3]Tutor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

To diagnose and to treat, is a crucial part of management of an endo-perio lesion. The sign and symptoms of endo-perio lesion are difficult to accountable for a general dental surgeon. For that reason, it needs more detailed examination and definite treatment plan. The outcomes of endo-perio lesion are highly unpredictable due its multiple etiological factors. The primary and secondary etiological factors of endo-perio lesions may have numerous variation and ultimately concludes the definite treatment plan complex. A 43-year-old female patientcame to Department of Periodontics, with a chief complaint of pain in right posterior lower tooth region.On clinical examination, there was 5mm of periodontal pocket, occlusal restoration in 47. The treatment plan was made as first endodontic treatment followed by periodontal treatment. So endodontic treatment was carried out first in 47 after oral prophylaxis. Then under local anesthesia, open debridement was done in 47 and bone graft was placed in the defect. Resorbable membrane was placed over the graft. Suture was placed and periodontal dressing was given and followed up to 9 months. She was very satisfied with the result.

Keywords: *Endo-perio lesion, endodontic treatment, periodontal treatment, alloplastic bone graft, resorbable membrane.*

Introduction

In endo-perio lesion, there is two compartments such as periodontal and endodontal compartment. The periodontal compartment is responsible for periodontal disease and endodontal compartment for pulpal disease. These two compartment are connected with each other by the presence of apical and lateral radicular foramina, which permit the passage of pathogen form one to another.[1] Simring and Goldberg first described the actual relationship between periodontal and pulpal disease in 1964.[2] The etiopathogenesis of the endo-perio lesion described following cases such as:

- Lesions that result from apical to coronal migration of pulpal pathogens and their toxins with or without fistula or sinus tract at the gingival margins depending upon the nature of infection.
- Originating from a marginal lesion which later on extended to more apical periodontal compartment. The periodontal and pulp are distinct from one each other and are anatomically connected through the foramina.
- Another form is the combination of the above, in which the differential diagnosis must attribute each portion of the lesion to its cause.

Periodontal disease causes a destruction of the bone in a coronal to apical direction and in endodontic lesion is from apex to coronal direction.[3] For this reason, it

is very difficult to find out the source of origin of the presenting lesion. It has already established fact that both pulpal and periodontal disease are primarily due to the disease process of the microbial infection.[4] Hence, both the disease process may originate as separate entities, but due course of disease progression, these may overlap each other. These diseases are frequently noticed as independent entities, which ultimately complicates the proper diagnosis.[5] There are several classification described the endo-perio lesion as follows.[5]

Classification:

1. Simon et al. 1972

i. Primary endodontic lesions

ii. Primary endodontic lesions with secondary periodontal involvement

iii. Primary periodontal lesions

iv. Primary periodontal lesions with secondary endodontic involvement

v. True combined lesions

2. Walton et al. 1996

i. Endodontic origin

ii. Periodontal origin

iii. Combined endo-perio lesion

iv. Separate endodontic and periodontal lesions

v. Lesions with communication

vi. Lesions without communications

3. World workshop 1999

i. Endodontic periodontal lesion

ii. Periodontal endodontal lesion

iii. Combined lesion

The present case report discussed an endo-perio lesion which was managed by guided tissue regeneration after completion of endodontic treatment.

Case Report: A 43-year-old female patient came to Department of Periodontics, with a chief complaint of pain in lower right posterior tooth region. On clinical examination, there was 5mm of periodontal pocket, large occlusal restoration, periapical abscess with sinus in 47 as shown in figure 1. There was presence of generalized stain and calculus. There was tender on percussion in 47. There was periapical radiolucency in intraoral periapical radiograph in relation to 47 as shown in figure 4A. The vitality test was found negative in 47.[6] The treatment plan was made as first oral prophylaxis (remove the plaque and calculus) to reduce inflammation, then endodontic treatment followed by periodontal treatment. The patient was free from any systemic diseases, and without tobacco chewing habits.

Figure 1: Preoperative view showing 5 mm periodontal pocket in 47

Treatment: Oral prophylaxis was carried out. Then endodontic treatment was carried out first in 47 after oral prophylaxis. Within 2 weeks the periapical abscess along with sinus was resolved. Then under local anesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine), full thickness flap was reflected and open debridement was carried out in 47 as shown in figure 2. Then DM bone {(Silicon Ion Containing 60% HA, 40% B-TCP), META-BIOMED CO., LTD, Osongsaengmyeong, Republic of Korea} bone graft was placed in the defect and resorbable guided tissue regeneration membrane (PerioCol GTR, Eucare Pharmaceuticals Private Limited, Chennai, Tamil Nadu) was placed over the graft as shown in figure 3. Suture was placed in such a manner that there was no exposure of membrane and graft. Then periodontal dressing (Coe-Pak, GC America INC, USA) was given to minimize the postoperative infection and hemorrhage. It also assists healing by preventing surface trauma during mastication, and protects against pain,which is induced during mastication, as a result of the wound contact with food or the tongue.

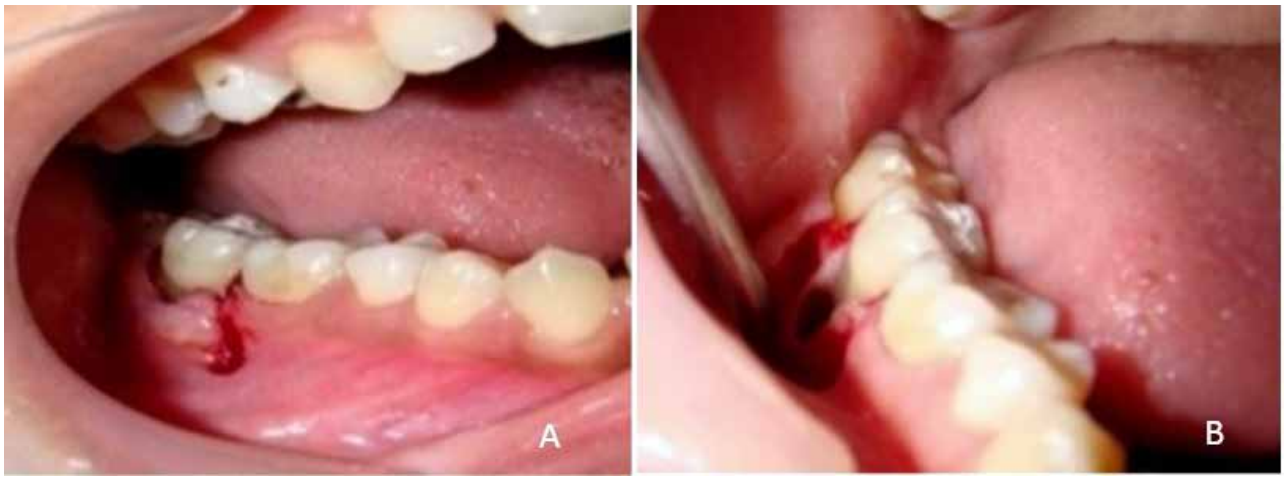

Figure 2: A (Both horizontal and vertical incision given), B (After complete debridement of the defect)

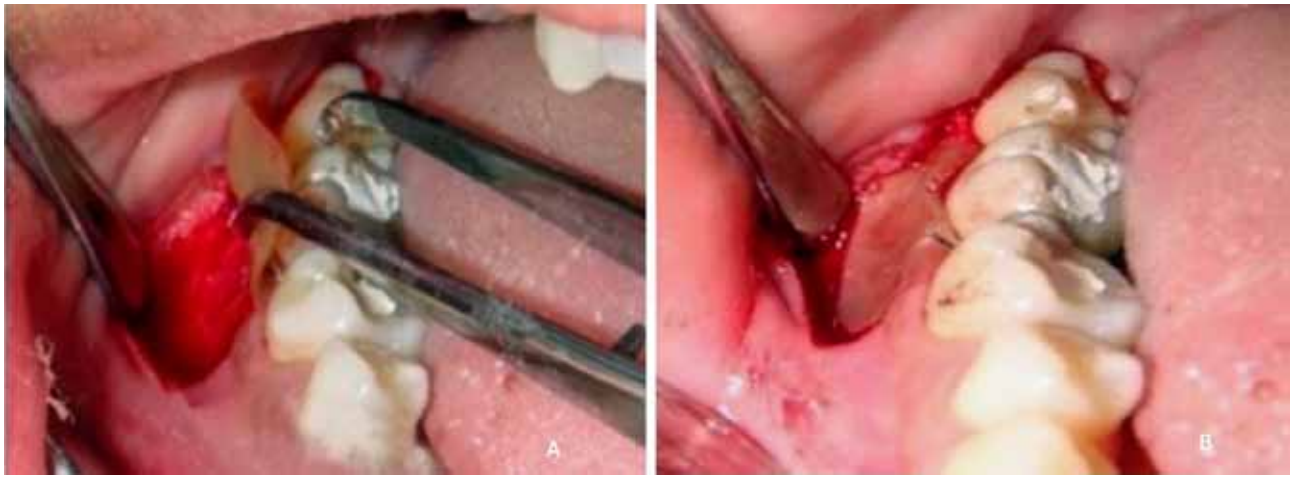

Figure 3: A (Bone graft placed in the defect), B (PerioCol GTR membrane placed)

Results

The present case was weekly follow-up visits for the first month. The reason was to have meticulous plaque control and had an optimum healing. After 2 weeks, suture was removed and washed with normal saline in the surgical site in order to clean the area. Later on, recall visits were done monthly during the next 9 month. These recall visits revealed that the patient maintained oral hygiene perfectly.

Figure 4: Postoperative view after 9 months

Figure 5: A (Preoperative), B (Postoperative) intraoral radiograph in relation to 47

After 9 months, IOPA in relation to 47 revealed there was completely filled up with bone and formation of lamina dura in the defect as shown in figure 5 and she was very satisfied with the result.

Discussion

Simultaneous presence of pulpal and periodontal disease, makes difficulty in diagnosis and treatment plan. Again it affects the sequence of treatment and long term prognosis too.[3] But it is not difficulty in diagnosis of primary endodontic or periodontal disease. For this type case, vitality test is the only easy tool to determine the actual causes of disease. If vitality test is found positive, it means the lesion is primarily periodontal origin, and if negative means primary endodontic origin.[6] In general, chronic inflammatory reaction of infected tooth can extend into the gingival sulcus and drains through sinus.[4,7] In this type case, the periodontal manifestation can resolve after successful endodontic treatment. In our case report, there was resolution of sinus tract after successful endodontic therapy, but there was 5 mm periodontal pocket still present.[8]It was also a case of primary endodontic and secondary periodontal lesion. In this type situation, endodontic treatment should be done first. As after complete debridement form root canal, there will be no infection inside the canal and also in lateral as well as accessory canals, which mainly responsible to connect from endodontal and periodontal compartments and vice versa. After hermetic seal obturation in root canal, there will be no space for any microorganisms and becomes sterile environment. In our case, endodontic treatment was carried out first then periodontal therapy. So after endodontic therapy, periodontal treatment was carried out. In our case, proper debridement was carried out after full thickness flap reflection. Generally autogenous bone graft or any platelet concentrates is ideal regenerating materials.[9–11] But to harvest autogenous bone graft makes a secondary surgical site. For that reason we placed synthetic alloplastic material{DM bone (Silicon Ion Containing 60% HA, 40% B-TCP), META-BIOMED CO., LTD, Osongsaengmyeong, Republic of Korea} in the defect. We used resorbable membrane (PerioCol GTR, Eucare Pharmaceuticals Private Limited, Chennai, Tamil Nadu) in order to prevent a second surgery need for replacement of nonresorbable membrane. The role of guided tissue regeneration membrane is to prevent migration of epithelial cell, and forms a weak long juctional attachment to the root surface which is not desirable.[12] Hence we used GTR membrane in our case for the above reason.

Conclusion

To manage an endo-perio lesion is not unidirectional, but it includes various treatment options. For the successful treatment of endo-perio lesion depends upon the diagnosis and treatment plan. When both endodontal and periodontal compartments are involved with disease, endodontic treatment should first carry out followed by periodontal treatment. In addition to conventional treatment procedure, other treatment modalities using advanced surgical techniques and materials such as regenerative procedures, radisection, and hemisection, bicuspidization should be considered as per clinical

conditions, which will ultimately result in a favorable long time prognosis.

4D Bioprinting, Newer Prospects in Regeneration

Utkalika Das[1], Gatha Mohanty[2], Rashmita Nayak[3]

[1]Tutor, [2]Senior Lecturer, [3]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The new concept which has come up in recent times being integrated with 3D bioprinting is 4-dimensional bio-printing. This is now considered the most appropriate solution for "tissue engineering". It has the potential to construct functional structure and also fabricate 3D patterns of biological architecture which can change shape under various stimuli by use of "stimulate responsive material". 4Dbio-printing provides a great potential for tissue engineering of bone. The properties like shape memory of the printed structure is used for repair of personalized bone defect and the properties such as functional maturation helps in promoting osteogenic differentiation of stem cells. This review aims to discuss the concept of 4D bio-printing and its application in "bone tissue engineering".

Keywords: *4Dbioprinting, Bone tissue engineering, Periodontal regeneration.*

Introduction

In the recent time, the 3D bio-printing technology concept has integrated time as the 4th dimension to fabricate complex functional biological architectural models. The 4Dbio-printing structure can go through a transformation in share or function overtime by the use of various stimuli-responsive biomaterials and the series of 4D bio-printing strategies. The application of bioprinting in tissue engineering guided tissue regeneration procedure remains unpredictable due to close proximity to the tooth surface.[1] To solve this dilemma 3D bio-printing was proposed by **Hull** et al in 1986.[2] 3D-bioprinting has been used for the fabrication of blood vessels, liver tissue, heart tissue and bone. However, there are certain limitations such as the initial condition of a printed object is only considered and assumed to be inanimate and static. Since the process of natural tissue regeneration involves 3D microarchitectures and extracellular matrix formation along with the generation of a tissue with a unique function,according to **Y.C.Li** et al[3] the complex conformational changes on tissue acquired by a mechanism that can respond to external or internal stimuli, 3Dbioprinting cannot mimic. **Skylar** et al in 2014[4] at MIT for the first time demonstrated 4Dbioprinting technology where multi-material prints were introduced having the capacity to transform overtime or change its shape. Fabrication of various 3D design architectures that are capable of undergoing dynamic configuration transformation inresponse to various stimuli were done thereby overcoming the limitation of 3Dbioprinting. 4Dbioprinting was defined by **Gao** et al. This is considered as the generation of cell filled 3D printed structures that can respond to external stimuli or internal stimuli respectively. They also included the functionalization and maturation of tissue with time, change in the shape, and change in functionality of the printed material overtime as two main characteristics of "4D bioprinting". The shape transformation feature has beenused to carry out personalized bone regeneration in the irregular type of bone defects. Reassembly of stimuli-responsive material and program cross-linking could be modulated in the mechanical properties of 4D constructed architecture.[5] Further, the functional maturation of 4Dconstruct of bone could also help in establishing a micro environment that

enhances the differentiation of stem cells and influences cell behavior.[6]

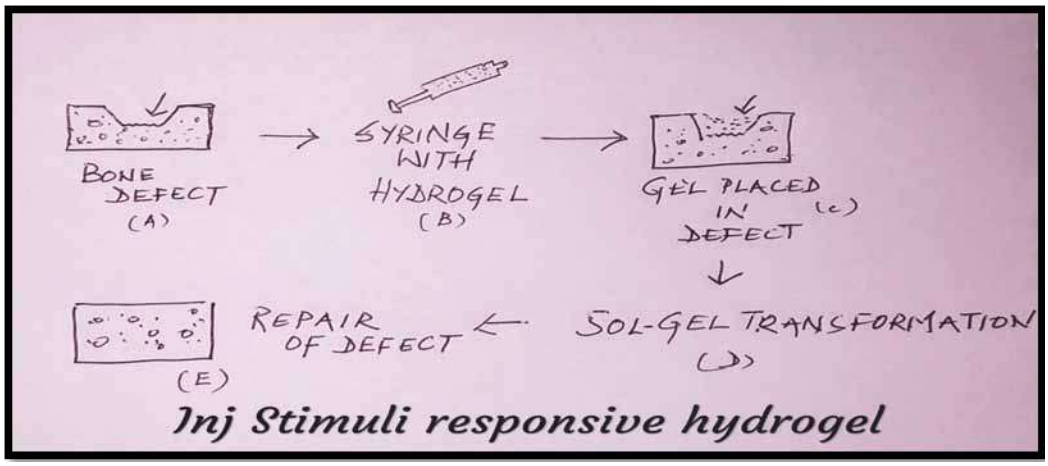
Important characteristics feature of 4D-bioprinting

1. Functional transformation
2. Shape transformation

Stimuli-responsive material

(a) **Physical stimuli**

- Magnetive responsive
- Humidity responsive
- Temperature-responsive
- Electro responsive
- Photo responsive

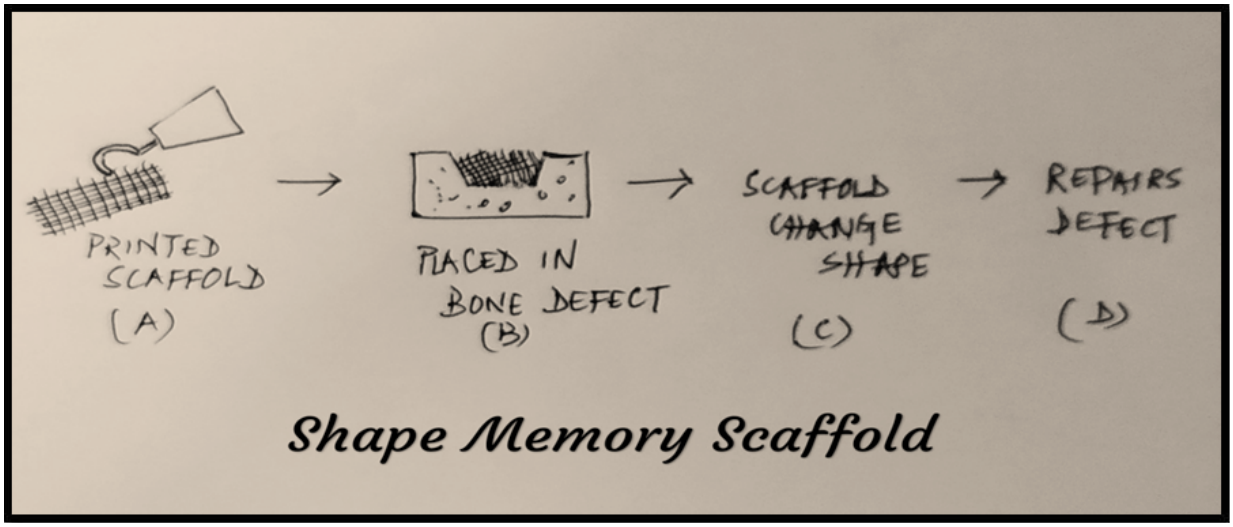


(b) **Chemical stimuli**

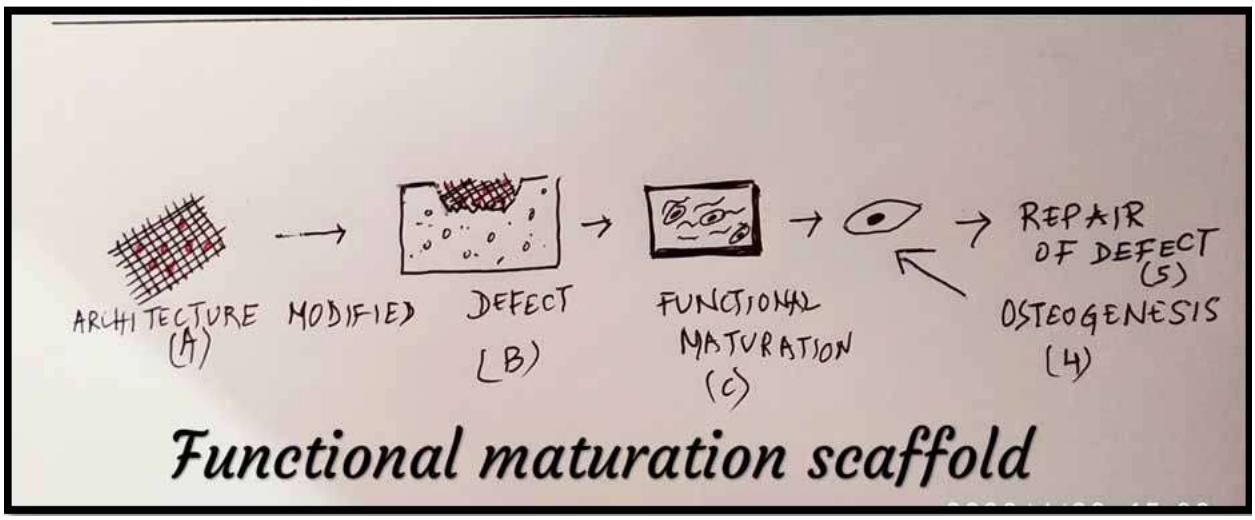
(c) **Biological stimuli**

3. CTF

Application: 4Dbioprinting is used for personalized bone defects especially the minor bone defects. The microvascular system and network of nerves within the bone tissue can be also constructed for a large bone graft substitute.



(a) Use of injectable stimuli-responsive hydrogel: In simple terms the thermostatic hydrogel is injected to bone defect and overtime gets transformed to a gel-like state at a temperature that is conducive to the human body,thereby repairing .the defect.



The hydrogels are thermo-responsive and are made up of polysaccharides. They also carry cells, HAP and CaPO4 cements, growth factors, inorganic composites like bioactive glass.[7] PNIPAM is one of the classical thermoresponsive material. This material along with chitosan and hyaluronic acid forms a suitable hydrogel that can be injected into the defect.[8] Another type of thermosensitive material available is a copolymer of polylactic acid,polyethylene glycol, and polyglycolic acid which can convert to gel under physiological condition.[9] These injectable hydrogels have mechanical strength that can be improved by the use of nanohydroxyapatite tricalcium phosphate and bioactive glass.[10] These hydrogels carry osteoblastic cells. The cells further have "alkaline phosphatase" activity and fill up irregular cells defect thereby providing of "mini-invasive repair" of bone defects. Mesenchymal stem cell differentiation has been enhanced with bioactive cues such as angiogenetic and osteogenic growth factors and are used by orthopedics in recent times.

2. 4Dbioprinting based on shape memory scaffolds: The shape memory scaffold is developed by 4Dbioprinting and implanted into the bone defect site. This scaffold changes its size to occupy the void space and repairs the defect. According to **F.S. Senatov** et alfused filament fabrication technique is used to obtain polylactide and hydroxyapatite porous scaffold.[11] The shape memory effect of the scaffold was stimulated by direct heating. These are used in self-fitting implants that repair small bone defects.

S. Miao et alused synthesized smart polymer that is PCL and cross-linker with castor oil-producing renewable bio-scaffold with shape memory and shape recovery effect at physiological temperature.[12] These scaffoldsare biocompatible and also biodegradable. More recently **S. Miao** et al fabricated a temperature-responsive scaffold that contained epoxidized acrylate materials.[13]

3. **4D bioprinting based on functional transformation mechanism:** During the post bioprinting stage, the biological activity of 3D-printed scaffolds and osteogenesis of stem cells can be improved by the biomimetic bony microenvironment. The establishment of this biomimetic microenvironment inspires the "functional maturation" of 3D-printed constructs, which is being reformed as polymeric "3D-printed scaffolds" by decorating them with a "cell-laden mineralized extracellular matrix" to imitate bony microenvironment. As time passes, a rotary flask bioreactor culturing, the printed bone structures became mature. Furtherit can be seen that the "extracellular-matrix-adorned" scaffolds showed evidence of better osteoinductive and osteoconductive properties than those of "bare 3D-printed scaffolds.

However, the bone tissues consist of complex hierarchical structures which further consists of both anisotropic mechanical as well as electromechanical properties. Barium titanate which is a smart biomaterial having a piezoelectric effect, has the capacity of stimulating the physiological electrical microenvironment. This smart biomaterial will act in response to functional stress as well as promote the growth of osteoblasts by showing bone inducing abilities and favourable biocompatibility. Piezoelectric materials have shown promising development in post printing stages.

4. **4D bioprinting with blood vessels and network of nerves:** The major challenge in"bone-graft-substitute engineering is regeneration of microvasculature along with the nervous networks. A combination of MSC's of mouse along with methacrylate alginate and hyaluronic acid hybrid hydrogels, a hollow self-folding tubes were fabricated. They had diameters closest to the smallest blood vessels. By entrapping enzymes in 4D hydrogel, pre-programmed calcification and fibrin biofilm formation could be triggered. "Bio-inspired 3D constructs" consists of bone-like similar structures that surround the constructed blood-vessels making a replica of vascularized alveolar bone constructs. 4D bioprinting of the "electro-responsive biomaterials" has shown scope for "nerve tissue regeneration".

Conclusion

4D bioprinting has emerged as a newer field for constructing a multilayered, constructive and functional bone tissue having complex structures. Fabrication of "shape-programmed", as well as functional structures,is possible in a more controlled manner. The advanced technology of this "4D bioprinting" will fulfill medical requirements and also it will help to explore its extensive purpose in the biomedical field. However, further researches are required in this field to work out the existing challenges so that 4D bioprinting can serve as a controlling means to ascertain dynamic along with hierarchical structures of natural tissues or organs.

Possible Pathways of Disease Communication of the Endo-Perio Lesions and their Management

Gopal Krishna Choudhury[1], Sangram Panda[2], Mirna Garahnayak[3], Abhilash Mohapatra[3], Pradyumna Sahoo[2], Rashmita Nayak[4]

[1]Professor and Head, [2]Reader, [3]Professor, Department of Prosthodontics, [4]Professor, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

The periodontal therapy deals with all the aspects of a periodontium as a whole including both the prevention and repair. Whereas the endodontic therapy deals with only the pulp and the periapical tissues. The relationship among the periodontal and endodontic disease has remain always a controversial part in the dentistry. However, to have the accurate treatment, a practitioner must possess a very sound knowledge of all the possible pathways of communication of an endo-perio lesion. Hence, this review paper aims at presenting the possible pathways of communication for the endo-perio lesions at a simpler way to help the clinician in their daily basis of perio-endo management.

Keywords: *Perio-endo lesions, pathways of inflammation of endo-perio.*

Introduction

Many literatures have shown the close speculative relationship among the pulpal and the periodontal tissues. The knowledge of the disease transmission between these two has become a mandatory protocol to reach the correct and accurate diagnosis.

1. **Atypical Anatomic Factors/Developmental Factors:**

A. **Mal-alignment:** Mal-alignment such as the presence of a multirooted tooth in a position usually occupied by a single-rooted tooth, or additional roots of a tooth, a predisposing factor to occlusal trauma and food impaction which predispose into endo-perio lesions.[1-5]

Corresponding Author:
Prof. Gopal Krishna Choudhury
Professor and Head, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India
e-mail: gopalchoudhury@soa.ac.in

B. **Lateral and Accessory Canals:** Large lateral, accessory canals in coronal and middle sections of roots, presence of additional canals, with resultant changes in root morphology in single and multirooted teeth are the pathways for the endo-perio lesion. Lateral and accessory canals may result from a lack of dentin elaboration around a blood vessel located in the periradicular connective tissue. When the roots begin to mature, lateral and accessory canals are generated. The apex from varied directions also carries not only the blood vessels but also the nerve bundles. Lateral and the accessory canals are usually generated when the maturation of the root takes place. If the continuity of the root sheath breaks, it leads to the formation of foramina which acts as a pathway for the inflammation leading to an endo-perio lesion.[4]

C. **Dentinal Tubules:** When there isan absence of cementum and the dentinal tubules get exposed on the root surface they serve as a potential communication between the periodontal ligament and the pulp. The radicular dentin tubules are well connected from the pulp up to the cement- enamel junction and the maximum density of it meets at the

range of 57,000 per square mm at the pulpal end. Thus, it is apparent that when such a large number of dentinal tubules are exposed, a pulpal response to such a trauma will occur like irreversible pulpitis and pulpal necrosis. [3]

D. Lingual Groove: These occur most frequently on the lingual surfaces of maxillary lateral incisors. Very often such a tooth is found pulpless and has a periapical lesion. Adequate root canal therapy may resolve the periapical lesion but may not resolve the periodontal defect associated with the developmental groove. Prognosis should be determined by the extent of the periodontal defect.[6,7]

E. Tooth Anomalies: Enamel pearls, cervical enamel projectionsor spurs or extensions into the furcation of multirooted teeth are found frequently. They help in retention of plaque leading to the formation of the periodontal lesion which in turn can lead to endo-perio slowly by time.[7]

F. Developmental Malformations: The type of developmental anomaly occurs when the tooth germ fails to form the other root-like vertical developmental radicular groove. It is seen mostly in the maxillary central incisor central fossa and lateral incisor. The healthy periodontium maintains its integrity until the intact position of the epithelial attachment. But once the breach of the attachment takes place and the groove becomes contaminated by the infection, the entire length forms an infra bony pocket which seems to be self-sustained. It leads to the niche of the tissue-like channel to microbial plaque and periodontal disease progression occurs. Slowly it leads to an endo-perio lesion. The course of the groove is followed by the bone destruction area, appreciated radiographically.[8]

2. Iatrogenic/Contributing Factors

A. Types of Trauma: Trauma can injury both the teeth and the alveolar bone, involving the pulp or PDL or both. Enamel fractures, crown fractures with or without involvement of the pulp, crown root fracture, root fracture and luxation and avulsion are examples of trauma.[5]

In the case of Enamel Fracture, chipping or cracks on the enamel surface of the tooth. There is no pulpal or periodontal involvement hence this vitality enriches the prognosis part.

In the case of crown root fracture, they are always oblique involvement of both the root and the crown part. Pulp may not be involved here, but the enamel, dentin, and the cementum is affected mostly in molars and premolars and less affected in the anterior teeth. Conservative restoration like composite resin or union reattachment of the fractured fragments is the line of treatment. But if the crown fracture involves the pulp involvement, these types of cases often becomes complicated. Hence the pulp exposure will dictate the restorative pulpal treatment. If the fracture is very extensive then root canal therapy is indicated. Pulpotomy and pulpectomy can also be a protocol which is decided by the stage does the tooth maturation lies. Sometimes, the amount of time-delayed for the start of the treatment, soon after the injury, may hamper the pulpal prognosis. The better prognosis can be achieved by the earlier treatment. When the fracture of the cusp extends beyond the subgingival margin, the case becomes much more challenging, the severity of the fracture decides the treatment part. Sometimes the fragmented fractured part of the tooth is splinted, stabilization with the coronal segment repositioning for 12 weeks to achieve the perfect pulpal and periodontal repair. Later on, root canal therapy along with periodontal therapy is recommended. Quite a times, the decision of the treatment is extraction been taken because of the hopeless prognosis. If the fractured tooth does not involve the pulp, then there is no requirement of the root canal therapy as healing takes place on its own.[8] In the case of luxation, the different types of injuries seen are mainly are concession, extrusion, lateral luxation and intrusive luxation. And the treatment is different for the different types of luxation injuries. In the case of root fractures following trauma, fracture can happen in the root in different directions, mesially/ distally, or facially/lingually. It may or may not involve the pulp chamber. A vertical root fracture can extend the entire length of the tooth and involve the gingival sulcus or pocket area but may also be incomplete and confined to either the coronal or the apical portions.(2) As an outcome of bacterial expansion in the fracture gap, the neighboring periodontal ligament will turn into the place of an inflammatory wound causing the collapse of the connective tissue fibers and alveolar bone.[1]

A. Perforations: Perforations either laterally or apically on the tooth are seen as a treatment failure or is a considered as undesirable complications of the clinical treatment. Prognosis of the teeth is impeded due to communications between the root canal system. Various reasons for usual

root perforations are carious lesions extending extensively root resorption by the error made by the operator during the preparation of the root canal orpost preparation. Hence the prognosis of the root perforation treatment depends on factors like how big is the size of the perforation, its location, and the right time in diagnosing it. The ability to seal the perforationdepends upon how far the repair material isbiocompatible. If immediate sealing of the perforation is done at the right time with good infection control, it leads to successful treatment. The popular root perforation sealer available are EBA super, composites, amalgam, cavity.[8]

B. Accidental Lateral Perforations: If the treated root perforation goes undetected or not successfully treated, it may give rise to many sites of inflammatory lesions in the marginal periodontium. They manifest as increased probing depth, suppuration, increased tooth mobility and loss of fibrous attachment. At the time of endodontic treatment, and in concurrence with the preparation of root canals for the insertion of the post, unintentional instrumentation can by accident forms perforation of the root and wounding of periodontal ligament. Perforations may be made through lateral walls of the root or the pulpal floor in multirooted teeth. At the site of perforations, the subsequent inflammatory reaction can result in the formation of a periodontal pocket, if the perforation is located close to the gingival margin.[9] Other complications include exacerbation of clinical symptoms, similar to those of a periodontal abscess. Eg: acute pain, swelling, drainage of pus from the pocket, increased tooth mobility and further loss of fibrous attachment. Treatment of a root perforation should be initiated once it has been spotted. Healing of the lesion in the periodontium depends largely on whether bacterial infection can be excluded from the wounded site by a tight seal of the perforation.[1] If the perforation is close to the sulcus area or conducted through the floor of a multirooted tooth, the inflammatory response may induce the proliferation of sulcular epithelium to form a deepened periodontal pocket.

C. Poor Restorations: The critical cause behind the failure of the endodontic treatment is the coronal leakage. And if the fracture of the coronal restoration is the reason behind coronal leakage and is delayed, there is a high risk of recontamination of the root canals. And sometimes, the exposure of the root canal to the oral cavity can lead to coronal leakage, coronal restoration plays a vital role in such cases as it forms a barrier between the bacterial contamination of endodontic treatment and the coronal leakage. Hence a very good endodontic obturation and a fantastic sealed coronal restoration is mandatory to protect the root canal system . And this does not end the coronal leakage but the cemented full crowns, as well as dentin bonded crowns, helps still better the coronal leakage long term prognosis of endodontic treatment areas.[5] There are certain precautions to be taken to avoid accidental perforation during the other endodontic treatment. They are: Rubber dam isolation is a must for performing cementation and space preparation postoperatively, heated plugger should be used during the preparation of the post space, the preparation should hold at least a minimum of 3 mm root canal filling, same as the root canal treatment, the post should also be well irrigated and well dressed, the delay should not happen to place the restoration for leak-proof, immediately after the completion of the endodontic treatment, only after 3 months of coronal seal, endodontic treated tooth should go for crown restorations.[5]

D. Internal And External Root Resorption: These are seen as pathologic process or sometimes even as a physiologic process. Delayed untreated external resorption cases may lead to invade of cementum, dentin and ultimately lead to pulpal space. Root resorptions are free from clinical symptoms. And the internal resorption cases if left untreated they may advance and end up in more complications like perforation of the external root surface. External root resorption where the external surfaces of the teeth are hampered. Internal tooth resorption starts when the pulp space affects the primary internal dentin. The main generating cause in root resorption is a root surface separated from its defensive blast cell layer. This type of separation may follow any damage to the cementoblasts cell layer. For the resorption to carry on, there is a mandatory requirement of a stimulus, an example may be a disease or a constant mechanical strength such as the one in orthodontic treatment.[10] Consequently the treatment of root resorption should be directed towards the cause of the continuance of the resorption, such as removal of the infected material in a root canal or by discontinuing orthodontic tooth movement.

E. Apical Foramen: The principal route between the

periodontium and the pulp is the apical foramen. Periapical pathosis is usually caused by the inflammatory mediators also by the bacterial end products. Through the apex/apical foramen, the inflammatory mediators reach the pulp by the portal entry from a deep periodontal pocket. External resorption of the alveolar crest also arises because of the periapical granuloma from the necrotic pulp and spreading toward the lateralparts of the root.[6]

F. **Empty Spaces Created By Destroyed Sharpey's Fibers:** Due to the destruction of the periodontium in cases of periodontal disease, the contents of the root canal system get exposed to toxic products. Thus there is direct communication established between the pulp and the oral cavity through the exposed dentinal tubules.[3]

G. **Cemental Agenesis or Hypoplasia:** When the root surface is exposed to the oral environment due to congenital absence or faulty cementum, especially at the cementoenamel junction, there is a direct spread of infectious products between the pulp and the periodontium.

H. **Exposure of Dentinal Tubules Following Root Planing:** Scaling and root planning are indispensable procedures in the treatment of periodontal disease. However, sometimes with the removal of bacterial deposits, cementum and superficial parts of dentin are also removed. Therefore, due to this instrumentation, dentinal tubules gets exposed and left unprotected to the environment. Subsequent microbial colonization of the exposed root dentin may result in bacterial invasions of the dentinal tubules. As a consequence, inflammatory lesions may develop in the pulp. The risk for bacterial penetrations and pulpal injury is further enhanced by the injudicious use of acid for the conditioning of the root surface in the attempts to promote periodontal tissue regeneration. During the maintenance phase of periodontal therapy, scaling and root planning or are frequently repeated procedures. At each recall session, the root surfaces are debrided and some dentin is removed. This remedy can consequence only in the deteriorating of the tooth structure and also wide reparative dentin formation in the pulp.[2]On rare occasions, deep periodontal scaling may expose lateral canals that in turn can induce severe symptoms of pulpal pain. This kind of lesion is termed 'retrograde pulpitis' and may also be initiated by exposure of the tissue around the apical foramen to the periodontal disease.

Conclusion

The result of periodontal inflammation on the pulp is controversial and conflicting always. It has been recommended that periodontal disease does not affect the pulp, until it involves the apex. There are different schools of thought; numerous studies recommended that the consequence of periodontal disease on the pulp is degenerative together with a rise in calcifications, fibrosis, and collagen resorption, as well as a direct inflammatory effect. On the other hand, it seems that the pulp never gets affected by periodontal disease, until the recession has started up an accessory canal to the oral environment. Hence, the management of combined lesions has toseek at eliminating equally both of the problems.

Treatment Plan for Ameloblastoma: A Review

Sthitaprajna Lenka[1], Aditi Ava Rath[2], Karishma Rathore[3]

[1]Professor, [2]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery Institute of Dental Sciences, [3]Tutor, Department of Public Health Dentistry, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Ameloblastoma is a tumor of odontogenic origin that exhibits 1% of all oral cavity tumors. Solid and multi-cystic are well chosen as locally aggressive, with elevated recurrence rates incase of conservative treatment. The objective of this review article is to analyze that the management of ameloblastoma should be done conservatively or radically. The appropriate management of ameloblastoma should reduce reappearance, reinforce function and aesthetic, and exhibit a minimum damage in the donor area. Planning of the treatment must be done based on the extent,position, andtype of the lesion.

Keywords: *Ameloblastoma, Surgery, Enucleation, Radical.*

Introduction

The second most common odontogenic tumor is ameloblastoma.[1] It is found particularly in the jaws, with a tough preference for the dorsal part of the mandible. Even though the tumor is benign, it is destructive, locally invasive and the recurrence rateis high even after adequate surgical elimination. The WHO tumors classification in 2005, mentioned that "the variation of ameloblastomas are the solid/multicystic, the extraosseous ameloblastoma, the desmoplastic and the unicystic type".[1] The exact pathogenesis of ameloblastoma is unknown. Various factors such as infection, non-healing wound,inadequate nutrition, as well as a probable correlation with the Human Papilloma Virusmay add to the cause.[2] Ameloblastoma can cause damageto the compact bone. This results in infringement of the soft tissues of the oral cavity disarranged occlusion ,dissymmetry,irritation and if the inferior alveolar nerve is affected it may lead toparesthesia.[1,3] Ameloblastoma in the former stage is identified through OPG accidentally if the patient would have come to do OPG for other reasons or because patients confer for symptoms to the consultant and then a histological examination is done for confirmation.[3] Currently,multi-cysticandsolid ameloblastomas are expressed as locally aggressive, with a greater chance of reappearance if conservative treatment is done.[4] Aggressiveness of ameloblastoma of Unicystic variety is lower, and the risk factor of reappearance is very minimum if treated conservatively. The peripheral ameloblastomas gives better feedback if local excision is done.[4]

The selective management of ameloblastoma is any ways an operative procedure, but the choice of surgery depends on its clinical nature. The better treatment procedure has always been a topic of debate for the treatment of ameloblastomas. Enucleation or marsupialization, is considered under conservative procedures along with curettage, and use of liquid nitrogen or Carnoy's Solution. Major surgical procedures such as segmental or Hemimandibulectomy comes under radical treatment.[5]

Literature review: World Health Organization defines ameloblastoma as "a benign lesion of follicular or plexiform aspect with a fibrous stroma. The most common feature of ameloblastoma is that it is a benign epithelial odontogenic tumor with no

element of ectomesenchyme."[6] Taking pathogenesis into account, the literature says that this lesion most likelyoriginates due tothe proliferation of the residual cell of the enamel organ. Along with this,it is also said that various molecules and alterations of genes have an impact on the triggering of odontogenic epithelium that leads to ameloblastomas.[7] Frequency of occurrence of ameloblastoma is more common in mandible than the maxilla. Among which 70% of cases are seen inthe mandibular body and 20% in the ascending branch of the mandible and rest 10%of the cases are found in the maxilla.[8]It is also noted that 15% of the ameloblastomas involve the maxillary sinus and the nasal floor. The involvement of the palate is negligible.[9] Pogrel et al. makes a review of 58 articles and found that"randomized clinical trials were available.[10] The results showed a recurrence of 60-80% with simple enucleation of solid and multicystic ameloblastoma, therefore, the treatment should be the segmental resection with 1 cm of margin to the bone, including a soft tissue margin. For unicystic ameloblastoma, the authors recommend an enucleation accompanied by a support technique. If not possible, a block resection with 0.5-1 cm margins would be the correct technique. Finally, the peripheral ameloblastoma responds well to the local excision."

A retrospective study is done by Hammarfjord et al.in which he hasdone the analysis and found that the reappearance of intrabony ameloblastoma in 48 patients and concluded that-"Radical treatment is recommended when recurrence and conservative option should be reserved for small intrabony ameloblastoma.[11] However, given the low rate of metastases, the chosen technique must consider the quality of life and comorbidities of the patient. Thus, the authors suggest a conservative treatment of ameloblastoma along with an annual follow-up for 10 years as a good alternative to processes that would involve aggressive resections, especially if there are no medical and personal factors that could compromise follow-up. It seems that enucleation can be the best alternative when assessing all the important aspects for the patient, but radical surgery is the correct option when the lesion is close to vital structures or when it cannot be treated conservatively."Simon et al. have done a cohort study where he has compared 64 patient's treatment procedures. These patients were treated radically. Out of 64 patients,32 patients have undergone immediate reconstruction during the same surgical procedure whereas 32 patients treated have not gone subsequent reconstruction. The success rate was more in patients who had reconstruction procedure immediately after surgery.[12]

Method of Diagnosis: Imaging tests such as X-rays,CT and MRI help the doctors to diagnose and determine the extent of ameloblastomas .and the confirmation of the disease is done by histopathological evaluations. CT scan is one of the relevant method of diagnosis for the determination of possibilities and extensions of ameloblastomas. Coinciding of images and dissertation errors are negligible in CT scan.[13,15] In histopathological examination, the appearance of islets, nests, and strands containing ameloblastic epithelial cells accomplished with a fibrous stroma is necessary to confirm the possibilities of occurrence of ameloblastomas. Follicular and plexiform patterns of ameloblastomasare most common, although there are also studies of unusual types, such as acanthomatous ameloblastomas with granular and basal cells.[15]

Treatments: The decision of the appropriate type of treatment is a very crucial step and the omission of the lesion should be the target on, considering the future social and personal aspect of a patient's life. Moreover,the treatment plan depends on the size,extent,type and histopathological feature of the ameloblastoma. More aggressiveness of surgery reduces the chance of reoccurrence.[16] If the lesion invades a greater portion of the cortical bone and anatomical structures, aggressive surgery should be opted to have discontinuation between bone pieces, along with the removal of periosteum and soft tissues.[17] Cosmetic surgery should be done postoperatively for a better lifestyle of the patient. A major drawback of management for ameloblastoma is the worsening of esthetics or facial appearance in the aggressive method surgical procedures that are done to remove the lesion.[18] This factor hampers the treatment procedures of the patient as they are isolated from the society. Education and Awareness among the patient and society about ameloblastoma is much essential to overcome this negative aspect.

Discussion

The most appropriate surgical treatment of ameloblastoma should be such that it should reduce the chance reappearances, should not hamper the functional and social status of the patient much and demonstrate a negligible distress in the donor area. Conservative techniques include minor surgical excision procedures such as marsupialization, enucleation,

curettage orcan be adjuvanted with cryotherapy, Carnoy's solution.[15,16] This type of treatment plan can be executed as a treatment option for less aggressive ameloblastomas. This type of treatment option has less effect on worsening the functional and esthetic part of the patient but the chances of recurrence are high if only enucleation has opted as a treatment option. In the case of aggressive tumors or if there is no possibility of combined conservative treatments, radical surgery with 0.5-1 cm of margins is preferred followed by cosmetic surgery as reconstruction procedure, forbetter outcomes. Radical surgery with an extent of 1 cm as margins and elimination of peripheral tissuesof the region followed by reconstruction is the choice of management for solid and multicystic ameloblastoma. Radical surgery rather than conservative management is always preferred in the case of large tumors.[17,18]

Conclusion

In this review, we concluded that aggressive surgery like radical surgery is the better treatment option in multicystic or solid and advanced unicystic tumors and should be followed up by the surgeon for the next 7-8 years. Adjuvant Conservative surgery with a constant follow-up for rest 20 years opts for the less aggressive type of ameloblastomas

Laser Protection is Everyone's Apprehension! An Update

Gopal Krishna Choudhury[1], Sangram Panda[2], Abhijita Mohapatra[3], Gunjan Srivastava[3], Abhilash Mohapatra[3], Rashmita Nayak[4]

[1]Professor and Head, [2]Reader, [3]Professor, Department of Prosthodontics, [4]Professor, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Today Laser is not anymore limited to big hospitals; it is easily accessible to the private clinics and private enterprises too. Anyone can go for laser practice today by attending a certified workshop on it. However, the main concern is the sound knowledge of its safety measures and management. This should be the primary goal for everyone involved in the sale, purchase and practice. There is a mandatory necessity of the safety administration or supervision to prevent or safeguard the laser hazards like understanding of standards, recognition of hazards and risks, carrying out of suitable control measures, and unfailing program audit to display eminence assurance. Hence, this review topic is taken to update the details of the dental laser hazards and its management.

Keywords: *Lasers, Tissues, Absorptions, hazards, complications, management.*

Introduction

The body tissue nicely absorbs the laser light. It can causes injury to the body tissues if the laser beam is much more enough powerful than the capacity of the tissue. The most sensitive part of our body to the laser beam is the skin and the eyes. The wavelength of the laser decides the amount of the laser beam to be absorbed by the targeted tissue. And the injury to the tissue is directly proportional to the amount of the laser light absorbed.[1]

Knowledge of Laser Science = Ability To Perform Risk Assessment = Development of Appropriate Safety Policies = Safer Staff = Safer Patient Care !!!

Hazard Classification and Corresponding Control:

A. Set I: This set of laser falls into the safest category as it is said to be nicely enclosed inside a safety cascade. Also it is not possible to remove the tightly enclosed cascade with hands. It can only be removed, if required, with the help of the respective tools meant for the removal of it.

B. Set II: This set of laser is not that dangerous if accidentally and unintentionally viewed but may prove dangerous if viewed continuously at a stretch for a longer time. This is due to the natural aversion response of the laser. The caution tag should not be taken out at any cost for the safety reminder to the operator. And also the laser light should not be focused directly at the operator eye or the patient eye. Even the patient is directed not to stare at the laser light during the operation even though with the safety goggles.

C. Set II 1A: This set of laser happens to be dangerous and cause injury when the optical safety tools wore by both the operator and the patient, accumulate the beam and reflect them directly into the eyes

D. Set II 1B: This set of laser happens to be dangerous and cause injury when the optical safety tools were

not aided by both the operator and the patient. On viewing the laser light without protective tools, it may prove highly dangerous.

E. SET 1V: It is the same as class 111 risks. On direct exposure along with the reflection of it, with the powerful laser light, the injury is caused. These lasers cause biologic risk from either straight or distributed reflection. Commonly any laser able to produce power larger than 500 MW nonstop wave production falls in this set.[2]

Types of Laser Hazards: There are many types of hazards observed during the clinical practice of laser in dentistry like[3]

1. Ocular/Optical injury
2. Tissue damage hazards
3. Respiratory hazards
4. Fire and explosion hazards
5. Electric hazards

1. Optical/Ocular hazards: The direct emission of the laser light along with the reflection of the same from the surface having a mirror effect can cause tremendous injury to the eyes. The primary optical injury found is the burning of the retina or the cornea. The wavelength with visible (400-780nm) and near-infrared (780-1400nm) are enough for the injury of the retina. Different types of wavelengths may cause different types of optical injuries. This is possible because of the much more focusing capacity of the retina and the cornea. This injury can also happen with a constant low-intensity reflection and turn into an irreversible injury leading to permanent destruction of the retina and the cornea, and finally into blindness. The blindness is due to the high heat energy which takes hardly a fraction of a second. Laser-like Argon and Nd: YAG can get transmitted into the eyes directly and the power becomes increased nearly 100, 000 times more because of the lens focus. Surfaces such as instruments, mirrors, and polished restorations have the potential to redirect laser energy. Nd: YAG lasers demand the safety glasses which are of green in color and argon laser demand for the colored glasses which are amber. However, CO_2 laser demand s for the clear glasses. The keys should be removed from the laser during the non-use period. Also, there should be a separate safety and a security maintenance room for the laser. The team with LSO-approved only should be eligible to access it. There should be clear safety warnings posted on the laser room entrance or the door for creating awareness.[4] The laser room should be nicely sealed with an opaque material to prevent leaching and leaking of the hazardous laser beam to the bystander. However, it is very much safe for the CO2: laser, as only plastic and glass walls, can absorb the laser radiation. There should always be an extra pair of goggles stored at the entrance of the laser room for the person entering the room for his eye safety.

2. Tissue Damage hazards: Skin hazards from the laser should not be ignored as it seems to be much painful than ever imagined. At times, there may be severe deep damage to the skin tissue. It happens sometimes by a mere accident and at times due to the negligence and carelessness of both the operator as well as the assistant. Especially it happens due to the lack of coordination between the assistance and the operator, assistance hands come in front of the laser optic tip causing a burn to the skin.[5] Skin burn can even happen to the patient if he is not made aware beforehand to keep off his hands from the operated site during the procedure. The patient must be well trained to raise his hand and give signs to interrupt the procedure if he wants to deliver something. But strictly he should be prevented from touching the operated area during the ongoing procedure to prevent mishap. The moment the skin comes in contact with the contact mode of the laser fiber optic, the laser misfire and causes very painful burns. Hence, the operator is expected to take off his foot from the foot pedal and keep the laser in the "standby"mode, till everything gets ready to start with the procedure. Once the assistance checks everything ready and gives thumbs up and changes the standby mode to start mode, then the operator can keep the foot on the pedal. The patient facial skin, adjacent teeth, and the adjacent soft tissue next to the operated site should be taken care of by placing wet sponge or wet gauze on it. Or else shattering of the tooth takes place if the adjacent enamel of the tooth and the pulp gets penetrated by the unwanted laser radiation. However, the tooth damaged by laser is highly resistant to dental caries though it looks very ugly. [4]

3. Fire and Explosion hazards: The surgical

materials used at the site of laser operation are highly vulnerable to catch fire and produce fire hazards. The material can be from the disposable drape made from the pulp of the wood, dry cotton and gauze swabs or sponges, tongue blades made of wood, and of course the material made out of plastic. Hence to prevent the mishap, surgical drapes made of polypropylene material are very much popular as they melt but never burst into fire in contact with the high energy laser tip.[6] Secondly, is the endotracheal tube, which is the highest source of risk during oral surgical procedures. Enough attention should be given to avoid the endotracheal tube coming in get in touch with the laser tip during the surgical procedures. This seems to be caused by the blow torch effect inside the airways of the patient which ignites. Hence these days new endotracheal tube supposed to be laser safe are available. Also it is mandatory to have the endotracheal tube airtight with the reflective part of the metal exposing outside to detect the endotracheal tube during the surgery. So that special attention can be provided to prevent the laser tip when it comes in contact with the tube. The distal end of it is the cuff which is always filled with the saline solution and blue dye made of methylene. It is to protect the laser beam from coming in contact with it. The time the fiber optic gets touched with the cuff, the dye which is a distinct blue, and visible, spills outside only to draw the attention of the surgeon and the anesthesiologist to take care of the laser-related puncture of the endotracheal tube cuff.[7] Also it is made up of stainless steel body which puts enough resistance to the laser perforation. In a little time back, the endotracheal tube was manually wrapped with foil but it is obsolete now to prevent the unwanted open area left unintentionally which can be a vulnerable issue for the laser to get ignited. Thirdly, safety measure is, to lessen the oxygen gas content of the anesthesia mixture by around nearly 30 % to prevent ignition mishap. Also the isolation of the nasopharyngeal throat with the pack of wet cotton or gauze pieces is recommended. It prevents the absorption of the high laser radiation and gives maximum protection to the patient.[8] The surgeon should not forget to remove the intrapharyngeal packs soon after the surgery is completed. The anesthesiologist should remind the surgeon by asking questions as: Is the removal of the pack done. It is in the guideline of anesthesiology practice by the MCI. Additionally, the anesthesiologist is also expected to keep an eye over the period from the pack insertion until the pack removal only to ensure that the pack is safely removed before the closure of the surgical procedure. Along with the surgeon, even the anesthesiologist should work hand to hand with the minute details of the surgical procedure to safeguard the patient from any mishap. However, even the surgeon must be aware of all the anesthetic details given to the patient to ensure the safety of the patient if at all any mishap happens. Not being aware will cause only chaos at the much needed time and it can cost the life of the patient instead of life-saving. Last but not least, the whole team comprises of the staff nurse, operator assistance, laser technical assistant and even the fire safety concerned department, emergency dept. should be very well informed of everything much before the safe going of the whole process. Not to forget, beforehand, a well prepared written plan of the action should be made among the entire team and well versed with minute details for the safety concern. A good and the right plan of action if properly taken, it helps rapidly at the time of mishap and proves a commanding life-saving action.

The sequence or the protocol recommended during any fire mishap: Immediately switch off the laser. Switch off all the anesthetic gases including the oxygen cylinder. The patient shifted to a safe place immediately. With the help of the bag and the mask, the patient should be ventilated with 100% oxygen gas in the other room by the emergency department. Saline solution to be used at the earliest to extinguish the flame. Cuff should be deflated immediately and it should be removed simultaneously. The entire tube should be taken off with care. Bronchoscope should be used to make the airways clean off from any foreign bodies like pack material or any combustible material which may block the airways. If the damage is under control care should be taken to restart the incomplete surgical procedure after assuring the patient assistance that everything is well. Even the patient is assured with enough faith if he is in a consciousness state to understand it. But in case of the extensive damage, the airway ventilator should be carried out with an emergency tracheotomy. Steroids of high dose and the indicated antimicrobials should be injected keeping the vital parameters of the patient in the watch. And the reschedule of the targeted surgical procedure is again newly planned keeping the patient parameters in watch. The fire mishap should be properly conveyed with all the, minute details and the

respective concerned officers of the fire mishap as well. Risk management team, manufacturer companies, law officers, humanrights, insurance companies, and the quality controlled hospital management too.Pt and his family should be well conveyed too with assurance and faith to prevent the unwanted unpleasant illegal issues later on. It is also to keep the faith on the hospital team too. Water should never be used to Do not use water to put off fires on electrical tools. The entire team accessing the laser should be aware of the fire extinguishers at the entrance of the laser room, and its application that is P.A.S.S. - pull, aim, squeeze, and sweep.[4]

4. **Electrical hazards:** At times back, out of all the laser hazards, electrical hazard was the most fatal during the initiation period of laser usage. The reasons were many, from the untrained to the uncertified and unauthorized or even quack practitioners. The qualities of the electrical safety were not taken care of and less knowledge of the precautions to be taken to control the mishaps, were brought into notice. Electric shock because of coming in contact with the capacitor, which is said to be charged to its maximum.[9] It resulted in electrocution and death immediately. Proper inspection and evaluation were not carried out at the earlier stage and even the repair work was neglected which brought many mishaps. Technicians were not well trained and even the surgeons were not certified with the special laser workshop and were not trained with the sound knowledge of the handling of the accidents and safety measures to be taken at the right time. Even the manufacturers did not give a clear caution tag on the laser to make the surgeon well cautioned enough. The proper wavelengths were not followed for the respective procedure. The high unwanted radiation because of high voltage caused many a times electric mishap. Also the direct current DC of the laser kept on charging for hours together even after the unplugged and switch off which became the reservoir of high fatal electric current. The indicator light which stands for the electrical malfunction should be very much aware of and if it goes off, immediately the laser technician or the service in charge should be informed to come and interrogate the problem. It should not be ignored and the procedure requiring laser should be immediately called off till it is repaired or it can be continued if there is any stand by laser available during the time.[7]

5. **Respiratory hazards:** The most unwanted is the byproduct of the laser, laser smoke, or the laserplume. Laser plume is a very unpleasant scent and this malodorous consists of steam that is then vaporized water, the particles of carbon, and few cellular products, which all together form laser plume.[10] This plume is very chocking and uncomfortable for the team working there in the operating room. It is also believed that this laser plume may prove highly dangerous to the respiratory patients as it is said to have consisted of various substances, such as formaldehyde, hydrogen cyanide, hydrocarbons, and other airborne mutagens. The size is hardly a little more than 0.3 u. It is found in the literature that the laser also gets filled with deadly human papilloma virus DNA, at the time of the surgery carried out to coagulate or to remove the papillomas growth through the laser. It can prove to be fatal for the patient next to him or the person coming in contact during the particular time, as it is an airborne infection. Huge evacuation for the laser smoke and with the filter size of 0.1 um is indicated in the operation area. The evacuation suction should successfully remove the laser plum in and around the area of 10 cm of the surgical area. Evacuation filters should be regularly monitored and should be replaced immediately when the time indicated of blockages of the pore and the efficiency ends here. To replace the blocked and old evacuation filters the service given person should be asked to wear the disposable gloves with proper mouth mask to get prevented from any air none pathogens built inside. Then the waste should be carefully disposed of with the recommended biohazard bags. The accumulated charred accumulated by the laser from the surgical area should be cleanly wiped out with an antimicrobial solution. Proper and righteous biohazard handling should be maintained for the materials used during the laser procedure. The right kind of the face mask and eye wear is highly recommended during the laser procedure in the infected patient to avoid the splattering of the infected tissues into the eyes or nose. Both for the operator as well as for the assistant too. And they too should be disposed of or sterilized for the next use.[7] Lastly, but not least, all the instruments used during the surgery touched or even not used or touched, including the loupes should be wiped off with approved sterilizing method and liquid.[4]

Conclusion

Safety is everyone's responsibility! Routine audit, troubleshooting, training, policy and procedure development, and compliance enforcement, are duties of

the LSO, but case by case, day by day, patient by patient, laser safety depends on every healthcare professional's commitment and vigilance. Lasers can offer patients a wonderful range of treatment options, from standard of care to experimental innovation. Laser users are constantly challenged to redefine who they are, what they do, and their scope of practice, with each new laser system or application. It must be remembered that every new system demands risk assessment and a review and revision of facility safety policies and procedures. Only through teamwork, communication, continuing professional education and training, and respect for the technology, can we establish the foundation fora truly effective laser safety program.

Otomycosis: A Comprehensive Review

Priyanka Debta[1], Santosh Kumar Swain[2], Smarita Lenka[3], Mahesh Chandra Sahu[4]

[1]Professor, Ph.D. Scholar, Department of Oral Pathology & Microbiology, IDS, Siksha 'O' Anusandhan Deemed to be University, K8, Kalinganagar, Bhubaneswar-751003, Odisha, India, [2]Professor, Department of Otorhinolaryngology, IMS and SUM Hospital, Siksha 'O' Anusandhan Deemed to be University, K8, Kalinganagar, Bhubaneswar-751003, Odisha, India, [3]Ph.D. Research Scholar, Siksha 'O' Anusandhan (Deemed to be University), K8, Kalinganagar, Bhubaneswar-751003, Odisha, India, [4]Scientist B, Division of Toxicology, ICMR-National Institute of Occupational Health, Meghaninagar, Ahmedabad-380016, Gujarat, India

Abstract

When the external auditory canal is infected with an isolated fungal infection, it is called Otomycosis. It seems to be a very common clinical condition found in the outpatient department of otorhinolaryngology all over the world. The etiological microorganisms that form biofilm inside the earcanal are mostly Aspergillus and Candida species. Improper self-cleaning,self-medication, and insert of unnecessary tools into the ear canal can lead to the onset of otomycosis. The major symptoms of otomycosis are earache,ear discharge, and hearing loss. So the right diagnosis is a must to take a percussive step during the primary stage of infection. But when infection is spread up to a mastoid area with suppurative condition then it needs special medical attention especially in patients with low immunity. This comprehensive review has the aim to bringattention to self-hygiene and proper health education to maintain a healthy life.

Keywords: *Otomycosis,external auditory canal, Asparigellus, Candida species.*

Introduction

Otomycosis affect external ear canal; is simply known as an ear infectious disease which causes inflammation, more seen in dusty, warm and humid area.[1] The fungal species (Candida/Aspergillus) are commonly found causative microorganisms oragents. Black pepper like appearance seen with Aspergillus niger and Aspergillus fumigates and candida albicans gives white fluffy otorrhoea.[2] Habit of swimming (not drying ear after swimming), long term persistence and recurrence infection in-ear, without proper consultancy of doctor use of ear drops, use of steroid containing medicine & oil, excessive accumulation of ear wax, not keeping ear clean, etc can because of otomycosis.[3] In recent years,because of having a week immune system opportunistic fungal infections have gained greater importance in medicine. However, such fungi are very common to all categories of people and produce infectionmostly in immunocompetent hosts[4]. Special care should be taken to prevent invasive bone(temporal) infection and hearing loss. So treatment should be administered as soon aspossible especially inpatient with low immunity.[5] If otomycosis treatment is not taken properly then there is a chance of recurrence.[6] Along with this, increasing cases of antifungal resistance is one of the causes of recurrence.[7,8] so adequate treatment and follow up should be done to prevent the invasion of fungal infection.[9] This comprehensive review aims to create awareness about otomycosis and its management.

Method of Literature Search: Research articles regarding otomycosis were searched through a multiple systemic approach. First we conducted an online search of the Scopus, PubMed, and Medline database with otomycosis, fungal infections of external auditory

canal, and antifungal treatment of otomycosis. The abstracts of the published articles were identified by this search method and other articles identified manually from citations. This manuscript reviews the details of otomycosis patients along with its important medical problems. This review article presents a baseline from where further prospective trials for otomycosis could be designed and helps as a spur for further research in this medical hazard.

Epidemiology: The complex structure of ear help in hearing as well as also maintain equilibrium. Ear problem cab of many types in different age groups of patients. One of the inflammatory condition; otitis externa (acute/chronic form) affect 4 in 100 people acute form and whereas 3-5% of the population suffer from chronic otitis externa.[10] In Saudi Arabia, one study showed around 49.3% of participated people had ear problems that 37% of elderly patients were having hearing impairment and 9.4%-2.9% of people showed otitis media.[11] A study done by Gorems et al showed,4 yrs age children had acute ear infection whereas 15-44 yrs age group patient showed chronic ear infection.[12] some of the studies[13,14,15,16,17] reported otomycosiswith high incidence in tropic countries.It has been seen that onset of otomycosis infection more in July- Aug months and young manage group patients showed more ear infection.[15,18,19] Some studies[13,14,17,20,21] done by pontes et al. (2009), Fasunla et al. (2008), Barati et al. (2011), Aneja et al. (2010) and Lia et al. (2012) reported female otomycosis in female although the prevalence of otomycosis is less in a female patient. Nazeer et al in 2015 reported high incidence of otomycosis at age range of 21-30 yrs group.[22]

Diagnostic Method: Otoscopy and biomicroscopy are the instruments help in the diagnosis of otomycosis. The otoscope has a light, a magnifying lens, and a funnel-shaped viewing piece, which use to examine the ear canal and eardrum. Biomicroscopy is a procedure of examination of tissues by microscopy. Some symptoms like severe itching, earache, ear discharge, and hearing loss reported by otomycosis patients.[23] In the case of otomycosis, with instillation of coconut oil into the external ear revealed high association (36.59% Nazeer et al[22] in 2015 reported a high association between otomycosis and use of coconut oil inside ear. Coconut oil capable of inhibiting spore germination[24,] therefore, help to keep conidia deposition in-ear and further facilitate the development of otomycosis. Another factor is the use of unsterile pins and sticks. This unhygienic way of cleaning ear leads to fungal infection development in the ear canal and it can also damage the skin which is protected from infection entry as a first defense.[22] Aspergillus fungal infection can be inspected by the presence of conidiophores in case of sporing aspergillus but when fungi at the hyphal stage then may not be picked up at the time of swabbing because hyphae gets embedded ear debris and wax. Thus right diagnosis is a must and lesion should not be overlooked and can prevent unnecessary exposure to antibiotics.[25]

Clinical Presentation: Ear blockage and pain could be the first symptom. This could be due to the accumulation of microbial colonization and blockage that leads to pain. Some other symptoms were also seen like discharge, itching,and otalgia.[26,27,28] Although, these symptoms are by no means specific to fungal infection. Yehia MM[29] et al 1990 suggested that the disease is not highly infectious. Initially mild discomfort pruritis with erythema seen then in moderate stage pain increase with oedematous erythema & seropurulent discharge. In severe condition may cause severe pain with hearing loss due to ear canal obstruction[10]

Etiopathogenesis: There is more chance of colonization of fungi at the outer surface of the ear as this surface having a humid area with suitable ph for microbes.[30] Clinical observation and microbiological testing must know the exact causative organism of infection.It was thought previously that only fungi are responsible for otomycosis but further studies showed an association of bacterial with this infection[23]. Pseudomonas aeruginosa and staphylococcus aureus association has been seen with otomycosis. Osguthorpe et al 2011reported the 10% of association of fungi with primary condition. it has been also observed through otoscopic examination that black fuzzy growth on cerumen may cause slight deafness due to obstruction of the external auditory canal.And among candida species candida albicans is seen to be more associated with otomycosis. Invasive otomycosis is more frequently caused by A. fumigatus than A. niger[1,31].

Treatment: Thus early diagnosis and the right treatment is must to prevent development of further complication. As bacterial infection also produce the same symptoms sometimes so microbial testing is a must before the start of treatment. Suction evacuation and proper cleaning is the first step of treatment and dryness of ear should be maintained.[31] Syringing of the canal should be avoided as it can cause perforation and

facilitate the progression of infection. Antifungal should be advice after antifungal sensitivity test. The topical therapy with antifungal or other antimicrobial agents is also necessary. Effective choices include clotrimazole cream, powder or solution (1%), amphotericin B (3%), flucytosine (10%), econazole cream (1%), thiomersal (Merthiolate) or Cresyl acetate solution. Salicylic acid, griseofulvin, and ketoconazole are less effective. Econazole (1%) solution is very effective in vivo in the treatment of otomycosis within 1-3 weeks (Bassiouny et al, 1986).[32]When topical antifungal not responding then systemic antifungal itraconazole for superficial infection and voriconazole for deeper infection should be prescribed.[33]

Conclusion

This study revealed that, most of the study of otomycosis found that predominant fungal species are Aspergillus and candida which showed great association with otomycosis. Treatment depend on microbial involvement and the general health of the patient. Empirical therapy of treatment should be avoided and should maintain proper self-hygiene to avoid complications.

The Diagnostic and Therapeutic Application of Laser Exclusively in the Periodontal Field

Rashmita Nayak[1], Abhijeeta Mahapatra[2], Rinkee Mohanty[3], Abhaya C. Das[4], Gatha Mohanty[5], Utkalika Das[6]

[1]Professor, Department of Periodontics and Oral Implantology, [2]Professor, Department of Prosthodontics, [3]Professor & Head, Department of Periodontics and Oral Implantology, [4]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [5]Senior Lecturer, Department of Periodontics and Oral Implantology, [6]Tutor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

When laser energy is used as a therapy modality for the prevention, treatment, and management of different types of periodontal disease, it emerged into a very exciting therapeutic tool bringing a huge success with it. Various types of lasers are available today in the modern technology world. Along with the types of lasers, also available the various options to choose the right wavelength according to the treatment modality. Not only is the laser used for root surface procedures, but also the soft tissue manipulation in the field of Periodontology. This makes periodontal treatment by dental laser a grand success as reported in a myriad of literature. The only mandatory condition applied to be applied is the sound knowledge of the clinician in choosing the right type of laser with the required wavelength for a particular periodontal procedure. No other field of dentistry still has seen so many marvelous transformations in the healing and success in the management of the soft tissue after a periodontal procedure. There is a huge application of the usage of Laser in the periodontal world exclusively, which is the goal of this review paper.

Keywords: *Periodontics, lasers, laser uses.*

Introduction

One of the first CO_2 lasers used for oral soft tissue applications was introduced in 1987. The history of laser therapy as applied to the field of Periodontics begin in the early 1960 with the development of the argon, carbon dioxide (CO_2), and neodymium: yttrium-aluminum-garnet (Nd:YAG) lasers. The next major advance in the expansion of laser technology for soft tissue use was the introduction of a contact delivery system for the Nd: YAG laser in 1984. A simple handpiece through which the fiberoptic is threaded, and then passed through a disposable tip allows the energy to be focused at the tissue surface for cutting or ablation or in an unfocused position above the tissue for other uses. This system opens up the door to a wide variety of clinical applications. YAG lasers have been used for osseous surgical and decay removal procedures, whereas the other laser types do not lend themselves to hard tissue applications. Lasers today are becoming smaller and more portable and are being used for an ever-increasing variety of periodontal and soft tissue applications. However, along with the therapeutic property, the dental laser also has the diagnostic property.[1-5]

Classification of Lasers in Periodontics Based on Their Usage:

1. **Therapeutic uses:** Non-surgical therapy and surgical therapy
2. **Diagnostic uses:** Detection of caries and dental calculus, measuring tooth mobility
3. **Prevention uses:** Antibacterial effect in the dentistry can be achieved through Laser toothbrush. It is achieved by using the low output semiconductor laser of almost 630 nm. Also,a low-level laser therapy toothbrush is been implicated in the treatment of dentin hypersensitivity.[5]
4. **Other application:** Instrument sterilization, Bio-stimulation

Laser and its usage exclusively in the periodontal field:

1. **Scaling:** The Er:YAG, CO_2 laser, and diode laser are highly absorbed in water which takes care of the temperature makes scaling easier exclusive of any carbonization. These lasers are also used for the bacterial reduction, often known as Laser Bacterial Reduction (LBR). With the thin fiber optics, these lasers are used for the sulcular debridement to make the gingival sulcus sterile free from the viable putative microorganisms and thus causes bacterial reduction.[6]
2. **Root planning:** The CO_2 laser is highly absorbed by water is used for root planning to achieve a clean smooth cemental surface for the proper periodontal ligament cells attachment.
3. **Sub Gingival Curettage:** The Nd:YAG and Er:YAG laser lasers are used for subgingival soft-tissue curettage These lasers are set at a particular wavelength suitable for it. CO_2 laser is efficiently used for the granulation tissue removal from the pocket during flap surgery along with the removal from the bony defects like craters. The advantage is these lasers can well differentiate between the healthy gingival and the infected granulation tissue, and thus does not sacrifice the healthy tissue. The patient comfort is maximum here as it a painless and within a much stipulated time.[7]
4. **Cauterisation of highly vascular lesions and hemangiomas:** The Argon laser is used here. It produces coagulation, vaporization, or both and helps in the cauterization of the highly vascular lesions in the oral cavity. The bleeding is minimal and the post-operative healing is very comfortable for the patient. It prevents recurring of certain vascular lesions like pyogenic granuloma.[4]
5. **"Laser pocket thermolysis":** Argon laser is been utilized to keep the line of control of the putative pathogenic microflora like Prevotella and Porphymonas in adjunct with SRP.It is done with the insertion of the tip and the tip is stimulated circumferentially till the base of the pocket, thus infection arising pathogens get carbonized with rapid healing.[4]
6. **Gingivectomy:** The Co2 laser is been used as it is very much effective in removing masses of soft tissue by ablation, as in phenytoin induced hyperplasia and gingival hypertrophy resulting from other inflammatory stimuli. It results in a dry neat bloodless site as the blood vessels get coagulated easilyand chances of bacterial risk also lessen to a great extent. Healing is fast and comfortable for the patient.[6]
7. **Enhance Guided tissue Regeneration:**The Er: YAG, Nd: YAG laser and CO2 laser are used to reduced inflammatory response, thermal necrosis, and a firm scar of the wound margin and less wound contraction which causes a delay in re-epithelialization. Thus the epithelialization growth is stopped and the periodontal cells are guided to grow and occupy the place for tissueregeneration.[1]
8. **Frenectomies:** The Co2 and Nd: YAG laserboth can be used here. When frenectomy is performed via laser ablation,neither sutures nor surgical packing is necessary as the surgical site heals by secondary intention. The laser frenectomy reduces frenal strain and encourages the health of the gingiva.
9. **Biopsy:** The Co2 laser is used only for the laser excisional biopsy to avoidelectrofulguration. As its penetration is poor, hence it is fit to use for the close to crucial anatomical structures.[1]
10. **Anesthetic effect:** The pulse duration of the Nd:YAG laser is 150u.s which is apparently below the level of the neuronal action potential, thus the anesthetic effectis achieved in the indicated diagnosis area.[3]
11. **Esthetic gingival procedures:** The Er: YAG laser is used mostly for this type of treatment. Crown lengthening, to treat gummy smile as it precisely ablates the soft tissues and also wound healing is

fast. Dr. Eshom (2002) popularized a procedure "closed-flap" crown lengthening to trim and shape bone tissue to accomplish biologic width without involving a soft tissue flap.[7,10]

12. **Exposure of unerupted and partially erupted teeth:** The Nd:YAG laser is used to ablate the soft tissues around theunerupted or partially erupted tooth for the orthodontic treatment. To place an orthodontic bracketto pull the unerupted tooth, tissue removal minimally and conservatively is mandatory to access the unerupted tooth. This laser is advantageous in creating a very conservative way of tissue removal, and also the bloodless surgical field is achieved.[8]

13. **Ablation of the hard tissues:** The Argon laser can be utilized as a smooth laser knife, for cases like Coronoplasty, Enameloplasty.[6]

14. **Hypersensitivity:** Dentin hypersensitivity can be treated successfully with the help of the lasers which are of two different categories like: Low-level lasers like GaA1As diode laseracts at the nerve level, thus eliminating sensitivity, and middle-level lasers like Nd: YAG and CO_2 lasers desensitize causing contraction and occlusion of the dentinal tubules.[9]

15. **Laser-Assisted New Attachment Procedure (LANAP):** LANAP, which ingrain free-running pulsed Nd:YAG laser, enhances the intangibleaim of renewal of attachment apparatus giving rise toa true regeneration. LANAP is a carefully intended management procedure which not only aims at bactericidal and detoxification effect but also aims to reduce the source of the infection.[1]

16. **Laser root conditioning or root etching**: The CO2, Nd:YAG, Er:YAG, Diode laser are used here. CO2 lasers are a popularize system to achieve root conditioning with a superior fibroblastic movement, cellular abundance, and larger fibroblast connection and possess a superior caliber for the removal of smear layers.[1]

17. **Depigmentation:** The Er:YAG laser is applied for the elimination of nonstandard gingival mark, like metal tattoos. When the oral tissue was seen to be filled with melanin pigmentation, it readily absorbs the blue-green visible light of the argon laser yielding a thermal effect from the conversion of the energy and thus causing ablation of the melanin pigments.[10]

18. **Osseous surgery:** Er:YAG laser is used for the removal of exostosis accompanied with the saline spray, collateral damage risk is minimized which is seen maximum with the Rotary instruments as they get entangled with the soft tissues during the resection procedure. Also it is preferred by the patient for the comfort, as less noise emitted while bone tissue grinding.[6]

19. **As an analgesic and anti-inflammatory agent:** The " LLLT" or the "Low-Level Laser Therapy"/ Therapeutic Lasers/Low-Intensity Level Laser are the other names whereas the therapy has been referred to as "Biostimulation" and "Biomodulation". These lasers are usually minor, very reasonable and function in the milliwatts ranging from 01-500 MW. The pain signals get blocked by the laser and thereby the sensitivity of the nerve comes down and also the pain perception is decreased significantly.[10,12]

20. **Accelerated tissue repair and cell growth:** The Nd:YAG laser generatesphoton that gets deeply penetrated inside the tissue and thereby its stimulation efficiency stimulates the cell center for energy production. This energy created helps the cell nicely to absorb the beneficial nutrients and also guides the cells to let go of the unwanted waste in a little time.[12]

21. **Laser in Implants:**

A. **Laser in ablating the soft tissues around the implant:** The Nd:YAG laser is used to ablate the oft tissues lying around the implant in the second stage for the implant fixture exposure. This laser has got the feature of carbonized tip for the absorption of the laser light radiation turning into thermal energy, which prevents penetration into the tissue deeply. If there is an adequate zone of attached gingiva around the implant and no trephining of bone is necessary, ablation of the overlying soft tissue around the implant can be achieved with little or no bleeding. The lack of hemorrhage, with the resulting clear field, and minimal tissue rebound often allow for the abutment placement and temporization in the same visit. Gingival troughing with the pulsed Nd:YAG laser is aconvenient, painless method of preparing for accurate impressions and is an excellent substitute for retraction cord. There is no blood in the field, and lased circumferential tissues heal quickly and painlessly.[7]

B. **Laser in Implant Maintenance:** The implication

of the Nd:YAG laser resulted in surface melting, loss of porosity, and other alteration including physical changes in the crystalline structure of the hydroxylapatite coating (Block et al 1992). So the usage of Nd:YAG is contraindicated in these cases. It has been shown that the CO_2 laser can be used for the second stage uncovering procedures in endosseous implants, sculpting tissue around the existing implant, control of mucosal abnormalities, and control of implant soft tissue complications. The CO_2 laser is ideal because its energy is rapidly absorbed by the high water content of mucosa so that the depth of tissue necrosis or vaporization is minute (only 100 – 200 microns). The potential harmful thermal energy is dissipated rapidly and does not reach the metal surface of the implant.[2]

C. **Treatment of Peri-Implantitis:** Every laser available in the market cannot be applied for the implant maintenance, exposing submerged implants, or for the treatment of peri-implantitis. Nd:YAG laser is never appropriate for implant treatment, because it simply ablates the implant surface made of titanium irrespective of yielded energy. On the other hand, a diode laser is preferred here, as it does not intermingle with the titanium surface of the implant.[6]

D. **The LAPIP Protocol:** This is coined by McCarthy as "Laser-Assisted Peri-Implantitis Procedure" as a modification of LANAP which could be applied in contaminated implants. Laser, takes off inflamed pocket tissue, dislocate the biofilms, and purify the root/implant plane. Drop off in inflammation and a laser-induced hemostasis added disinfected the tissue outpouring a tough blood clot to lock the method.[1]

Waterlase System: Waterlase-^{TM} uses hydrokinetic technology, laser-energized water to cut or ablate soft and hard tissues. Laser-powered hydrokinetic system (LPHKS) uses an Er, Cr: YSGG crystal. With this particular wavelength less hemostasis is seen and anesthesia is not typically required. This not only increases patient comfort and acceptance, but also allows performing the procedure in the entire mouth in one sitting. Post-operative discomfort is also minimized. Using the Waterlase, one can carry out all of the subsequent procedures-Frenectomy and frenotomy, gingivectomy, gingivoplasty, curettage, vestibulopathy, operculectomy, gingival troughing for crown impressions, soft tissue crown lengthening, expose unerupted teeth (hard and soft tissue impactions); flap surgery, full-thickness flap; partial-thickness flap, degranulating bone, osseous surgery as osteoplasty and osseous recontouring; osteotomy; osseous crown lengthening; removal of diseased granulation tissue from the bony defects; laser soft tissue curettage of the post-extraction tooth sockets and the periapical area during apical surgery and perforating the bone to access the blood supply.[6]

Conclusion

The regular usage of the laser has become very beneficial and comfortable for both the surgeon as well as for the patient. It seems to be a very flourishing and promising field in the future with the advancement of science and technology. It aids in a much easier way than the conventional treatment protocols in dentistry. There is a great hope of usage of laser in both medical as well as in the dental field ahead of time.

Abstract

The Mouth is the mirror of the human body that reflects systemic disorders, and various systemic pathologies find expression in the oral region. Oral manifestations may be the initial feature or the only presenting sign in mucocutaneous diseases. Mucocutaneous disorders share two features in common: An immune-mediated pathogenesis and possibly common clinical appearance termed as 'Desquamative gingivitis'. Desquamative gingivitis is mostly a manifestation of a wide array of vesiculobullous disorders; however, it may also result due to endocrine disturbances, chronic infections, and allergic/chemical reactions. Hereby, presenting a case of oral lichen planus with Desquamative gingivitis as the sole manifestation in a 35-year-old female patient.

Keywords: *Desquamative Gingivitis, Oral Lichen Planus, Wickham's striae.*

Introduction

Tomes and Tomes (1894) were the first to describe chronic desquamative gingivitis. However, the term 'chronic diffuse desquamate gingivitis' was coined by Prinz in 1932 for chronic diffuse inflammation cases.[1] Immune-mediated oral mucosal disorders frequently manifest as desquamative gingivitis (DG).[2]Chronic desquamative gingivitis is a clinical condition typified by the intense desquamation, erythema, ulceration and erosion of the marginal and attached gingiva, and blistering. The term "desquamation" originates from the Latin word 'Desquamare', meaning scraping fish flakes. Desquamation refers to the 'erosion of epithelial tissues, skin peeling, and exfoliation.[3] Earlier, Desquamative Gingivitis was regarded as a pathological entity of obscure etiology, possibly precipitated by the deficiency of sex hormones in postmenopausal females.[4] McCarthy et al., in 1960, suggested that desquamative gingivitis is not a conclusivelesion but a gingival response including vesiculobullous disorders and allergic reaction to chemicals/allergens. So only desquamative gingivitis suggests a specific clinical manifestation and is not a definite diagnosis.[5] Nisengard and Levineconsidered the following criteria(s) for a clinical diagnosis of DG: (i) Gingival erythema doesnot result from plaque, (b) gingival desquamation, (c) other intraoral and sometimes extraoral lesions, and (d) complaint of pain in the mouth, mainly due to spicy foods.[6]

Case Report: A female patient aged 46yrs reported with a complaint of burning sensations in the mouth mainly in the maxillary and mandibular gums for 6 months. History reveals that 6 months back the patient experienced burning sensations in the maxillary

gingiva, while taking spicy foods. Personal history reveals that the patient has attained menopause a few months back. Her medical history was unremarkable. Did not havea history of vesicle formation in the oral cavity. General physical examination did not reveal any cutaneous, ocular, and genital lesions. On clinical examination, there was a area of desquamation involving interdental, marginal and attached gingiva in relation to 14,15,16,24,25,26,34,35,36 & 44,45,46 region (Fig. 1 & 2). The desquamated area was surrounded by slender, faint white radiating striations (Wickham's striae). There was a loss of stippling in the desquamated lesion. The area showed bleeding on probing. palpationin the region did not give rise toa new lesion (Negative Nikolsky's sign). Taking into account chronic history, characteristic clinical presentation (desquamative gingivitis bordered by Wickham's striae, absence of vesicle formation, and negative Nikolsky's sign), a provisional diagnosis of desquamative gingivitis secondary to Erosive Lichen planus was given. An incisional biopsy was performed in the maxillary right posterior region in gingiva. Histopathology revealed acanthotic epithelium with a band like lymphocytic infiltrates and saw tooth rete pegs(Fig. 3).Fibrinogen bands in the basement membrane zone were observed on direct immunofluorescence study (Fig. 4). The histopathological and immunofluorescent confirmed the diagnosis as desquamative gingivitis secondary to erosive Lichen planus. After scaling, the patient was prescribed corticosteroids (Turbocort paste) to apply 3-4 times daily for 15 days and vitamin C chewable tablet (tab Celine BD x 15 days). However, the patient didn't turn up for follow up.

Discussion

The oral physician should be familiar with the varied clinical manifestations of desquamative gingivitis and should be able to formulate a precise differential diagnosis. The pathogenesis of Desquamative gingivitis associated disorders usually falls in 2 major categories- a) Cell-mediated (e.g. Oral Lichen Planus, and lupus erythematosus), b) auto-antibody-mediated (e.g. Pemphigus Vulgaris, and Mucous membrane pemphigoid). Pemphigus Vulgaris shows hyperkeratosis, while Mucous membrane pemphigoid shows blistering.[7]

According to Glickman and Smulow, desquamative gingivitis represents a clinical feature common to a wide array of disorders. A classification was formulated taking into account the etiologic factors, together with histologic and immunologic features.

A. Cutaneous disorders

- Contact stomatitis
- Psoriasis
- Lichen planus
- Cicatricial pemphigoid
- Pemphigus
- Bullous pemphigoid
- Epidermolysis bullosa acquisita

B. Disturbances of Endocrine

- Hormonal imbalance in postmenopausal females and following oophorectomy
- Testosterone imbalance
- Hypothyroidism

C. Response toAge

D. Exaggerated gingival response to biofilms

E. Idiopathic

F. Chronic infections

- Histoplasmosis
- Chronic candidiasis
- Tuberculosis

The term lichen planus (LP) is coined from the Greekword lichen meaning; tree moss and planus is a Latin word meaning; flat. The first person to describe the condition was Erasmus Wilson (1869)[9] Lichen planus (LP) is a chronic inflammatory, immunological disorder that affects the skin, nails, hair, and mucous membranes. Cutaneous lichen planus (CLP) lesions present with characteristic 6 "Ps"- "Purple, Polygonal, Planar, Pruritic, Papules, and Plaques", and frequently affect the flexor surfaces of the extremities.[10] Cutaneous LP lesions are recurrent, not contagious, exhibit self remission, and sometimes cause pruritis.[11]The oral lesions are recalcitrant to therapy, rarely undergo self remission, exhibit chronicity, and present varied clinical manifestations. The precise etiology of the OLP lesions could not be delineated. Lichen planus, an auto-immune disorder, is mediated by CD 8 + T cells, macrophages, and Langerhan's cells. Immune mechanisms trigger apoptosis resulting in cell destruction and the appearance of characteristic histological changes.[13]

OLP is frequently associated with psychosomatic

ailments (stress, anxiety, and depression). There exists ever al endogenous or exogenous predisposing factors for OLP. Exogenous factors include drugs (antihypertensive drugs & NSAIDs), amalgam restoration, infections (HCV & H. pylori), and food allergies. Endogenous factors include genetic factors and autoimmunity.[14]

The disease affects 0.5%-2% of the general population, with a female predilection between 30-70 years of age.[14] However, published literature has reported the infrequent occurrence of OLP in the pediatric population.[15] Our patient was a 46-year-old female who reported with burning sensations in the maxillary gingival region. The patient has attained menopause last year and was under depression.

The oral lesions have been classified into 6 types-reticular (most common form), erosive, papular,plaque-like, atrophic, and bullous (least common form).[15]The majority of the lesions are bilaterally symmetrical. The Buccal mucosa is the most frequently affected site, although, lesions are also seen on the dorsum and lateral aspect of tongue, vestibule, lip, and gingivae.[16] One of the characteristic clinical manifestations of OLP is the presence of Wickham's striae. This was named after Louis Frédéric Wickham who described the clinical appearance of OLP as the presence of greyish striae and dots.[17]

About 10% of OLP patients present with the disease localized to the gingiva, is termed as desquamative gingivitis (DG). DG can present as reticular, erosive, or atrophic subtypes. DG lesions may be aggravated during periods of psychological stress, anxiety, mechanical trauma (Koebner's phenomena), and chronic low-grade irritation.[18] OLP with isolated desquamative gingivitis may be characterized clinically by the presence of erythematous lesions (atrophic LP), ulcerations (erosive and/or ulcerated LP) or vesiculobullous lesions (bullous LP). OLP generally has a typical clinical presentation and distribution, but the atrophic and erosive forms exhibit diagnostic challenge.[19]

Our patient presented with diffuse desquamative lesions in the maxillary and mandibular posterior gingival region. The desquamated lesion was bordered by faint grayish-white striae on the periphery.A detailed anamnesis, thorough physical examination, and histopathology are the keystone for diagnosis. However, clinical diagnosis usually sufficesin classical lesions (Wickham's striae, erythematous area).[20] The characteristic clinical manifestations usually encompass bilaterally symmetrical reticular lesions. The essential histopathological features are liquefaction degeneration of the epithelial basal layer, hyperkeratosis with ortho and/or parakeratosis, band-like lymphocytic infiltrate in the connective tissue area, and sawtooth rete pegs.[12] In the present case, histopathological and Immunofluorescence findings were consistent with OLP.

Published literature has established an ODP association with multiple systemic comorbid conditions like as diabetes, hypertension, metabolic syndrome, thyroid disorder, psychosomatic diseases, renal disease, gastrointestinal disorder, and genetic predisposition to cancer. These systemic symptoms shows that OLP should be considered as a systemic disorder. All Doctors should work with primary healthcare physicians to rule out causative factors for the associated comorbidities.[22]

There exists no definite management protocol for OLP. Patient education and motivation to maintain meticulous oralhygiene is mandatory. Therapy primarily focuses on minimizing the duration and condition of symptomsincreases. Reticular and plaque formsthat are not symptomatic do not require pharmacologic intervention, the patient is advised to follow up.[23] Various medications are prescribed to check OLP which includes steroids (topical, intralesional, and systemic), retinoids, immunosuppressive, and immunomodulators. These treatment protocols can be used to control as there are variations in patient responses.[24] The patient was prescribed low potency topical steroids (Turbocort) to apply topically and chewable vitamin C tablets.

Figure 1: Desquamative gingivitis with Wickham Striae

Figure 2: Desquamative gingivitis with Wickham Striae

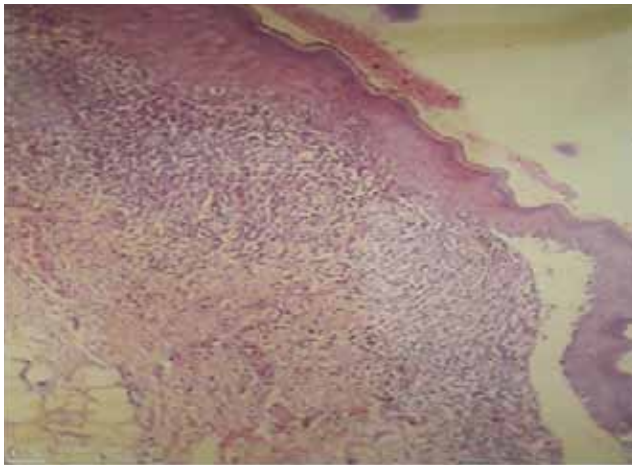

Figure 3: Acanthotic epithelium with basal cell degeneration and saw tooth rete pegs

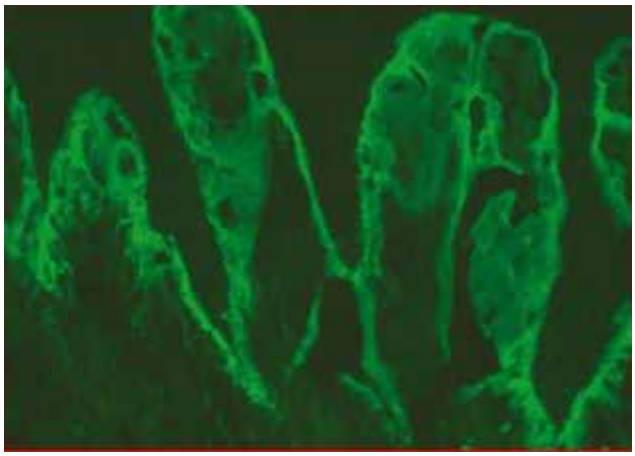

Figure 4: Shaggy bands of fibrinogen on basement membrane

Conclusion

Desquamative gingivitis per se is not a disease entity, but, a manifestation of a wide array of disorders. Gingival desquamation may present as the only manifestation in some cases; while it may be associated with other oral and extraoral manifestations, like Wickham's striae in lichen planus, Nikolsky's sign in pemphigus, ocular involvement in mucous membrane pemphigoid which helps in diagnosis. Cases where gingival desquamation is the only presenting feature; care should be taken for proper diagnosis as they may mimic plaque-induced gingivitis. Thus familiarization of various clinical presentation of gingival desquamation is essential for early diagnosis, treatment planning, and combating potential complications.

Cone Beam Computed Tomography Analysis of Three Method of Intracanal Calcium Hydroxide Placement

Naomi Ranjan Singh[1], Siba Prasad Jena[1], Lora Mishra[2], Debkant Jena[2],Sumit Dash[2]

[1]Senior Lecturer, [2]Professor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Aim: To compare and evaluate the quality of three different method of intracanal placement of calcium hydroxide paste through CBCT.

Methodology: Thirty single-rooted mandibular premolars were decoronated and cleaning and shaping was done using Protaper Rotary Files(till F4). The canals were divided into the following three groups which were filled with a radiopaque calcium hydroxide paste based on three insertion method (n = 10, each): using a Master Gutta-percha cone (MGP), Pastinject (PIT), and a technique combining conventional hand files with ultrasonic activation(UST). The quality of fillings was assessed using CBCT by examining the number of canal walls coated dividing the root into thirds. Statistical analysis was done using the Chi-square test of independence.

Results: The canals filled with combined technique (hand files with ultrasonic activation) had a better coating of canal walls followed by Master GP cone and Pastinject, with significant differences between them.

Conclusion: From the images obtained through CBCT analysis, calcium hydroxide placed utilizing hand files with ultrasonic activation (UST) produced better coating of canal walls over Master GP and Pastinject techniques.

Keywords: *Calcium Hydroxide; Intracanal medicament; Placement method.*

Introduction

The reduction or elimination of bacteria is one of the important objectives adding to the success of an endodontic treatment. Cleaning and shaping or chemomechanical preparation of the root canal is a vital phase of endodontic intervention and it has been found even after cleaning and shaping, bacteria may still be viable.[1,2] Therefore, intracanal medication may be a valuable adjunct to such cleaning and shaping procedures in the disinfection of the root canal system, reducing the endodontic microbiota.[3-8] Calcium hydroxide [$Ca(OH)_2$] is acknowledged as the most effective intra-canal medicaments used in endodontic intervention due to its bactericidal properties.[9] It has been effective in killing microorganisms through direct contact and hence advised to be close to the appropriate tissues as well as to be used with maximal density and depth till the working length of the root canal to permit its biological effects.[10] Several method have been employed for intra-canal $Ca(OH)_2$ placement, however, none of the studies have assessed method of placement three-dimensionally.[11-20] Hence, this study aimed to compare and evaluate the quality of three different method of intracanal placement of calcium hydroxide paste through CBCT.

Materials and Method

Thirty single-rooted mandibular premolars extracted for orthodontic reasons were selected. The teeth were examined for fracture, cracks, or any other defect after which they were stored in a normal saline solution that was changed daily. Samples were radiographically examined for the presence of a single canal. The crowns were decoronated at 15 mm from the apex to standardize the root length. The working length was determined by subtracting 1mm from the length at which #10 K file tip extruded apically. Cleaning and shaping of the root canals were done with Protaper Rotary Files (Dentsply Maillefer, Ballaigues, Switzerland) using the crown-down technique up to size #40(F4). During the preparation, the root canal was irrigated with 2 ml of 5.25% Sodium Hypochlorite solution after each instrumentation and the final rinse was carried out using 5 ml of 17% ethylenediaminetetraacetic acid (EDTA) for 1 min followed by a final flush of saline. After cleaning and shaping, the canals were dried with paper points (Dentsply Maillefer, Ballaigues, Switzerland). Three U-shaped wax rims were prepared and ten teeth were randomly embedded in each rim in such a way that there was 3 mm of modeling wax all around the teeth to simulate the soft tissue around teeth and increase image contrast. All the teeth were numbered from 1 to 30. In this way, the position of each sample remained constant.

The teeth were grouped based on three insertion techniques of a ready-mix paste of Calcium hydroxide (AvueCal, Dental avenue) which was dispensed on a glass slab.

- Group 1, Master apical GP (MGP, n=10): A Protaper Universal GP cone F4 (DentsplyMaillefer) coated with $Ca(OH)_2$paste was inserted into the canal till the apex and removed in a counterclockwise direction. This process was repeated three times for each tooth.
- Group 2, Pastinject (PIT, n=10): A Pastinject #35 paste carrier (MicroMega) coated with $Ca(OH)_2$ paste was inserted into the working length of the canal 2mm short from the apex, rotating at 500 rpm on a contra-angled handpiece, then withdrawn in a continuous movement while maintaining contact with the surface of the canal wall. Slight pumping motion was applied. This process was repeated thrice for each tooth.
- Group 3, Conventional hand files with ultrasonic activation (UST, n=10): A #40 hand K-file coated with $Ca(OH)_2$paste was inserted into the canal up to the root apex and removed with counterclockwise movement, after which the ultrasonic file was layered with the same paste and inserted into the canals, 2 mm short of the working length and activated at full power mode(with the water off), then withdrawn through the use of short, vertical pumping movements while maintaining contact with the canal wall. The process was repeated thrice for each tooth.

Outcome Assessment: Post $Ca(OH)_2$ placement CBCT imaging was done for all the samples, and the assessment of root canal filling of each specimen was estimated by two examiners using NNT viewer software version 7.2 by NewTom Cone beam 3D imaging in MPR view. The assessment of paste fillings was executed based on the number of canal walls (buccal, lingual, mesial and distal) coated dividing the root into thirds (cervical, middle and apical). Scoring was given as 0,1,2,3 and 4 depending on the number of walls coated in each third. Statistical analysis was done using the Chi-square test of independence for studying the association between Method/technique (Master GP, Pastinject & Conventional Hand file plus Ultrasonic Activation) and the number of walls coated. IBM SPSS Statistics 24, SPSS South Asia Pvt. Ltd. was used for data analysis.

Results

The association of wall coating with the type of technique used for the placement of Ca $(OH)_2$ in the coronal third is presented in Table 1 and the analysis did not find any significant difference (p=0.329) as a maximum number of the walls were coated with the paste in the coronal third with all the three techniques. However, analysis of the middle third revealed significant association of wall coating with the type of technique used (p=0.001) showing the highest number of wall coating with Conventional Hand file plus Ultrasonic Activation (UST) followed by Master GP (MGP) and the least with Pastinect (PIT) as presented in Table 2. Analysis of the Apical third showed a significant association of wall coating with the type of technique (p=0.014) with the UST technique having the highest number of wall coating followed by Master GP (Table 3).

Discussion

Calcium hydroxide is the most common inter-appointment dressing used as an adjunct to root canal disinfection after cleaning and shaping, especially in teeth with periapical lesions, and at least 1 week of its intracanal placement is recommended to reduce the number of residual bacterial load.[15] There are various therapeutic effects of a $Ca(OH)_2$ such as inhibition of osteoclastic activity, degradation of bacterial lipopolysaccharides, dissolving of soft tissues and apexification, etc. Even though the use of $Ca(OH)_2$ has now subsided with the use of other calcium silicate-based materials, it is still considered as the gold standard.

The maximum biological effects of $Ca(OH)_2$ is achieved when it is filled with the highest density along the entire canal working length which depends on the method in which calcium hydroxide is delivered into the root canal.[16,17] Various techniques have been employed

for intra-canal $Ca(OH)_2$ placement and it has been found that Lentulo-spiral provided better coating of canal walls.[14,15] However, results from another study showed Pastinject to be better than Lentulo-spiral.[21] Hence, in the present study Pastinject was used which gave the least result in coating the canal walls. This result contradicted the results of a study done by Deveaux et al. where Pastinject provided better root canal filling when compared with four other techniques which also included Lentulo-spiral and ultrasonic file.[11]

The use of ultrasonic files in the present study was derived from a study by La et al., where ultrasonic files were used for the placement of root canal sealers. However, the authors observed the ultrasonic vibrations to disrupt the sealer.[22] In the present study, a combined technique (UST) of K-file combined with Ultrasonic activation was employed which was found to be superior compared to the other two method, especially in coating the apical third of the root canal. This can be due to the ultrasonic vibration which enhanced the peripheral displacement of the medicament, even into the apical third, after the canal was adequately filled by manual K-file.

The use of Master Gutta-percha cone (MGP), which in the present study was found to be better after UST technique, was derived based on the results obtained from a study in which Master GP produced better coating of root canal sealer when compared to rotary and manual lentulo-spiral which was due to its better fitting to the prepared root canal as its size coincides with the last rotary file used during chemo-mechanical preparation.[23]

Calcium hydroxide that is oil-based although possessing an advantage of prolonged duration of action of the medicament also holds the disadvantage of difficulty in removing from the root canal. It has been found that residual calcium hydroxide on the canal walls obstruct sealer penetration into the dentinal tubules thereby affecting the bonding of resin sealer adhesion to dentin which markedly increases the chances of apical leakage of a root canal treated teeth.[24] Hence, in the present study a water-soluble Calcium hydroxide paste was used as it can be easily removed when compared with oil-based preparation.

A novel nondestructive technology in the dental-maxillofacial imaging, which has added to the ease in diagnosis and treatment plan, is the use of Cone Beam Computed Tomography (CBCT). Along with the 3D interpretation, it has various other advantages some of which are: lower radiation dose, shorter acquisition time, less space requirement, interactive display modes, etc.[25] Although CBCT has been used for the analysis of different techniques for calcium hydroxide removal, there is no literature available regarding its usage for intracanal placement of calcium hydroxide. Hence, CBCT imaging was done for the specimens in the present study.

The investigation done in the present study was limited to root canals with non-complicated anatomy. Hence, further study may be carried out in root canals with complicated internal anatomy along with the use of different types of vehicles and consistencies to ascertain the effectiveness of the technique in a clinical scenario, especially in the tooth with periapical lesion along with the use of CBCT.

Conclusion

Considering the limitations and assessing the images obtained through CBCT analysis, it can be stated that Calcium hydroxide paste placed using hand files with ultrasonic activation (UST) produced better coating of canal walls over Master GP and Pastinject techniques in single-rooted teeth.

Role of Stem Cells in Dentistry: A Review

Satabdi Pattanaik[1], Shashirekha Govind[2], Lora Mishra[3], Debkant Jena[3], Siba Prasad Jena[1]

[1]Senior Lecturer, [2]Professor & Head, [3]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The current strategy of dental treatment is based on 3 elements- restore, retain and revitalize. Replacing the lost or diseased tissue with the same natural tissue is a challenge in the field of dentistry. Keeping this in mind, the use of stem cells has emerged as a potential way for its ideal replacement. Stem cells are undifferentiated cells, which can differentiate or multiply into particular types of cells and tissues. Besides stem cells, scaffolds and growth factor abandoned their role in the field of regeneration. Stem cells can be easily isolated from the orofacial region and have the property to differentiate into osteogenic, odontogenic, adipogenic, neurogenic components. This review article will discuss both embryonic and adult stem cells, sources, and their role in the process of regeneration along with tissue engineering strategy.

Keyword: *Stem Cells, Sources of Stem Cells, Tissue Engineering.*

Introductions

Stems cells are special and multitalented cell types that can divide indefinitely and have the capacity of self-replication to give rise to a peculiar cell type.[1] Research of Stem cell is a very challenging topic in the era of modern biomedical investigations and stands steadily at the core of "Regenerative medicine". Substantial use of stem cells in various fields for the process of tissue regeneration and/or repair has gained tremendous interest.It can radically change the treatment of some diseases like Parkinson's disease, Alzheimer's disease,lymphoma, leukemia, brain and spinal cord injuries, teeth missing, blindness and vision impairment, hearing loss, heart failures and even paralysis.[2,3] The investigators isolated a class of pluripotent stem cells from a human embryo in the year 1998 and grow them in culture.[1] The emerging problem faced by medical and dental practitioners is organ failure or tissue loss. Various prostheses or mechanical devices have been used to replace the original tissues but none of them restore the original form and function of the damaged or loosed tissues. Hence, the integrity of the host tissue is not properly maintained. Additionally, these prostheses can induce inflammatory reactions in the host tissue and can undergo wear upon prolonged use as well.[4] Stem cell development and its implementation in these cases dramatically reduced the problems as it restores the normal form and function of the original tissue.

During recent years stem cell research is being continued for the development of novel regenerative therapies in dentistry. This article is focussing on the basics of stem cells and their possible role in dentistry. Unspecialized cells found in all multicellular organisms, which under appropriate signal can generate cells with different and more restricted properties, are called a stem cell stem cell or progenitor cells. All the stem cells, regardless of their source, have three general properties: prolonged self-renewal capacity; they are unspecialized; asymmetric replication to become one of the many different types of cells on receiving the appropriate signals from their environments. Signals can be in the

form of chemicals, e.g- growth factors, physical like the contact of cell with the adjacent cells, and contact with molecules in the environment.

Different sources of stem cells:

Sources can be either of the following:

1. Embryonic stem cells
2. Adult stem cells

Apart from these, stem cells can also be harvested from other sources like fetal stem cells, Umbilical cord stem cells, placental derived stem cells.

Embryonic stem cells (ESCs): ESCs- as the name suggests these stem cells are derived from the embryos, 2-11 days old (blastocytes).[5] These blastocytes contain 50-150 cells and differentiate into 3 germ layers:- endoderm, mesoderm, and ectoderm.[6] ESCs can grow in the laboratory and later used in research purposes. However, the inner cell layer of a fertilized embryo has been used for the cell culture. Legal or ethical consideration is required for this type of culture. Another variety of embryonic cells is Embryonic germ cells (EGCs). EGCs are pluripotent stem cells, originates from the primordial germ cells, give rise to gametes, and have the capacity to differentiate into all the three germ layers(4). Nevertheless, major drawbacks of this ESCs are they have the potential to induce tumorigenesis and immune rejection.[7,8]

Adult stem cells: Adult stem cells are otherwise called as postnatal or somatic stem cells. These cells are easier to isolate and no ethical or legal consideration is needed for this. The main goal of this adult stem cell is to maintain and repair the tissue of the concerned area and this cell founds in a particular area of the tissue called "stem cell niche". As mesenchymal tissues are the resident of most of the adult stem cells, they are togetherly called multipotent mesenchymal stromal cells (MSCs) or mesenchymal stem cells. Originally these were found in the bone marrow cells and are of 2 varieties a) hematopoietic stem cells and b) bone marrow stromal cells.[9] Other than bone marrow they can also be derived from the dental tissues, adipose tissues, skin, and other adult tissues.[10]

Sources of stem cell for tooth development: Epithelial-mesenchymal interactions lead to the formation of the tooth. Epithelial stem cells (EpSC) form ameloblasts, whereas Mesenchymal stem cells (MSC) give rise to osteoblasts, odontoblasts, cementoblasts, and fibroblasts of the periodontal ligament. These stem cells are influenced by chemical transmitters called signals.

Mesenchymal Stem Cells: For tissue engineering following are the mesenchymal progenitors that have been assessed.

Stem cells from human exfoliated deciduous teeth (SHED): Mesenchymal progenitors are mainly isolated from the pulpal connective tissue of deciduous incisors of humans.[11] They possess unique characteristics like self-renewal and multi- differentiation. Along with this, it can stimulate the formation of bone matrix in a lamellar pattern by organizing the host tissue.[12]

Adult dental pulp stem cells (DPSC): Authors have been investigated that adult dental pulp carries precursors can form odontoblast under suitable signals like pulp capping materials.[13] Pericytes found in the pulp can differentiate into both osteoblasts and odontoblasts. It also has the properties of self-renewal and self- differentiation. Another unique characteristic of DPSC is that it can differentiate into pro-osteoblasts even after 2 years of refrigeration, because the surface antigen present remained unchanged and give rise to dental tissue.[14]

Stem cells from apical papilla (SCAP): As the name suggest it is derived from the apical part of the human dental papilla. SCAP has higher proliferative capacity as well as higher efficiency than periodontal ligament stem cells. Along with the above it has an added advantage is that it can be easily isolated from human third molars. For immature stem cells developing dental papilla tissue provides greater source than the developed dental papilla tissues. SCAP has better in vitro proliferation capacity and also has superior regeneration capacity as compared to DPSCs.[15]

Stem cells from the dental follicle (DFSC): It has been observed after *in vivo* implantation of dental follicle cells new periodontal ligament, cementum, and alveolar have been formed.[16] Usually DFSCs are obtained from extracted 3rd molar at an early age.

Periodontal ligament stem cells (PDLSC): Progenitors present in the periodontal ligament have the property of self-renewal and can produce other tissues particularly cementum, periodontal ligament, and alveolar bone.[17] PDLSCs can also be obtained from the extracted tooth. The use of nitric oxide along with the proliferating PDLSC could be a challenging approach

for the management of periodontal diseases.[18] Authors have investigated the formation of PDL and cementum when PDLSCs were allowed to culture with apical tooth germ cells upon transplantation in mice.[19]

Bone marrow-derived mesenchymal stem cells (BMSC): It was observed BMSCs have the capability to produce cementum, periodontal ligament, and alveolar bone when these cells had implanted inside the deformed periodontal tissues. BMSCs have less odontogenic potential than DPSCs indicating all embryonic origin is quite different from each other.[20] They are closely related to bone morphology as well as with the pathology so mainly used in the regeneration process. These are mostly used in cases of regeneration as they have a very close relationship with the bone morphology and pathology. On the other hand it acts like microenvironmental modulators as it strives anti-inflammatory actions soon after transplantation.[21] BMSCs have tremendous effect in cases with osteopenia and bone defects using tissue engineering or cryotherapy.[22]

Tooth germ progenitor cells (TGPCs): TGPCs are spindle-shaped in morphology and have a high proliferation rate, usually isolated during the late bell stage from the dental mesenchymal tissue of 3 rd molar.[23] Unlike dental papilla stem cells TGPCs have odontogenic, osteogenic, neurogenic differentiation capacity.[24] A *in vitro* study showed TGPCs were capable of producing tube-like structures, signifying the confirmation of vascularization.[24]

Salivary gland derived stem cells (SGSCs): These stem cells arelined with epithelial cell, contains exocrine secretionand originates from endoderm. Mainly submandibular gland is selected from the isolation of stem cells as they have high proliferative capability and have the ability of expressing the associated markers.[25]

Epithelial Originated Dental Stem Cells: Epithelial derived dental stem cells are believed to be lost soon after the eruption of the tooth into the oral cavity. Enamel regeneration would be difficult as enamel producing ameloblasts are lost. Stem cell is the alternative approach for the creation of enamel surface. These stem cell types of stem cells can be isolated from-

1. **Epithelial stem cells from developing molars:** Epithelial stem cells usually isolated from the 3rd molar of juvenile or newborn animals.[26]
2. **Epithelial stem cell from rodent incisor:** An EpSC niche,found in the labial cervical loop of rodent incisor is accountable for the enamel matrix formation.[27] Since EpSC require implantation of rodent cells in the human mouth, it cannot be used in humans for treatment purpose.

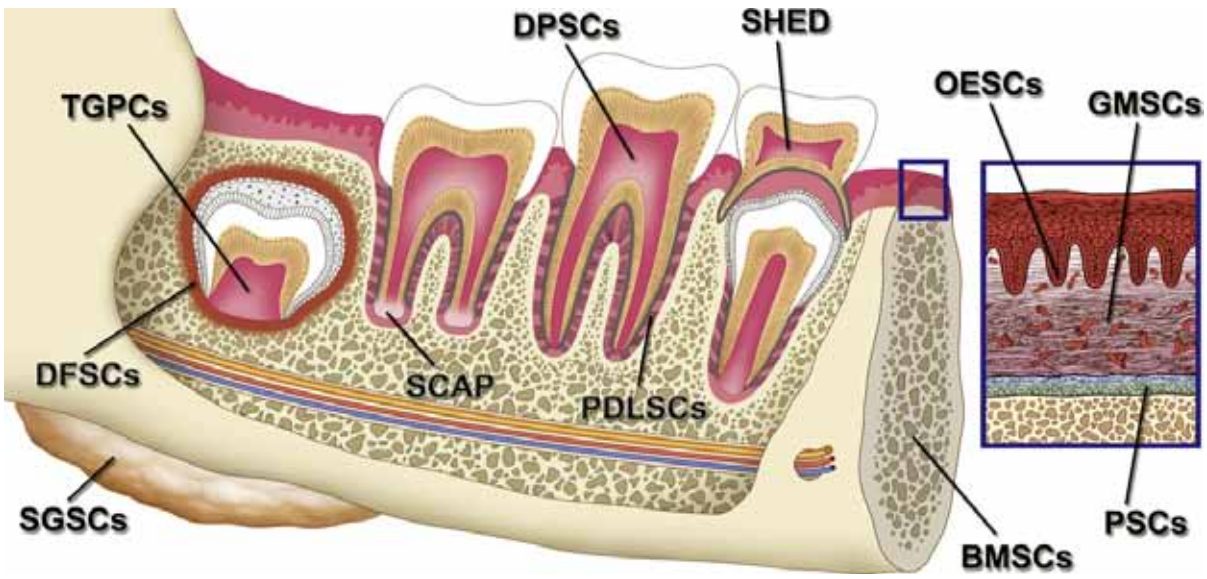

Fig. 1: Sources of adult stem cells:- Tooth germ progenitor cells (TGPCs), Dental follicle stem cells (DFSCs), Salivary gland derived stem cells (SGSCs), Stem cells from apical papilla (SCAP), Dental papilla stem cells (DPSCs), Periodontal ligament stem cells (PDLSCs), Stem cell from human exfoliated deciduous teeth (SHED).

Types of Stem Cell:

Stem cells can be totipotent, pluripotent, or multipotent.

Totipotent (omnipotent) can differentiate into any cell type.

Pluripotent stem cells- it can differentiate into nearly all cells, but not all cell types.

Multipotent stem cells can differentiate only into cells of a closely related family.

Identification of Stem Cells:

4 ways to identify the stem cell:

1. Fluorescent antibody cell sorting:-with the use of flow cytometer stem cells can be identified from clusters of different cells by staining the cell with antibody markers.
2. Immunomagnetic bead selection.
3. Immunohistochemical staining
4. By using physiological and histological criteria- like differentiation, proliferation, mineralizing activity.

Possible Uses of Stem Cell Technology:

Tissue engineering

Repair of defective tissues/organs

Delivery of gene therapies

Delivery of chemotherapeutic agents

Regenerative dentistry: Both mesenchymal and epithelial cells are required for the regeneration process or to laid down odontogenic cells. Mostly Pre natal germ cells are preferred over postnatal for regeneration because they possess high propensity regarding the genesis of normal tooth structure.[28]An injectable self hydrogel (autogenic stem cells) along with inorganic bone is used for temporomandibular joint regeneration.[28,29] Bioengineered TMJ can be constructed by using a biomimetic capsule that contains adult mesenchymal stem cells.[29] For regeneration of young permanent tooth apexification and apexogenesis are the ideal candidates, as they permit root development in both the lateral and vertical directions. Thus, improving the prognosis. A study has been suggested that DPSCs and BMSCs have the potential to induce dentinogenesis and osteogenesis respectively, as a result of the formation of dentin like tissues (30). SCAPs can also produce odontoblasts and the later is responsible for root completion in immature permanent tooth and deposit dentin like structures. When SHED is implanted inside the scaffold, it was able to produce odontoblast like cells.[31] It was observed by *Gotlieb EL et al,* that when SHED was incorporated into the polylactic acid scaffolds containing bone morphogenic protein 2 (BMP-2) and transforming growth factor (TGF-b1), produced structures that are similar to pulp tissue components.[32]

To date, tooth prosthesis has significantly lower characteristics in terms of esthetics and function as compared to natural teeth. Therefore the field of tooth engineering is an upcoming research project which uses stem cells to create a natural tooth by which replacing a missing tooth or missing part of a tooth and its attachment apparatus is facilitated. Proper isolation and culture of stem cells for both in vivo and in vitro conditions play an important role in tooth engineering.

Protocols for tooth engineering: Tooth regeneration is completely dependent on the close association of epithelial and mesenchymal cells along with the interaction of stem cells with the extracellular matrix molecule and scaffold to facilitate tooth engineering (fig-2). Usually scaffold is a crucial supporting structure that forms the framework for cellular function and behavior. Materialused in scaffold should not be toxic, less side effect, highly biocompatible, and should be easy to prepare. Undoubtedly, it might be said that scaffold material could indicate the direction for tissue engineering.[33]

The generation of periodontal tissues is dependent on four basic components. The appropriate signals, cells, body signals, and scaffolds (Fig-3). Collagen matrix type I, hydroxyapatite and tricalcium phosphate has been widely used in scaffold to increase the osteoinductive property.[34] Overall, tissue engineering is dependent on 3 essential elements: cells, scaffold, and growth factors (Fig-4).

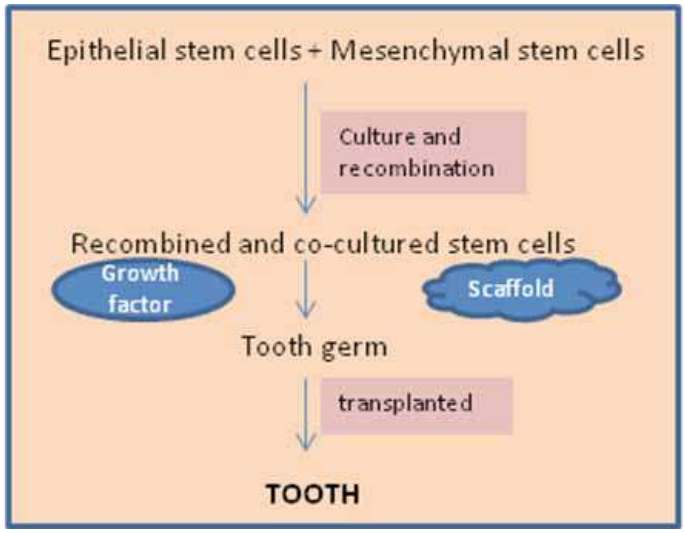

Fig 2: Formations of fully functional tooth after introduction of tooth germ into the alveolar bone.

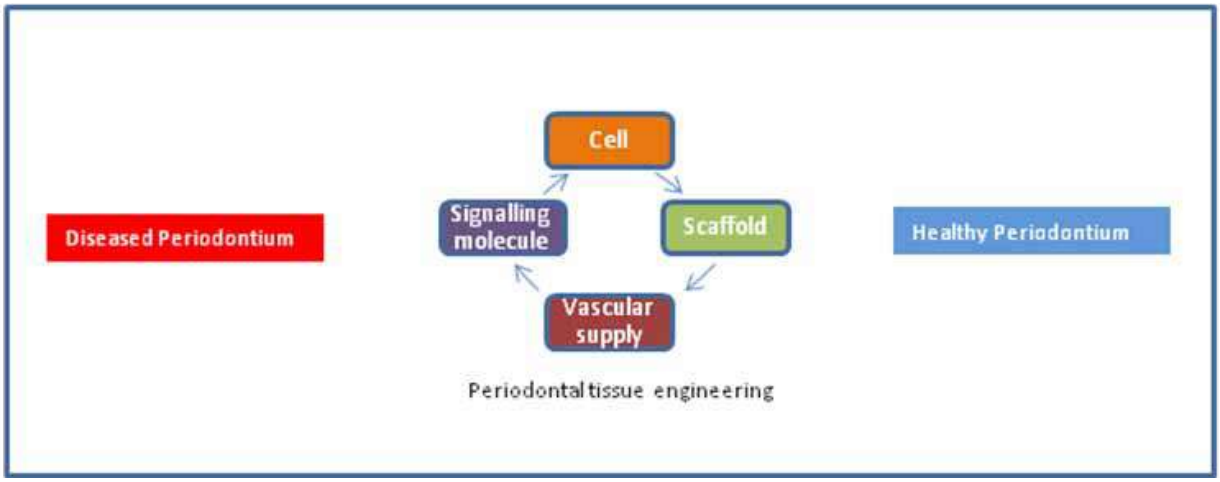

Fig 3: Necessary elements for periodontal tissue engineering

Tissue Engineering Strategies:

1. **Cell injection technique:** This approach involves the injection of talented cells, mainly stem cells inside the defects and it indicates regeneration of tissues over there. Some of the disadvantages of this technique are improper localization of injected cells and poor engraftment. To improve the localization and also to avoid communication with the immune system, the use of a delivery vehicle has been tested. The introduction of a delivery vehicle has been a successful approach as cells found inside the vehicle have the capacity of proliferation and differentiation.[35]

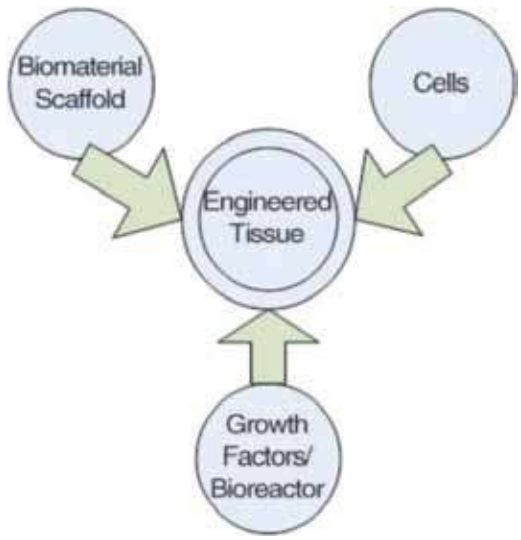

Fig 4: Triad of tissue engineering

2. **Cell induction therapy:** To get the better off from the cell injection technique, this technique was planned to induce osteoinductive property at the site of the requirement by enrolling the circulatory body cells. Any exogenous biological constituents should not be used for the process of osteogenesis.

3. **Cell seeded scaffolds:** This approach involves the isolation of a particular group of cells from a biopsy specimen, which was taken from the donor or recipient. Mostly, mesenchymal cells are preferred for this strategy. Oral mucosal or gingival derived mesenchymal cells are the best choice for this approach due to their immunomodulatory and anti-inflammatory properties. These MSCs can treat various immune-related diseases and help in the repair of wounds. Isolated cells are enlarged in culture medium and then seeded into the synthetic or artificial scaffold (Fig- 5), which holds the mesenchymal cells in position during their growth period and determines the shape of the tissue as well.[36] Here, cells differentiate, proliferate, and finally form the desired tissue. The new tissues formed are then implanted into the subjects.

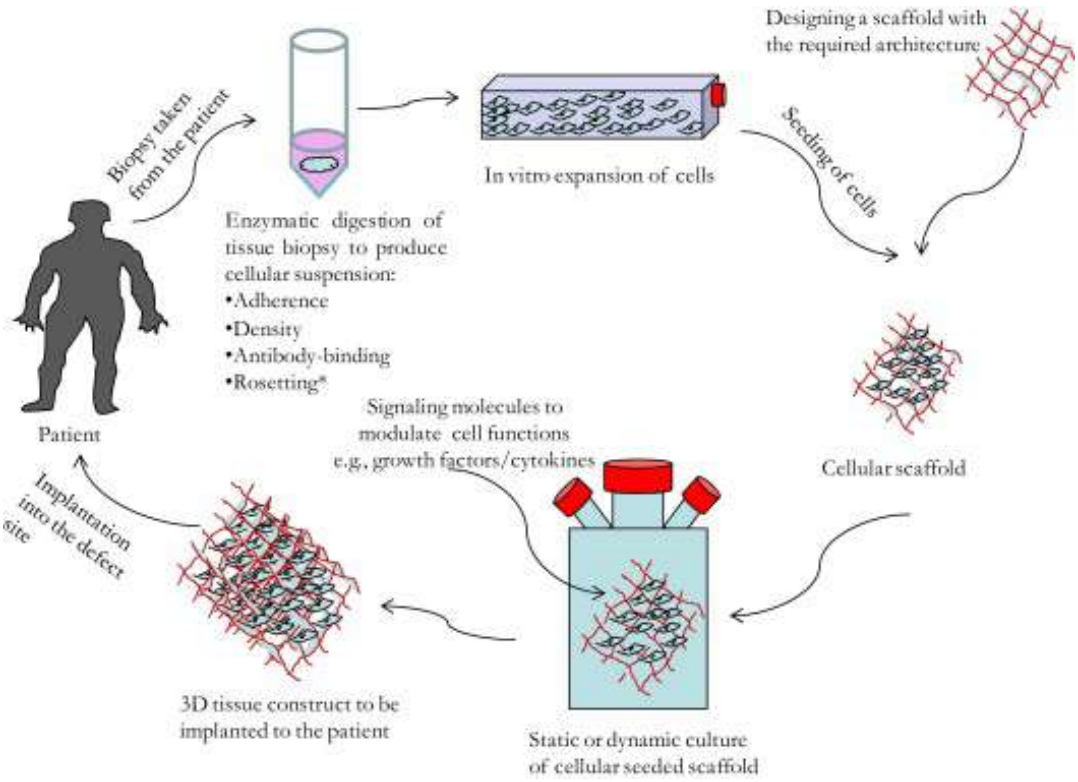

Fig. 5: Schematic presentation of cell-matrix tissue engineering strategy by Tomlinson et al (37).

Conclusion and Challenges

The use of stem cells in regenerative dentistry is capable of bringing quantum advances in treatment for our patients. Apart from some practical obstacles still to be overcome, the stem cell knowledge can be implemented in regenerative dentistry. More advancement in the field of stem cell research should be done upon which we can build future strategies for the tissue engineering of teeth. Stem cells have plenty of application in the field of dentistry, dental professionals must recognize the outcome of the emerging zone of regenerative dentistry and should implement those during conventional dental treatment. To make the nonvital tooth fully functional, researchers need to grow blood and nerve supply to that particular tooth. Stem cell brought many promising hope among the researchers. Shortly, stem cell is the future of dentistry.

Antimicrobial Resistance: A Dentists' Prospective

K. Swapna Kumari[1], Patitpaban Dash[2], E. Subudhi[3], Satabdi Pattnaik[4], Naomi Ranjan Singh[3], Debkant Jena[5], Lora Mishra[5]

[1]Tutor, [4]Senior Lecturer, [5]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences,[2]Associate Professor, Center of Biotechnology, [3]Professor, Biomics and Biodiversity Lab, Centre for Biotechnology, School of Pharmaceutical Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Antimicrobial resistance has turned from prediction to reality in a few decades and exerts a significant burden globally with a loss of approximately seventy thousand lives each year. Dentistry accounts for approximately three to eleven percent of all antibiotic prescriptions worldwide. The human oral cavity is a huge reservoir of more than 750 microbial species. Oral microbial biofilm formation such as dental plaque that initiates periodontal diseases and dental caries is the major reason for the antimicrobial therapy failure and rise in resistance against the action of antimicrobials. Biofilm bacteria embedded with a matrix of extracellular polysaccharides are more than 10,000 times less sensitive to antimicrobials than free-floating planktonic bacteria. A thorough understanding of the mechanism will provide an effective solution to combat the current problem such as developing novel antimicrobials, method that enhance the effectiveness of antibiotics by modifying the antibiotic structure or disrupting biofilm, or altering the outer membrane structure of bacterial cell walls to neutralize the resistant enzymes. Use of novel strategies e.g. nano-drug delivery system to facilitate drug entry into the cell; liposome for efficient local delivery of drug of choice in the treatment of caries, periodontitis and also for anesthetic purposes. This paper provides a review of the literature based on the studies on oral biofilm, its formation, and importance in drug resistance, mechanism of drug action and development of its drug resistance and various measures to combat it and the scope of dentists in limiting the progression of antibiotic resistance.

Keywords: *Antimicrobial resistance, Biofilm, Dental caries, periodontitis, Dentistry, Mechanism.*

Introduction

Resistance to antibiotics and adverse events associated with antibiotic use has now become a major threat to global health. It prompts the major challenge for the health providers all over the world and poses a threat to the rising mortality and morbidity. Over the first few decades the increased antibiotic-resistant gene transmission in virtually every species of bacteria for every class of antibiotics available from man and animals has been documented.[1] We are now having a huge list of multidrug-resistant bacteria with either a few or non-responsive antibiotics.[1] The possibility for a bacteria to develop resistance against antibiotics goes back to the 1930s as suggested by Dr. Flemming in his published description "discovery of penicillin".[2] The concept we have understood that "the success of antibiotics in improving morbidity and mortality rate worldwide" has created the present scenario "the resistance developed due to use of these antibiotics is responsible for increased morbidity and mortality". This is due to the microbial ability to withstand the adverse conditions involved and get transformed to protect themselves thereby deactivating the curing

potential of antibiotics.[3] Antibiotic resistance is now a potential threat to mankind as there is a gradual rise in the number of pathogenic bacteria becoming multidrug resistance or completely resistant to various antibiotics currently available. Antimicrobial resistance has turned from prediction to reality in a few decades and exerts a significant burden globally with a loss of approximately seventy thousand lives each year.[4]

Dentistry accounts for approximately three to eleven percent of all antibiotic prescriptions worldwide.[5] The human oral cavity is a huge reservoir of more than 750 microbial species.[6] Studies suggest that the normal human flora may act as a reservoir for antibiotic-resistant genes which under the right conditions are then able to be transferred to pathogenic species.[7,8] Oral microbial biofilm formation such as dental plaque that initiates periodontal diseases and dental caries is the major reason for the antimicrobial therapy failure and rise in resistance against the action of antimicrobials.[9,10]

Microbial biofilms are formed by colonization of various unicellular organisms to form a community that is attached to any solid surface and adherence of other microorganisms within a polymeric matrix made up of exo-polysaccharide thereby forming a complex community.[11] These biofilms initiate changes within microorganisms thereby exhibiting characteristics different from their planktonic counterparts, their susceptibility to various antibiotic agents, that includes responses against immunological reactions, their interaction with the host tissues, or their physiological properties.[12] Biofilm bacteria embedded with a matrix of extracellular polysaccharides are more than 10,000 times less sensitive to antimicrobials than free-floating planktonic bacteria. Biofilm creates a protected environment for the growth and survival of microbes in a hostile environment.[13]

The oral or dental biofilm that colonizes on the surfaces of the tooth is a complex three-dimensional structure that is formed of around 100-300 cell layers[12] and is a potential reservoir for the oral pathogenic microorganisms.[6,14] A number of gram-negative bacteria involved in periodontal infections such as *P. gingivalis, A. actinomycetemcomitans, F. nucleatum, P. intermedia, B. forsythus, S. intermedius, T. denticola*. These members are responsible for increased periodontal pocket formation as well as tooth loss.[14,15] Biofilms formed by bacteria protect themselves from antimicrobial agents and host immune responses as; (i) It protects against oxidative stress (ii) effluxes out antibiotics (iii) provides protective measures by its polysaccharide matrix and stops easy diffusion of antibiotics.[16,17]

The sequential events that occur during the formation of plaque on dental surfaces are; (1) A pellicle is formed on the tooth surface from proteins and glycoproteins present in saliva. (2) Bacterial molecules are adsorbed by the pellicle formed on the tooth surface through weak physical forces. (3) Reversible addition of oral bacteria to the tooth surface through binding between specific molecules present on the surface of the microbial cell with the complementary receptor present in the formed pellicle over the tooth surface. These constitute the primary colonizers particularly Streptococci sps and Actinomycetes sps. (4) Subsequently other microorganisms colonize to form secondary colonizers by coadhesion with primary colonizers through cell surface adhesion to the receptors present in primary colonizing organisms. This creates a rise in the microbial diversity in the plaque biofilm. (5) Bacterial proliferation takes place by multiplication resulting in the rise of biomass and formation of biofilm matrix by synthesis of exo-polymers. (6) Plaque growth and maturation takes place and all together they behave as a complex organism. There is growth and colonization of anaerobic organisms.

Due to the release of exo-polymers by the colonized microbes the penetration of the antibiotic agents is restricted into the 3-d structured plaque biofilm and also novel properties are exhibited by the slowly growing microorganisms on the biofilm surface.[18,19]

This paper provides a review of the literature based on the studies on oral biofilm, its formation, importance in drug resistance, mechanism of drug action and development of its drug resistance and various measures to combat it and the scope of dentists in limiting the progression of antibiotic resistance.

Mechanism of drug resistance by biofilms: Several groups of antimicrobial therapeutic agents (e.g:- β lactams, metronidazole, tetracyclines, quinolones) are practiced for the treatment of oral infections in addition to dentifrices and oral rinses (chlorhexidine, triclosan, fluoride)

In course of time oral microbiota develop resistance following many different mechanisms such as

1. Production of hydrolytic enzymes to inactivate antibiotics.[11]

2. Effluxing out the antibiotics taken up by the bacteria.[11]
3. Bringing conformational changes in drug targets by causing mutation in genes responsible for.[18,19]
4. Differential expression of porin proteins in biofilm cells reduced the accession of antibiotics resulting in antibiotic resistance in gram-negative bacteria.[20]
5. The formation of biofilm is controlled by quorum sensing of molecules which coordinates the gene expression to regulate the virulence factor.[21]
6. Bacteria present in biofilm adapt themselves to changed physiological conditions in response to exposure to antimicrobial agents and reduce their growth rate.[22]
7. Formation of exopolysaccharide biofilm matrix by bacteria retards the permeability of antibiotics following different mechanisms e.g: electrostatic interaction, absorption, enzymatic neutralization, hydrophobicity.[20,22]

Fig 1: Different ways of development of antimicrobial resistance in biofilms

Mechanism of Antibiotics and Development of resistance: Antibiotics work by affecting things that bacterial cells have but human cells don't. Bacteria and human cells differ in the structure of their cell membranes, method of protein synthesis or DNA replication mechanisms. Some antibiotics affect the cell membrane of the bacterial cells, while some affect the protein building mechanisms, while some act on the DNA copying machinery that is specific to bacteria.

Different families of antibiotics have different ways of killing microbial pathogens.

Beta-Lactam: It generally includes antibiotics like: Penicillins, cephalosporin. Beta-Lactams act on the gram-negative microorganisms by inhibiting the synthesis of bacterial cell walls. They interrupt the links between the peptidoglycan components in the transpeptidation process of the cell wall of gram-negative bacteria. These drugs can bind to PBP (penicillin-binding proteins), the enzymes that are involved in final stages of formation of the cell wall during the growth and division of the organism, and ultimately results in incomplete cell wall formation and cell lysis.[23] Antibiotic resistance developed against beta-lactamase is due to the presence of the enzyme beta-lactamases, present in many gram-negative and some gram-positive organisms that prevent the antibiotics to bind to the specific PBPs.[24]

Tetracycline: It belongs to the broad-spectrum group of antibiotics. It possesses the ability to bind with the 30s ribosomal subunit in the mRNA translational complex resulting in inhibition of protein synthesis.[25,26] It has a wide range of activity against gram-positive and gram-negative bacteria, mycoplasmas (without cell wall), protozoan parasites, chlamydia and rickettsia. Resistance to tetracycline is primarily due to the acquisition of new genes in the bacteria.[27] Due to various side effects, including staining of the teeth, other abdominal discomfort and damage to the kidney, this drug is not in much use.

Metronidazole: It is a nitroimidazole group of antibiotics that can be prescribed in adjunct to other groups of antibiotics or alone to treat oral infections and also other inflammatory diseases.[28] It is most effective against obligate anaerobic microorganism such as *Fusobacterium, Peptostrptococcus* species, *Bacteroides, Prevotela, Clostridium.*[29,30] The nitro group of metronidazole after entering into the cell through diffusion gets reduced thereby releasing toxic products that degrade the microbial DNA and also interferes in the synthesis of new DNA.[31,32] Four genes that codes for nitroimidazole reductase, the enzyme that carries out the enzymatic reduction of nitroimidazole to its respective derivatives are found to confer some level of resistance in colonic Bacteroides species but the presence of such genes in oral species is not clear.[33,34]

Quinolones: These are the chemotherapeutic bactericidal drugs eradicating bacteria by interfering with DNA replication. It acts on the DNA gyrase, a type-II topoisomerase which is essential for the replication of DNA and also recombination following repair.[1] Quinolones bind to DNA gyrase and DNA resulting in the formation of a stable complex that prevents the DNA gyrase for recombination of cut strands of DNA. Resistance to quinolones is found in a variety of anaerobic organisms are either due to alterations in DNA gyrase or for reduction in antibiotic accumulation.[35]

Fluoride: This is an anion of fluorine used extensively as a constituent in mouthwashes, toothpaste and oral supplements as dental caries preventive agents.[36,37]The fluoride ions interact with the mineral content of the tooth and induces remineralization and also prevents demineralization caused by cariogenic bacteria.[38] Studies suggest that fluoride acts on the enzyme enolase in the glycolytic pathway resulting in growth inhibition and reduction in the production of acid from oral streptococci such as *S.mutans*.[39,40] Administration of fluoride is restricted owing to the development of dental and skeletal fluorosis along with fluoride resistance found in oral bacteria.[41]

Chlorhexidine: It is the most effective antiseptic agent, is a cationic poly biguanide with hydrophilic and hydrophobic properties that acts as both supragingival and mucosal plaques[42,43]due to its dicationic nature, it can bind reversibly to the negatively charged molecules in the oral cavity and persist for a long duration after its application.[43] Chlorhexidine is active against a group of organisms including gram-positive and gram-negative bacteria aerobes, facultative anaerobes, and yeasts by causing damage to the inner cytoplasmic membrane.[42,44] Not only it inhibits plaque formation, but it also reduces plaque adhesion to the tooth surface by blocking the acidic groups of glycoproteins that are present in saliva. It brings about ultra-structural alterations within the oral biofilm by being adsorbed on to extracellular polysaccharide or competing with agglutination of calcium ions in plaque resulting in a reduction in the adhesion of bacteria to the tooth surface.[45]

Triclosan: It is a non-ionic phenolic molecule used majorly in dentifrices having a broad-spectrum antimicrobial effect against gram-positive and gram-negative microorganisms.[46] A numerous randomized, controlled clinical trials summarized the efficacy of triclosan as a plaque reducing agent and also exhibits anti-inflammatory properties for improving gingival health.[46-49]

Role of dentists in reducing antibiotic resistance: As health care provider**s,** dentists should be aware of their contribution towards developing antibiotic resistance and limit their role in exacerbating it. Studies suggest that about 66% of the prescribed antibiotics are not clinically indicated.[4] The pathophysiology of the pulpal diseases should be emphasized and understood and inadvertent use of antibiotics in the treatment of acute endodontic infections to relieve pain without intervening endodontic treatment should be avoided. Antibiotics are ineffective in eliminating the pathogens in the root canal system as there is reduced blood circulation in the necrotic or infected pulp. Surgical or endodontic intervention is required to alleviate the symptoms and infection.[50] Antibiotics should be prescribed for localized infection in those with systemic involvement.

Dentists should follow some guidelines[51, 52]

1. Accurate diagnosis should be obtained before prescribing any antibiotics
2. Obtaining the involved microbial analysis presenting the infection and prescribing the suitable antibiotic
3. Rather than adopting broad-spectrum antibiotics one should prefer the narrowest spectrum antibiotic.
4. Avoid prescribing antibiotics if it can be managed without.
5. Should not prescribe for unknown or improperly understood infections
6. Should thoroughly review the medical history of the patient to avoid adverse effects of a specific group of antibiotics if any.
7. Should not be biased by the demand of patient or pressure due to competitive healthcare providers
8. Should be avoided in infections due to fungus or virus or traumatic aphthae ulcers
9. Prescribed when systemic spread of bacterial infection is evident.
10. Should advise patients for proper dosage and duration of prescribed antibiotics.
11. Should update self about appropriate oral infection management from conferences, journals, continuing dental education (CDE) programs.
12. Should discourage and educate the patients not to avail antibiotics over the counter.

Conclusion

The scale and speed of increasing antibiotic resistance has become a global concern where the solution is required at every level. A thorough understanding of the mechanism will provide an effective solution to combat the current problem such as developing novel antimicrobials, method that enhance the effectiveness of antibiotics by modifying the antibiotic structure or disrupting biofilm, or altering the outer membrane structure of bacterial cell walls to neutralize the resistant enzymes. Use of novel strategies e.g. nano-drug delivery system to facilitate drug entry into the cell; liposome for efficient local delivery of drug of choice in the treatment of caries, periodontitis, and also for anesthetic purposes.

Social Media as a Tool in Dental Public Health

Sourav Chandra Bidyasagar Bal[1], Radha Prasanna Dalai[1], Darshan V.[1]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India.

Abstract

Facebook, WhatsApp, Instagram like social media are becoming an emerging instrument in the twenty-first century to reach every person. Dentists can use any of the social media to give oral care to people. The daily users of the SM are more than one billion per day. If the dentist can make a beautiful blog regarding oral care millions of people will get its benefits. Cost regarding uses of social media in recent days is approximately very less and affordable by maximum people. It will beneficial to all age group people from small children to elderly people. Various Social networks in recent year providing important massage like how we are coordinating each other in developing society and promote our dental health with this media. When SM is used in a proper way it has a lot of beneficiary effect on people regarding dental and general health. The first growth in dental science and its link with recent advance web technology bring the dental science to a top-level.

Keyword: *Social media, dental health, web 2.0.*

Introduction-

Since the last twenty years due to evolution in technology the one way and two-way communication changes out of our imaginary expect. It is due to the easy availability of networks, cell phones, portable devices in every corner of our country. Mainly internet is available everywhere irrespective of geographic location. The rapid evolutionary growth of all aspects like skill to develop knowledge in people, availability of 4g, 5g network, tempo in communication, developing awareness among the community regarding better health has a key role in oral health promotion.[1,2]

In the twenty-first century it became a great challenge for every health educator, that how fast suitably they are representing the health information. Before the twenty-first century, health-related facts are available through television, newspaper some times in audio communication through radio but now due to evolution in technology it is out of the orbit of old media. Health and oral health important information is rapidly available in new advanced social networking sites on Instagram, Facebook, tweeter, google etc. Anyone now can easily assess to any of the following sites and collect important information as they want. Anyone can assess any health website regarding their different gender, socio-economic classes. Nowadays small children around nine to ten-year-old are using I-phone with face time, android phone with google duo and grandparents interchanging photograph via internet.[3,4]

Various Social networks in recent year providing important massage like how we are coordinating each other in developing society and promote our dental health with this media.(5), Recently available community media are FB, Instagram, Twitter, Google, snap chat, tumbler, etc which are accessed by millions of peoples daily throughout the world. The use of social media now became very cost-effective and available in different android phones at less price with large numbers of users.[6,.]

Social network is a perfect platform from which the goal of the Ottawa chapter can spread to a large population. So nowadays it is very much essential to use social network sites for the publicize of health and oral health tips to maintain excellent quality of dental health. There is a special bond between social network and health in recent days.[7,8]

Different social networks are excellent in spreading news with a thousand base and billions of members. Social network is defined as "a set of network-platform which constructs with Web 2.0 advanced technology, which permits members to make and interchange their text [10]. Social networks are highly popular because of interlinked with their huge friend circle, family members along long distances throughout the whole globe.[11]

Various Social networks like FB, Instagram, Twitter, Watsapp are widely used by various departments for communicating throughout the globe. Social network in its initial days used for interacting with people among the various community but in recent days it is used in various teaching aids.[9]When the first internet was introduced it has very few members for blog generator named web 1.0 but its modified version in recent days is web 2.0 and it has a huge number for blog creation. FB, youtube, Watsapp, tweeter, Wikipedia, Snapchat are coming under web tech.[10].

Social educational platform are twitter, FB, Wikipedia, yahoo, second life, youtube from which we can give the health education to a huge number of population.[11]

Social network and its link to dental health:

Use of social medial in dental health education:

1. Voice messages of every dentist about oral education spread through FB, Whatsapp, Instagram, Twitter, Snapchat, youtube which can educate people in the latest way to maintain excellent oral health.
2. Financial, mental support in every steps any dental disease till recover
3. Users can ask any doubt regarding their dental problems and solve them easily.
4. Social media make people aware that what is the importance of dental professional in the matter of oral-facial health.
5. Various slogan regarded oral health considered as a pillar of oral health, aware people about the inter-link of dental disease to general systemic disease.
6. Various dental surveys are conducted through FB,Watsapp, Instagram, zoomapp, google meet etc.
7. In social media, we can create well designed tailored product which can easily fit for immune-suppressed person, pregnant women, hospitalized patients, old aged patients.
8. Beautiful children oral care programs are launching in the 21st century through FB, Instagram, Twitter, etc.

There is limited social site regarding dental education likeoral cancer site and another for oro systemic health care. There is no proper Indian web page regarding oral health is available till date. Some tips regarding oral health are there in the IDA site but these tips are not much more helpful to people. But in the private sector, there are lots of sites for dental education all of them are business purposes. Private dental educational tips video are available through FB,Whatsapp, Instagram, Snapchat, personal private web pages etc.[12]

Facebook

FB in recent periodsbecame the highest using social interacting medium web around the whole globe except China. Total users of FB are around one billion. Per day millions of people interchange pictures and comments among themselves. When FB introduced to the market, Initially it was only for school students but latter it opens to all. FB provides a personal private operating option to every user. Individual users can make their post private to some users or the public.[1] User can send their request of friendship to any user and who got the request later accept the proposal and can view his/her FB profile. Every FB user profile has details about their Name, DOB, marital status, educational status, location, and many more. All users can update any video, picture massage in their respected profile and can attach those documents to any of their friends who are using FB. Friends can give comments on that status. Personal mail can be sent by FB. Various groups can be created in FB for medical educational purposes.[13]

Twitter: Twitter introduce to the market in the year two thousand six. It permitted its user to put tweets as small messagesless within hundred forty words. Every user of twitter can send small blogs on any topicslike recent breaking news, daily life events, etc. Today twitter is introduced into different fields like medical, engineering, MBA, MCA, Research field, etc. It allows

strong interaction between teachers and students. A Professor named Cole W. from Pennsylvania State University uses 2 display boards one for himself another for training. By this, the trainee can pass their comment, question, doubts and solve it easily.

George et al stated that interaction of twitter became more successful in interaction with writing syllabus for medicos and meaning full strategy for next-generation doctors. Future doctors can interact easily with their patient and among themselves.[14]

Vlogs: vlogs, or video blogs are tape recorders made by one person and its period is very short. Video blog hassome drawbacks because of less validity. Video lectures and Vlogs are not the same things. Blogs should always contain important information and encouragement. The main motive of this blog is to provide important educational tips and easy learning for each mate in the groups.[15]

YouTube: In the year nineteen ninety-seven YouTube introduced to the market. It is the generation of web two point zero Technology.

Anybody can create their channel and post video. Here we can find videos like educational video, street play video, medical lecture, etc.Professor can upload educational video. Any student can share the video. A dental institute of new york university has its youtube channel, students of these universities share dentistry videos in this channel. Most of the universities in the world have their channel. In recent days medical theory lectures are given by youtube. Some surgical procedures of endodontics, prosthodontics, periodontics, and oral surgery are provided in you-tube. Statistical studies of public health also available in youtube.[16]

Simple Syndication Feeds: Simple Syndication feeds are a suitable site to get recent informative data. RSS does not get information from different web it creat its blogs. Simple Syndication Feeds has its web as knowyourteeth.com for dental disease knowledge.[17]

The first motto and aim of social media in promoting oral health should contain true, beneficial perfect health-related data from different reputed profession with much more expertise. Various networking site provide their address including their treatment procedure. Online registration for dental treatment online tobacco counseling, online Consultancy are available in recent days. After significant interpretation of various network site providing different test target is to achieve a better quality of health and excellent oral hygiene.

Disadvantage of social media: Poor quality information- some times the data about health available on social sites is not sufficient or not proper. Many information regarded health present in social media is without authors. Professional image may disrupt- it occurred occasionally when some surgeon post pic of surgery with intact instrument it could harm the patient as well as doctors image. During giving suggestions patients privacy can hamper. Breaking in the patient-doctor bonding. Some time patients send request in SM like FB that interrupted the HCP-patient bond.[18]

When well organized SM crusade some important beautiful massage regarding health or oral health in Instagram or WhatsApp,or FB it became viral with some true evidence. SM is the best way to campaign and make the public aware of their health nowadays. Various health sectors are now linked to SM and campaign through SM for better public health and on the other hand it became beneficial for the public because every day lakhs of people are newly connecting to SM. Recently SM became a suitable tool for spreading awareness regarding health and dental health among people. Some time SM is affected by politics. There is maximum benefit to improve oral health by SM because now every age group people are attached to SM the dentist can make a blog, video about the harmful effect of the use of smokeless and smoke tobacco. When people see this type of video they aware themselves and stay away from this products.[17,18]

Limitation of SM: Each second is important for every HCP (health care professional) so it is not possible to post every aspect of health-related posts on SM. Because posting a massage video is time taking. Secondly payback from the expenditure on SM. Illiterate people can not get benefit from SM. Below the poverty line, people get rid of these facilities. In India language is another limitation. [19,20]

Conclusion

When SM is used in a proper way it has a lot of beneficiary effect on people regarding dental and general health. But mishandling the power of SM has put a negative impact on people as well as on HCP. There is a proper guideline for the dentist to use social media on oral health to get more effective results. The first growth in dental science and its link with recent advance web

technology bring the dental science to a top-level. But in India dentofacial health care facility through SM is at the beginning. Some limitations are there in its acceptability like financial, quality of the data, hampering the privacy of people.[31,32]

Abstract

The older group of people (above sixty-five years) are facing lots of health and oral health issues due to the phenomenon of getting old. For that reason, this group needs the most attention to their health. Towards the end of the 20th century, the configuration of various age groups of people transformed tremendously. There are more older people and much more entered into the older group. This dynamic change has a direct effect on oral and systemic health. Dentist has great hand in solving the oral problem in geriatric people. Dentist should always consider the nutrition factor of geriatric patients. Topmost problem regarding the oral care facility in the older population is underestimated the oral disease Proper dentist population ratio throughout our nation to provide better dental care. Regular screen camps in different places to find older patients and gave them special care because due to rapid dental caries, periodontal disease, tooth loss the old people facing various problems.

Keyword: *Oral Disease, Xerostomia, Aging.*

Introduction

There are various developmental stages of Human beings. Development phases are starting from birth (infancy, childhood, young adult, adult, older adult, old aged). All the above phages are biological or natural phenomena. As the human being getting older various changes found inside his body. The longevity of human life is increasing day by day in the twenty-first-century due lunching of modern medicine and different kind of modern public health programs. The older group of people (above sixty-five years)are facing lots of health and oral health issues due to the phenomenon of getting old. For that reason this group need most attention to their health.[1]

Towards the end of 20nt century,the configuration of various age group of people transformed tremendously. There are more older people and much more entered into an older group. This dynamic change has a direct effect on oral and systemic health. Among these older age group people, the physical condition of some people required attention to their dental health in the dental clinic but not all.[1,2] As per the report of world health organization, the number of the population throughout the globe increasing annually is around two percent and on the other hand the percentage people crossing the age sixty-five, is around three percent. From estimation it is calculated that till 2050 there will maximum changes in age composition in developed and rapidly developing nations. According to UN estimation the older age group reaches around twenty percent from the whole population of the globe.

In 2020 the total population of our India is around 1.3 billion. From 1.3 billion older people above sixty-year age are around eight percent (around eighty million). Various oral cancers like squamous cell carcinoma mostly found in older age group and maximum oral cancer case found in republic India.[3]

As the human being entering to the older age group, he/she may develop some systemic disease. In the presence of various systemic diseases in old age he/she lost his ability to maintain his oral health. The person lost his ability to maintain oralhygiene properly, which direct or indirectly affects the lifestyle of that individual. Though this type of condition is not life-threatening but hamper some part of quality of life. For the proper care should be taken by the dentist to maintain their oral hygiene. Special dental care should mandatory for older group citizen.[3]

Different category of older: Citizen from sixty-five years to seventy-four comes under young older are physically active and healthy Citizen from seventy-five years to eighty-four comes under middle old are little different from physically active and healthy older goes through some systemic disease. The last one is above eighty-five years come under the oldest group and not physically active. This group is very much venerable to most oral diseases. Sudden proliferation in the age of sixty-five years since the last ten years in the world and India comes in that.[4]

Condition of Oral health among the older population:

Impact of various Nutrients among older groups and its utilization in dental care: The availability of a Sufficient amount of nutrients products in the body plays an important role in improving the oral health and general health of the older population. Deficiency in the nutrients inside the body hurts the normal physical and mental activity of older people. Worst dental health may be a crucial point for nutritional status and health. Any disability in the oral cavity has a significant contribution to less eating practice among the old age group. A mobile tooth, mild to moderate pain in the tooth or faulty prosthesis can reduce the ability of chewing habits. Less amount of nutrition harms the dental care of old people. So proper nutrition should mandatory for proper oral care of older people.

Due to a decrease in the process in BMR(basal metabolic rate) the food calorie amount of body also decreases in old generation people, which leads to a decrease in mass of the muscle and physical activity in old people. Decrease in appetite process of the body and less food intake there is a deficiency in the amount ofCa, I, and Zn in women. Around Eight thousand kJ calorie need for eighty years old people. Physical active old need around 1gm/kg protein everyday. Process Necrosis of tissue is more in old people for that they need more protein. Bedridden older patients have less chance to expose to sunlight for a long time so they are more risk for developing osteomalacia due to less SUNSHINE VITAMINE. Vitamin C, iron also required. [5]

Oral health has significant hand genera health in old people. Tooth loss and faulty prosthesis has a direct negative impact on mastication and test sensation. Defective mastication can be corrected by replacement of proper prosthesis. Correction in the mastication by proper prosthesis can change the dietary habit and increase the nutrient amount in the body of old people. Prevalence of Cervical caries and root caries is more in old people. Dentist has great hand in solving the oral problem in geriatric people. Dentist should always consider the nutrition factor of geriatric patients. If there is some nutritional problem dentists have to solve it in the proper method which will be effective on the later stage.

Problems arise due to decrease of salivary secretion in geriatric patients: The normal function of the salivary gland hampered due to aging is a normal phenomenon. It adversely affects dental health. Saliva in the oral cavity act as a safeguard for the upper respiratory tract and upper part of the digestive tract from various infections. It also regulates some sensorimotor fibers. Xerostomia make the oral environment suitable for various micro-organism. Major changes found in major salivary glands due to atrophy of acinar cells due to increasing age. Degenerative alteration also found in various salivary gland-like parotid, submandibular with advanced age. Changes found in palatine and lingual gland also due to old age.[6] Salivary dysfunction is less in old age people who are comparatively physically healthy and active. A salivary gland dysfunction can be reversed to normal function. Xerostomia leads to dental caries in old group population.[6]

Oro mucosal changes due to the aging phenomenon: The mucosa of the oral cavity acts as a first-line defense in the oral cavity. Defect in function of oral mucosa made the oral environment favorable for various pathogenic organisms harvest inside the mouth. All the layers of the oral mucosa have their protective function.Keratin synthesized by oral mucosal epithelial tissue, which maintains oral mucosal. Adipose tissue of oral mucosa mainly defends oral mucosa.[7]Epithelial cell turnover done by oral mucosa in the oral cavity and it

is a protective mechanism. Data from different surveys says that oral mucosa became thin with an increase, which is associated with loss of stippling and elastic nature of mucosa. Some changes marked in tongue like depopulation. An increase in the number of Candida albicanscauses candidiasis or oral thrush. Healing takesa long time.[8]
